CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

animals	birds	Psittacidae	*Aprosmictus erythropterus*	red-winged parrot		C		59/3
animals	birds	Ptilonorhynchidae	*Ptilonorhynchus maculatus*	spotted bowerbird		C		64
animals	birds	Ptilonorhynchidae	*Ptilonorhynchus nuchalis*	great bowerbird		C		8
animals	birds	Rallidae	*Porphyrio porphyrio*	purple swamphen		C		2
animals	birds	Rallidae	*Tribonyx ventralis*	black-tailed native-hen		C		1
animals	birds	Rallidae	*Gallinula tenebrosa*	dusky moorhen		C		11
animals	birds	Rallidae	*Fulica atra*	Eurasian coot		C		18
animals	birds	Recurvirostridae	*Himantopus himantopus*	black-winged stilt		C		52
animals	birds	Recurvirostridae	*Recurvirostra novaehollandiae*	red-necked avocet		C		2
animals	birds	Rhipiduridae	*Rhipidura leucophrys*	willie wagtail		C		149
animals	birds	Rhipiduridae	*Rhipidura albiscapa*	grey fantail		C		4
animals	birds	Scolopacidae	*Tringa nebularia*	common greenshank		SL		1
animals	birds	Scolopacidae	*Tringa stagnatilis*	marsh sandpiper		SL		1
animals	birds	Strigidae	*Ninox boobook*	southern boobook		C		6
animals	birds	Threskiornithidae	*Platalea regia*	royal spoonbill		C		5
animals	birds	Threskiornithidae	*Threskiornis molucca*	Australian white ibis		C		15
animals	birds	Threskiornithidae	*Platalea flavipes*	yellow-billed spoonbill		C		1
animals	birds	Threskiornithidae	*Threskiornis spinicollis*	straw-necked ibis		C		33
animals	birds	Threskiornithidae	*Plegadis falcinellus*	glossy ibis		SL		6
animals	birds	Turnicidae	*Turnix velox*	little button-quail		C		2
animals	insects	Lycaenidae	*Theclinesthes miskini miskini*	wattle blue (Australian subspecies)				1
animals	insects	Nymphalidae	*Euploea core corinna*	common crow				1
animals	insects	Nymphalidae	*Junonia villida calybe*	meadow argus				1
animals	insects	Nymphalidae	*Hypolimnas bolina nerina*	varied eggfly				1
animals	insects	Papilionidae	*Papilio aegeus aegeus*	orchard swallowtail (Australian subspecies)				1
animals	insects	Papilionidae	*Papilio demoleus sthenelus*	chequered swallowtail				1
animals	malacostracans	Parastacidae	*Cherax quadricarinatus*	redclaw				1
animals	mammals	Bovidae	*Bos sp.*	cattle	Y			1
animals	mammals	Emballonuridae	*Taphozous georgianus*	common sheathtail bat		C		1
animals	mammals	Emballonuridae	*Taphozous troughtoni*	Troughton's sheathtail bat		C		1/1
animals	mammals	Macropodidae	*Lagorchestes conspicillatus*	spectacled hare-wallaby		C		2
animals	mammals	Macropodidae	*Petrogale purpureicollis*	purple-necked rock-wallaby		V		9/1
animals	mammals	Macropodidae	*Macropus robustus*	common wallaroo		C		4
animals	mammals	Macropodidae	*Macropus rufus*	red kangaroo		C		1
animals	mammals	Macropodidae	*Macropus agilis*	agile wallaby		C		2
animals	mammals	Muridae	*Pseudomys johnsoni*			C		9
animals	mammals	Muridae	*Zyzomys argurus*	common rock-rat		C		3
animals	mammals	Pteropodidae	*Pteropus scapulatus*	little red flying-fox		C		1
animals	mammals	Tachyglossidae	*Tachyglossus aculeatus*	short-beaked echidna		SL		1
animals	mammals	Vespertilionidae	*Chalinolobus gouldii*	Gould's wattled bat		C		1
animals	mammals	Vespertilionidae	*Vespadelus finlaysoni*	Finlayson's cave bat		C		1/1
animals	ray-finned fishes	Ambassidae	*Ambassis macleayi*	Macleay's glassfish				14
animals	ray-finned fishes	Ambassidae	*Ambassis species*	northwest glassfish				27
animals	ray-finned fishes	Ambassidae	*Parambassis gulliveri*	giant glassfish				5

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
animals	ray-finned fishes	Ambassidae	*Ambassis sp.*					31
animals	ray-finned fishes	Ariidae	*Neoarius leptaspis*	boofhead catfish				2
animals	ray-finned fishes	Centropomidae	*Lates calcarifer*	barramundi				23
animals	ray-finned fishes	Clupeidae	*Nematalosa erebi*	bony bream				706
animals	ray-finned fishes	Eleotridae	*Oxyeleotris selheimi*	blackbanded gudgeon				186
animals	ray-finned fishes	Eleotridae	*Oxyeleotris lineolata*	sleepy cod				22

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

Recovery Actions Database

Title: Species list for 'Back on Track' priority species in Southern Gulf

Extracted: 18/06/2014 10:34:48

Search Criteria: [Back on Track Rank (NRM Back on Track Rank), NRM Region (Southern Gulf)]

NRM Region of Occurrence	Kingdom	Plant/Animal Type	Species Scientific Name	Species Common Name	NRM BoT Rank	State BoT Rank	NCA Status	EPBC Status

Southern Gulf	*Plants*	*Water plants*	*Aponogeton queenslandicus*		High	Medium	Least concern	

Appendix B Fauna Study Sites

2011 Study Sites

Terrestrial fauna study sites sampled during the 2011 surveys are described and illustrated below.

DSFS1 was located in a dry watercourse in the north-west corner of the Project site. Photo Plate 14 provides graphic representation of the study site centred around the pitfall trapping line.

Photo Plate 14 Pitfall Line at DSFS1

DSFS2 was positioned in a dry waterway, adjacent to steep rocky hills in the centre of the site. Photographic representation of the pitfall trapping line and typical habitat at DSFS2 is shown in Photo Plate 15.

Photo Plate 15 Pitfall Line at DSFS2

DSFS3 was located in on the pediment slope of a Snappy Gum dominated hillside. A photograph of the fauna site and the associated pitfall trapping line is shown in Photo Plate 16.

Photo Plate 16 Pitfall Line at Study Site DSFS3

DSFS4 was located in a dry watercourse dominated by *Melaleuca bracteata*. A photograph of the pitfall trapping line at DSFS4 is shown in Photo Plate 17.

Photo Plate 17 Pitfall Line at DSFS4

DSFS5 was located on top of a stony hillside dominated by *Acacia phlebocarpa.* The pitfall trapping line at DSFS5 is shown in Photo Plate 18.

Photo Plate 18 Pitfall Line at DSFS5

TR01 was located in the south-western corner of the Project site among Cloncurry Box hills. Photo Plate 19 provides graphic representation of the study site centred around the pitfall trapping line.

Photo Plate 19 Pitfall Line at TR01

TR02 was located in the east of the Project site on undulating Snappy Gum hills. The fauna site and pitfall trapping line in particular are shown in Photo Plate 20.

Photo Plate 20 Pitfall Line at TR02

TR03 was located in the centre of the Project site among Snappy Gum hills. Photo Plate 21 provides graphic representation of the study site centred around the pitfall trapping line.

Photo Plate 21 Pitfall Line at TR03

TR04 was located on the creek flats of a mapped watercourse in the centre of the Project site. The pitfall trapping line established within fauna site TR04 is shown in Photo Plate 22.

Photo Plate 22 Pitfall Line at TR04

TR05 was located on the lower slopes of a hillside dominated by Snappy Gum. The pitfall line and typical habitat at fauna site TR05 is shown in Photo Plate 23.

Photo Plate 23 Pitfall Line at TR05

TR06 was located on a stony hillside in the south-east of the Project site. Fauna site TR06 is shown in Photo Plate 24 along with the pitfall trapping line established at the time of the survey.

Photo Plate 24 Pitfall Line at TR06

TR07 was positioned in close proximity to the DSFS5 on an undulating hill dominated by Snappy Gum and Bloodwoods. The pitfall line established at TR07 is shown in Photo Plate 25 which also provides graphical presentation of the study site.

Photo Plate 25 Pitfall Line at TR07

TR08 was located toward the centre of the Project site on the creek flats of a mapped watercourse. The fauna site and pitfall trapping line as established at the time of the survey are shown in Photo Plate 26.

Photo Plate 26 Pitfall Line at TR08

2014 Fauna Study Sites

FA1 was positioned in a Cloncurry Box drainage line in the south-west portion of the Project site. The low vegetation canopy was dominated by Cloncurry Box and associated with a dense understorey of *Melaleuca bracteata* and a sparse ground layer on sandy clay soils. The ground layer was dominated by Buffel and cattle tracks were prominent throughout the habitat area. The shallow creek channels were dry at the time of the survey with minor erosion in some areas. Photo Plate 27 provides graphic representation of the study site centred around the pitfall trapping line.

Photo Plate 27 Pitfall Line at FA1

FA2 was located in River Red Gum Riparian woodland on the major creek that passes through the south-west corner of the site. The vegetation canopy is dominated by River Red Gum while the understorey is dominated by Arid Peach and Turpentine. The ground layer is sparse due to grazing cattle movements on the creek embankments and the rocky nature of the high bank. The habitat area contains moderate cover of leaf litter, a few logs and many hollows within the River Red Gum trees. The fauna site runs along a major creek which was dry at the time of the survey. A photograph of the fauna site, centred around the pitfall trapping line is shown in Photo Plate 28.

Photo Plate 28 Pitfall Line at FA2

FA3 was located in the mid-western portion of the Project site on an outcropping rocky hilltop. This outcropping hill occurs as part of a series of rocky ranges that form the dominant landform in this area of the Project. The vegetation community consists of low open woodland of Snappy Gum with the occasional Hill Kurrajong, an understorey of Arid Peach and Turpentine and a Soft Spinifex (*Triodia pungens*) dominant ground layer. The rocky outcrop landform provides an abundance of habitat for reptiles and rock-wallabies. A few hollow-bearing trees occur at the rear of the outcrop. The rocky outcrop that forms the focus of the FA3 is shown in Photo Plate 29.

Photo Plate 29 Rocky outcrop habitat at FA3

FA4 was centred around low open woodlands of Cloncurry Box on an ephemeral drainage line and valley flat located in the west of the Project site. Either side of the valley flat features low relief rocky hills that are dominated by Snappy Gum and Turpentine. This fauna site featured good habitat variety with plenty of leaf litter, grassy tussocks, fallen timber and cracking bark. Combined these features were found to support an abundance of retiles. A photograph of the fauna site and the pitfall trapping line, in particular, is shown in Photo Plate 30.

Photo Plate 30 Pitfall Line at FA4

FA5 was located in Cloncurry Box woodlands on a small dry drainage line in the central-western portion of the site. The Cloncurry Box dominant canopy is accompanied by the occasional Northern Swamp Box, while the understorey contains a mix of Turpentine, Arid Peach, Conkerberry and Whitewood. Buffel and Soft Spinifex co-dominate the ground layer. The fauna site was surrounded by Snappy Gum dominant hills. Habitat features include small hollows, rocks, leaf litter and grassy tussocks. A photograph of the pitfall trapping line at FA5 is shown in Photo Plate 31.

Photo Plate 31 Pitfall Line at FA5

FA6 was located in low open Snappy Gum woodlands on a rocky hill in the south-east of the Project site. The Snappy Gum dominant vegetation community consists of the occasional bloodwood in the canopy, Arid Peach and Tabletop Wattle in the understorey and a ground layer of Kangaroo Grass, Soft Spinifex and Mountain Wanderrie Grass. The site featured good habitat variety with many grass tussocks, low shrubs, outcropping rock habitat, some leaf litter and fallen timber. A broad landscape photographic view of FA6 is shown in Photo Plate 32.

Photo Plate 32 Low Open Snappy Gum Woodland on Hillsides at FA6

FA7 was located in low open Snappy Gum woodland on a rocky outcrop and hillslope in the east of the Project site. The vegetation canopy was dominated by Snappy Gum with associated Arid Peach and a shrub layer of Tabletop Wattle, Soap Bush and Turpentine. The ground layer was dominated by Soft Spinifex, Common Fringe-sedge and *Paspalidium distans*. The site contained moderate habitat variety with plenty of outcropping rocks, crevices and grass tussocks but little leaf litter, fallen timber or tree hollows. A portion of the hilltop rocky outcrop at FA7 is shown in Photo Plate 33.

Photo Plate 33 Rocky outcrop habitat at FA7

FA8 was located along a River Red Gum creek in the north of the Project site. The riparian canopy was typically dominated by River Red Gum while Northern Swamp Box forms a dense understorey in the upstream reach of the fauna transect. The creek consisted of a sandy to rocky, cobble bed with boulder outcrops occurring sporadically. There was a good cover of leaf litter and an abundance of tree hollows. The upstream section of the creek at FA8 is shown in Photo Plate 34.

Key:

LC – This species is classified as Least Concern under the NC Act

I – Introduced species

NL – This species is not listed under the EPBC Act as a species of conservation significance

* A species listed in the bottom section of the table that is not also listed in the top section should be considered as possibly present. Likelihood of occurrence and call identification issues for these species are discussed in the 'Reliability of species ID' section on the following pages.

Species nomenclature:

Species names used in this summary follow Churchill (2008), except for the free-tailed bats (Molossidae), which follow van Dyck & Strahan (2008) and Adams *et al.* (1988).

Call identification & reporting standard:

No bat call identification guide or key exists for the region from which these data were collected.

Call identification was based on published call descriptions (Milne 2001; Reinhold *et al* 2001; and Pennay *et al.* 2004); and on reference calls collected from various locations in Queensland, New South Wales & the Northern Territory.

Determination of species' identification was further refined by considering probability of occurrence based on distributional information presented in Churchill (2008) and van Dyck & Strahan (2008).

The format and content of this report complies with nationally accepted standards for the interpretation and reporting of Anabat data (Reardon 2003); latest version available from the Australasian Bat Society on-line at http://www.ausbats.org.au/.

Anabat echolocation data interpretation summary

Client: AARC (Mark Sanders via Paul Jackson) **Balance Job no.:** AARC1103

Project name/location: Mt Remarkable, NW of Cloncurry (March 2011)

Reliability of species ID

***Nyctophilus* species**

Nyctophilus bats generally produce distinctive calls, but the species cannot be reliably differentiated from call data. The species most likey to be present in the study area is *N. geoffroyi* . Three other species (*N. arnhemensis* , *N. daedelus* and *N. walkeri*) also occur in the far north-west of Queensland but are primarily restricted to moist habitats such as watercourses lined with pandanus and paperbark.

Vespadelus caurinus / V. finlaysoni

These species produce distinctive calls with hooked pulses at higher frequency (>50kHz) than any other species (with similar pulse shape) that would occur in the area. Most calls attributed to this species pair were in the range 57-58kHz, with a couple of sequences having slightly lower frequency (*ca.* 55kHz). The higher frequency is most likely to represent *V. caurinus* and the lower frequency *V. finlaysoni* ; however, the full range of both species is poorly known, so all calls were attributed to the pair rather than attempting an unreliable species split.

***Chalinolobus gouldii / Scotorepens balstoni / Mormopterus* species**

C. gouldii (28-34kHz) has steep and curved pulses that usually alternate in frequency by 2-3kHz. *S. balstoni* (30-36kHz) pulses are also steep and curved but do not alternate in frequency. *Mormopterus* sp (30-34kHz) pulses are generally much flatter; however, pulses sometimes steepen when flying close to vegetation and brief calls may be confused with calls from the other two spp. Similarly, *C. gouldii* and *S. balstoni* pulses sometimes lack steep initial broad-band frequency sweeps when flying in open space and these calls can appear similar to those of *Mormopterus* .

A number of steep-pulsed calls at 30-34kHz were listed as either *C. gouldii* or *S. balstoni* because they were brief and/or weak and/or showed inconclusive evidence of frequency alternation and could not be reliably distinguished. *C* alls with similarly low quality but obviously less steep pulses could have been from any of these three species. If from *Mormopterus* sp., these calls probably represent one of the un-named species in the *M. 'loriae'* complex, presumably *M.* 'species 5' (Adams et al. 1988).

Scotorepens greyii / Chalinolobus nigrogriseus

Signficant frequency overlap occurs in the range 36-39kHz, but pulse shape is sometimes diagnostic. Some *C. nigrogriseus* have flatter body of longer duration (2/3 of total pulse duration) compared with cup-shaped body of shorter duration in *S. greyii* . Most calls (and all from this survey), however, exhibit pulses with intermediate features or a mixture of pulse types and cannot be reliably differentiated.

Scotorepens greyii / Vespadelus baverstocki

S. greyii (35-40kHz) calls overlap in frequency with and have very similar pulse shapes to *V. baverstocki* (39-46kHz). A number of calls within the frequency overlap zone (39-40kHz) could have been from either of these species.

Cherephon jobensis / Saccolaimus flaviventris / Taphozous georgianus / T. troughtoni / Mormopterus beccarii

Frequency overlap occurs between these spp across a range of about 12kHz: *C. jobensis* (15-21kHz); *S. flaviventris* (17-22kHz); *T. georgianus* (21-23kHz); *T. troughtoni* (23-25kHz); *M. beccarii* (21-27kHz). Where good quality signals are recorded (i.e. long duration call sequence with numerous clearly defined pulses) species identity is usually discernible due to the shape and uniformity of pulses within the sequence. Most of the calls from this survey were of sufficient quality to be reliably attributed to one or other of these species. A few calls in this frequency range, however, were too brief and/or weak and/or noisy to be reliably identified.

Unknown bat - linear w. 45° knee Fc42-45kHz

A number of calls recorded in this survey exhibit distinctive pulse shape and frequency characteristics that cannot be readily attributed to any known species that would occur in the study area. The broad initial frequency sweep is steep with a distinct "knee" in the lower third and a straight, downward-sloping body at about 45° to the initial slope. The body lies between about 42-47kHz, with characteristic frequency (Fc) ranging from 42-44kHz.

The calls are superficially similar to those of *Miniopterus orianae oceanensis* , which is not known to occur west of Cape York. Given the frequency range of these calls and the presence of call sequences attributed to *Vespadelus baverstocki* during the same periods as these unknown calls were recorded, it is probable that they represent an unusual variant of that species, rather than another unknown species.

Unidentified bat calls

Many calls were too brief and/or weak and/or contained too much interference to enable reliable identification to species. All such calls were within frequency ranges of one or more species otherwise identified from the data and do not represent additional species.

* A species listed in the bottom section of the table that is not also listed in the top section should be considered as possibly present. Likelihood of occurrence and call identification issues for these species are discussed in the 'Reliability of species ID' section on the following pages.

Species nomenclature:

Species names used in this summary follow Churchill (2008).

Call identification & reporting standard:

Call identification was based on published call descriptions for Qld (Reinhold *et al* 2001), NSW (Pennay *et al.* 2004) and the Northern Territory (Milne 2001); and on reference calls collected from various localities in Queensland.

Determination of species' identification was further refined by considering probability of occurrence based on distributional information presented in Churchill (2008) and van Dyck & Strahan (2008).

The format and content of this report complies with nationally accepted standards for the interpretation and reporting of Anabat data (Reardon 2003); latest version available from the Australasian Bat Society on-line at http://www.ausbats.org.au/.

Anabat echolocation data interpretation summary

Client: AARC (Mitch Gregory) **Balance Job no.:** AARC1113

Project name/location: East of Mount Isa, 10-26 October 2011

Reliability of species ID:

Chalinolobus gouldii* or *Scotorepens balstoni

C. gouldii (Fc=28-34kHz) has steep and curved pulses that usually alternate in frequency by 2-3kHz. *S. balstoni* produces pulses of similar shape that overlap in frequency (Fc=30-35kHz), but which lack frequency alternation. Numerous calls were positively attributable to both species based on these criteria; however, a few brief or poor quality calls in the range could have been from either species.

S. greyii or Chalinolobus nigrogriseus

These species' calls overlap in frequency and often have similar pulse shapes; however, they can sometimes be differentiated on subtle differences in pulse shape (*S. greyii* pulses are more curved and have upward-sloping tail *cf.* no tail or down-sloping tail in *C. nigrogriseus*). A number of calls were reliably attributable to *S. greyii* based on this characteristics, but some calls had intermediate pulse shape features and could have been from either of these species.

Mormopterus eleryi (=*Mormopterus* 'species 6') is also known to produce calls similar to those of *S. greyii* (Reardon *et al* 2008) and may hae been responsible for some of these calls.

***Nyctophilus* species**

Nyctophilus bats generally produce distinctive calls, but the species within the genus cannot be reliably differentiated from call data. Just one call was attributed to this group - it had the typical linear pulse shape of the genus, but the sequence was weak and very noisy. The species most likely to be present in the study area is *N. geoffroyi* although it is possible that both *N. daedelus* and *N. arnhemsis* also occur at this locality.

Mormopterus* species or *C. gouldii

Several *Mormopterus* species produce calls around 30-34kHz, which overlap in frequency with those of *C. gouldii* ; however, differentiation is often possible due to the flatter pulse shape in *Mormopterus* and lack of frequency alternation that is common in *C. gouldii* . Most calls in the frequency range were reliably attributable to *C. gouldii* ; however, a number of calls appeared to have consistently flat pulses andcould havebeen from *Mormopterus* sp.

The distribution and taxonomy of the *Mormopterus* species that use this call type is somewhat confusing; and it is difficult to know which species may occur in the study area. Potential candidates for this call type include: inland free-tailed bat (*M.* 'species 3') and little northern free-tailed bat (*M.* 'species 5'/*M. loriae*). The hairy-nosed free-tailed bat (*M. eleryi* /*M.* 'species 6') also occurs in this region, but has calls more like those of *S. greyii* (see above).

C. jobensis or S. flaviventris

C. jobensis (15-21kHz) calls generally have uneven or erratic pulse shapes and frequency within a given call sequence, compared with mostly uniform pulse shape and regular frequency in *S. flaviventris* (17-22kHz). Most of the calls within the relevant frequency range were reliably attributed to one or other of these species; however, a few calls were too brief and/or weak and/or noisy to be reliably attributed to either species.

S. flaviventris or Mormopterus beccarii

These species are generally distinguishable on frequency differential (*S. flaviventris* <22kHz; *M. beccarii* >23kHz) and pulse shape (steeper curves in *M. beccarii*). Numerous calls were attributed to *S. flaviventris* on this basis, and a few also to *M. beccarii* . Several brief calls, however, had intermediate pulse shapes with frequency around 22-23kHz and could have been from either species.

M. beccarii or Taphozous georgianus

T. georgianus calls (23-25kHz) overlap completely in frequency with those of *M. beccarii* (21-27kHz). Where good quality signals are recorded (i.e. long duration call sequence with numerous clearly defined pulses) *T. georgianus* calls generally have more consistent pulse shape and frequency within the sequence. Several calls were attributed to *M. beccarrii* based on the steeper and somewhat more erratic pulse shape; however, a few calls had flatter, more even pulses and could have been from either species.

Unidentified bat calls

Many calls were brief and/or weak and/or lacked conclusive evidence of identifiable characteristics, thus precluding reliable identification to species level. All such calls were within frequency ranges of one or more species otherwise identified from the data and do not represent additional species.

Methods

Data receipt and processing

Bat call data were recorded using Anabat (Titley Scientific, Brisbane) and Song Meter SM2 detectors (Wildlife Acoustics, USA), with the Anabat recordings saved in Anabat raw data format and the SM2 recordings saved as compressed audio files (WAC format).

Two data sets were received for analysis, with the accompanying field data sheets indicating the following expected contents:

Data set	Detector name	Recording dates	Site
1	Anabat	Nights of 4/2/14 - 6/2/14	FA6
	Song Meter 2	Nights of 30/1/14 - 1/2/14	FA1
		Nights of 2/2/14 - 4/2/14	FA4
		Nights of 5/2/14 - 6/2/14	FA5
	Song Meter 6	Nights of 30/1/14 - 1/2/14	FA2
		Nights of 2/2/14 - 4/2/14	FA3
		Nights of 5/2/14 - 6/2/14	FA7
2	Song Meter 8	Nights of 25/2/14 - 26/2/14	AQ1
		Nights of 27/2/14 - 28/2/14	AQ4

All received data files were converted to Anabat sequence file format (zero-crossing analysis, or ZCA files) prior to call analysis. The Anabat data file from Data Set 1 was converted with the *CFCread* program (Corben 2012), yielding 180 sequence files recorded over the three nights. Wildlife Acoustics' *Kaleidoscope* software was used to convert the SM2 WAC files. This process yielded some 1800 files for the two SM2 detectors submitted in Data Set 1; however, no bat call data could be extracted from the WAC files received in Data Set 2.

Relatively few sequence files were recorded from Site FA5 compared with the other sites where SM2 was deployed; and no data were recorded by SM6 at Site FA7. This lack of data from the final two nights of survey by each detector suggests that the batteries may have failed rather than reflecting a true absence of bat activity at those sites.

Bat call identification

All sequence files were analysed using *AnalookW* (Corben 2013) and a subset of 623 files containing representative samples of all call types recorded at each site were selected for identification. Species identification was achieved manually by comparing the *AnalookW* call sonograms with those of regionally-relevant reference calls and with published call descriptions (e.g. Reinhold *et al.* 2001; Milne 2002; Pennay *et al*. 2004).

Species' identification was also guided by considering their probability of occurrence based on general distribution information (Churchill 2008; van Dyck *et al.* 2013) and/or database records obtained from Wildlife Online (http://www.ehp.qld.gov.au/wildlife/wildlife-online/index.html) and/or the Atlas of Living Australia (http://www.ala.org.au).

Reporting standard

The format and content of this report follows Australasian Bat Society standards for the interpretation and reporting of bat call data (Reardon 2003), available on-line at http://www.ausbats.org.au/.

Species nomenclature follows van Dyck *et al.* (2013).

Results & Discussion

Some 800 individual bat calls were selected for identification.

Ten call types were identified positively to individual species, with two others attributable to genus level but not further differentiated. These unresolved calls included:

- near-vertical, linear FM pulses with characteristic frequency (Fc) of 40-50 kHz, from a *Nyctophilus* species bat (*N. arnhemensis, N. bifax* and *N. geoffroyi* all potentially occur in the study area); and
- relatively flat FM-qCF pulses with Fc=30-32 kHz, probably representative of a small *Mormopterus* species (similar to calls produced by *M.* 'species 3').

Glossary

Technical terms used in this report are described in the following table.

Approach phase	The part of a bat *call* emitted as the bat starts to home in on a detected prey item; a transitional series of *pulses* between the *search phase* and *feeding buzz*, that become progressively steeper and shorter in duration.
Call	Refers to a single bat call, made up of a series of individual sound *pulses* in one or more *phases* (*search, approach, feeding buzz*).
CF (=Constant Frequency)	A type of *pulse* in which the dominant component consists of a more-or-less 'pure tone' of sound at a Constant Frequency; with *shape* appearing flat on the sonogram. Often also contains a brief *FM* component at the beginning and/or end of the CF component (*viz.* FM-CF-FM).
Characteristic frequency (Fc)	The frequency of the flattest part of a *pulse*; usually the lowest frequency reached in the *qCF* component of a pulse. This is often the primary diagnostic feature for species identification.
Duration	The time period from the beginning of a *pulse* to the end of the pulse.
Feeding buzz	The terminal part of a *call*, following the *approach phase*, emitted as the bat catches a prey item; a distinctive, rapid series of very steep, very short-duration pulses.
FM (=Frequency Modulated)	A type of *pulse* in which there is substantial change in frequency from beginning to end; *shape* ranges from almost vertical and linear through varying degrees of curvature.
FC range	Refers to the range of frequencies occupied by the *characteristic frequency* section of *pulses* within a call or set of calls.
Frequency sweep or "band-width"	The range of frequencies through which a *pulse* sweeps from beginning to end; Maximum frequency (Fmax) – minimum frequency (Fmin).
Knee	The transitional part of a *pulse* between the initial (usually steeper) frequency sweep and the *characteristic frequency* section (usually flatter); time to knee (Tk) and frequency of knee (Fk) can be diagnostic for some species.
Pulse	An individual pulse of sound within a bat *call*; the *shape*, *duration* and *characteristic frequency* of a pulse are the key diagnostic features used to differentiate species.
Pulse body	The part of the *pulse* between the *knee* and *tail* and containing the *characteristic frequency* section.
Pulse shape	The general appearance of a *pulse* on the sonogram, described using relative terms related to features such as slope and degree of curvature. See also *CF, qCF* and *FM*.
qCF (=quasi Constant Frequency)	A type of *pulse* in which there is very little change in frequency from beginning to end; *shape* appears to be almost flat. Some pulses also contain an *FM* component at the beginning and/or end of the qCF component (*viz.* FM-qCF).
Search phase	The part of a bat *call* generally required for reliable species diagnosis. A consistent series of *pulses* emitted by a bat that is searching for prey or and/or navigating through its habitat. Search phase pulses generally have longer duration, flatter slope and more consistent shape than *approach phase* and *feeding buzz* pulses.
Sequence	Literally, a sequence of *pulses* that may be from one or more bats; but generally refers to a *call* or part (e.g. *phase*) of a call.
Tail	The final component of a *pulse*, following the *characteristic frequency* section; may consist of a short or long sweep of frequencies either upward or downward from the Fc; or may be absent.

Methods

Data receipt and post-processing

Bat call data were recorded at six sites (three nights per site) using three Song Meter SM2BAT detectors (Wildlife Acoustics, USA), with an Anabat detector (Titley Scientific, Brisbane) recording over four nights at one additional site.

Data received for analysis included the following:

Detector name	Recording dates	Site	Files received
Anabat	Nights of 4/8/14 to 7/8/14	FA6	2079 Anabat zero-crossing analysis files
Song Meter 6	Nights of 2/8/14, 3/8/14 & 4/8/14 Nights of 5/8/14, 6/8/14 & 7/8/14	FA4 FA5	25 WAV files 254 WAV files
Song Meter 8	Nights of 2/8/14, 3/8/14 & 4/8/14 Nights of 5/8/14, 6/8/14 & 7/8/14	FA2 FA8	55 WAV files 60 WAV files
Song Meter 10	Nights of 2/8/14, 3/8/14 & 4/8/14 Nights of 5/8/14, 6/8/14 & 7/8/14	FA1 FA7	20 WAV files 55 WAV files

All Song Meter WAV files were post-processed with Wildlife Acoustics' *Kaliedoscope Version 2.0.3* to generate call sequence files in Anabat zero-crossing analysis (ZCA) format.

Bat call identification

All ZCA sequence files were analysed using *AnalookW* (Corben 2014), with species identification achieved manually by comparing the *AnalookW* call sonograms with those of regionally-relevant reference calls and with published call descriptions (e.g. Reinhold *et al.* 2001; Milne 2002; Pennay *et al*. 2004).

Species' identification was also guided by considering their probability of occurrence based on general distribution information (Churchill 2008; van Dyck *et al.* 2013) and/or database records obtained from Wildlife Online (http://www.ehp.qld.gov.au/wildlife/wildlife-online/index.html) and/or the Atlas of Living Australia (http://www.ala.org.au).

Reporting standard

The format and content of this report follows Australasian Bat Society standards for the interpretation and reporting of bat call data (Reardon 2003), available on-line at http://www.ausbats.org.au/.

Species nomenclature follows van Dyck *et al.* (2013).

Results & Discussion

The Anabat unit failed to record any bat calls over the four-night deployment at Site FA6. All sequence files contained just background noise generated by insects and/or wind and/or other environmental disturbance.

Similarly, Song Meter 6 recorded only insect calls and other non-bat noise; consequently, there are no bat species records from this dry season survey for Sites FA4 or FA5.

The *Kaleidoscope* conversion process generated 185 ZCA sequence files for the other two Song Meter detectors; however, only 109 of those files contained recognisable bat calls.

The number of calls recorded at each site was very low (see Table 1), which possibly reflects reduced bat activity due to cool overnight temperatures and windy conditions. Furthermore, call quality was also quite low, with most calls having weak and fragmented pulse structures, which significantly reduced the reliability of species identification.

Only two species were positively identified form this data set: *Chaerephon jobensis*, recorded at FA7 and FA8; and *Taphozous georgianus*, recorded at FA2.

Up to seven other species may also have been present, with four additional call types recognised, each potentially representing two species. Poor recording quality and similarities in the call characteristics of some species that probably occur in the study area prevented reliable identification of these calls. The unidentified call types represented the following species groups:

- *Chalinolobus gouldii* and *Scotorepens balstoni*
    - FM-qCF pulses with characteristic frequency (Fc) around 30-33 kHz, but all calls with highly variable pulse shape and frequency characteristics
    - no clear inter-pulse frequency alternation that would readily differentiate *C. gouldii*
    - no calls with clearly uniform pulses that would be attributable to *S. balstoni*
    - both species probably responsible for some of the calls
- *Scotorepens greyii* and *Chalinolobus nigrogriseus*
    - FM-qCF pulses with Fc around 37-40 kHz
    - mostly quite short duration pulses so considered most likely from *S. greyii* but pulse shapes and frequencies inconsistent so cannot discount *C. nigrogriseus*
- *S. greyii* and *Vespadelus baverstocki*
    - FM-qCF pulses with Fc around 41-43 kHz
    - considered more likely to be from *V. baverstocki*, but only a few very brief and weak calls so possibly just *S. greyii* at upper limit of frequency range
- *Vespadelus caurinus* and *V. finlaysoni*
    - FM-qCF pulses with Fc=55-57 kHz
    - most likely from *V. finlaysoni* but all calls very messy and poor quality
    - nearest records for *V. caurinus* are in the Boodjamulla National Park area, so these calls more likely from *V. finlaysoni.*

Technical terms used in the above call descriptions are explained in the Glossary.

Glossary

Technical terms used in this report are described in the following table.

Approach phase	The part of a bat *call* emitted as the bat starts to home in on a detected prey item; a transitional series of *pulses* between the *search phase* and *feeding buzz*, that become progressively steeper and shorter in duration.
Call	Refers to a single bat call, made up of a series of individual sound *pulses* in one or more *phases* (*search, approach, feeding buzz*).
CF (=Constant Frequency)	A type of *pulse* in which the dominant component consists of a more-or-less 'pure tone' of sound at a Constant Frequency; with *shape* appearing flat on the sonogram. Often also contains a brief *FM* component at the beginning and/or end of the CF component (*viz.* FM-CF-FM).
Characteristic frequency (Fc)	The frequency of the flattest part of a *pulse*; usually the lowest frequency reached in the *qCF* component of a pulse. This is often the primary diagnostic feature for species identification.
Duration	The time period from the beginning of a *pulse* to the end of the pulse.
Feeding buzz	The terminal part of a *call*, following the *approach phase*, emitted as the bat catches a prey item; a distinctive, rapid series of very steep, very short-duration pulses.
FM (=Frequency Modulated)	A type of *pulse* in which there is substantial change in frequency from beginning to end; *shape* ranges from almost vertical and linear through varying degrees of curvature.
FC range	Refers to the range of frequencies occupied by the *characteristic frequency* section of *pulses* within a call or set of calls.
Frequency sweep or "band-width"	The range of frequencies through which a *pulse* sweeps from beginning to end; Maximum frequency (Fmax) – minimum frequency (Fmin).
Knee	The transitional part of a *pulse* between the initial (usually steeper) frequency sweep and the *characteristic frequency* section (usually flatter); time to knee (Tk) and frequency of knee (Fk) can be diagnostic for some species.
Pulse	An individual pulse of sound within a bat *call*; the *shape*, *duration* and *characteristic frequency* of a pulse are the key diagnostic features used to differentiate species.
Pulse body	The part of the *pulse* between the *knee* and *tail* and containing the *characteristic frequency* section.
Pulse shape	The general appearance of a *pulse* on the sonogram, described using relative terms related to features such as slope and degree of curvature. See also *CF, qCF* and *FM*.
qCF (=quasi Constant Frequency)	A type of *pulse* in which there is very little change in frequency from beginning to end; *shape* appears to be almost flat. Some pulses also contain an *FM* component at the beginning and/or end of the qCF component (*viz.* FM-qCF).
Search phase	The part of a bat *call* generally required for reliable species diagnosis. A consistent series of *pulses* emitted by a bat that is searching for prey or and/or navigating through its habitat. Search phase pulses generally have longer duration, flatter slope and more consistent shape than *approach phase* and *feeding buzz* pulses.
Sequence	Literally, a sequence of *pulses* that may be from one or more bats; but generally refers to a *call* or part (e.g. *phase*) of a call.
Tail	The final component of a *pulse*, following the *characteristic frequency* section; may consist of a short or long sweep of frequencies either upward or downward from the Fc; or may be absent.

1.0 Summary

Feral pigs are one of the most widespread and damaging pest animals in Queensland and they are difficult to control in some situations. Feral pigs are widely distributed and inflict damage on the environment, lower agricultural production and the general amenity of Queensland.

Feral pigs also pose a disease risk to humans and the native and domestic animals of the State. They are found across most of the State and are susceptible to many exotic and endemic diseases.

Benefits also accrue from feral pigs as they provide income to many professional and amateur hunters, and the revenue gained from the export of 'wild boar' products increase export income and injects money into many small rural communities.

There are few control methods available: baiting, trapping, shooting, hunting and exclusion. The control method used varies with the habitat, safety of people and animals, and the size and location of the area to be treated.

2.0 History

Feral pigs have been part of the Queensland landscape since about 1865. The theory that feral pigs, sometimes known as 'Captain Cookers' were derived from deliberate releases or escapes from Cook's time at Cooktown in north Queensland has been discounted. The only pigs landed by Cook were killed by a fire deliberately lit by Aborigines (Pullar 1953). There has also been some speculation that pigs were introduced from New Guinea by travellers to Cape York. This too has been shown to only be the case for the later part of last century (Pullar 1953), as there are no words in the local Aboriginal language for 'pig' before this time (Pullar 1950; Pavlov *et al.* 1992).

Feral pigs were derived from stock that were let loose or wandered away from where they were being kept, often under semi-feral conditions as settlement progressed across the State. To this day, pigs are still being introduced, both accidentally (escapes from piggeries or truck accidents) and deliberately (usually by recreational hunters), to many parts of the State.

These pigs were probably descendants of Berkshire and Tamworth pigs that were introduced to Australia, including pigs transported as part of the First Fleet (Choquenot *et al.* 1996). These pigs probably then crossed with various breeds from Europe and Asia that were brought into Australia by early settlers from these regions.

3.0 Current and Predicted Distribution

Feral pigs are distributed across much of the State (Fig.1). The distribution of feral pigs is related to their strict requirements of daily water and dense foliage for protection from weather extremes, particularly heat to which they have a poor tolerance. Even so, pigs have become established within a wide variety of habitat types from the Arid Zone to the Wet Tropics. In the more arid areas, the distribution of pigs is quite seasonal and their distribution is restricted to watercourses, associated floodplains and man-made water supplies.

Fig. 1. Relative distribution of feral pigs in Australia.
Commonwealth of Australia copyright reproduced by permission from *Managing Vertebrate Pest - Feral Pigs* Choquenot *et al* 1996 after Wilson *et al* 1992

Because feral pigs usually have quite definite home ranges, and only disperse during times of major disturbance or limitations on food resources, they have been slow dispersers across much of Queensland. Because of this, feral pigs are still colonising new areas. Some coastal areas and areas around Cunnamulla and within the Wet Tropics World Heritage Area, have only been colonised by feral pigs within the last 30 years. Many cases of feral pigs establishing in new areas are because of deliberate introduction by recreational hunters, particularly in State Forests and on other State lands.

It is estimated that there are some 4 to 6 million feral pigs in Queensland (Mitchell, *pers. comm*.). No detailed survey has been conducted to accurately estimate the size of the population, however some research has been conducted on densities in different habitat types. About 75% of the estimated population is thought to inhabit tropical north Queensland (J. Mitchell, pers comm).

There is great difficulty in accurately estimating the numbers of feral pigs because of their secretive behaviour and the dense vegetation that forms their preferred habitat. Pig numbers also vary quite considerably from season to season, and from habitat to habitat. Table 1 illustrates some of the different densities of feral pigs for a variety of habitats.

Table 1. Reported densities of feral pigs for various districts and habitats.

DISTRICT	HABITAT	DENSITY	REFERENCE
Goondiwindi	pasture woodland, forests and wheat crops	0.1-3.9 pigs/sq km	Wilson *et al* 1987
Aurukun	floodplain, swamp and woodland	1>20 pigs/sq km	Dexter 1990
Aurukun	floodplain, swamp and woodland	1-40 pigs/sq km	J.Mitchell, pers comm.
Lilyvale	floodplain, swamp and woodland	4.2 pigs/sq km	J.Mitchell, pers comm.
Lakefield National Park	floodplain, swamp and woodland	4 pigs/sq km	Mitchell 1998

4.0 Estimates of Current and Potential Impact

4.1 Impact on Primary Production

The impact of feral pigs on agriculture takes three forms (Choquenot *et al* 1996):

- value of the direct losses to agricultural production;
- value of the continuing expenditure on pig control; and
- value of lost opportunities to take profit from alternative investment of this expenditure.

It is difficult to accurately provide a dollar figure to the economic damage caused by pigs as some localities will suffer less damage because of naturally low pig numbers or adequate control methods that reduce their impacts. Despite these problems, some estimates have been made of the magnitude of costs of feral pigs.

The national loss to agriculture by feral pigs has been estimated to be in the order of $100 million, but this may be a conservative estimate (Choquenot *et al* 1996).

Pigs are responsible for damage to a variety of industries. They reduce the yields of grain crops (Benson 1980, Caley 1993), damage and consume pastures (Hone 1980), reduce yields of sugar cane and some tropical fruits such as bananas, mangoes, pawpaw and lychees (McIlroy 1993), damage netting fences, damage and pollute water sources (Tisdell 1982; O'Brien 1987) and prey upon newborn lambs (Plant *et al* 1978; Pavlov *et al* 1981; Hone 1983; Choquenot 1993).

Lamb predation by feral pigs is estimated to range from 18.7% to 32% for the semi arid rangelands (Pavlov *et al* 1981; Plant *et al* 1978). Estimates for losses to grain crops in Queensland are shown in Table 2.

Table 2. Estimated value of lost crop production for Queensland 1996

CROP	% REDUCTION IN YIELD*	VALUE#
Wheat	3	$ 1.9m
Sorghum	5	$ 9.1m
Barley	1	$ 0.3m
Maize	3	$ 0.6m
Total		$ 11.9m

* Based on Tisdell 1982
# This figure is for the end of a severe drought and the winter crop figures are significantly lower than average, with the sorghum crop being inflated due to a breaking of the drought allowing large areas to be planted to summer crops.

In 1991 it was estimated that the cost of feral pig damage to sugar cane crops was in the vicinity of $628 000, which equated to a reduction in yield of 25510 tonnes of sugar cane (McIlroy 1993). The value of other crop losses has not been accurately assessed, but pigs are known to cause severe, but often

localised, damage to crops such as potatoes, melons, mandarins, strawberries, pumpkins and tropical fruits (bananas, mangoes, lychees, pawpaws and pineapples). One farmer in the Tully area reported losses of up to 140 bunches of bananas per month (valued at between $4,200 and $12,600) for a twenty hectare plantation, but average losses in the area are about 20 bunches ($600 - $1800) per month (Noble 1996).

The damage caused to pasture and competition with domestic stock is difficult to estimate, as there is considerable variation across pasture types and their biomass. It has been shown that pig activity reduces pasture availability and can lead to the establishment of less desirable pasture species, including weeds (Hone 1980). Most work to date on the impacts of pigs on grazing industries has been concentrated on the predation of lambs and the effects on the sheep grazing lands of semi-arid New South Wales, which is similar in some respects to the southern sheep grazing areas of Queensland.

It has been estimated that Queensland spent approximately $1.1 million in 1984 on feral pig control, which equates to about $2.2 million in today's dollar values (Choquenot *et al* 1996). This amount includes both government and private expenditure on control by various means. It does not include amounts spent by recreational hunters who also contribute to control. This estimate of expenditure is based upon estimates of landholder and government expenditure on control, and so should only be used as a guide to current control costs.

4.2 Impact on the Environment

The impacts of feral pigs on the environment takes one of two forms: damage to habitats or direct damage to animal species.

Degradation of habitats is probably the most obvious form of environmental damage caused by pigs. This damage can be because of rooting, trampling, tusking or rubbing trees and consumption of plants and soil organisms.

The rooting behaviour of pigs has been linked to areas of high soil moisture such as drainage lines and swampy areas (Hone 1988, 1995; Mitchell 1993). This rooting behaviour can severely disrupt the composition of the soil's microorganisms, and subsequently nutrient cycling. Rooting can also disrupt the regeneration of plants, change the composition of the plant community, and allow water erosion to occur in drainage areas where the soil has been severely disturbed.

Pigs can physically destroy vegetation by trampling it along their paths or in the areas where they wallow. Pigs will often have a favourite rubbing tree, but this has not been linked to territory marking. This behaviour is to remove parasites and to relieve irritations. They also tusk trees as part of their normal behaviour. Undermining and rooting during feeding can lead to trees being uprooted.

Although pigs are known to feed on most parts of a wide variety of native and exotic plants, they usually prefer the softer higher energy parts, tubers and fruits. Their negative impact on plant communities is partially balanced by the positive impact of their aiding in the spread of some plants by passing their seeds in dung. This spread of plants also includes weed species.

The feral pig has also been implicated in the transmission of plant diseases such as rootrot fungus (*Phytophthora cinnamomi*) and other plant pathogens. Introduction is usually via contaminated mud and soil carried by pigs and by the physical damage to plants that allows diseases to enter through the wounds.

Feral pigs are known to consume numerous native animals including earthworms, amphipods, centipedes, beetles and other arthropods, snails, frogs, lizards, snakes, the eggs of freshwater crocodiles (C*rocodylus johnstoni*), turtles and their eggs and small ground nesting birds and their eggs (Pullar 1950; Tisdell 1984; McIlroy 1990; Mitchell 1993; Roberts *et al* 1996).

Without definitive information on the prey eaten, rates of predation, density and status of prey and whether predation is density dependent (Choquenot *et al* 1996) it is impossible to accurately determine what effect pigs have on native fauna, apart from the observable damage to individual animals.

Competition with other animal species has not been proven, but there is some evidence that pigs may compete directly with some specialist feeders such as the Cassowary (C*asuarius casuarius*) (Choquenot *et al* 1996) and other species such as the brolga (*Grus rubicundus*) and magpie geese (*Anseranas semipalmata*) (Tisdell 1984).

4.3 Disease

The feral pig poses a serious threat to Queensland's livestock industries and human health through being a potential carrier, or amplifier, of many endemic and exotic diseases. The diseases that pose the greatest threat are listed in Table 3.

Table 3. List of endemic and exotic diseases carried by feral pigs.

ENDEMIC	**EXOTIC**
Brucellosis (*Brucella suis)*	Foot and Mouth Disease (FMD)
Tuberculosis (*Mycobacterium spp*.)	Classical Swine Fever
Porcine Parvovirus	Aujeszky's Disease
Leptospirosis (*Leptospira spp*)	Japanese Encephalitis
Melioidosis (*Pseudomonas pseudomallei*)	Swine Vesicular Disease
Sparganosis (*Spirometra erinacei*)	African Swine Fever
Murray Valley Encephalitis	Trichinosis
	Rabies
	Screw-worm Fly infestations

Of the exotic diseases, Foot and Mouth Disease (FMD) poses the greatest threat to Queensland's economy. It has been estimated that a FMD outbreak would cost more than $3 billion nationally and if it were to persist in the order of $0.3 - 4 billion annually (Wilson and Choquenot 1996). FMD could have devastating effects on the livestock industries of Queensland, particularly if it were introduced through Cape York, where early detection and eradication

would be difficult. The Department of Primary Industries and the Commonwealth have formulated a national approach to exotic disease management, the Australian Veterinary Emergency Plan (AUSVETPLAN).

4.4 The Pig as a Resource

Many people are of the opinion that the feral pig should be managed as a resource rather than eradicated as a pest. Control programs are usually conducted that do not utilise the feral pig as a resource. These control programs are conducted because of the economic and environmental damage caused by feral pigs and the legislative requirement in all mainland States except the ACT and South Australia.

The feral pig marketed as 'Wild Boar', has been harvested for export since 1980. The main markets for Australian wild boar meat are European Union countries (particularly Germany, France, Italy, Belgium/Luxembourg) and Japan and Sweden. The EU countries have traditionally consumed wild boar meat, and with high human populations and decreasing boar populations in those countries, they have increasingly become dependant on imports for much of their wild boar meats.

Australia now supplies some 20-30 percent of the wild boar consumed, and is now close to overtaking Poland as the worlds largest supplier of wild boar (Ramsay 1994). This market is very volatile, with sales and prices fluctuating from year to year. The market seems to be dependent on the length and severity of the northern winter, which effects the supply of local wild boar.

The Australian Game Meat Producers Association has prepared a Code Of Practice for Humane Shooting, Harvesting and Hygienic Handling of Game Animals. This code of practice provides guidelines to shooters and pig 'chasers' on how to harvest and handle the product so that it is suitable for the export market.

The value of wild boar exports has varied between $10 and $20 million over the last few years because of Australia's drought conditions and the variability of European supply and demand (Ramsay 1994). The number of carcasses processed in Australia is shown in Table 4.

Table 4. Number of wild boar carcasses processed in Australia 1989-1992.

YEAR	CARCASSES
1989	203 837
1990	96 962
1991	101 006
1992	271 133

It has been estimated that there are about 3000 Queensland Meat and Livestock accredited shooters in Queensland and 1200 licensed professional kangaroo shooters who take pigs opportunistically (Dee, pers. comm.). There are also numerous other shooters and hunters who do not sell carcasses. Recreational feral pig hunters across Australia make a significant impact on pig numbers, as well as injecting funds into local economies where they hunt (Tisdell 1982).

In Queensland in 1996 there were about 70 seasonal chiller boxes operating that received approximately 65 000 carcasses, which was about 60% of the national total. Based on this percentage of the national trade, Queensland harvests between $6 and 12 million worth of feral pigs per year (Ramsay 1994). These boxes are located as far north as Lakeland and Doomadgee, but the grain growing areas provided the greatest and most constant supplies of 'wild boar'. The average price paid to 'hunters' in 1996 was 90 cents/kg, but by mid 1997 averaged about 70-75 cents/kg. Preferred carcasses are between 30 and 60 kg with anything below 26 kg being rejected and carcasses over 90 kg being difficult to chill and process. In 1997 there were four export licensed processing works in Queensland, located in Longreach, Roma and two at Eagle Farm in Brisbane. The game meat processing industry in Queensland employs up to 80 people during times of peak production/harvest (Dee, pers. comm.).

4.5 Cost:Benefit Relationship

Whilst the game meat industry and recreational hunters play an important role in controlling feral pigs in some localities, there is an overall net cost to the broader community from feral pigs. The damage done to crops, pastures, fences, water facilities and livestock can be quantified ($100M), and are in excess of the value of the 'wild boar' market ($20M) even without including the costs to the environment and the potential costs from exotic disease.

5.0 Biology and Ecology

5.1 Habitat Requirements

Feral pigs are found in a wide variety of habitats, ranging from dry arid areas, to high mountainous forests and grasslands, to dense tropical rainforest. The two requirements that feral pigs have that restricts their distribution in these habitats are daily water and suitable cover.

5.2 Diet

The feral pig is considered to be an opportunistic omnivore (Choquenot *et al* 1996), and it has been known to consume the following groups of foods:

fruits and seeds: grains, fruits, rainforest fruits;
foliage and stems: grasses, sugar cane, banana trees;
rhizomes, bulbs and tubers: including tuberous crops such as potatoes;
fungi; and
animal material: carrion, earthworms, lambs, arthropods.

The foods consumed vary from region to region and the potential food sources are limited by availability rather than preference for any one food type.

Pigs have a relatively high-energy requirement, particularly during lactation, and growth of young pigs (Choquenot *et al* 1996). Sows require about 15% of their diet to be crude protein in order to successfully suckle their young. This protein requirement can be met from plant material, but is met more commonly from animal matter such as earthworms, carrion, arthropods, frogs and reptiles. Animal matter rarely exceeds 5-18% of a pigs diet (Giles 1980; Pavlov 1980).

Feral pigs will relocate in response to food availability, particularly seasonal requirements for higher protein and energy associated with reproduction and growth.

5.3 Social Structure and Behaviour

The most common groupings of feral pigs is either a few sows and their young, bachelor groups (individuals less than 18 months of age), or individual boars (usually older than 18 months). After weaning pigs will remain with their mother until the next litter, or in the case of sows, until they mate (Masters 1979; Giles 1980; Pavlov 1980).

Group size varies with age, sex, food and water availability and disturbances (such as hunting or other control measures). Group size can range from solitary boars to groups of 100 or more sharing a locally scarce resource such as a single waterhole during droughts.
Feral pigs habitually make use of trails, shelter areas, feeding and watering areas (subject to availability), rubbing and tusking trees and wallows. Even though they are habitual in their use of such areas, there is no evidence that feral pigs, of either sex, actively defend territories.

The size of a feral pig's home range depends on a number of variables, sex (males have larger home ranges than females) and resources. Food availability and quality is thought to be the main determining factor influencing home range size. Home range size varies from as little as 0.16 sq km for furrowing sows, to greater than 40 sq km for individual boars in the semi arid rangelands (Saunders 1988; Giles 1980).

Feral pigs are most active at night or during times of cooler temperatures (late afternoon, early morning, cooler weather, rainy or overcast conditions. They may become active during periods of disturbance from hunting or other human activities such as stock mustering (Pullar 1950; Giles 1980; Saunders and Kay 1991).

5.4 Reproduction and Population Dynamics

The feral pig is polyoestrus; adult sows have a 21-day oestrus cycle and a gestation period of 112-114 days. Their breeding is limited by food availability and quality (particularly the dietary requirement for about 15% protein). If food quantity and quality is available then feral pigs have the ability to produce two litters every 12-15 months (Giles 1980; Pavlov 1983; Ridpath 1991).

Sexual maturity in feral pig sows is dependent on weight (25-30 kg) rather than age, similar to domestic pigs (Masters 1979; Giles 1980; Pavlov 1980). The litter size of feral pigs generally averages between 4.9 and 6.3 piglets, but may be as high as 10 under favourable conditions (Choquenot *et al* 1996).

Juvenile mortality ranges from 10-15% under favourable conditions to 90 or 100% during periods of drought (Masters 1979; Giles 1980; Saunders 1988). Adult mortality ranges from 15 to 50% depending upon food availability and quality, predators (including hunting pressure) and disease.

The potential for pig populations to grow is estimated by their exponential rate of increase (r). The corresponding (e^r) value provides the approximate multiplication rate. Table 5 gives an indication of the potential rates of increase of a feral pig population starting at 100 (female) pigs without external influences such as harvesting, control, immigrations or emigrations.

Table 5. Potential rates of population increase for a base population of 100 feral breeding sows.

HABITAT	REFERENCE	e^r	After 1 year	After 2 years
Semi-arid rangelands	Choquenot 1994	0.97	197	388
"	Giles 1980	1.82-2.0	282-300	795-900
Tablelands	Saunders et al 1990	1.28	228	519
Wet/Dry Tropics	Caley 1993	0.78 (max)	178	316

6.0 Efficacy of Current Control Methods

6.1 Exclusion and Habitat Modification

Fencing is effective for feral pig control for small high value areas such as cropping and lambing paddocks. Fencing has not been adopted as a large scale control method for several reasons: initial high expense, high maintenance costs, low cost effectiveness for large areas and relocation of the problem rather than overcoming it.

Several trials have been conducted to determine the most effective fence design (Hone and Atkinson 1983; Plant 1980; Tilley 1973). Electrification significantly increases the effectiveness of fencing to exclude or reduce the movements of feral pigs. The most effective fence design features 8/80/15 hinge joint, steel posts at 5m intervals, two top barb wires, and an electrified outrigger wire 25 cm above ground level (Hone and Atkinson 1983). This electrified fence design costs near $2500/km to construct.

Habitat modification, e.g. clearing remnant vegetation or closing water points, is rarely used as a control technique, as it results in the destruction of habitats for native species, is poor soil conservation practice and usually only moves the problem to another location.

Changes in management practices sometimes occur when pigs are a serious economic problem. The change in management usually revolves around altering the duration of lambing, but this was shown to be ineffective by Hone (1987). A more effective change in management involves lambing in paddocks away from areas of known pig activity, or changing from sheep breeding and wool growing to wool growing alone, or even cattle production in extreme cases of pig predation. The shift in enterprise may involve potential lost income to the landholder.

6.2 Poisoning

Poisoning is the most cost effective and efficient control method currently available for feral pig control (Korn 1986). The use of poisons is restricted, with baits containing 1080 only being able to be prepared by registered operators.

1080 (Sodium monofluroacetate) poison is the one of only two products registered for use in Queensland to control feral pigs, the other being CSSP (see below). 1080 poison has many attributes that make it suitable for general usage; it is found in many native plant species, therefore native animals have a certain inbuilt tolerance to it, and it degrades readily in soil. There are several disadvantages in using 1080; it is highly toxic to dogs, it has no antidote and secondary poisoning, via animals consuming carcasses, can occur.

1080 has been widely used for feral pig control across Queensland and can be used with meat (in western and northern grazing areas), grain, pellets or vegetables, as the bait material. Prefeeding is usually conducted for a period of 2 or 3 days before poisoning to attract as many pigs as possible to the bait station.

Not all pigs within an area will take baits (depending on alternative food availability, density of baits and pigs). The success rates of baiting vary considerably, with population reductions ranging from 58% to 99.4% (Hone and Pederson 1980; Bryant and Hone 1984). The success of baiting also varies with operator experience and incidence of vomiting. Pigs are known to vomit following 1080 ingestion, and males are known to vomit more than females independent of amount of poison ingested (Hone 1987). This vomiting behaviour by feral pigs will reduce the effectiveness of current baiting campaigns and may lead to bait shyness for future campaigns. Anti-emetic compounds have not been shown to reduce the amount of vomiting by feral pigs (O'Brien *et al.* 1986).

Warfarin, an anticoagulant, is another poison that has been trialed for use in feral pig control. It has not however been registered for use by the National Registration Authority for broad scale use. It has several benefits over other poisons, it has an antidote (Vitamin K), can require several doses before causing death, secondary poisoning does not occur, it does not cause vomiting and is cheaper than 1080. It does however have some disadvantages: it is not specific, requires several doses before becoming effective and can take several days before mortality occurs.

Phosphorus based poisons (Sayers Alport Phosphorus-SAP and CSSP) have been used in the past by landholders. They cause a long and painful death, and consequently are not used or recommended by the Department of Natural Resources and Mines. Because they could previously be purchased by landholders without restriction, they have been widely used and stored by landholders. The exact amount of these poisons used in pig control is unknown. These poisons also have serious impacts on non-target species as dose rates vary and there is no control over the use of stocks held by landholders.

6.3 Recreational Hunting

It has been estimated that recreational hunters kill 15-20% of the feral pig population in accessible areas annually (Tisdell 1982). The use of recreational hunters to control pig numbers is seldom effective as recreational hunters only kill a small percentage of the population, disperse pigs through regular disturbance and hunt on relatively small, easily accessible areas.

However the value of recreational hunters to the broader community must not be overlooked, recreational hunting can provide significant revenue to small communities.

Hunters have been known to introduce pigs to 'clean' areas to provide themselves with hunting opportunities in the future. Hunters have also been known not to take small pigs or sows or to castrate males or to cut the ears off pigs to make them more difficult to catch with dogs, thus insuring 'sport' in future seasons. These actions are in direct opposition to effective pig control.

The use of dogs to hunt pigs, either to flush them out of shelter, or to chase and catch them has been criticized by animal welfare groups, but is currently legal throughout Queensland. A review of the animal protection legislation by the Department of Primary Industries may alter this situation. The success of dogs capturing pigs has been studied and results show that solitary pigs are caught on 90% of the occasions when chased (Caley 1993), when groups of

pigs are encountered only one is usually caught and only about 70% of those chased are caught (Oliver *et al.* 1992). Another risk associated with using dogs is them becoming lost and their subsequently becoming 'feral', preying on stock and native animals.

6.4 Trapping

Trapping of feral pigs has gained increasing acceptance as trap designs improve, feeding behaviour is better understood and the restrictions on the use of poisoned baits increases. Trapping is relatively expensive and labour intensive and so not practical for large scale control. Trapping is environmentally friendly, relatively humane and some costs can be defrayed against the sale of pig carcasses. However, the success of trapping has been found to vary from 28% of the population (Saunders *et al* 1993), to 81% (Choquenot 1993).

Some of the other advantages of trapping over other control methods are that (Lukins 1989):

- trapping does not interfere with normal pig behaviour (unlike shooting or dogging);
- the number of pigs is known exactly, and carcasses can be removed safely;
- it is a flexible technique and can be fitted into routine property activities, making it economical in terms of labour, materials and number of operators; and
- properly designed traps can be moved or re-used as necessary. Good trapping makes use of opportunities as they arise.

Hone *et al* (1980) outlined the points that landholders and managers need to consider when trapping:

- type of trap to use;
- number of traps to use;
- where to put traps;
- number of nights each trap is used;
- type and amount of bait to use; and
- amount and duration of pre-feeding.

Several trap types are successful. The relative success and design of trap to use depends on the local environment, materials, number of pigs to be trapped and presence of non-target species such as cassowaries (Figure 2.).

Some of the other factors that may influence the decision to trap include: it is time consuming and expensive to initially build and maintain traps.

The Department of Natural Resources and Mines advises landholders to consider trapping when poisoning is impractical, or as a follow up to poisoning. The Department also advises landholders to reduce disturbance to pigs from shooting or dogs before and during the trapping period.

Hone (1984) has described the important steps in trapping:

- feeding sites should be placed where feral pigs are active, for example, water points and pop-holes in fences;
- initially, feed the pigs with bait such as grain and pellets (fermented material is often attractive), vegetables or fruit, meat or carrion;
- build the trap where feed is being taken, and leave it open and baited, but not set, for one or two nights;
- then set the trap each night;
- if the feed is being taken, continue to trap until no more pigs are caught;
- leave the trap unset and feed a different bait from that used initially;
- if feral pigs start taking the bait, set the trap for several nights; and
- once no bait is taken, start feeding elsewhere before moving the trap.

6.5 Biological Control

Pathogens and immunocontraception via a vector have been suggested as possible biological control methods for feral pigs.

These methods have not been pursued, as it would be difficult if not impossible to stop the spread of any disease or disease borne immunocontraception to domestic pigs. The feral pig industry, and the associated export and flow on revenue would also be significantly affected by any such disease.

Fig.2 Cassowary Safe Feral Pig - Box Trap (Mitchell and Dorrington)

6.6 Fertility Control

Currently there is no work being carried out on producing an immunocontraceptive bait for feral pigs. There is research being conducted on finding an immunocontraceptive for control of rabbits, foxes and rodents. As with these other species, there are problems involved in possibly developing such a control method (Bomford 1990):

- lack of long-acting contraceptive compounds (making repeat dosing necessary);
- high costs of delivery by baits (particularly when repeat dosing is needed);
- less effect on population size than when an equivalent number of pigs are killed, due to repeat dosing requirements; and
- potential effects on non-target species.

Because delivery methods are the same it would be far more efficient to provide a poisoned bait than an immunocontraceptive bait.

6.7 Shooting (helicopter and ground shooting)

Shooting has been used as a control method ever since feral pigs first became a problem in Queensland. Shooting, particularly from the ground is a very labour and resource intensive method, and cannot be used to control pigs over large areas, particularly when pigs are at low densities. Shooting, both ground and air, can cause pigs to disperse and requires a great deal of skill for it to be cost effective.

The use of helicopters in recent times has made shooting a more economic option, particularly in inaccessible areas. Helicopter shooting still has some shortcomings. Some habitat types can conceal pigs from the air making them difficult to shoot and shooting cannot be used as a stand alone control measure, as it will only reduce the population by a limited amount.

It has been proposed to use ‘Judas’ pigs in a similar way as ‘Judas’ goats are used in feral goat control. This method involves the use of a radio collared individual to locate other animals after it is released and rejoins a group. Because pigs are not as gregarious as goats, this method has limited application and is seldom used.

6.8 Control During Exotic Disease Outbreaks

In the event of an exotic disease outbreak, financial and legal control constraints take on less importance and the amount of control required is increased. The procedure for an exotic disease outbreak, as set out in the AUSVETPLAN, requires that containment of the disease within a geographic area occurs first, and secondly that vector population reduction is carried out as quickly as possible. Monitoring of the adjoining vector population for disease incidence must also be carried out to assess the rate of spread of the disease.

To successfully plan an eradication campaign for containment of an outbreak of exotic disease within a feral pig population several factors, including the delay in first detecting infected animals, the prevalence of infection and the size and location of the area to be decontaminated must be determined (Pech and McIlroy 1990). In order to eradicate an exotic disease, it is necessary to reduce the vector population to the threshold at which the disease will not spread. This varies for different areas but has been estimated to be in the order of 95%. However, in simulated exercises reductions in the order of 40-80% have been achieved. This result indicates that current planning and control measures for pigs will need to be modified to achieve successful reduction of populations to required levels.

7.0 Animal Welfare Considerations

In Queensland the *Animals Protection Act* 1925, gives no protection to any feral animal but does provide, in broad terms, that procedures to destroy declared animals must not constitute 'unreasonable, unnecessary or unjustifiable ill-treatment'. Ill-treat is defined as : ill-treat, wound, mutilate, overdrive, override, overwork, abuse, worry, torment, torture and cause any animal unnecessary pain or suffering; also overload or overdrive when loaded, and overcrowd, and unreasonably beat or kick.

This legislation is currently being reviewed. Once the legislation review is complete, a new Act is expected to be tabled in 1998. This new legislation will be prepared by the Department of Primary Industries in consultation with animal welfare groups, the pet industry, environmental groups, primary producers and the Department of Natural Resources and Mines and will have broad community input.

As mentioned above, the use of dogs in chasing and capturing pigs has been condemned by animal welfare groups, but remains legal in Queensland. There have been suggestions that the practice has been withdrawn from the recommended methods list in NSW, and penalties of up to $10 000 being applicable for using this method of pest control.

8.0 Management and Control Practices

8.1 Legislative Status in Queensland

The feral pig is a declared animal under Section 69 of the *Rural Lands Protection Act* 1985. It is categorized as an A1, A2 and A6 animal for the whole State, which means that:

A1 in respect of an area if the introduction of those animals into that area should, in the opinion of the Governor in Council be prohibited;

A2 in respect of an area if those animals-
(i) are not vertebrate animals native to that area; and
(ii) should, in the opinion of the Governor in Council, be destroyed in that area;

A6 in respect of an area if the keeping and selling of those animals in that area should, in the opinion of the Governor in Council, be subject to prescribed conditions and restrictions.

Penalties applicable to landholders for noncompliance with the provisions of the Act, are shown in Table 6.

Table 6. Offences and penalties applicable to feral pigs in Queensland.

OFFENCE	MAX. FIRST OFFENCE	MAX. SECOND OFFENCE
Failure to control	$375	$1,500
Failure to comply with direction	$1,500	$3,750
Introduction of Category A1 animals	$7,500	
Restrictions on keeping and selling A6 animals	$3,750	
Liberating declared animals	$7,500	

Section 80 of the *Rural Lands Protection Act 1985* places the responsibility for control of declared animals with the landholder, and there is a penalty of $375 for failure to control. As can be seen from the list of penalties, people releasing feral pigs into areas for hunting purposes are liable to a $7,500 fine, and persons who keep feral pigs are liable to fines up to $3,750.

The Department of Natural Resources and Mines policy is to 'reduce the impact of feral pigs through coordinated and sustained control programs in strategic areas of Queensland where feral pigs constitute a high risk to agricultural production and/or the environment.'

The policy states that A2 animals shall be subject to 'sustained control in strategic areas in concert with commercial utilisation where appropriate for established pests.' This has been further explained by defining:

Sustained control as ' the implementation of control on a regular basis to keep population at or below a threshold density at which the benefit of control is equal to or greater than the cost of control. Sustained control requires the development of pest animal management plans that include regular and integrated control options. (Integrated control is the use and combination of multiple control techniques).'

Commercial utilisation (harvesting and hunting) as ' utilising animal pests as a resource is particularly appropriate for some species such as the feral horse, feral pig, feral goat and rabbit. Commercial utilisation can be integrated with other control methods to regulate pest animal numbers and should be incorporated in management plans.'

8.2 Management Strategies in Queensland

8.2.1 Pastoral Zone

In the pastoral zone, the main management strategy is baiting, including aerial bait dispersal. This strategy is used because any program needs to cover large areas, but should be concentrated around areas where pig activity is greatest such as around, but not too close to, drainage lines and watering points. The actual impact of feral pigs in these extensive grazing areas, particularly the cattle grazing areas, is limited. Commercial utilisation by professional and recreational hunters also forms part of the overall control strategy, as it is control at a low cost to the landholder. Because this zone takes in arid and semi arid regions, feral pig numbers are subject to wide variations due to climatic extremes that lead to food and water shortages, but also occasional large numbers.

8.2.2 Wet Tropics

The Wet Tropics presents unique problems due to the inaccessible nature of the terrain, high conservation value, plentiful food and water, and proximity to urban settlement. Control is mainly by using traps (cassowary and wallaby safe) with limited baiting in some areas. Trapping is conducted at accessible sites that border or are in close proximity to agricultural enterprises and urban settlement. Broadscale baiting is not possible because of the presence of endangered fauna and tourists. A project to determine the impacts of feral pigs on the natural environment in this region, and a successful community based trapping program has been running in this area for several years. Shooting and 'dogging' are considered to be ineffective control methods because of the thick vegetation and the potential for dogs to escape or become lost, and become problems themselves.

8.2.3 Agricultural Zone

Feral pigs cause a great deal of damage to agricultural crops, particularly grain crops (as shown in Table 2) and considerable resources are allocated to control in this zone. The main means of control is capturing either with dogs or in traps, or hunting. The feral pig or 'wild boar' industry provides a significant input into local economies, and also controls a significant number of pigs. Baiting is carried out to a lesser extent depending on landholder

perceptions of hunting, the extent of the problem, proximity to chiller boxes, prices paid for carcasses and availability of alternate food sources.

8.2.4 Near Urban Situations

Feral pigs are reasonably common in these situations, and are sometimes found in surprising numbers: approximately 100 feral pigs were found along a creek line in the Redland Bay area, south of Brisbane in 1996. Feral pigs in these situations cause damage to parklands, for example Mt Glorious National Park, and to gardens and hobby farms. Control options in these situations are limited. Baiting can only be used in areas where it is considered to be safe by the local Land Protection Officer. Trapping is considered to be the safest and most effective control option. Hunting is of limited value because of firearms restrictions and the problems of using dogs. Exclusion fencing is practiced and is effective for high value areas.

8.3 Property Management Strategies

The Bureau of Resource Sciences (BRS) (Choquenot *et al.* 1996) has outlined four stages of a strategic management program at both the local and regional level:

Problem definition - The problem, if it is real or perceived, needs to be defined. This process will compare the dollar or conservation value of the damage caused by feral pigs, with the benefits received from controlling them. The estimation of environmental costs and benefits is difficult and requires the costing of intangible factors.

Developing a management plan - The main components of developing a management plan is to establish: a set of objectives (interim and long-term goals), a time frame to achieve goals, and indicators for measuring performance. There are several options for the level of control, these range from local eradication, strategic management, commercial management, crisis management or no management, depending on the particular situation. Strategic management offers the most flexible option, as it allows for changes in economic, environmental and pest circumstances. Control techniques need to be included in the preparation of the plan.

Implementing the plan - In order to effectively implement the plan, it is essential to gain broad support for the plan. Stakeholders should be identified and their involvement and 'ownership' of the plan should be encouraged.

Monitoring and evaluating progress - Monitoring of both the operational (cost effectiveness) and performance (effectiveness of the management plan) components of the plan is essential if changes are to be made, and mistakes rectified.

This approach to preparing an effective management plan will allow for the preparation of a dynamic plan that can be adapted for a variety of situations and changing circumstances.

9.0 Acknowledgments

This assessment has drawn heavily from information contained within the Bureau of Resource Sciences publication “Managing Vertebrate Pests - Feral Pigs” (Choquenot, McIlroy and Korn 1996). Additional information and data has been include so as to give the assessment a Queensland emphasis.

Information has also been supplied by Cliff Dee (Wild Game Resources), Graham Hardwick, Barry Toms and Jonathon Lee.

1.0 Summary

Mice cause serious damage to Queensland grain crops during mouse plagues. The problem is most severe on the Darling Downs where plagues are more frequent but major crop damage has also occurred in recent years in the Dawson and Callide catchments and around Goondiwindi. Mice are a problem in other crops as well, especially vegetable crops, and on pig and poultry farms within these regions.

Mice are also a serious nuisance in homes and buildings during a plague. They contaminate foodstuffs, destroy paper and cloth goods, and gnaw on electrical equipment and other possessions. Because they can transmit *Salmonella* (which causes food poisoning), they constitute a potential health hazard if they are in food preparation areas.

Control of mice is usually achieved by trapping and poisoning. Trapping is effective in buildings that can largely be made 'mouse-proof' by blocking all holes and placing sealing strips on doors. The few mice that enter are easily removed by trapping. Where buildings cannot be rodent-proofed (e.g. sheds), a number of rodenticides are available for use.

No rodenticide is currently registered for broadacre use, although zinc phosphide bait is presently under consideration by the National Registration Authority for Agricultural and Veterinary Chemicals (NRA). If it receives registration, strategic baiting will then be an option available to farmers. At present, their management options are restricted to habitat manipulation, except during major plagues, when the NRA provides temporary registration of a rodenticide for in-crop control.

Plagues vary in timing and location within a district according to the degree to which on-farm environmental factors are conducive to a build up in mouse numbers. For this reason each farmer needs to monitor mouse numbers on their farm at regular intervals so they can take appropriate management actions to control mice when their numbers are building up and thus restrict the amount of crop damage. Tracking mouse numbers through time can provide an advance warning of a plague.

Regular broadscale monitoring is undertaken on the Darling Downs each year (in June, September, October and November) by the Department of Natural Resources and Mines. A one per cent trap success or greater (that is, 9 or more mice caught in 940 traps) in spring is considered the commencement of the increase phase. Conversely, a plague is not expected if the September trap return is lower than one per cent.

Mice are not a declared pest under the *Rural Lands Protection Act 1985* so there is no legal requirement that they be controlled. The Queensland Department of Natural Resources and Mines' policy on mice includes provision for the department to monitor rodent populations on the Central Darling Downs and provide short and long term predictions on the potential for plague development.

2.0 History

House mice (*Mus domesticus*) are introduced pests probably arriving in Australia at the time of European settlement (Singleton and Redhead 1989). They are now distributed throughout the continent and are ubiquitous in agricultural areas where they are usually found in areas of long grass (e.g. along fencelines), within crops and stubble, and around sheds and houses. At most times, their numbers are low but when seasonal conditions are favourable, their numbers can increase to such a level that they become a serious pest, causing damage to crops, stored products and equipment. These events are called mouse plagues.

The earliest reported plague of mice in Queensland was in 1917 on the Darling Downs. From then until 1980, plagues occurred on average once every 10 years, but since 1980 the incidence of plagues has increased (Singleton and Brown 1998). Between 1980 and 1995, a plague has occurred on the Darling Downs on average every three years. This increase in frequency of plagues has been attributed to the progressive adoption in recent years of conservation farming practices such as stubble retention that provides undisturbed habitat for mice for long periods of the year (Singleton and Brown 1998).

The trigger for a mouse plague is considered to be above-average autumn rainfall—particularly if the rain follows one or two years of drought. Saunders and Giles (1977) suggested that this relationship arises because populations of mice and their natural predators, pathogens and parasites decline during a drought, and then when conditions again become favourable, mouse populations reach plague proportions before these normal agents of mortality are re-established. However Redhead *et al.* (1985) proposed that drought-breaking rain, rather than drought *per se,* was the important factor, as it ensured a good growth of grasses in the following spring when the breeding season of mice begins. If conditions continue to be favourable, breeding continues through summer and, by autumn, mice can be in plague proportions (Redhead and Singleton 1988; Singleton 1989).

3.0 Current and Predicted Distribution

Although mice are found throughout Queensland, plagues of mice occur primarily in the grain-growing areas (Fig. 1). It appears from a questionnaire sent to members of the Queensland Grain Growers Association in 1997 that the frequency of plagues varies between grain-growing areas. For example, the questionnaire returns indicated that four plagues had occurred on the Darling Downs between 1992 and 1997. In contrast only one plague occurred in Goondiwindi and South West Queensland (in 1995), and one in the Dawson and Callide Valley regions (in 1997). Very few problems were experienced with mice in the Lockyer, Burnett and Emerald regions over the five years.

Figure 1. Map of grain-growing areas in Queensland The extent and frequency of plagues also varied between farms within each region. Although the Darling Downs had experienced four plagues between 1992 and 1997, the majority of farmers experienced only one plague within this time interval (Table 1).

Table 1. Number of plagues experienced between 1992 and 1997 by Darling Downs respondents (*n*=204) to a questionnaire (from Donkin and Caughley 1998).

No. of plagues experienced	% of respondents
0	22
1	53
2	23
3	2

These results show how spatially and temporally variable plagues can be. A farmer will experience a mouse plague according to the degree to which on-farm environmental factors are conducive to a build up in mouse numbers. For this reason farmers need to monitor mouse numbers on their farms at regular intervals to detect the onset of a plague. They will then be able to take appropriate management actions to control mice at that time and thus restrict the amount of crop damage.

Regular broadscale monitoring can track mouse numbers through time to provide an advance warning of a plague. Such monitoring is undertaken by the Department of

Natural Resources and Mines on the Darling Downs and the data collected are entered into a model that predicts the probability of a plague at least six months in advance.

3.1 Monitoring Methods

3.1.1 Trap Lines

The monitoring on the central Darling Downs by the Department of Natural Resources and Mines is undertaken each year in June, September, October and November. Forty-seven trap lines with 20 break-back traps in each (total of 940 traps) are set for one night. The number of mice caught is entered into a model developed by the Queensland University of Technology that predicts the probability of plague the following autumn. For example, a one per cent trap success or greater (that is, 9 or more mice caught in 940 traps) in September is considered the commencement of an increase phase that will lead to a plague the following autumn. Conversely, a plague is not expected if the September trap return is lower than one per cent.

Lines of break-back traps in different habitats could also be used by farmers for on-farm monitoring. The method gives a good indication of abundance and provides a cheap, simple and effective means of keeping track of mouse numbers over time.

3.1.2 Bait Cards

Bait cards have been introduced recently as a technique for estimating the likely effectiveness of crop baiting. Bait cards are 10cm x 10cm square pieces of white paper that are soaked in canola oil and pegged out overnight in a crop or other habitat. To obtain a reasonable estimate, at least five cards should be placed 5-10 metres apart at each site.

The bait card technique is a less reliable indicator of mouse numbers. The amount of a card eaten is largely a reflection of the numbers of mice and the availability of food for the mice rather than the numbers of mice present *per se*. When food is plentiful, the cards may be largely untouched even when mouse numbers are high. However, if bait card take is greater than 10%, it indicates (i) that mouse numbers are high and (ii) the mice will readily take the bait and cost-effective control will be achieved.

3.1.3 Visible Sightings

There are a number of visual sighting techniques available to farmers. The presence of burrows or of worn paths between cracks on the cracking clay soils of the Darling Downs are good indicators that mice are present. The number of burrow entrances counted per unit area in crops, contour banks and along grass verges and fencelines gives an indication of mouse activity. Freshly dug soil at the entrance to a burrow indicates that the burrow is active.

Counting numbers of mice seen on a road regularly travelled at night can provide an indicator of mouse abundance. Another visual method can be the number of mice seen in a one minute period after switching on a light in a shed.

3.1.4 Rate of Bait Removal

The rate of removal of baits placed in sheds and around grain stores is a good indicator of whether mouse numbers are increasing or decreasing.

3.1.5 Crop Damage

Crop damage from mice is not a good indicator of mouse numbers as it is often unnoticed until it is severe. Signs of high mouse activity include chewed stems or damage to seed heads. Debris such as seed husks at the base of plants suggests the damage to seed heads has been caused by mice rather than insects or birds.

4.0 Estimates of Current and Potential Impact

The impact of mice on various primary industries and on rural communities has been quantified for other states. Few hard data exist for the Queensland situation but some of the data from other states can be used to gain an appreciation of the scale of the impact mice have on all of these areas.

4.1 Impact on Primary Production

Mice can have a serious economic impact on a range of farming enterprises. The principal enterprise affected is grain growing, but vegetable growers, orchardists, graziers and intensive livestock producers can also suffer significant losses during a plague. In addition to production losses, farmers incur damage to machinery and vehicles, insulation in ceilings and walls of buildings, electrical equipment and fittings, and to household items and personal possessions.

The impact varies considerably between enterprises and between years. In most years mouse numbers are low and the damage they cause is unnoticeable, but when their numbers irrupt to plague densities in grain-growing areas, the damage on farms in the affected areas and in adjacent rural townships is measured in millions of dollars (Caughley *et al.* 1994).

4.1.1 Impact on grain growers

Mice can damage grain crops at all stages of growth (Redhead and Singleton 1988). Generally, plagues irrupt in autumn at the end of a protracted breeding season and thus in Queensland the potential for damage is greatest to maturing summer crops. Mouse numbers usually decline over winter but the timing of the decline varies. If survival is high early in winter, mice can also cause severe damage to winter crops through attacking the embryonic seed heads within the tillers.

Following the 1997 Central Queensland mouse plague and baiting program a questionnaire was sent to graingrowers involved in the baiting program Caughley *et al* (1998b). For the landholders who responded, the winter crop losses prior to baiting were between 0-$100,000+; they estimated that baiting prevented further crop losses of between $1,000-$100,000+. If the estimates of the landholders who responded were typical for all landholders who baited, the total crop losses prior to baiting would have been in the order of $2.8 million, and baiting would have prevented a further $4.8 million of damage.[1] The average cost of baiting per landholder was $2,800, which provides an average cost benefit ratio of 12:1 (range 2:1 to 48:1).

In 1995, a major mouse plague was experienced on the Darling Downs and around Goondiwindi. As in 1997, a questionnaire was sent to farmers at the end of the plague. From the responses, the estimated damage to crops prior to the baiting campaign (in this case the poison used was strychnine) was in the order of $18 million; the damage prevented was estimated to be in the order of $45 million (Miller 1996). The average loss per respondent was $27,000 (range $0–$400,000), and the damage prevented $65,000 (range $0–$1,125,000). The average cost of baiting to the farmer was $1,750. No estimates of other on-farm losses and costs were made in either 1995 or 1997.

[1] The total figures are estimates for all landholders who baited, and do not include other landholders who may have suffered damage but did not bait.

The economic impact of a plague in Victoria in 1993 was evaluated by Caughley *et al.* (1994) from data gathered from 257 farmers who responded to a phone-in. In this plague, the average crop loss of the respondents was $51,100 (Table 2). Other economic losses were experienced from damage to machinery, stores, and household goods but these were small by comparison with the loss in crop production (Table 2).

Table 2. Average amount lost per grain-grower, based on information provided by those who responded to the phone-in during the 1993 mouse plague in Victoria (from Caughley *et al.* 1994).

Estimated losses in crop production	$51,000
Resowing costs	$ 2,900
Baiting costs	$ 760
Damage to sheds, machinery, household goods	$ 1,360
Total	**$56,120**

The total loss reported by the respondents was $14.4 million. The response came from 7% of the farmers in the affected shires in Victoria, but how many more farmers experienced damage in the region is unknown. In South Australia, damage from mice was also widespread in 1993. The Department of Primary Industries, South Australia estimated the losses to grain-growers in that State was in the vicinity of $46 million (Caughley *et al.* 1994).

Various estimates of crop losses have been made in other plagues. Saunders (1987) reported that a plague in 1969–70 cost grain growers in southern New South Wales, Victoria and South Australia in the order of $14 million (NPV $117 million). In 1979–80, losses in Victoria were in the order of $15–20 million (NPV $46–61 million) (Redhead 1988). In 1984, surveys conducted by Government agencies in South Australia, Victoria and New South Wales placed losses in excess of $13 million (NPV $22 million).

Damage is recorded in localised areas in years between major plagues. For example, a plague in the Murrumbidgee Irrigation Area in 1994 caused an estimated $8 million of damage (Croft and Caughley 1995). Over the past 30 years, the average *annual* impact of mice on the Australian grain-growing industry was conservatively placed at $8 million by Caughley *et al*. (1994). Not surprisingly, the increasing incidence of mouse plagues (Singleton and Brown 1998) is deemed a matter of considerable concern both in Queensland and nationally.

4.1.2 Impact on sheep and cattle graziers

No value has been placed on losses experienced by graziers during mouse plagues. In Victoria in 1993, farmers reported severe depletion of medic pastures and a resultant loss in stock condition, especially in ewes and lambs (Caughley *et al.* 1994). Other losses experienced by graziers were damage to stored hay and wool bales. As with all other farmers in affected regions, graziers would have also suffered losses from damage to sheds, equipment and household goods, to which needs to be added the cost of bait to control the numbers of mice.

4.1.3 Impact on horticulturalists

Mice cause damage to a range of horticultural crops during plagues. Vegetable growers report losses in broccoli, tomatoes, capsicum, chilli, garlic, pumpkins and melons. Grapes, apples and other soft fruit are also damaged and serious losses can occur in almond and pistachio orchards. In the 1984 plague, losses to vegetable growers were placed at $100,000 (NPV $162,000) in Victoria (Redhead 1988). No estimates are available for other areas or plagues but losses are likely to be significant.

4.1.4 Impact on intensive livestock producers

Pig and poultry farmers in plague-affected areas can sustain major losses in livestock production, arising from stress (pigs in particular are highly stress-labile) and from direct physical attacks by mice upon the animals themselves (Table 3). Feed costs also increase. During the 1993 plague in Victoria, producers reported feed costs rose by up to 50%. Mice also block feed lines, gnaw on electrical wiring in air conditioners and waste disposal units, and cause damage to sheds (particularly the insulation in the walls). The losses experienced by intensive livestock producers during the 1993 plague were in the order of $530,000 in the worst affected area in north-western Victoria (Caughley *et al.* 1994).

Table 3. Losses experienced by pig and poultry producers in Victoria during the 1993 plague (from Caughley *et al.* 1994).

Pigs		Poultry	
Sows		**Layers**	
Conception rate		Weight	Down 30-50%
Litter size	Down 20-50%	Mortality	Up 15%
Litter mortality	Down 20-30%		
Baconers	Up	**Eggs**	
Growth rate		Number	Down 20%
Mortality	Down 20%	Size and quality	Down
Carcase quality	Up		
	Down 10%		

4.1.5 Off-farm impact

During plagues, mice often cause damage in rural townships. The types of off-farm impacts on rural businesses include:

- Damage to plant and equipment (particularly electrical appliances);
- Spoiling and consumption of perishables intended for sale;
- Lost business opportunity from not stocking, and therefore not selling, products considered at risk (e.g. packet foods); and
- Cost of redirected time and effort spent trapping and cleaning to protect goods and maintain health and hygiene standards.

Businesses where there are few food resources for mice (e.g. banks, machinery sales or fuel distributors) are not affected to the same extent as those that stock perishable goods. However, in all businesses, electrical and electronic equipment is at risk.

Only one detailed assessment of the off-farm economic cost of a mouse plague to townspeople has been conducted. During the 1993 plague, rural townspeople were interviewed across a broad spectrum of retail businesses and community services in South Australia[2] (Caughley *et al.* 1994). Everyone interviewed indicated that their most significant cost was the time required to mouse-proof, bait, trap, clean, and search for and dispose of carcasses; in many instances, these costs were incurred every day for the duration of the plague (in this case, for four months). For the purposes of their assessment, Caughley *et al.* (1994) costed all such time at $10 per hour.

Apart from time, the losses incurred were principally from damage to goods and electrical equipment. Three factors determined the extent of damage experienced: type of business, its location and type of construction. Retail outlets with large quantities of feed or foodstuffs, such as rural suppliers, grocers, supermarkets and bakeries, suffered more than other businesses. Secondly, those situated on the edges of town had more problems than similar businesses located centrally. Thirdly, the age and construction of the business premises determined how easy it was to exclude mice. Rural suppliers recorded the highest losses (Table 4). Their businesses were usually located on the edges of towns, their stock included large amounts of produce palatable to mice (e.g. grain and seed supplies, organic fertilisers and pet foods), and their premises were often open sheds that were impossible to mouse-proof. Food retailers, hotels and motels also experienced high costs. Goods and equipment were damaged and high labour costs were incurred in cleaning premises to the standard required by council health regulations. Schools and hospitals incurred similar costs in maintaining standards of hygiene.

Table 4. Average costs to retailers, community services and residents interviewed in plague-affected regions of South Australia, 1993, and some extrapolated estimates for the region (data from Caughley *et al.* 1994).

Service or business	No. sampled	Average cost	No. in plague area	Estimated total (South Aust.)
Retailers				
Rural suppliers	9	$7,451	45	$335,295
Food retailers	33	$2,304	100	$230,400
Hotels and motels	13	$2,496	82	$204,672
Other (e.g. finance)	72	$ 778		
Community services				
Schools	9	$2,734	24	$65,616
Hospitals	7	$2,107	36	$75,852
Councils, postal and emergency services	14	$ 814		
Households*	48	$ 280		

* Household costs do not include a costed labour component.

Telephone communications can be vulnerable to damage during mouse plagues. Not surprisingly, automatic exchanges in plague-prone areas are constructed to be mouse-proof and they are regularly checked by technicians who lay rodenticide baits as an extra precaution. Despite this state of preparedness, mice gained access to

[2]Note: the estimates were of costs incurred up to the time of the survey. No flow-on costs beyond the duration of the plague nor costs incurred prior to the plague (for example, construction costs in making buildings mouse-proof) were included. Some of the costs identified by a business or individual would have come from the sale of goods or services by another, but no method was available to balance the ledger.

one exchange in South Australia during the 1993 plague. It cost $30,000 to replace the damaged equipment; after parts were replaced, mouse-proofing the building cost a further $600.

Another enterprise that is highly vulnerable during mouse plagues is grain handling. Losses to grain stored in vertical silos are small since the structures are essentially mouse-proof. However, some grain is still stored in horizontal sheds on the Eyre Peninsula in South Australia and during the 1993 plague, mice caused considerable, though uncosted, losses in these sheds. In Victoria, in addition to silos, grain is stored in horizontal sheds and covered bunkers. With the onset of the plague in 1993, the Victorian grain-handling authorities instituted specific measures to limit losses; these included increased vigilance (bunker covers were checked weekly for holes or other signs of mouse infestation); the removal of grain from districts where the plague was severe; and the increased use of rodenticides around horizontal storage sheds. Between April and October, $12,000 was spent on bait. South Australian grain handling authorities spent $25,000 on bait over the same period. No estimates of losses to stored grain have been made in Queensland where grain is stored in similar ways to other states.

Many other off-farm costs of mouse plagues are intangible. For example, redirection of State Government staff to managing mouse plagues is usually uncosted. The one exception is for the 1995 plague on the Darling Downs where Fisher (1996) estimated that the cost to Queensland Government Departments of the strychnine baiting campaign was $311,000.

4.2 Impact on the Environment

The impact of mice on the environment has not been researched. Potential impacts could be:

- Competition with native fauna for food resources;
- Depletion of seed banks in pastures and native vegetation;
- Increased risk of soil erosion through the consequent reduction of ground cover;
- Increased predator pressure on native species at the end of a plague if predator numbers have increased in response to availability of mice during the plague; and
- Transmission of disease to other fauna.

Another important potential environmental impact is non-target mortalities arising from poisons used to control mice. Several rodenticides may legally be used around sheds and buildings, the most commonly used products being the anticoagulants brodifacoum (Talon™) and bromadiolone (Bromakil™). These baits take several days to kill and, as a consequence, can indirectly kill predators that feed on mice that have consumed poisoned bait. Carcasses of Australian kestrels (*Falco cenchroides*) are not infrequently seen around grain handling facilities.

Non-target mortality also occurs during broadacre baiting campaigns. Monitoring during the strychnine baiting campaign in Queensland in 1995 found approximately 120 birds that were considered to have died from strychnine poisoning (Lundie-Jenkins and Brown, 1996). After the same baiting campaign, landholders reported over 300 bird carcasses of a variety of species found after the baiting campaign, but the cause of death could not be confidently attributed to the strychnine baiting (Miller 1996). Strychnine was detected in carcasses of the following species: apostle bird, cockatiel, crested pigeon, feral pigeon, galah, sulphur crested cockatoo, Australian kestrel, black-shouldered kite, letter-wing kite, crow, emu, magpie and magpie lark. The greatest proportion of the bird deaths came from a single site where the bait had

been distributed 10 m beyond a fenceline into bordering woodland. By comparison, the effect of the baiting campaign on populations of non-target species had been minimal when bait had been distributed according to the established protocols.

Monitoring during the strychnine baiting campaign in 1993 in South Australia found 665 birds believed to have been killed by strychnine (Bird 1995). Most were granivores (67% of species and 98% of individuals found) and the commonest species killed were crested pigeons and feral pigeons.

In contrast, non-target mortalities recorded during the zinc phosphide baiting campaign in Central Queensland in 1997 were very few (Caughley *et al*.1998). The only species whose carcasses were found and tested positive for phosphine were Torresian crow (*n=4*) and Australian magpie (*n=1*). Similar low non-target mortality has been reported with zinc phosphide baits in the United States (Ramey and Sterner 1995; Parker and Hannan-Jones 1996). However, native rodents may have been poisoned if they were present in the areas baited. None were found dead during monitoring but they are known to occur at very low densities in crops and grassy habitats in Central Queensland.

The environmental fate of poisons not consumed has received some attention. Strychnine is gradually adsorbed onto soil particles where, in soils with high clay content, it breaks down within 45 days (Kookana *et al.* 1997). No evidence of crop uptake or of movement into water bodies has been recorded. Studies in the United States have also shown that zinc phosphide breaks down rapidly and its use does not lead to contamination of soils or water bodies (Parker and Hannan-Jones 1996).

5.0 Biology and Ecology

Three salient aspects of the biology of mice explain their pest status. The first is their diet, the second their propensity for gnawing, and the third is their reproductive capacity.

5.1 Diet

Mice are highly opportunistic feeders. They predominantly feed on grass seeds but also eat invertebrates and other plant material. They are cannibalistic during plagues.

In the laboratory, a mouse consumes 3–4 grams of food per day. Saunders (1987) calculated that during a plague in a sunflower crop mice were eating around 12 kg of sunflower seeds per hectare per day. If numbers remained high up to harvest, more than half a tonne would have been consumed per hectare, reducing the yield by some 29%. However, mice often eat only part of a seed so calculations such as these can underestimate the true level of damage.

5.2 Gnawing behaviour

The upper and lower incisors of all rodents grow continuously and are constantly ground down by grinding or by gnawing. Mice frequently gnaw on any hard surface. They are notorious for the damage they cause by gnawing on plastic. Telephone cables and electrical wiring are particularly susceptible. In addition to the direct damage, the gnawing on wiring can cause fires, set off alarms and disrupt telecommunications.

5.3 Reproductive Capacity and Population Dynamics

Mice living in buildings may breed throughout the year but in the field breeding is mostly in spring and early summer. The start of breeding is usually triggered by the increase in seed and insect availability in spring (Bomford 1987; Tann *et al.* 1991). The proportion of females breeding at any time is a function of the quality of the food as well as the quantity (Bomford and Redhead 1987), both of which are largely determined by rainfall. If the summer is hot and dry, reproduction ceases, but if conditions are favourable, mice will continue to breed through into autumn.

Mice are highly fecund (Table 5). The young grow rapidly and reach sexual maturity early. They are also good dispersers and quickly colonise new areas when conditions are favourable. Conversely, mortality is often high and the life span short.

Table 5. Reproductive potential of the house mouse (*Mus domesticus*) (from Caughley *et al*. 1998b).

Breeding season	From spring to autumn, depending on seasonal conditions (can breed throughout the year)
Mean litter size	6 (range 1-10; nipples 10)
Post partum oestrus	Yes
Gestation	19-20 days (although delayed implantation of up to two weeks has been reported)
Weaned at	18-21 days
Age at 1st breeding	5 weeks

Female mice can produce a litter each month during the breeding season. If the breeding season extends well into summer and the number of females participating remains high, then the doubling time for a population can be as short as three to four weeks and a plague may develop. In Fig. 2, the solid line shows the growth of a mouse population leading to a plague. Plotted on the same graph is population growth (the dotted line) that does not result in a plague. The principal differences between the two curves are: (i) starting density (i.e. number of mice at the start of the breeding season and (ii) the length of the breeding season. Quite small differences in population dynamics can produce large differences in abundance.

Figure 2. **Mouse Population Trends** The solid line represents the growth of a hypothetical mouse population where the starting density is 20 mice per hectare and breeding extends over eight months of the year, the proportion of females breeding each month between September and April as shown. The dotted line presents for comparison the trend in numbers of a population where the starting density is 10 mice per hectare, the breeding season is only four months long (September to December), and 80%, 70%, 60% and 40% of females participate in breeding in each of these months respectively.
Note: In both curves, litter size is set at six young per female, the sex ratio at birth at 1:1 and the age at first breeding in females at 2 months. No mortality is factored in.

This graph clearly indicates the potential for mouse populations to increase from very low numbers to large numbers in a relatively short period ie 8-9 months. The graph also shows (dotted line) that if only half the original population is present and if the breeding season is reduced then the population will not increase as dramatically.

5.4 Other Behavioural Characteristics

Mice are primarily nocturnal although they are often seen during the day when numbers are high. Mostly they spend the day in nests they have created in natural cavities or in shallow burrows e.g. in cracked soils. They tend to live in small colonies that are probably groups of related individuals. Burrows used by each group are clumped and distinct runways may be visible between their entrances. When populations are high, these runways become more obvious from their frequent use.

5.4.1 Feeding behaviour

Laboratory studies show that mice may feed from up to 20-30 different sites each night, eating only a little at each location. Consequently, the optimal baiting strategy recommended for mice is to offer a small amount of bait at a large number of sites (MacDonald and Fenn 1994).

5.4.2 Sensory capabilities

Mice have poor sight but very acute senses of smell, hearing, touch and taste. Odours are produced by specific glands and are present in urine and faeces (MacDonald and Fenn 1994). All mice mark extensively with urine, creating a network of odours on every object in their environment. They recognise other members of the group and negotiate in total darkness by these odours.

Because mice have an acute sense of smell, a number of chemical repellents have been tested as a means for excluding mice. None of the repellents has been successful for more than a short time (Smith 1994). Ultrasonic devices similarly repel for little more than a day or two (Kaukeinen 1994).

6.0 Efficacy of Current Control Methods

Management of mouse plagues at the farm level has largely been directed towards reducing mouse numbers after farmers notice damage to their crops. The reduction is usually attempted by the use of poisons.

6.1 Poisoning

6.1.1 In crops

In the past, a multitude of chemicals has been used in and around the perimeter of crops during mouse plagues. For example, during the 1970 plague in New South Wales, the chemicals[3] used included strychnine, arsenic, phosphorus, 1080, the organochlorines DDT, Dieldrin and Endrin, the organophosphates Parathion, Phosdrin and Lucijet, the fungicide Thiram and the anticoagulants Ratsak and Racumin (Ryan and Jones 1972).

Because of its effectiveness, strychnine has been the most widely used chemical but its availability has been progressively restricted since the 1980's because of its toxicity. Nonetheless, during the 1993–94 plague, it was given temporary registration by the National Registration Authority for Agricultural and Veterinary Chemicals (NRA) for broadacre distribution in South Australia and Victoria, and again during the mouse plague in southern Queensland and northern New South Wales in 1995.

However, the use of strychnine as an in-crop rodenticide was finally banned in 1997, not because of its dangers but because of Australia's need to meet international residue standards for exported products. No maximum permissible residue level (MRL) has been assigned for strychnine by the International Codex Committees on Pesticide Residues and Residues of Veterinary Drugs in Food. When no MRL is assigned, it is by default set at zero. It is impossible to prove zero residues because all assay techniques have a lower limit of detection.

Consequently, when mouse plagues irrupted in several areas of Australia in 1997, temporary registration was given by NRA to a bait formulation containing zinc phosphide. Zinc phosphide baits are widely used overseas as in-crop rodenticides and an MRL exists for the bait's breakdown product, phosphine. Good results were achieved with the bait, and the Victorian manufacturing company has applied to the NRA for registration of its product. In the interim, a minor off label permit has been issued by the NRA to allow use of the bait where and when necessary, which is valid until 30 June 1999.

Value of baiting during mouse plagues

Several studies have attempted to estimate the cost/benefits of baiting mice in crops. The first study was during a plague in the Murrumbidgee Irrigation Area in 1979–80 when Saunders (1986) baited a sunflower crop with strychnine and achieved a 90% reduction in mouse numbers. He calculated that, had the mice not been killed, they would have eaten 3.4g per mouse per day over the seven weeks remaining to harvest, equivalent to 29% of the yield. The cost of baiting (excluding labour) was $8/ha; the value of the crop was $640/ha. Baiting may thus have prevented a loss of $130/ha, giving a benefit/cost ratio of 16:1. The calculation presumes neither re-

[3] Most of these chemicals are now banned or are not registered for use on rodents.

invasion of the baited crop by mice from unbaited areas nearby, nor the possibility of a natural decline in mouse numbers over the time between baiting and harvest.

A study by Singleton *et al.* (1991) evaluated the cost/benefit of baiting with bromadiolone in summer soybean crops in the Namoi Valley using responses to a questionnaire sent to farmers. At baiting costs[4] of $45/ha and a crop value $400/ha, they estimated that the break-even point would have been when crop damage was around 11%. The extent of crop damage varied considerably between farms and between areas but on average, the damage exceeded 11%. Therefore, for more than half the respondents, the benefit of baiting would have exceeded the cost.

Mutze (1993) conducted an economic assessment of strychnine baiting in a wheat crop at the time of flowering in 1987. The baiting reduced mouse numbers by 46%. Although by the time of harvest two months later, densities were similar to pre-baiting levels, Mutze found baiting had reduced the level of damage to the grain heads by 81%. Mouse numbers were only around 50 per ha at the time of the study so the actual tonnage lost was small, approximating a 2% reduction in yield. Mutze concluded that even at those relatively low densities the cost of baiting was close to the gain in yield.

No studies have been conducted on the effectiveness of perimeter baiting but Kay *et al.* (1994a) evaluated the effect of baiting refuge habitats around irrigated soybeans with bromadiolone. They found that baiting significantly reduced the number of mice inhabiting the refuge habitat and reduced the rate at which mice invaded and colonised the adjacent crops. No significant reductions in crop damage were detected because mouse numbers overall were low.

6.1.2 Around buildings

Poisons are also widely used to control mice around buildings. Several rodenticides are registered for use in and around buildings (see Appendix B).

6.2 Trapping

Break-back traps are commonly used around houses and sheds. Trapping is preferable to baiting in these areas since:

- There is no danger of accidental poisoning of children and pets; and
- Mice do not die (and smell) in wall cavities and other inaccessible nooks and crannies.

During plagues, farmers also often use water traps where a greased bottle with a food attractant in the neck is balanced over a bucket of water. Mice fall into the water when trying to reach the food. There are numerous variations on trap designs used by farmers. If a record of the number of mice caught is kept, all of these trapping methods can provide an index of mouse numbers and allow a farmer to judge the size of the mouse problem at any given time.

Trapping is also used for monitoring mouse numbers over time in fields. For example, multiple catch traps are used in broccoli crops by the landholder on 'Wando' on the Darling Downs, and break-back traps are used by the Queensland

[4]Comprising cost of bait and grain ($4.20); cost of bait stations ($20) (which could be re-used) and cost of labour ($21) (1989$ values) (Singleton *et al.* 1991).

Department of Natural Resources and Mines personnel to follow trends in mouse numbers over transects in grain-growing areas.

6.3 Exclusion

Exclusion is a highly successful way of reducing the damage caused by mice in buildings. Houses and storages are made rodent-proof by sealing all holes, keeping doors closed, fitting traps to drains, screening all vents, etc. Barrier fencing in doorways is successfully used to exclude mice in some businesses in Queensland (e.g. seed merchants, peanut processors). Two major types of barriers are used: electric pads and counter-levered fences made of steel that allow access of machinery but prevent the entry of mice.

6.4 Habitat Modification

Undisturbed areas such as roadside verges and fencelines can act as refuge habitat for mice (Mutze 1991; Chambers *et al.* 1996). Other refuge habitats are areas where weeds or rubbish is allowed to accumulate (Singleton 1989). Reducing mice by habitat modification involves removing weeds and debris around crops, buildings and storages and controlling growth of grasses and weeds along fencelines and roads by ploughing, burning, grazing or applying herbicides. These methods are used variously by farmers throughout plague-prone areas. Other forms of habitat modification widely used are slashing and working stubble. Some of these methods may however conflict with soil conservation principles and practices, and so need to be carefully considered as part of a holistic approach to on-farm management.

6.5 Other Control Measures

6.5.1 Use of raptor perches

An option that has been researched both in Australia and overseas is the placement of raptor perches in or at the margins of crops to increase the level of predation (Howard *et al*. 1985; Kay *et al*. 1994b). While it is recognised that birds of prey cannot eat enough mice to prevent a plague (Sinclair *et al*. 1990), they can slow the rate of plague formation by several weeks.

6.5.2 Chemical repellents

Because mice have an acute sense of smell, chemical repellents have been tested as a means of control. However, as noted earlier, research has shown that the repellent effect tends to be short-lived.

6.5.3 Ultrasonic devices

Similarly, studies have shown that ultrasonic devices are unsuccessful as a practical means of rodent control (Meehan 1984; Howard and Marsh 1985). Although the animals initially withdraw from a loud new ultrasonic noise, they start to ignore it within a few days. As Smith (1994) commented, ‘behavioural modification is only effective if the animal can choose a more attractive alternative. If food or harbourage is short, or population density is high, methods that do not exclude absolutely may be overcome because the animal perceives that the alternatives are worse’.

6.5.4 Biological Control

The potential for a parasitic nematode, *Capillaria hepatica*, to control mouse populations was investigated in Australia by Singleton and his co-workers (Singleton and McCallum 1990). If mice infected with the parasite have less frequent litters,

population growth rate would be slowed and plagues would be prevented. Field trials on the Darling Downs and in the Mallee in Victoria, however, failed to demonstrate any decline in breeding by mouse populations that were experimentally infected with *C. hepatica* (Singleton *et al*. 1995; Singleton and Chambers 1996) and the research has been discontinued.

Singleton and his co-workers at the Cooperative Research Centre for Biological Control have now directed their research towards immunocontraception using a mouse-specific virus[5] that is present in nearly all Australian mouse populations (Chambers *et al*. 1997). Laboratory trials to date have shown that the virus will carry foreign material and that the modified virus will replicate in mice. The next step in the research is to identify an appropriate fertility blocking protein to attach to the virus and to study the behaviour and epidemiology of this modified virus.

[5] Murine Cytomegalovirus (MCMV)

7.0 Human and Animal Welfare Considerations

7.1 Disease

Rodents are vectors of a number of diseases that affect humans and livestock. In Australia, most of these pathogens are absent or rare but there are a few that cause problems. Perhaps the commonest are *Salmonella* bacteria that can be spread by a range of animal species (including humans). The bacteria are usually transmitted to people through food contaminated with infected urine or droppings, and can cause acute gastroenteritis (Stevenson and Hughes 1988).

Another known pathogen in mice in Australia is *Streptobacillus moniliformis* that causes rat bite fever in people and other animals (Taylor *et al.* 1994). During plagues, mice are caught occasionally with polyarthritis or abscesses ('lumpy tail') that are caused by the pathogen. Although no transmission to humans from infected mice has been recorded, one person in Australia has died from the pathogen following a bite from a wild rat (Taylor *et al*. 1994).

The best means of limiting the risk to humans from these pathogens is to exclude mice from foodstuffs and to maintain high standards of cleanliness in food preparation and eating areas. Protection of feed storages and good shed hygiene are likewise important in intensive livestock operations.

For livestock, the most serious disease that mice may transmit is swine encephalo-myocarditis that led to substantial pig mortalities on some properties in New South Wales during the mouse plagues of 1970 and 1984 (Acland and Littlejohns 1975; Seaman *et al.* 1986). Intensive livestock farmers also reported an increase in the incidence of other infectious diseases during mouse plagues. Scouring is a frequent problem in pig herds during plagues with mice aiding the transfer of bacteria between pens. During the 1984 NSW and 1993 SA plagues, infection with *Erysipelas* was reported in some herds.

7.2 Other health risks

7.2.1 Risk of poisoning

During a mouse outbreak, people take risks with poisons, using them in ways that they would not normally countenance. No poisoning of humans has been attributed to rodent baits during mouse plagues in Australia but accidental poisoning of domestic pets occurs quite frequently. During the 1993 mouse plague in South Australia, one veterinarian treated 40 dogs that according to their owners had eaten rodent bait (Caughley *et al.* 1994).

As a part of any education program prior to mouse plagues, town residents must be alerted to the dangers to pets of accidental poisoning and offered advice on how to prepare baits in bait stations or to lay them in places inaccessible to dogs.

7.2.2 Risk of fire

Mice gnawing on electrical wiring can cause fires in homes and other buildings. For intensive livestock farmers, the risk is magnified if their sheds are lined with

polyurtheane insulation since it gives off cyanide gases when it burns which is lethal to both livestock and firefighters.

7.3 Animal Welfare Issues

7.3.1 Impact of mice on livestock

During the 1993 SA plague, mice caused considerable damage to penned animals (Caughley *et al.* 1994). Poultry had their feet gnawed and, as a direct result of stress and stress-related injuries, the birds lost condition, egg production declined and mortality increased. In piggeries, breeding sows and piglets were the most seriously affected and badly gnawed animals had to be destroyed to end their suffering.

Destocking is one option available to intensive livestock producers during a mouse plague but the costs of destocking and restocking are high. Farmers usually choose to persist with baiting and the constant care of their animals.

7.3.2 Humane control of mice

With regard to mice, the primary animal welfare issue is that the control methods selected are those that cause the minimal pain, distress and discomfort to the animals being controlled. Measurements of the humaneness of rodenticides are largely subjective, but in animal welfare terms, a poison, which acts quickly to kill or leave an animal unconscious, is better than one that takes a considerable time to act.

8.0 Legislation and Policy

8.1 Legislative Status of Mice in Queensland

Mice are not a declared pest under the *Rural Lands Protection Act 1985* so there is no legal requirement that they be controlled. As the house mouse is not a native species there are no laws governing their control other than the *Animals Protection Act 1925* and *via* health regulations[6].

The use of chemical poisons is constrained by Government regulations in Queensland. A number of rodenticide poisons are registered (see Appendix B) and may be used in and around buildings, animals sheds and storage facilities. No rodenticide is registered for use in grain crops although temporary registration has been given for the broadacre distribution of strychnine and zinc phosphide during the 1995 and 1997 mouse plagues respectively.

8.2 Queensland Department of Natural Resources and Mines' Policy on Mice

The Queensland Department of Natural Resources and Mines' does not have any legislative responsibility to control or enforce the control of the house mouse but has assumed a coordination role for non-urban situations. The departments' exact role is outlined in the policy on rodents that states.

"The Department of Natural Resources and Mines will:

(a) Monitor rodent populations on the Central Darling Downs and provide short and long term predictions on the potential for plague development;
(b) Provide graingrowers with technical advice on available mouse control strategies;
(c) Undertake research to support the registration of a rodenticide suitable for incrop baiting of mice;
(d) Undertake research into integrated long term management strategies for the control of mice in farming areas;
(e) Accept responsibility for coordinating large scale emergency mouse control operations;
(f) Collaborate with industry (eg GrainGrowers Association), State Departments (Primary Industries, Environment and Health), interstate counterparts and research and development organisations, including CSIRO, as necessary to satisfy Queensland's requirements for mouse control consistent with national standards;
(g) Cooperate with industry and other organisations in the development of control options for other rodent species, subject to availability of funding.

The Department of Natural Resources and Mines will not:

(a) Declare any rodent species."

[6] An authorised health officer may give 'reasonable directions' to the owner or occupier of premises to destroy any rats and mice on those premises or to rectify conditions that are conducive to their breeding.

9.0 Recommended Management and Control Practices

The Queensland Department of Natural Resources and Mines and Mines advocates the following management and control practices.

9.1 Managing Mice around Buildings

Controlling mice in and around buildings is important for all people living in plague-prone areas. In homes, trapping is recommended, rather than the use of poisons, to avoid accidental poisoning of children or pets and to prevent the unpleasant smell of decaying mice if they die in wall cavities and inaccessible areas.

Good hygiene is very important. Because mice can carry a number of diseases, washing hands with soap and water after handling dead mice, and washing food preparation surfaces, plates, utensils, etc. before use, are strongly recommended.

If possible, houses should be made ‘mouse-proof’ by locating the routes mice are using to enter the house, blocking holes with steel wool, and placing sealing strips on doors. Foodstuffs and precious items should be stored in mouse-proof containers.

In sheds, a combination of trapping, baiting and storing goods in rodent-proof containers or on rodent-proof stands is recommended measures. Baits should be used according to directions on the manufacturer’s label. Bait blocks and pellets should be laid in bait stations to prevent mice from scattering the bait and to guard against the accidental poisoning of children and pets. The simplest design is a small plastic container with a lid, with small holes cut in the sides to give mice access to the bait.

Grassy areas around sheds and homes should be kept mown, building materials stored upright and piles of rubble or other material removed.

9.2 Managing Mice on Farms

A number of agronomic practices are available to broadacre farmers to limit the impact of mice. The best forms of defence are methods that reduce the amount of shelter and food available to mice. General farm hygiene is important - that is, cleaning up piles of rubbish and any spilt grain, and keeping grass down by slashing or spraying along roads and around verges, haystacks, etc. Minimising grain spill at harvest is also very important.

Slashing, working or burning stubble reduces both the availability of food and shelter for mice, but stubble retention is an important method for controlling soil erosion and retaining soil moisture. Controlling mice by stubble management needs to be balanced against the benefits of its retention. To optimise stubble management practices, farmers should assess the number of mice in the stubble and make their decision accordingly.

Monitoring

Regular monitoring of mouse numbers enables farmers to undertake management actions to control mice before they begin to damage crops. In order to prevent mouse damage to crops, the most important times to check mouse numbers are prior to flowering for each winter and summer crop, checking both within crops and within adjacent stubble on each occasion.

There are two principal means of monitoring. The first is break-back traps which can be set out overnight in crops, stubbles and other habitats in a line of 20 or so traps. These traps are a cheap, simple and effective means of keeping track of mouse numbers over time.

The second method is to use bait cards that are 10cm x 10cm square pieces of white paper that are soaked in canola oil and pegged out overnight in crops and in other habitats. The amount of card eaten serves as an index of mouse numbers. To obtain a reasonable estimate, at least five cards should be placed 5-10 metres apart in each habitat.

The bait card technique is a less reliable indicator of mouse numbers than break-back traps, since the amount of a card eaten is largely a reflection of the paucity of food available for the mice rather than the numbers of mice present. When food is plentiful, the cards may be relatively untouched even when mouse numbers are high. However, if bait card take is greater than 10%, it indicates (i) that mouse numbers are high and (ii) the mice will readily take the bait and cost-effective control will be achieved.

Baiting

At present, no rodenticide is registered for in-crop mouse control although an application for the registration of zinc phosphide bait is currently before the National Registration Authority for Agricultural and Veterinary Chemicals. If it receives approval, baiting crop and stubble areas will be an option available to farmers. Research has shown that the best results will be achieved by baiting when alternative food is scarce (for example, in crops before flowering commences and in stubble about one month after harvest). Recommended strategies for use of bait will be published by the Department when the product receives registration.

Appendix 1. A Summary of the Biology and Ecology of the House Mouse

Scientific name: *Mus domesticus*
Common name: House mouse (*also* Field mouse)

Size

- Head/body length 55-100 mm
- Tail length 75-100 mm
- Weight 10-25 g

Description

- Brown, grey or black above; white, pale yellow or grey below. Fur soft, short. Distinguished from similar species by notched upper incisors and musty smell.

Reproductive characteristics

Breeding season	Mostly between spring and autumn, but can breed throughout the year
Mean litter size	6 (range 1-10; nipples 10)
Post partum oestrus	Yes
Gestation	19-20 days (although delayed implantation of up to two weeks has been reported)
Weaned at	18-21 days
Age at 1st breeding	5 weeks

Diet

- Principally seeds but omnivorous and highly opportunistic.

Behaviour

- Predominantly nocturnal except when population density is high.
- Social, living in small groups of related individuals, usually with in a home range that appears to be defended at certain times or at certain population densities. Most young disperse on reaching adulthood.
- Burrows are often complex with interconnecting tunnels. Usually shallow (less than 20 cm below the surface) but in light soils can be 100 cm or more deep. Stores of seed can sometimes be found in burrows. Also nests in natural cavities, e.g. in wood piles, back of stoves, between walls.

Appendix 2: Rodenticides that are registered for use in Qld

Department of Natural Resources and Mines

RODENTICIDES REGISTERED FOR USE IN QUEENSLAND			
Product Name	**Active Ingredient**	**Pack Sizes**	**Registered Usage Area**
Ditrac All Weather Blox Rodenticide	Brodifacoum	1.8 kg, 4 kg, 8 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings
Ditrac Rodenticide	Brodifacoum	2 kg, 5 kg, 10 kg	Unspecified Perimeter baiting adjacent to crops
Farmoz Rodex B Rat Blocks	Brodifacoum	2 kg, 5 kg	Commercial/Industrial Buildings Domestic Buildings Public Services
Farmoz Rodex B Rodenticide Pellets	Brodifacoum	300 g, 5 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Public Services Perimeter baiting adjacent to crops
Hortico Ratsack 1 Shot Rat and Mouse Bait	Brodifacoum	150 g (2 x 75g)	Unspecified
Klerat Rodenticide Wax Blocks	Brodifacoum	10 kg	Sugarcane
Mortein Rat Kill, Rat & Mouse Killer	Brodifacoum	150 g (4 x 37.5g), 450 g (12 x 37.5g)	Unspecified
Oztec Ratal Rodenticide Pellets	Brodifacoum	200 g, 1 kg, 10 kg, 140 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Public Services Perimeter baiting adjacent to crops
Talon Rodenticide All Weather Rodenticide Wax Blocks	Brodifacoum	75 g, 1 kg, 2.4 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Public Services
Talon Rodenticide Pellets	Brodifacoum	50 g, 200 g, 1 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Public Services Perimeter baiting adjacent to crops
Bromakil Super Rat Bait	Bromadiolone	500 g, 2 kg, 5 kg, 15 kg	Commercial/Industrial Buildings Domestic Buildings Public Services Perimeter baiting adjacent to crops
Bromakil Super Rat Blocks	Bromadiolone	1.4 kg	Commercial/Industrial Buildings Domestic Buildings Public Services
Bromakil Super Rat Drink Concentrate	Bromadiolone	500 mL	Commercial/Industrial Buildings Domestic Buildings Public Services
Contrac Blox	Bromadiolone	1.8 kg, 8 kg, 9 kg	Commercial/Industrial Buildings Domestic Buildings Public Services
Contrac Rat and Mouse Bait	Bromadiolone	5 kg (100 x	Commercial/Industrial Buildings

		50g), 10 kg	Domestic Buildings Public Services Perimeter baiting adjacent to crops
Contrac Rodenticide	Bromadiolone	5 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Public Services Perimeter baiting adjacent to crops
Country Di-O-Lone Super Rat Grain Bait	Bromadiolone	500 g, 1 kg, 2 kg, 5 kg, 10 kg, 20 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Perimeter baiting adjacent to crops
Rattex Bromablock	Bromadiolone	5 kg	Buildings Sewers/Drains
Rattex Grain Bait	Bromadiolone	5 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Perimeter baiting adjacent to crops
Rentokil Bromakil Bait for Rats and Mice	Bromadiolone	200 g	Domestic Buildings
Rentokil Bromakil Mouse Mix	Bromadiolone	750 g, 3 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Public Services Perimeter baiting adjacent to crops
Rentokil Bromakil Rodenticide Concentrate	Bromadiolone	1 L, 5 L, 20 L	Commercial/Industrial Buildings Domestic Buildings Public Services
Rentokil Bromakil Super Rat Bait Sachets	Bromadiolone	2.5 kg (100 x 25 g)	Domestic Buildings
Rentokil Bromakil Super Rat Blocks	Bromadiolone	500 g, 2 kg, 5 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Public Services
Rentokil Bromakil Super Rat Drink	Bromadiolone	500 mL	Commercial/Industrial Buildings Domestic Buildings Public Services
Rentokil Bromakil Super Rat Grain Bait	Bromadiolone	2 kg, 4 kg, 15 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Perimeter baiting adjacent to crops
Rentokil Bromakil Super Rodent Blocks Rodenticide	Bromadiolone	140 g	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings
Rentokil Bromakil-P Rodenticide Pellets	Bromadiolone	200 g, 1 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Perimeter baiting adjacent to crops
Tomcat All-Weather Blox	Bromadiolone	112 g, 224 g, 784 g, 900 g, 1.8 kg, 4 kg, 8 kg, 9 kg	Commercial/Industrial Buildings Domestic Buildings Public Services
Tomcat Rat and Mouse Bait	Bromadiolone	50 g, 200 g, 300 g, 500 g, 1.75 kg, 2.5 kg, 3.5 kg, 5 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Public Services Perimeter baiting adjacent to crops
Yates Mouser One Shot Mouse Bait	Bromadiolone	33 g	Domestic Buildings
Yates Rat Attack One Shot Rodenticide	Bromadiolone	200 g (4 x 50 g)	Commercial/Industrial Buildings Domestic Buildings
* Rampage Rat and Mouse Bait	Cholecalciferol	1 kg, 1.5 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings
Barmac Racupak Ready to use Rodenticide	Coumatetralyl	100 g	Industrial Sites/Factories
Racumin 8 Bayer Rat and	Coumatetralyl	1 kg, 10 kg	Commercial/Industrial Buildings

Mouse Rodenticide Bait Concentrate and Tracking Powder			Domestic Buildings Farm/Agricultural Buildings Meatworks (non-product areas) Wharves
Racumin Domestic Mouse and Rat Bait	Coumatetralyl	150 g	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Meatworks (non-product areas) Wharves
Racumin Mouse and Rat Blocks Ready to use Bait Blocks	Coumatetralyl	1440 g	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Meatworks (non-product areas) Wharves
Racumin Mouse and Rat Bait Pelleted Bait - ready to use	Coumatetralyl	1.5 kg, 15 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Meatworks (non-product areas) Wharves
Ratex Mouse and Rat Bait	Coumatetralyl	1 kg, 5 kg, 15 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings Meatworks (non-product areas) Wharves
Hortico Double Strength Ratsak Ready to use Rat Bait	Warfarin	250 g, 350 g, 1 kg, 2.5 kg	Unspecified
* Rattex Gel	Warfarin	500 g	Commercial/Industrial Buildings
* Rattex Tracking Powder	Warfarin	5 kg	Commercial/Industrial Buildings Domestic Buildings
RCI Ratblitz Bait	Warfarin	3 kg, 13 kg	Unspecified
Terminator Mouse and Rat Bait	Warfarin	300 g, 1.5 kg, 8 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings
Storm Wax Block Rodenticide	Flocoumafen	500 g, 3 kg, 10 kg	Commercial/Industrial Buildings Domestic Buildings Farm/Agricultural Buildings

* Supply/use restricted to licensed Pest Control Operators

PEST ANIMAL
PA21 December 2013

Cane toad

Bufo marinus

The cane toad is not a declared pest in Queensland, so there is no legal requirement to control them.

Their original introduction in 1935 was to control agricultural pests, but they proved ineffective.

For the past 60 years, cane toads have been expanding their territory in Australia, and are capable of colonising at least four of the mainland Australian states.

As the toad's geographical range continues to expand, concern has increased about their detrimental environmental effects, particularly on the wetlands of the Northern Territory.

Studies into the feasibility of biological control have commenced.

History of introduction and spread

The cane toad or giant toad is an amphibian, native to Central and South America. Cane toads have been introduced throughout the world as a biological control for insect pests of agriculture, most notably sugarcane.

A consignment of cane toads from Hawaii was released into Queensland cane fields in 1935. The introduction was surrounded by controversy as to the potential costs and benefits to Australia.

It was hoped that the toad would control Frenchi and greyback beetles—pests of economic importance to the sugarcane industry.

By 1941, however, it had become evident that the cane toad was exerting only limited control over its intended prey. There were two main reasons for this:

- Greyback beetles are only rarely in contact with the ground and Frenchi beetles invade cane fields at a time when the toads are absent due to a lack of protective cover.
- The cane toad has a wide-ranging and indiscriminate diet, and it was not solely dependant upon its intended prey.

The unlimited food source, suitable environment and low rates of predation allowed dynamic reproduction and spread. Toads were recorded in Brisbane only 10 years after release. The toad continues to thrive and has now invaded the Northern Territory and New South Wales (see Map 1).

Map 1. Distribution of the cane toad in Australia

The cane toad's advance is only limited by environmental factors, such as the availability of water for breeding, tolerable temperatures, suitable shelter and availability of food.

Toads at the frontier of their range of expansion may be larger than those in established populations. This is most probably due to greater food supply, combined with a lower incidence of disease.

Description and general information

In comparison with native frog and toad species, adult cane toads have a distinctive head and face, and are large and heavily built creatures (adults may grow to 20 cm).

Following their aquatic larval stages (eggs and tadpoles), cane toads are generally encountered at night near any source of light. Cane toads are ground-dwelling—they are poor climbers and unable to jump very high.

A definite visor or awning extends over each eye and a high angular bony ridge extends from the eyes to the nose.

The parotid glands (see Figure 1) are perhaps the most characteristic feature of the adult cane toad. These glands are large, protuberant, and are situated on the head behind each ear. These glands carry a toxin.

Map 2. Distribution of the cane toad in Queensland

Figure 1. Distinguishing features of the cane toad

The cane toad's hands and feet are relatively small and lack discs at the tips of the digits. Webbing is absent between the fingers but is distinct and leathery between the toes.

Colouring on the dorsal (upper) surface may be brown, olive-brown or reddish-brown. The ventral (under) surface varies from white to yellow and is usually mottled with brown.

Warts are present on all cane toads; however, males possess more than females. Warts are dark brown at the caps.

Mating

Mating can occur at any time of the year and depends only on available food and permanent water. The mating call is a continuous purring trill that sounds like a running motor.

In situations where females are scarce or absent, male cane toads may have the ability to undergo a sex change to become fertile females; however, this has not been proved.

Eggs

Both cane toads and native frogs spawn in slow-moving or still water, but their eggs can be easily distinguished.

Cane toad eggs are laid in long, gelatinous 'strings' with the developing tadpoles appearing as a row of small black dots along the length. The strings are unique to cane toads, generally appearing as blobs of jelly attached to water plants or debris. Native frogs generally produce egg clusters as mounds of foam floating on the water surface.

Compared with native species, cane toad egg production is dynamic and a single clutch can contain up to 35 000 eggs. Remove any cane toad eggs found in the water and allow to dry out.

Figure 2. Drawing of toad spawn from *Wildlife of greater Brisbane*

Tadpoles

The cane toad is the only species in Australia that has a pure black tadpole. Native frogs have lighter-coloured undersides with a great range of colours and markings—cane toad tadpoles may turn paler colours to almost transparent at night.

Cane toad tadpoles are small and usually congregate in vast, slow-moving shoals. This 'shoaling' behaviour is uncharacteristic of most native species.

Unlike cane toad tadpoles, native species develop lungs at an early stage and periodically rise to the surface in order to exchange their lung gasses. Large groupings of tadpoles that do not break the water surface for air indicate cane toads.

Young toads

Following emergence from the water, the young toadlets usually congregate around the moist perimeter of the water body for about a week before they eventually disperse.

Young toads are very difficult to distinguish from the native *Uperoleiea* species, which also have parotid glands, but all *Uperolelea* species have bright red patches in the groin area.

Under ideal conditions toadlets may reach adult size within a year.

Toxicity

Bufo marinus produce venom in glands occurring in most of the skin on their upper surface. The venom is concentrated in the parotid glands as a creamy-white solution, which is released when the animal experiences extreme provocation or direct localised pressure (e.g. grasped by the mouth of a predator).

The parotid solution is highly toxic and when ingested it produces drastic acceleration of the heartbeat, shortness of breath, salivation and prostration. It is extremely painful if accidentally rubbed into the eye.

Ingestion of toads by domestic and most native animals can result in death. In some recorded cases, death has occurred within 15 minutes.

Field observations suggest that some predatory Australian species have learned how to feed safely on cane toads.

Birds have been observed flipping toads over to avoid the parotid glands. Predatory reptiles may have more trouble adapting, being unable to remove a toad from the mouth once they start feeding.

Effects on wildlife

The cane toad is poisonous at all stages of its life cycle and most native frog larvae and many aquatic invertebrates are dramatically affected by their presence.

Cane toads are voracious feeders that consume a wide variety of insects, frogs, small reptiles, mammals and even birds. Perhaps the only limiting factor to the prey taken is the width of the cane toad's mouth.

It has been suggested that cane toad competition for food and breeding grounds has been responsible for reducing the populations of some native frogs. However, many native frogs are arboreal (tree-dwelling) and occupy different niches. Cane toads don't have the native frogs' ability to 'shut down' during dry seasons when resources are limited.

Pressure from cane toads may displace native animals (frogs and other species) where they are already suffering due to manipulation of their habitat by humans and grazing animals. Animals that use waterholes as retreat sites during the dry season are especially vulnerable—toads will congregate here in large numbers.

Public health

Cane toads readily eat animal and human faecal material and, in areas of poor hygiene, they have been known to transmit disease such as salmonella.

Control

Control of cane toads is not enforced as there is currently no available effective broad scale control. Individuals and community groups have carried out removal campaigns to decrease numbers and slow the invasion front.

Fencing is recommended to keep toads out of ponds intended for native fish and frogs; a height of 50 cm is sufficient. Bird wire with 1 cm holes may keep toads out of an area.

Research indicates that spread can be delayed in semi-arid areas by blocking access to water holes.

Individual toads may be killed relatively humanely using a commercial spray available from hardware stores or may be stunned and decapitated (only by experienced operators). The removal of eggs from small water bodies such as frog ponds can be effective

Researchers have successfully mitigated impacts in recently colonised areas by 'training' predators however, large scale application of this technique is difficult.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland (call 13 25 23 or visit our website at www.biosecurity.qld.gov.au).

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture, Fisheries and Forestry (DAFF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAFF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

DECLARED CLASS 2 PEST ANIMAL

July 2014

Wild dog control

Canis familiaris

The term wild dog refers collectively to purebred dingoes, dingo hybrids and domestic dogs that have escaped or been deliberately released.

Wild dog control methods include baiting, trapping, shooting, fencing, and the use of guardian animals to protect stock. A planned strategy using a combination of these methods that also considers wild dog behavior will enable effective management.

Declaration details

Wild dogs are a declared Class 2 pest animal under Queensland legislation. As such, all landholders in Queensland are required to reduce the number of wild dogs on their properties.

Management strategies

To increase wild dog control effectiveness, it is essential that control programs are coordinated among adjoining properties.

Queensland research has shown that in some situations wild dogs can quickly re-colonise baited areas due to a number of factors including inconsistent bait programs which do not provide comprehensive wild dog control across the landscape. Such programs may alter the dynamics of wild dog populations in the area. To prevent livestock attacks and enhance wild dog management, it is important for producers to work together using a variety of control methods.

Wild dog ecology and seasonal variations can also influence the likelihood of wild dogs coming into contact with a control tool. The timing of control should consider seasonal variations and the availability of water (where water is restricted) and then target watering points. Many land owners bait using 1080 twice a year to target wild dogs during peaks in activity associated with breeding (March/May) and then again in September/November to target pups and juveniles. However, baiting and trapping is recommended at all times when wild dogs are active.

Control

Baiting

Poison baits are the most economic, efficient and effective method of controlling wild dogs, especially in inaccessible or extensive areas. Baits can be laid quickly by hand, from vehicles and from aircraft.

Currently there are two poisons legally available for wild dog control. These are 1080 (sodium fluoroacetate) and strychnine.

Subject to restrictions, 1080 baits, either manufactured or prepared from fresh meat can be obtained through people approved under the Health (Drugs & Poisons) Regulation 1996. A permit from the Queensland Department of Health is required for land owners to purchase strychnine. Strychnine can be used both in baits and on traps. The use of both 1080 and strychnine require adherence to the associated conditions of supply.

The use of poison baits will control some but not all wild dogs. Baits should be used in conjunction with all other control tools and not be relied on as a total control method.

Meat baits are attractive both to wild dogs and a range of non-target species. When using meat baits, they can be strategically positioned as wild dogs' keen sense of smell enables them to find baits intentionally buried in sand or otherwise hidden under bushes or in hollow logs. Meat baits may also be tied to prevent their loss to non-target species.

These meat bait placement techniques help to:

- reduce the risk of poisoning non-target species
- increase wild dog contact, hence receiving a lethal dose
- minimise bait removal by non-target scavengers
- deter ants (ant-covered baits are believed to be less attractive to wild dogs).

Heavy rain within two weeks of baiting can leach 1080 from baits, but baits may still remain toxic for a considerable time.

Trapping

A key success to trapping wild dogs (using foot-hold traps) depends on the skill of the operator. Visit www.feral.org.au to watch a PestSmart video on best practice techniques for wild dog trapping.

For humane reasons and to prevent escape, poisoning traps with strychnine is recommended to quickly kill captured wild dogs. A properly poisoned trap becomes a lethal device rather than a holding device.

A mixture of dog faeces and urine is a popular lure used by trappers. Attractiveness of lures varies with seasons and locations. No single lure has yet been found that is consistently attractive to all wild dogs and repeated use of one lure can lead to aversion amongst remaining dogs.

Traps are best placed in areas of high wild dog activity (known as leads). Here the wild dog is most likely to find and investigate the decoy/odour.

A wild dog scent post (an area where urine or faeces have been deposited) can be found by walking with a domestic dog on a lead along a known pad. Trap placement in relation to the scent post can be optimised by observing the domestic dog's behaviour as it approaches. Factors to consider are:

- where on the bush it smells
- placement of feet while urinating/defecating/sniffing
- how it approaches and where it scratches in relation to the pad and scent post.

Padded, laminated or offset foot-hold traps, in a well tuned and functioning state are recommended.

Shooting

Shooting is an opportunistic method, mostly used for control of small populations or individual problem animals.

Fencing

Property fencing suitable to exclude wild dogs is expensive to build and requires continual maintenance to repair damage caused by fallen timber, fire, floods, feral and domestic animals, as well as vegetation regrowth. However, a properly maintained fence can restrict movement into an area where wild dogs have been controlled.

Electric fences suitable for wild dogs have been developed. Electrifying a fence creates a fear of the fence itself and deters wild dogs from approaching.

For property fencing to be successful, the fence must be maintained in good order and ongoing wild dog control conducted within the protected area to limit livestock impacts.

Fencing is the most effective method of protecting livestock and pets from wild dog attack on small acreage blocks.

A fence can also be a good area to place baits and traps when wild dogs are active.

Livestock guardian animals

Livestock guardian animals have been used to protect livestock from predators in Europe, Asia and America. Some producers in Queensland have decreased predation on sheep and goats using this method. The use of trapping and poisoning in conjunction with guardian animals must be well planned and managed to ensure guardian animal safety.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland (call 13 25 23 or visit our website at www.biosecurity.qld.gov.au).

This fact sheet is developed with funding support from the Land Protection Fund.

EXECUTIVE SUMMARY

AustralAsian Resource Consultants was commissioned by the CopperChem Ltd and Syndicated Metals Ltd Joint Venture to perform an Aquatic Ecology Assessment for the Barbara Copper Project. The aim of this Aquatic Ecology Assessment report is to describe and assess the environmental values of the waterways in the Investigation Area and recommend strategies to minimise potential impacts on aquatic ecosystems.

The Barbara Copper Project is located approximately 60 kilometres north-east of Mount Isa in north-west Queensland. The Project involves the development of an open cut copper mine. Mining will use conventional drill and blast, load and haul techniques. Copper ore will be transported by road train to an offsite processing plant. The Investigation Area is currently used for cattle grazing and mineral exploration.

Several small, unnamed drainage lines flow across the Investigation Area. These waterways are ephemeral and flow only after heavy rainfall. Site waterways drain into the Leichhardt River, which flows into the Gulf of Carpentaria. There are no wetlands within the Investigation Area boundary. Lake Julius, a large lacustrine wetland listed on the Directory of Important Wetlands in Australia, is located approximately 17 kilometres downstream of the Investigation Area.

A combination of desk-based and field-based investigations was undertaken to investigate the aquatic ecology of the Investigation Area. Database searches identified 20 species of threatened fauna and 40 species of Marine and/or Migratory animals (mostly birds) within the local region. No threatened ecological communities or threatened aquatic flora species were identified in the database searches. Category B Environmentally Sensitive Areas are mapped in the west of the Investigation Area as Endangered Regional Ecosystem 1.3.7: River Red Gum (*Eucalyptus camaldulensis*) woodland on channels and levees. No Category A or C Environmentally Sensitive Areas are mapped in the Investigation Area.

Two field surveys were undertaken to further investigate the aquatic ecology of the Investigation Area. Surveys were scheduled to fall within the wet season (February 2014) and the dry season (July 2014). A total of 12 sites were assessed for the following parameters:

- Stream morphology/habitat quality;
- Sediment particle size and metal concentration;
- Surface water quality;
- Macroinvertebrate diversity and abundance;
- Aquatic fauna diversity and abundance; and
- Riparian flora diversity and abundance.

Stream morphology was assessed using a modified version of the Australian River Assessment System protocols developed by the Department of Natural Resources and Mines. The broad habitat type, channel pattern, water level and flow, substrate character and cover, bed and bank stability, and riparian cover at each site were described. Each site was given a score out of 135, with higher numbers indicating favourable habitats.

Stream sediment monitoring was undertaken both upstream and downstream of Project activities. Samples of the stream-bed substrate were taken at regular intervals along a 50 metre stretch of the creek bed at each site. The sub-samples were mixed to obtain a composite sample, sealed in sterilised glass jars and sent to a National Association of Testing Authorities accredited laboratory for analysis.

Water quality sampling was undertaken at all sites that held water at the time of sampling. Field readings of pH, electrical conductivity, temperature and dissolved oxygen were recorded and surface water samples were collected. Samples were sent to a National Association of Testing Authorities accredited laboratory for analysis.

Macroinvertebrate samples were taken at all survey sites that contained water at the time of sampling. Macroinvertebrates were collected using a D-frame pond net and employing a kick-sampling method. Macroinvertebrates were preserved in ethanol and sent to a third party laboratory for identification.

Sampling of aquatic fauna using box and opera style traps was undertaken at sites where sufficient water was present. Spotlighting was carried out in riparian areas at night to detect nocturnal wildlife. Specialised electronic bat call recorders called Songmeters were set up in riparian areas. Recordings were sent to an experienced bat call analyst for species identification.

Riparian flora species composition was investigated using secondary transects, which are 20 x 50 metre plots. Species, abundance, density and projected foliage cover and height for the tree and shrub layers were recorded.

The Australian River Assessment System analysis results for the survey sites fell within the moderate to good habitat range. Scores were limited by erosion and impacts from cattle.

Stream sediments were found to be extremely coarse. High levels of gravel, cobbles and sand were detected in the sediment samples. Metals levels in sediments were typically low, and fell below the applicable guidelines at all sites, with the exception of copper levels at sites AQ4, AQ7 and AQ1 and nickel levels at site AQ5.

Water quality at the survey sites was impacted by the stagnant and ephemeral nature of site waterways. pH values outside the applicable guideline range were recorded at several sites (AQ1 in the wet season, AQ4, AQ7, AQ8, AQ11). Conductivity levels were high in the dry season, with all sites exceeding the applicable guideline. Site AQ4 recorded conductivity levels in excess of the guideline in the wet season. Dissolved oxygen levels were below the guideline range at most sites (AQ1 in the dry season, AQ2, AQ4, AQ6, AQ7, AQ11, AQ12). Total nitrogen and total phosphorus exceeded the guidelines at all sites in both surveys.

Metals levels in water were generally below the guideline limits, with a few exceptions. In the wet season, total and dissolved silver (at AQ4, AQ6 and AQ7), total and dissolved copper (at all sites), total zinc (AQ8), total and dissolved aluminium (at AQ4, AQ7 and AQ8) and dissolved aluminium at AQ1 were above applicable guidelines. In the dry season, total and dissolved copper (at AQ1, AQ8 and AQ11), total copper (AQ12), total and dissolved manganese (AQ12), total aluminium (AQ11 and AQ12) and total zinc (AQ11 and AQ12) exceeded the guidelines. Elevated metals levels are likely to be the result of mineralisation in the Project region.

Macroinvertebrate abundance, diversity and Stream Invertebrate Grade Number – Average Level scores for the Investigation Area were fairly low. These results are likely attributable to poor water quality and habitat availability in the ephemeral streams sampled. Stream Invertebrate Grade Number – Average Level scores fell within Quadrant 3 of a biplot, with the exception of AQ1, which fell within

Quadrant 1. Scores in Quadrant 3 indicate the impact of the harsh physical conditions associated with ephemeral waterways. Scores in Quadrant 1 indicate favourable habitat and chemically dilute waters.

A total of 153 species of plants were identified in the riparian areas of the Investigation Area. Regional Ecosystem 1.3.7b – River Red Gum (*Eucalyptus camaldulensis*) woodland on channels and levees occurs on parts of the watercourses of the Investigation Area. This Regional Ecosystem occurs mostly outside the Project disturbance footprint. No flora species of conservation significance were found in the Investigation Area. Thirteen weed species were recorded in riparian areas during the surveys.

A total of 67 species of fauna were recorded in the riparian areas of the Investigation Area, consisting of 14 mammals, 40 birds, five amphibians, six reptiles, one fish and one crustacean species. Two species of conservation significance, the Near Threatened Golden-backed Honeyeater (*Melithreptus gularis laetior*) and the Vulnerable Purple-necked Rock-wallaby (*Petrogale purpureicollis*) were recorded in riparian areas outside the Project disturbance footprint. Four introduced species, including two declared pests (Feral Pig, *Sus scrofa* and Wild Dog, *Canis familiaris*) under the *Land Protection (Pest and Stock Route Management) Act 2002* were detected during the surveys.

A number of potential impacts of Project development on aquatic and riparian areas were identified:

- Vegetation clearing, leading to erosion and siltation;
- Removal of small areas of potential habitat for a near threatened species (Golden-backed Honeyeater);
- Removal of approximately 1.8 hectares of Regional Ecosystem 1.3.7b, which has a Biodiversity Status of Endangered, to enable construction of the new site access road;
- Clearing of approximately 6.5 hectares of riparian vegetation and fauna habitat;
- Diversion of a minor drainage feature in the vicinity of the north pit;
- Construction of creek crossings;
- Release of hazardous substances, overflow of contaminated stormwater or wastewater to waterways; and
- Increases in pest and weed species and abundance.

The following mitigation strategies are recommended to address these potential impacts:

- Minimising clearing in riparian areas;
- Conducting clearing in a staged manner;
- Preserving tree hollows;
- Use of a spotter-catcher as required during clearing works;
- Rehabilitation of cleared riparian areas at site closure;
- Utilisation of sediment and erosion control structures during construction and operation;
- Vehicle washdowns;

- Implementation of Pest and Weed Management Plans and control programs;
- Regular water and sediment monitoring;
- Implementation of a Receiving Environment Monitoring Program;
- Diversion of clean water and treatment of contaminated water;
- Planting up of diversion channel area with local native riparian flora;
- Correct storage, handling and use of hazardous substances;
- Appropriate design of creek crossings and diversions;
- Staff training and awareness; and
- Potential offsetting of clearing of riparian vegetation.

1.0 INTRODUCTION

AustralAsian Resource Consultants (AARC) was commissioned by the CopperChem Ltd and Syndicated Metals Ltd Joint Venture (JV) to perform an Aquatic Ecology Assessment for the Barbara Copper Project (the Project).

1.1 SCOPE OF STUDY

This report describes and assesses the ecological features of the Project site and outlines recommended strategies to minimise the potential impacts of the Project on aquatic fauna and flora.

The scope of this study is to assess the environmental values of the surface waterways (e.g. rivers, creeks, streams and other waterbodies, including drainage lines and wetlands) which occur within and immediately upstream/downstream of the Project in terms of:

- Values identified in the *Environmental Protection (Water) Policy 2009*;
- Watercourse descriptions, including both quality and quantity;
- Morphology of watercourses, including riparian zone vegetation and watercourse form;
- Downstream water resource uses, including their significance to the local community and/or environment;
- The diversity, abundance and conservation significance of aquatic and riparian biota.

This scope was addressed through a combination of desktop and field-based investigations of the Project site and surrounding area.

2.0 PROJECT AND SITE DESCRIPTION

2.1 PROJECT LOCATION

The Project is located approximately 60 kilometres (km) north-east of Mount Isa in north-west Queensland. The Project can be accessed from the Barkly Highway and Lake Julius Road.

The regional location of the Project is illustrated in Figure 1.

2.2 PROJECT DESCRIPTION

The Project involves the development of an open cut copper mining operation. The area studied for this report (the Investigation Area) is made up of the western section of Mineral Development Licence (MDL) 499 and Mining Lease Application (MLA) 90241. Mining operations will be confined to MLA 90241 (referred to in this report as the Project Area). The Project access road will pass through MDL 499.

The proposed mine plan will include open cut mining of the copper resource, with ore to be trucked to a nearby, established third party processing plant via a new access road. Mining of the copper ore will involve conventional drill and blast, load and haul techniques. The ore will be loaded into road trains on site and transported offsite for processing.

A first order drainage feature near the north pit will be partially diverted to enable development of the pit.

2.3 CURRENT LAND USE

The current land use of the Investigation Area is low intensity cattle grazing and exploration. The Project Area has a long history of exploration and small scale mining activities.

Figure 1 Regional Location of the Project

2.4 REGIONAL CLIMATE

Climate data for the Project region was sourced from the Australian Bureau of Meteorology (BOM). Rainfall data was sourced from the nearest BOM rainfall monitoring station, located at West Leichardt Station. Temperature data was sourced from the Mount Isa Aero Station. Mean monthly temperature data for the period 1967 to 2014 and mean monthly rainfall from 1894 to 2014 are presented in Figure 2. Figure 2 shows that there is significant seasonal variation in rainfall and temperature in the Project region. Rainfall is highest during the months of November to March. Average annual rainfall for the region is 430.4 millimetres (mm).

Figure 2 Mean Monthly Rainfall and Temperature Data for the Mount Isa Region

2.5 SURFACE WATERS AND DRAINAGE

The Investigation Area is crossed by numerous small, unnamed first and second order drainage lines. One larger, third order watercourse flows through the south-western and north-western areas of the Investigation Area. These waterways drain north-west to form an unnamed third order creek which flows into the Leichhardt River. The Leichhardt River flows north into the Gulf of Carpentaria. Waterways on and around the Investigation Area are shown in Figure 3.

There are no major watercourses or permanent water sources in the Investigation Area. Drainage lines in the Investigation Area are typically dry and only flow after heavy wet season rainfall.

Figure 3 Waterways of the Investigation Area

3.0 DATABASE SEARCHES

Databases collate information on flora and fauna species identified from previous surveys, community records and other sources. Searches of the following relevant databases were conducted to identify aquatic flora and fauna species that may inhabit the Investigation Area:

- Protected Matters Search Tool: This is the Commonwealth Department of Environment's (DoE) database, which provides information on matters of National Environmental Significance and other matters protected by the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) for a nominated area;

- Wildlife Online Database: This is the Queensland Department of Environment and Heritage Protection's (EHP) database of flora and fauna sighting records; and

- Recovery Actions Database: This database contains a list of fauna and flora species of high conservation significance (termed 'priority species') for each of the Queensland Natural Resource Management Regions.

These databases provide information on the threatened and significant species that may occur in the search area.

A search of the Queensland WetlandMaps database was also conducted, in order to identify any wetland areas known to be present in the Investigation Area.

A 100 km search radius based upon on the Investigation Area centroid was employed for the Wildlife Online and Protected Matters searches. The results of the database searches revealed that several fauna species of conservation significance that have habitat requirements intrinsically linked to aquatic systems are known from the region, as discussed below.

Database search results are included in Appendix A.

3.1 THREATENED SPECIES

3.1.1 Threatened Ecological Communities

The database searches did not identify any Endangered Ecological Communities within the search area.

3.1.2 Flora

No aquatic flora species of conservation significance were identified by the desktop searches.

Weeds of national significance (WoNS) and other introduced plants considered by the Commonwealth Government to pose a significant threat to biodiversity are included in the Protected Matters Search results. Riparian and aquatic WoNS identified from the Protected Matters Search are summarised in Table 1 below.

The WoNS program coordinates the national effort against 32 of Australia's worst invasive plants. A national strategy for each WoNS nominated weed specifies actions to better manage each weed.

The Queensland legislation applicable to weed species management is the *Land Protection (Pest and Stock Route Management) Act 2002* (LP Act), which lists declared weed species and categorises them into three classes:

- Class 1 – can cause adverse economic, environmental and social impacts. Once established in Queensland, Class 1 pests are subject to eradication from the state.

- Class 2 – established in Queensland and have, or could have, an adverse economic, environmental or social impact.

- Class 3 – established in Queensland and have, or could have, an adverse economic, environmental or social impact. The primary objective of Class 3 listing is to prevent sale, therefore preventing the spread of these pests into new areas.

Declaration under the LP Act imposes a legal responsibility for control by all landowners on land under their management.

Table 1 Aquatic WoNS and Significant Weed Species of the Project Region

Scientific Name	Common Name	Preferred Habitat	Conservation Status	
			Commonwealth	State
Cryptostegia grandiflora	Rubber Vine	Initially invades waterways, expanding outward to hillsides and pastures. Rubber Vine is established throughout most of Queensland, including north-west Queensland	WoNS	Class 2
Eichhornia crassipes	Water Hyacinth	Grows in ponds and slow moving waterways, such as rivers, dams, lakes and wetlands. It forms dense floating mats. Widespread across tropical and subtropical regions of eastern Australia	WoNS	Class 2
Jatropha gossypifolia	Bellyache Bush	Common along roadsides and riverbanks. Also found in grasslands and open woodlands. Established in northern Queensland, with smaller outbreaks across the state	WoNS	Class 2
Parkinsonia aculeata	Parkinsonia	Adapted to a wide range of soil types, found along watercourses in sub-humid and semi-arid areas of Queensland	WoNS	Class 2
Prosopis spp.	Mesquite	Can inhabit a range of climatic zones. Infestations often begin at waterways. Can form dense populations in a range of conditions and soil types. In Queensland this weed is mainly found in arid western areas	WoNS	Class 2

Scientific Name	Common Name	Preferred Habitat	Conservation Status	
			Commonwealth	State
Salvinia molesta	Salvinia	Salvinia is an aquatic weed which favours still or slow-flowing waterbodies. It has the ability to grow rapidly over the water surface forming a thick mat of vegetation	WoNS	Class 2
Tamarix aphylla	Athel Pine	Athel Pine flourishes in or near sandy watercourses, where it can form dense stands. It is well suited to arid and semi-arid areas. It is found throughout the Australian mainland, with the exception of Victoria	WoNS	Class 3

3.1.3 Fauna

The database searches identified 20 threatened fauna species in the Project region that inhabit aquatic and/or riparian habitats. These species are presented in Table 2. The likelihood of these species occurring in the Investigation Area is discussed in Section 5.7.7.

Table 2 Threatened Fauna Species of the Project Region

Scientific Name	Common Name	Conservation Status	
		EPBC Act	NC Act
Birds			
Accipiter novaehollandiae	Grey Goshawk	NL	NT
Erythrotriorchis radiatus	Red Goshawk	V	E
Ephippiorhynchus asiaticus	Black-necked Stork	NL	NT
Heteromunia pectoralis	Pictorella Mannikin	NL	NT
Epthianura crocea crocea	Yellow Chat (Gulf)	NL	V
Erythrura gouldiae	Gouldian Finch	E	E
Falco hypoleucos	Grey Falcon	NL	NT
Lophoictinia isura	Square-tailed Kite	NL	NT

Grantiella picta	Painted Honeyeater	NL	V
Pezoporus occidentalis	Night Parrot	E	E
Poephila cincta cincta	Black-throated Finch (southern)	E	E
Stictonetta naevosa	Freckled Duck	NL	NT
Rostratula australis	Australian Painted Snipe	E, Ma, Mi	V
Reptiles			
Elseya lavarackorum	Gulf Snapping Turtle	E	V
Emydura subglobosa worrelli	Diamond Head Turtle	NL	NT
Fish			
Pristis pristis	Freshwater Sawfish	V	NL

NC Act – *Nature Conservation Act 1992*
E – Endangered
V – Vulnerable
NT – Near Threatened
NL – Not listed
Ma – Marine species
Mi – Migratory species

The Protected Matters Search also identified 40 migratory and/or marine species listed under international treaties for the Project region. Migratory bird species listed under international conventions are listed as Special Least Concern wildlife under the *Nature Conservation Act 1992* (NC Act). Migratory and marine species for the Project region are listed in Table 3.

Table 3 Migratory and Marine Species of the Project Region

3.2 REGIONAL PRIORITY SPECIES

The Back on Track species framework was designed to identify fauna and flora species of high conservation significance (termed 'priority species') for the Natural Resource Management regions of Queensland. The Back on Track priority species lists include species that are not listed as threatened under State or Federal legislation.

The Project is situated in the Southern Gulf National Resource Management Region. There are 33 priority species identified in this region; 25 of which have habitat requirements linked to aquatic systems. The aquatic priority species are:

- Eight bird species;
- Five fish species;
- Three mammal species;

- Six reptile species; and
- Three plant species.

The majority of these species are marine species and tropical species, which do not occur in the Investigation Area.

3.3 WETLAND HABITATS

A review of the EHP interactive WetlandMaps database and the Map of Referrable Wetlands showed that there are no mapped wetlands (including referable wetlands) within the Investigation Area. Riverine waterbodies have been identified passing through the Investigation Area (Figure 4). No wetlands of national or international importance have been recorded in the Investigation Area, including those nominated under the Ramsar Convention.

Lake Julius, a major lacustrine wetland listed on the Directory of Important Wetlands in Australia, is located approximately 17 km downstream of the Investigation Area. Lake Julius is mapped as a General Ecological Significance Wetland on the map of referrable wetlands.

The Map of Referrable Wetlands and Queensland Wetland Map for the Investigation Area are presented in Appendix A.

Figure 4 Wetlands of the Investigation Area

3.4 ENVIRONMENTALLY SENSITIVE AREAS

Environmentally Sensitive Areas (ESA) mapping presents Category A, B, and C areas of conservation significance, including those under international agreements (e.g. Ramsar sites), fish habitat areas, declared catchment areas, Wild River nominated waterways and areas listed under the Directory of Important Wetlands. A search of the EHP database for ESAs shows that there are areas of Category B ESA in the west of the Investigation Area, as illustrated in Figure 5 below. The Category B ESAs are a Regional Ecosystem (RE) with a Biodiversity Status of Endangered: RE 1.3.7b River Red Gum (*Eucalyptus camaldulensis*) woodland on channels and levees.

No Category A or C ESAs are present within or adjacent to the Investigation Area. No areas defined as World Heritage Areas, Ramsar sites, forestry areas, Wild River nominated waterways or essential fauna habitat are present within or adjacent to the Investigation Area.

Figure 5 ESA Mapping for the Investigation Area and Project Site

4.0 METHODOLOGY

4.1 MONITORING SITES

Monitoring site locations were selected upstream and downstream of planned infrastructure to enable future monitoring of any impacts on aquatic ecosystems. Monitoring site locations are shown in Figure 6.

A total of 12 sites were assessed for the following parameters:

- Stream morphology/habitat quality;
- Sediment particle size and metal concentration;
- Aquatic fauna diversity and abundance;
- Riparian flora diversity and abundance;
- Surface water quality; and
- Macroinvertebrate diversity and abundance.

Figure 6 Monitoring Site Locations

4.2 STREAM MORPHOLOGY

A habitat assessment was performed at all sites using a modified version of the Australian River Assessment System (AUSRIVAS) protocols developed by the Department of Natural Resources and Mines. AUSRIVAS is a nationally standardised method for giving an assessment of the biological health of inland rivers within Australia. The broad habitat type, channel pattern, water level and flow, substrate character and cover, bed and bank stability, and riparian cover at each site were described in accordance with the AUSRIVAS datasheets. Certain sections in these datasheets relating to water flow information were unable to be completed due to absence of flowing water at the time of the survey. Each surveyed site was given a score out of 135, with higher numbers indicating favourable habitats normally associated with healthy waterways. Table 4 below provides a framework for interpreting habitat assessment scores.

Stream morphology sampling sites are illustrated in Figure 6.

Table 4 Key to AUSRIVAS Habitat Assessment Scores (possible given score meanings)

Habitat Assessment Score	Interpretation
0 – 35	Habitat is poor. There is limited habitat availability for in-stream fauna. There is little variation in velocity and depth of water, and the creek bed consists of a single sediment type. The water body typically consists of a small, shallow pool. Streamside vegetation, if present, consists of grasses and sedges. There is moderate to significant erosion on the banks.
36 – 70	Habitat variety is moderate. This could be due to leaf litter and other vegetation or detritus in the water, or the presence of boulders and rocks. The streamside vegetation consists mainly of grasses and sedges. There is moderate evidence of bank erosion, and the percentage of vegetative cover on the banks is less than 50%.
71 – 100	Habitat is relatively good. The bank is stable, there is variety in depth and velocity within the water body and substrate type is variable and tending towards boulders and rocks. Streamside vegetation is of trees and shrubs, adding to the bank stability. The percentage of streamside cover by vegetation is relatively high.
101 – 135	Indicates a pristine and favourable habitat. There is no bank erosion and the dominant vegetation is trees. There is great variety in depth and velocity, and the habitat is quite complex, offering many types of protection for fauna. This is usually afforded by logs and branches, leaf litter, variety in substrate type, variety in water depth, and presence of vegetation living within the water body.

4.3 STREAM SEDIMENT SAMPLING

Background stream sediment monitoring was undertaken in watercourses potentially affected by the Project, both upstream and downstream of Project activities. Sediment samples were obtained from all survey sites (refer to Figure 6). Five sub-samples of the stream-bed substrate were taken at regular intervals along a 50 metre (m) stretch of the creek bed at each site. The sub-samples were then mixed to obtain a composite sample, sealed in sterilised glass jars and sent to a National Association of Testing Authorities (NATA) accredited laboratory for analysis of the parameters outlined in Table 5. Results were compared to the Australia and New Zealand Environment and Conservation Council (ANZECC) (2000) Interim Sediment Quality Guidelines (ISQG) presented below in Table 5.

Table 5 ANZECC (2000) Stream Sediment Trigger Values

Parameter	Units	Low ISQG	High ISQG

Boron (B)	mg/kg	n/a	n/a

4.4 SURFACE WATER QUALITY SAMPLING

Water quality sampling was undertaken at all sites that held water at the time of sampling (refer to Figure 6) to determine water quality at the time of survey, in order to aid in the interpretation of biological data. Field readings of pH, electrical conductivity (EC), temperature and dissolved oxygen (DO) and surface water samples were collected. Samples were immediately refrigerated and sent to a NATA accredited laboratory for analysis. The results were compared to the ANZECC (2000) Guidelines for both Aquatic Ecosystems (slightly-moderately disturbed systems) and Livestock Drinking Water. The applicable trigger limits from these guidelines are presented below in Table 6.

Table 6 ANZECC Water Quality Guidelines

Parameter	Units	ANZECC (2000) Livestock Drinking Water	ANZECC (2000) Aquatic Ecosystems
pH	pH units	n/a	6.0 - 7.5
Conductivity (EC)	µs/cm	n/a	20 - 250
Dissolved oxygen (DO)	%	n/a	90 - 120

4.5 MACROINVERTEBRATE SAMPLING

Macroinvertebrates are invertebrates that can be seen with the naked eye. The types and numbers of macroinvertebrates found in a waterway can be used as biological indicators (bio-indicators) of the health of aquatic environments for the following reasons:

1) They are generally sensitive to the cumulative impacts of a wide range of disturbances and pollutants;

2) They are abundant in freshwater systems;

3) They are relatively easy to identify; and

4) They are easy to collect (Chessman, 2003).

Macroinvertebrate sampling was undertaken at all survey sites where water was present (refer to Figure 6).

Macroinvertebrates were collected using a D-frame pond net (350 mm x 250 mm with 250 micrometer (µm) mesh) and employing a kick-sampling method (the substrate in the waterbody was disturbed and the net passed through the resulting plume to obtain benthos- and water column-dwelling macroinvertebrates). Separate samples of edge habitat and bed habitat were undertaken where possible. Only edge samples could be obtained for small water bodies.

Macroinvertebrates were placed in a white sorting tub and 'live-picked' using a pipette and tweezers for a period of 30 minutes. Macroinvertebrates were placed in a vial containing 70% ethanol and sent to a NATA accredited laboratory for identification to family or sub-family level. This data was then plotted on a Stream Invertebrate Grade Number – Average Level (SIGNAL) bi-plot for interpretation of the health of the waterbody.

The SIGNAL Index was developed by the National River Health Program as a tool for the bioassessment of water pollution and considers the taxonomic composition of the invertebrate assemblage to determine river health. Each macroinvertebrate is given a grade number between one and ten based on their sensitivity to various pollutants (Chessman, 2003), with a lower number indicating a higher tolerance to a range of conditions. The SIGNAL Index value is calculated by averaging the pollution sensitivity grade numbers of the families present at each site. Refer to Chessman (2003) for families excluded from SIGNAL scoring results.

Once plotted on a bi-plot, the SIGNAL Index and the number of invertebrate families found in a stream used together can provide an indication of the types of pollution and other physical and chemical factors that affect macroinvertebrate communities (Chessman, 2003), depending on their position within the graph (refer to Figure 7).

Quadrant 3 Often indicating toxic pollution or harsh physical environments	**Quadrant 1** Indicates favourable habitat or chemically dilute water
Quadrant 4 Usually indicating urban, industrial, or agricultural pollution	**Quadrant 2** Often indicating high salinity or nutrient levels (may be natural)

Figure 7 Bi-plot Interpretation

4.6 AQUATIC FAUNA SAMPLING

Sampling of aquatic fauna (fish and crustaceans) was undertaken at sites where sufficient water was present. Box traps and opera traps baited with dog biscuits were deployed in sections of the waterbody likely to contain aquatic fauna. All fauna captured during the survey were identified, their abundances recorded, and released back to the water.

Spotlighting was carried out at night in aquatic habitat, in an attempt to observe nocturnal wildlife that are not likely to be detected by other survey methods, such as frogs, nocturnal birds and certain reptiles. The creek banks were randomly traversed by two ecologists wearing headlamps, at a slow walking speed (approximately 1 km/hour) to facilitate intensive listening and thorough visual searching. While this technique improves the likelihood of detecting small cryptic species, it is a time consuming activity that does not permit the coverage of large areas. A total of four spotlight hours were undertaken in riparian areas.

Specialised electronic bat call recorders called Songmeters were set up in riparian areas adjacent to waterholes in the wet and dry seasons. Bat call recorders were used to record micro-bat calls at specific sites believed to provide potential bat habitat. Recordings were made at four sites in the dry season, shown in Figure 8. Recordings were sent to an experienced bat call analyst (Mr Greg Ford – Balance! Environmental Pty Ltd) for positive species identification.

Figure 8 Bat Survey Locations

4.7 AQUATIC FLORA SAMPLING

Riparian flora species composition was investigated at ten secondary transects along riparian areas in the wet season and 12 secondary transects in the dry season. Secondary transects are 20 x 50 m plots. Data recorded in these plots includes a list of all species observed from all the major layers of vegetation. Species that fall outside the plot but are typical of the community are also listed. In addition, abundance for individual species in each strata is recorded, including density and projected foliage cover and height for the tree and shrub layers. This sampling method is in accordance with the *Methodology for Survey and Mapping of Regional Ecosystems and Vegetation Communities in Queensland* (Neldner et al. 2012).

5.0 RESULTS AND DISCUSSION

Surveys of the Investigation Area were undertaken from 24 February to 1 March 2014 (wet season survey) and 1 to 7 July 2014 (dry season survey). A total of ten sites were assessed in the wet season. An additional two sites containing surface water were located and added to the survey in the dry season. A total of 12 sites were assessed in the dry season survey (refer to Figure 6).

5.1 WEATHER CONDITIONS AT THE TIME OF SURVEY

Weather conditions in the first survey (24 February to 1 March) were typical of the wet season, with storms and rain showers experienced on most days of the survey. A total of 58.6 mm of rainfall was recorded during the survey. Water levels in the creeks surveyed fluctuated dramatically over the course of the survey. The weather conditions during the second survey (1 to 7 July 2014) were dry, sunny and cool. Only 1.4 mm of rainfall was recorded in the two months preceding the second survey.

5.2 HABITAT ASSESSMENT

5.2.1 AQ1

Site AQ1 is located in the third order drainage feature that passes through the western edge of the Investigation Area. This reference site lies outside the Project Area and outside the catchment in which the Project disturbance footprint is located. The drainage feature was observed to be flowing for several days during the wet season survey. By the time of the dry season survey, only a small waterhole (7 m x 4 m) in a rocky backwater remained. Large numbers of birds were observed drinking from this waterhole.

The channel at AQ1 is approximately 10 m wide, with banks from 1 m to 3 m high. The bed consists mainly of sand, with small areas of bedrock and boulders. Riparian vegetation is dominated by mature River Red Gums (*Eucalyptus camaldulensis*), *Acacia hemsleyi* and Couch (*Brachyachne convergens*). Cattle grazing adjacent to the pool have created large bare areas and grassy areas. The banks were assessed as being moderately unstable, with grasses dominating the bank cover.

Photo Plate 1 Site AQ1 (wet season)

5.2.2 AQ2

Site AQ2 is located upstream of the Investigation Area, just outside the south-eastern boundary of MDL 499. AQ2 is located upstream of site AQ1, on a tributary of the drainage feature that runs through the south-western portion of the Investigation Area. This reference site lies outside the Project Area and outside the catchment in which the Project disturbance footprint is located. A large, shallow pool was present at AQ2 in the wet season, which dried out completely by the time of the dry season survey.

The channel at AQ2 is approximately 8 m wide, with convex banks from 0.5 to 2 m in height. The substrate is dominated by gravel, with some small areas of bedrock and boulders. Riparian vegetation is sparse, and dominated by mature River Red Gums, Northern Swamp Mahogany (*Lophostemon grandiflorus*), *Acacia hemsleyi*, Couch and Twirly Windmill Grass (*Enteropogon ramosus*). The banks showed signs of erosion and cattle grazing, and were assessed as moderately unstable. There were large bare patches on the banks in the dry season.

Photo Plate 2 Site AQ2 (wet season)

5.2.3 AQ3

Site AQ3 is located on a first order drainage feature in the west of the Investigation Area. This minor drainage feature was dry in both surveys. AQ3 is located outside the Project Area and the catchment in which the Project disturbance footprint is located, downstream of the existing access road.

The channel at site AQ3 is narrow (0.5 – 2.5 m) and shallow, with banks to 0.5 m. The bed consists of sand and gravel with a cobble armour. Riparian vegetation is dominated by Cloncurry Box (*Eucalyptus leucophylla*), Turpentine (*Acacia chisholmii*) and Golden Beard Grass (*Chrysopogon fallax*). The banks are moderately stable, with little erosion present. Shrubs are the prevalent streamside cover.

Photo Plate 3 Site AQ3 (wet season)

5.2.4 AQ4

Site AQ4 is located in the central portion of the Project Area, at the junction of two small drainage features and the source of Watercourse B. A large, shallow pool of water was present at this site in the wet season survey. AQ4 was completely dry at the time of the dry season survey. AQ4 is located immediately upstream of a vehicle track through the creek. AQ4 is situated downstream of the Project disturbance footprint.

The creek channel at AQ4 is approximately 8 m wide. The creek banks are approximately 1 m high. The bed of the creek at AQ4 consists primarily of sand and gravel. The riparian vegetation at AQ4 is dominated by River Red Gums, Northern Swamp Mahogany, Soapbush (*Acacia holosericea*), Mimosa Bush (*Vachellia farnesiana*), Golden Beard Grass and Twirly Windmill Grass. The ground layer had been grazed by cattle. The banks were assessed as moderately unstable and covered mostly with grasses.

Photo Plate 4 Site AQ4 (wet season)

5.2.5 AQ5

Site AQ5 is located on a first order drainage feature in the north of the Project Area. No water was observed at AQ5 in either of the surveys. AQ5 is located downstream of the Project disturbance footprint.

The channel at AQ5 is 4 – 7 m wide, with banks to 3 m in height. The bed consists of cobbles, pebbles and sand. Riparian vegetation is dominated by Northern Swamp Mahogany, River Red Gum, Black Tea-tree (*Melaleuca bracteata*) and Silky Browntop (*Eulalia aurea*). Banks were assessed as stable, with trees forming the main component of streamside cover.

Photo Plate 5 Site AQ5 (dry season)

5.2.6 AQ6

Site AQ6 is located in a small first order drainage feature in the north of the Project Area. AQ6 is located outside the catchment in which the Project disturbance footprint is located, and can therefore be considered a reference site. A series of pools were present at this site in the wet season. All pools had dried up by the time that the dry season survey was conducted.

The channel at AQ6 is steep and rocky, with steep rock outcrops on either side of the creek. The channel is approximately 4 m wide, with the banks consisting of rock outcrops to 15 m in height. The bed is formed from large boulders and slabs of bedrock. Riparian vegetation is very sparse due to the low amount of topsoil present at this site. Northern Swamp Mahogany (*Lophostemon grandiflorus*) dominated the tree and shrub layers in the channel. Lemon-scented Grass (*Cymbopogon bombycinus*) dominated the sparse ground layer. The banks were assessed as stable, with no erosion present. Bank cover consists primarily of rocks.

Photo Plate 6 Site AQ6 (wet season)

5.2.7 AQ7

AQ7 is located on a second order watercourse (Watercourse B) in the north of the Project Area, downstream of the Project disturbance footprint and sites AQ6, AQ4, AQ5, AQ8, AQ9 and AQ10. A large pool of water was present at AQ7 in the wet season. This pool was dry during the dry season survey.

The creek at AQ7 is approximately 8 m wide, with convex banks to 2.5 m in height. The bed of the pool consists mainly of gravel, with large sections of bedrock and boulders. Riparian vegetation is dominated by River Red Gums, Northern Swamp Mahogany, Soapbush, Soft Spinifex (*Triodia pungens*) and Twirly Windmill Grass. Banks were assessed as moderately stable. Bank cover consisted mainly of trees.

Photo Plate 7 Site AQ7 (wet season)

5.2.8 AQ8

Site AQ8 is located in a first order drainage feature in the north-east of the Project Area, downstream of AQ10 and upstream of AQ4. AQ8 is located outside the catchment in which the Project disturbance footprint is located, and can therefore be considered a reference site. A large, deep waterhole is present at this site. This waterhole is thought to be permanent, due to its large size and depth. High numbers of birds were observed drinking at this site in the dry season.

The channel at AQ8 is extremely rocky, with a small dry waterfall immediately upstream of the pool. The pool exceeds 1 m in depth in places. The channel is approximately 12 m wide and banks are roughly 1.5 m high. The bed consists of a combination of bedrock, boulders and gravel. Riparian vegetation cover around the pool is sparse, and dominated by Northern Swamp Mahogany and Tall Sesbania Pea (*Sesbania javanica*). The banks were assessed as stable, with no erosion observed. Bank cover consists mainly of rock.

Photo Plate 8 Site AQ8 (wet season)

5.2.9 AQ9

Site AQ9 is located in the upper reaches of a small first order drainage feature in the east of the Project Area. AQ9 is located within the Project disturbance footprint. No water was observed at this site in either of the two surveys.

The channel at AQ9 varies in width, with an average width of 6 m. The gently sloping banks are 0.5 – 0.75 m in height. The channel bed is composed mainly of cobbles, with areas of gravel and small sections of outcropping bedrock and boulders. The riparian zone is confined to the creek channel, and is dominated by Northern Swamp Mahogany, Black Tea-tree and Northern Wanderrie Grass (*Eriachne obtusa*). The trees form dense thickets in parts of the channel. The banks were assessed as moderately stable, and were covered mainly with grasses.

Photo Plate 9 Site AQ9 (wet season)

5.2.10 AQ10

Site AQ10 is located at the source of a small first order drainage feature in the far east of the Project Area. AQ10 is located outside the catchment in which the Project disturbance footprint is located, and can therefore be considered a reference site. This site was surveyed during heavy rain in the wet season. Only a very small flow was observed in the channel. AQ10 was completely dry during the dry season survey.

The channel at AQ10 is very narrow (maximum 1 m) and shallow (approximately 0.3 m), with a bed of cobbles and gravel. The riparian vegetation consists mainly of Cloncurry Box, Soapbush and Golden-beard Grass. The banks were assessed as moderately stable, and were covered mainly by shrubs.

Photo Plate 10 Site AQ10 (dry season)

5.2.11 AQ11

Site AQ11 is located in a second order watercourse (Watercourse B) downstream of the Project Area and the Project disturbance footprint, approximately 1 km west of the north-western boundary. This site was not located until the dry season survey. One small pool and two larger pools were present at AQ11 in the dry season survey.

The channel at AQ11 is wide (15 m) and surrounded by steep rocky outcrops. The pools were approximately 0.5 m in depth at the time of survey. The right bank (looking downstream) is a gentle convex slope of approximately 1.5 m in height, while the left bank is composed of vertical bedrock to 1 m in height. The bed is composed mainly of bedrock, with areas of gravel, sand and silt. The bed had been trampled by cows, causing high turbidity in the water at the time of the survey. Algae were also observed in the water.

The riparian zone at AQ11 is confined to the channel, and dominated by River Red Gum, Northern Swamp Mahogany and *Acacia hemsleyi*. The ground layer has been stripped by grazing cattle. The creek banks were stable and covered mainly by rock.

Photo Plate 11 Site AQ11 (dry season)

5.2.12 AQ12

Site AQ12 is located in a first order drainage feature slightly to the south of the north-eastern boundary of the Project Area. AQ12 is located outside the catchment in which the Project disturbance footprint is located, and can therefore be considered a reference site. This site was not located until the dry season survey. A very small pool of water was present at this site in the dry season. AQ12 is likely to form a much larger pool during the wet season, as the channel is quite deep at this point.

The channel width varies at AQ12, ranging from a maximum of 20 m wide at the pool to 10 m wide immediately downstream. The pool is located at the foot of a large, vertical section of bedrock. The pool was very small (2 m x 2 m) at the time of survey and less than 0.3 m in depth. The water was very turbid, contained algae and had a high solids load. The pool has a sandy bottom, while the channel downstream is composed mainly of pebbles and gravel. Deposition of fine sediment was noted at the pool. The banks of the pool are gentle and convex, to approximately 4 m in height.

Riparian vegetation is not present at the pool itself, possibly because of trampling and grazing by livestock. Immediately downstream of the pool the riparian vegetation consists mainly of Northern Swamp Mahogany and Northern Wanderrie Grass. The banks were assessed as moderately stable, although vegetation cover was fairly low and bank cover was dominated by bare ground.

Photo Plate 12 Site AQ12 (dry season)

5.2.13 SITE SCORES

Each of the survey sites was assessed using the AUSRIVAS habitat assessment methodology. Sites were assessed in both the dry season survey and the wet season survey, with the exception of AQ11 and AQ12, which were only assessed in the dry season. Site scores are provided in Table 7. All sites fell with the 'moderate' to 'good' habitat range. Scores in the wet and dry season were similar. The habitat assessment results reflect the ephemeral nature of the survey sites and the impacts of grazing and erosion.

Table 7 AUSRIVAS Habitat Assessment Results

Site	Habitat Assessment Score / 135	
	Wet Season	Dry Season
AQ1	78	86
AQ2	75	79
AQ3	73	78

AQ9	76	79
AQ10	83	82
AQ11	-	85
AQ12	-	83

5.3 STREAM SEDIMENT

5.3.1 Particle Size

Stream sediments were typically very coarse, with a high component of gravel, cobbles and sand. The particle size distribution results are presented in Table 8, Figure 9 (wet season) and Figure 10 (dry season).

Table 8 Particle Size Distribution Results

Figure 9 Particle Size Distribution – Wet Season

Figure 10 Particle Size Distribution – Dry Season

5.3.2 Metal Concentrations

Sediment samples were taken at each survey site in both surveys and tested for a suite of metals. Metal concentrations in sediment are shown in Table 9 (wet season) and Table 10 (dry season). Metals levels at most sites were below both the low and high ISQG. A small number of exceedences of the ANZECC low ISQG were recorded, and are highlighted in the tables in orange. No exceedences of the high ISQG were recorded. The full laboratory analysis results are presented in Appendix B.

In the wet season, copper levels above the low ISQG were recorded at AQ4 and AQ7. Copper levels above the low ISQG were also recorded at AQ1 and AQ4 in the dry season. Nickel levels at AQ5 were above the ISQG in both the wet season and dry season.

Antimony and silver levels were below the LOR at all sites. The LOR for these parameters is higher than the low ISQG, so it is not possible to ascertain if the results comply with the applicable guideline limits.

5.4 WATER QUALITY

Water quality results for the wet season survey are presented in Table 11. Dry season water quality results are presented in Table 12. Exceedences of the ANZECC guidelines are presented in bold, orange font in the tables.

Physicochemical water quality in the Investigation Area was moderately poor. pH values tended to be slightly alkaline, and were above the ANZECC aquatic ecosystems guideline range at several sites (AQ1 in the wet season, AQ4, AQ7, AQ8, AQ11). Conductivity levels were high in the dry season, with all sites exceeding the ANZECC guideline. Site AQ4 recorded conductivity levels in excess of the ANZECC guideline in the wet season. Dissolved oxygen levels tended to be low, and were below the ANZECC guideline range at most sites (AQ1 in the dry season, AQ2, AQ4, AQ6, AQ7, AQ11, AQ12). The high pH and conductivity values and the low DO levels recorded are typical of stagnant, ephemeral waterbodies.

Nutrient levels (i.e. total nitrogen and total phosphorus) exceeded the ANZECC guidelines at all sites in both surveys. These high results are likely to be attributable to natural factors, as no artificial nutrient sources (such as fertilisers and sewage) are present in the Investigation Area. Nitrogen sources include decaying organic matter and animal waste. Phosphorus is found in rocks and soil, and is released to water through weathering and erosion. Animal and plant wastes are also a source of phosphorus. Nutrient levels tend to be high in ephemeral waterbodies, due to concentration from evaporation.

Metals levels in water were generally below the ANZECC guideline limits, with a few exceptions. In the wet season, total and dissolved silver (at AQ4, AQ6 and AQ7), total and dissolved copper (at all sites), total zinc (AQ8), total and dissolved aluminium (at AQ4, AQ7 and AQ8) and dissolved aluminium at AQ1 were above ANZECC aquatic ecosystems guidelines. Metal results were similar in the dry season, with total and dissolved copper (at AQ1, AQ8 and AQ11), total copper (AQ12), total and dissolved manganese (AQ12), total aluminium (AQ11 and AQ12) and total zinc (AQ11 and AQ12) exceeding the ANZECC guidelines. Copper, zinc and aluminium are naturally abundant elements and their elevated levels are likely to be the result of mineralisation in the Project region. High silver levels are also likely to be attributable to the local geology. High manganese levels were detected only at site AQ12. Manganese is an abundant metal in soil, and it is possible that trampling of the soft, sandy bed at AQ12 by cattle increased manganese levels at this site. No breaches of the Livestock Drinking Water guidelines were detected.

It should be noted that the ANZECC aquatic ecosystems guideline for silver is lower than the LOR for silver. This prevents a valid comparison of silver results below the LOR with the guideline limit.

The full water quality results are presented in Appendix B.

5.5 MACROINVERTEBRATES

Macroinvertebrate samples were taken from all sites where surface water was present. In larger pools where bed and edge habitats were present, separate samples from the edge and bed were taken. Where pools were very small or only one habitat type was present a single sample was taken. Sites AQ1, AQ2, AQ4, AQ6, AQ7 and AQ8 were sampled in the wet season. AQ1, AQ8, AQ11 and AQ12 were sampled in the dry season.

Macroinvertebrate diversity was fairly low, ranging from five taxa (at AQ12 and AQ1 bed habitat in the dry season) to 13 taxa (at AQ8 in the dry season). Total abundance was also relatively low, ranging from 40 individuals (in bed habitat at AQ1 in the dry season) to 136 individuals (at bed habitat at AQ8 in the wet season).

The Plecoptera (stoneflies), Ephemoptera (mayflies) and Trichoptera (caddis flies) (PET) are three orders of macroinvertebrates that are widely regarded as particularly sensitive to water pollution. Few PET taxa were recorded in the samples taken from the Investigation Area. No stoneflies were recorded in either survey. A single caddis fly was recorded at AQ4 in the wet season. Two individual caddis flies were recorded at sites AQ8 and AQ11 in the dry season. Higher numbers of mayflies (up to 18 individuals) were recorded. One mayfly taxon was recorded at most sites in the wet season, with two taxa at AQ7. A single mayfly taxon was recorded at both AQ8 and AQ11 in the dry season. These low numbers of PET taxa are indicative of poor water quality and/or low habitat quality.

SIGNAL scores were generally low (<4), which is reflective of the ephemeral nature of the waterways sampled. SIGNAL scores were similar between sites and across seasons, ranging from 2.53 (at AQ12 and AQ1 edge habitat in the wet season) to 3.43 (at AQ1 bed habitat in the dry season). These low scores are attributable to the poor water quality and lack of habitat availability in the small, ephemeral waterbodies sampled.

The SIGNAL scores were plotted on a biplot to assist in interpretation of the results. The SIGNAL biplot is shown in Figure 11. All sites fell within Quadrant 3 of the biplot, with the exception of AQ8 (dry season), which fell into Quadrant 1. Scores within Quadrant 3 can be indicative of either pollution or harsh physical conditions. The ephemeral nature of the waterways in the Investigation Area, drought and wet season flooding create harsh physical conditions for macroinvertebrates. Scores in Quadrant 1 indicate favourable habitat and chemically dilute waters. It is likely that AQ8 fell into Quadrant 1 because it is the only permanent water source in the Investigation Area, and provides a variety of habitat types in a large, deep pool.

The laboratory results for the macroinvertebrate samples are shown in Appendix C.

Figure 11 SIGNAL Biplot

5.6 AQUATIC FLORA

A total of 153 species of plant were identified in the riparian areas of the Investigation Area. A full list of these species is presented in Appendix D.

5.6.1 Communities of Conservation Significance

RE 1.3.7 – River Red Gum (*Eucalyptus camaldulensis*) woodland on channels and levees occurs on sections of the larger watercourses and drainage features of the Investigation Area. Approximately 75 ha of this community are found in the Investigation Area. This RE is listed as Least Concern under the *Vegetation Management Act 1999*, but has an EHP Biodiversity Status of Endangered. RE 1.3.7 is described as 'Fringing woodland of *Eucalyptus camaldulensis*, with *Melaleuca bracteata* on levees of smaller channels and *M. argentea* on those of larger ones. *Lophostemon grandiflorus* usually present, occasional *Terminalia aridicola*. *Eucalyptus microtheca* or *E. leucophylla* on finer textured soils. *Melaleuca leucadendra* may dominate creek lines where water is available for extended periods each year. Occurs on recent levees and channel deposits of larger tributaries; alluvial soils.' The vegetation observed on site is consistent with the sub-community RE 1.3.7b 'Riverine wetland or fringing riverine

wetland. Fringing woodland of *Eucalyptus camaldulensis*, usually with *Lophostemon grandiflorus* and *Melaleuca bracteata* and/or *M. dissitiflora*. Occurs on recent levees and channel deposits of medium and smaller tributaries which are dry for most of the year; alluvial soils.'

The areas of RE 1.3.7b in the Investigation Area contain a large number of mature, hollow-bearing trees which provide excellent habitat for a range of bird, bat and arboreal species. The ground layer of this community has been heavily modified by the introduction of Buffel Grass and by cattle grazing in the Investigation Area. At the regional scale, RE 1.3.7 has been severely degraded by high total grazing pressure. The extent of RE 1.3.7 in reserves is low (EHP, 2014).

The extent of RE 1.3.7b in the Investigation Area and the Project disturbance footprint are shown in Figure 12. Only 1.8 ha of the 75 ha of RE 1.3.7b on site will be directly impacted by Project activities.

Figure 12 RE 1.3.7b and the Project Disturbance Footprint

5.6.2 Plants of Conservation Significance

No flora species of conservation significance were found in the Investigation Area. No aquatic plants of conservation significance are known from the local area; therefore it is unlikely that any threatened aquatic plants occur on site.

5.6.3 Weed Species

The introduced species Mimosa Bush (*Vachellia farnesiana*), Buffel Grass (*Cenchrus ciliaris*), Elastic Grass (*Eragrostis tenuifolia*) and Asthma Plant (*Chamaesyce hirta*) were commonly observed growing in riparian areas. Rubber Vine (*Cryptostegia grandiflora*), which is a WoNS and a Class 2 declared weed, was recorded at site AQ5. Other weeds recorded in low numbers in riparian areas were Spinyhead Sida (*Sida acuta*), Flannel Weed (*Sida cordifolia*), Paddy's Lucerne (*Sida rhombifolia*), Star Burr (*Acanthospermum hispidum*), Feathertop Rhodes Grass (*Chloris virgata*), Southern Crabgrass (*Digitaria ciliaris*), Awnless Barnyard Grass (*Echinochloa colona*) and Malvastrum (*Malvastrum americanum*). No aquatic weeds were recorded at the survey sites.

5.7 AQUATIC AND RIPARIAN FAUNA

A total of 67 species of fauna were recorded in the riparian areas of the Investigation Area, including two threatened species and four introduced species. A full list of the fauna species recorded in the riparian sections of the Investigation Area is presented in Appendix E.

5.7.1 Mammals

The waterholes on the Project site are water sources for large mammal species, such as macropods. Riparian areas also provide habitat and drinking water for smaller mammal species, such as bats.

Twelve mammal species were positively identified in riparian habitat in the Investigation Area. A further two species of bat were identified as possibly present in the Investigation Area. No aquatic mammals were observed during the surveys. Common Wallaroos (*Macropus robustus*) were occasionally observed in riparian areas and were sighted drinking at waterholes in the dry season. A Purple-necked Rock-wallaby (*Petrogale purpureicollis*) was observed on boulders adjacent to site AQ6 in the wet season (Photo Plate 13). The corpse of a Purple-necked Rock-wallaby was observed at AQ6 in the dry season survey. The Purple-necked Rock-wallaby is listed as Vulnerable under the NC Act. Site AQ6 will not be disturbed by Project activities. Detailed information on the Purple-necked Rock-wallaby is provided in the Barbara Copper Project Terrestrial Flora and Fauna Assessment (AARC, 2014).

Seven species of bats were recorded in the riparian areas of the Investigation Area. A further two species may also be present, but they could not be reliably identified from the bat call data recorded. Commonly recorded species included Gould's Wattled Bat (*Chalinolobus gouldii*), Hoary Wattled Bat (*Chalinolobus nigrogriseus*), Little Broad-nosed Bat (*Scotorepens greyii*) and Finlayson's Cave Bat (*Vespadelus finlaysoni*). A full list of the bat species recorded during the survey is presented in Appendix F.

Photo Plate 13 Purple-necked Rock-wallaby (*Petrogale purpureicollis*) at AQ6

Two exotic mammal species, European Cattle (*Bos taurus*) and Feral Pigs (*Sus scrofa*), were also recorded in riparian areas. Both these species utilise waterholes heavily for drinking water. Damage to riparian vegetation and habitat was observed as a result of these large animals accessing waterholes. Wild Dog (*Canis familiaris*) tracks were also noted at several waterholes in the Investigation Area. Wild Dogs are likely to utilise waterholes for drinking water and also to prey upon drinking fauna.

5.7.2 Birds

The waterholes of the Investigation Area provide birds with drinking and bathing water. Dense riparian vegetation provides habitat for small bird species, such as finches and fairy-wrens. Stands of River Red Gum provide nesting and foraging habitat for a range of species. The high densities of birds at waterholes provide an important food source for predators, such as snakes and raptors. Waterhole habitat will not be disturbed by Project activities.

Large numbers of birds were recorded in the riparian areas of the Investigation Area. A total of 40 bird species were recorded in the two surveys. During the dry season, several bird species were observed bathing and drinking at the remaining waterholes. Large flocks of Diamond Doves (*Geopelia cuneata*), Zebra Finches (*Taeniopygia guttata*) (shown in Photo Plate 14), Budgerigars (*Melopsittacus undulatus*) and Double-barred Finches (*Taeniopygia bichenovii*) were encountered at all waterholes in the dry season. Collared Sparrowhawks (*Accipiter cirrocephalus*) were observed preying on these birds at AQ8 and AQ11.

No aquatic bird species were recorded in the Investigation Area. One wetland species, the Black-fronted Dotterel (*Elseyornis melanops*) was observed in low numbers at AQ1 during the wet season.

One species of conservation significance, the Golden-backed Honeyeater (*Melithreptus gularis laetior*) was observed in riparian habitat in the Investigation Area. Three Golden-backed Honeyeaters were observed in the trees at AQ4. The Golden-backed Honeyeater is listed as Near Threatened under the NC Act. Site AQ4 is located outside the Project disturbance footprint. Detailed information on the Golden-backed Honeyeater is provided in the Terrestrial Flora and Fauna Assessment (AARC, 2014).

Four bird species listed as Marine species and one species listed as both Migratory and Marine were recorded in the Investigation Area. Listed Marine species recorded were:

- Black-faced Cuckoo-shrike (*Coracina novaehollandiae*);
- Dollarbird (*Eurystomus orientalis*);
- Sacred Kingfisher (*Todiramphus sanctus*);
- Magpie-lark (*Grallina cyanoleuca*); and
- Rainbow Bee-eater (*Merops ornatus*).

The Rainbow Bee-eater is also a listed Migratory species.

These five species are all widespread, common and mobile species. Suitable habitat for these Marine species will remain in the undisturbed portions of the Investigation Area and throughout the local area. No significant impact on any of these species is expected to occur as a result of project development.

Photo Plate 14 Zebra Finches (*Taeniopygia guttata*) drinking and bathing at site AQ8

5.7.3 Amphibians

Amphibian habitat in the Investigation Area is limited by the ephemeral and rocky nature of the site waterways. The waterholes of the Investigation Area (particularly AQ1 and AQ8) provide habitat and breeding areas for amphibians. This habitat will not be disturbed by Project activities.

A total of five amphibian species were recorded in the Investigation Area. Most species observed were tree frogs and burrowing frogs, which are well adapted to the arid conditions of the Investigation Area. High numbers of Green Treefrogs (*Litoria caerulea*) and Desert Treefrogs (*Litoria rubella*) were observed and heard calling at waterholes. During the wet season, high numbers of tadpoles (mainly *Cyclorana australis*, see Photo Plate 15) and juvenile frogs were observed. A single Ornate Burrowing Frog (*Platypectrum ornatum*) was observed at AQ1 in the wet season. The introduced Cane Toad (*Rhinella marina*) was heard calling in several areas of the site during the wet season and sited in low numbers at AQ1 in the dry season.

No amphibians of conservation significance were recorded during the surveys.

Photo Plate 15 Northern Snapping Frog (*Cyclorana australis*)

5.7.4 Reptiles

Six reptile species were observed in the riparian habitat of the Investigation Area. No aquatic reptiles were observed. Gilbert's Dragons (*Amphibolurus gilberti*) were observed drinking from small waterholes in the dry season survey. A large Olive Python (*Liasis olivaceus*) was observed swimming in the large waterhole at AQ8 (shown in Photo Plate 16). Waterholes such as AQ8 are excellent food sources for snakes, and will not be disturbed by Project activities. Four skink species were also recorded in riparian habitat.

Photo Plate 16 Olive Python (*Liasis olivaceus*) at site AQ8

No reptiles of conservation significance were recorded in the Investigation Area.

5.7.5 Fish

The only species of fish captured in the Investigation Area was the Spangled Perch (*Leiopotherapon unicolor*), shown in Photo Plate 17. Small numbers of juvenile Spangled Perch were captured at AQ1 in both surveys. No fish were captured at any other survey site. Large numbers of deceased and dying juvenile Spangled Perch were observed in a very small waterhole in the south-west of the Investigation Area in the dry season. The fish were severely affected by low oxygen availability in the drying waterhole.

The Spangled Perch is widespread, occurring in a broad range of habitat types such as streams, lakes, bores, dams and billabongs. It occurs in abundance in most coastal drainage systems in northern and eastern Australia; north of the Greenough River in Western Australia and as far south as the Murray-Darling River system in New South Wales (Allen et al. 2003). The Spangled Perch is common throughout the region in which the Project is located. It is known to be tolerant of varying and harsh conditions (Pusey et al. 2004).

Photo Plate 17 Spangled Perch (Leiopotherapon unicolor)

Desert Rainbowfish (*Melanotaenia splendida tatei*) were observed in waterholes across the Investigation Area at the end of the wet season. The Desert Rainbowfish occurs in central desert areas in Queensland and the Northern Territory in a broad range of habitats, including rivers, creeks, lakes, reservoirs, and swamp areas. They tend to inhabit areas with low water flow (Allen et al. 2003). The Desert Rainbowfish is common throughout the region in which the Project is located. Rainbowfish are known to be tolerant of varying and harsh environmental conditions (Pusey et al. 2004).

Fish abundance and diversity at the Investigation Area were low. This is likely due to the fact that the waterways that run through the Investigation Area originate within or very close to the site. These low-order waterways are highly ephemeral and do not provide permanent fish habitat. It is thought that the fish observed in the Investigation Area are likely to have swum upstream onto the site in the wet season. Most fish are likely to die out during the dry season, as the only permanent water source observed within the Investigation Area is the waterhole at AQ8. AQ8 is located outside the Project disturbance footprint. No fish were observed or captured at AQ8.

5.7.6 Crustaceans

Several Inland Freshwater Crabs (*Austrothelphusa transversa*) were captured in the waterways of the Investigation Area during the wet season (Photo Plate 18). Both living and deceased crabs were observed in the dry season survey. No other crustacean species were observed in the Investigation Area.

Photo Plate 18 Inland Freshwater Crab (*Austrothelphusa transversa*) captured on the Project site

5.7.7 Fauna of Conservation Significance

Aquatic and riparian species of conservation significance that are known from the broad region but were not observed in the Investigation Area by AARC during the aquatic ecology surveys are further detailed below. These species have been identified from wildlife database searches and scientific literature searches. Table 13 provides an assessment of the likelihood of these species utilising the Investigation Area.

Table 13 Threatened Species of the Project Region (identified by database search)

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Threatened Species					
Accipiter novaehollandiae	Grey Goshawk	NL	NT	This species prefers rainforests, forests, forested gullies and valleys, taller woodlands, timbered watercourses and may be found in open country during autumn dispersal (Pizzey and Knight, 2007).	Unlikely to occur on site as there is little suitable habitat available.
Ephippiorhynchus asiaticus	Black-necked Stork	NL	NT	Prefers open freshwater environments, including the margins of swamps, creeks and shallow floodwaters over grasslands (Pizzey and Knight, 2007).	Suitable habitat may exist temporally along the creeks of the site during flow events. Given the ephemeral nature of the creeks, they are unlikely to form important habitat for the species, and any impacts on the species are expected to be minimal.
Erythrotriorchis radiatus	Red Goshawk	V	E	Found over wooded and forested land with a mosaic of vegetation types in tropical and warm temperate climates in coastal and subcoastal areas (Marchant and Higgins, 1993).	Unlikely to occur on the site due to lack of suitable mosaic of habitat types. The site is also located outside the typical range of this species.
Erythrura gouldiae	Gouldian Finch	E	E	In Queensland the species occurs sparsely along the Gulf Coast and in the southern Cape York Peninsula. Grassy flats, trees near water, scrublands with spinifex. Breeds in savannah woodland on stony hills with Eucalypts over dense, tall native grasses (Pizzey and Knight, 2007).	Suitable habitat for this species exists on the site. Suitable habitat also occurs widely throughout the region in which the Project is located. The site is located outside the typical range of this species. It is unlikely that the Project will impact this species.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Epthianura crocea crocea	Yellow Chat	NL	V	Occurs in the Lake Eyre and Gulf of Carpentaria drainage basins in inland Queensland. Inhabits low vegetation around the margins of ephemeral wetlands, floodplains, swamps, dams, salt lakes, clay pans, lagoons, sewage ponds and bore drains (Curtis et al., 2012).	Unlikely to occur on the site due to lack of suitable wetland habitat.
Falco hypoleucos	Grey Falcon	NL	NT	Inhabits plains, gibber deserts, sandridges, pastoral lands and timbered watercourses in inland Australia (Pizzey and Knight, 2007).	Suitable habitat for this species exists on site. It was not observed during the surveys. Given the mobility of this species it is unlikely to be impacted by Project development.
Grantiella picta	Painted Honeyeater	NL	V	Inhabits mistletoes in Acacia woodland, Eucalypt forests and woodlands, Black Box on watercourses, trees on farmland and gardens in eastern Australia (Pizzey and Knight, 2007).	A small amount of potentially suitable habitat for this species occurs on the waterways of the site. It was not observed during the surveys. Suitable habitat for this species will continue to exist on waterways in the undisturbed portions of the site and in the local area. No significant impact is expected.
Heteromunia pectoralis	Pictorella Mannikin	NL	NT	Tall grass in Acacia woodlands near water; grassy flats, spinifex, crops and sparsely wooded areas. Widely distributed in far north Australia and common in that area (Pizzey and Knight, 2007).	Suitable habitat for this species exists throughout the site and wider region. No individuals were observed during the surveys. It is possible that Pictorella Mannikins inhabit the site. No significant impact is expected on the species, as they are locally common and will continue to inhabit undisturbed portions of the site and the local area.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Lophoictinia isura	Square-tailed Kite	NL	NT	Occurs mainly in open forests and woodlands, usually in coastal and subcoastal areas (Marchant and Higgins, 1993).	This species is widely distributed across mainland Australia and is known to inhabit timbered watercourses. There is some potentially suitable habitat for this species on the waterways of the site. Much of the suitable habitat for this species will be retained, and as it is a highly mobile species it is unlikely to be impacted by Project development.
Malurus coronatus	Purple-crowned Fairy-wren	NL	V	Primary habitat for the Purple-crowned Fairy-wren consists of river-fringing vegetation with a dense mid-storey and a high tree canopy, typically dominated by River Pandanus (*Pandanus aquaticus*) or Rivergrass (*Chionachne cyanthopoda*) beside permanent freshwater pools (Curtis et al., 2012).	The only potentially suitable habitat for this species is found at the waterhole at AQ8. However, AQ8 lacks the vegetation structure preferred by the Purple-crowned Fairy-wren. It is considered unlikely to occur in the Investigation Area.
Nettapus coromandelianus	Cotton Pygmy-goose	NL	NT	Occurs in eastern coastal Queensland, with some records from the Mount Isa region. This species occupies deeper freshwater swamps, lagoons and dams with semi-emergent aquatic plants (Pizzey and Knight, 2007).	Unlikely to occur on site due to the lack of suitable aquatic habitat.
Numenius madagascariensis	Eastern Curlew	Ma, Mi	NT	This species occupies estuaries, tidal mudflats, sandpits, salt marshes, mangroves, occasionally fresh or brackish lakes or bare grassland near water (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Pezoporus occidentalis	Night Parrot	E	E	Occurs in inland Austalia. Inhabits spinifex hummock grasslands on rocky ranges, breakaways or open herbaceous flats around salt lakes and occasionally Mitchell Grass (*Astrebla* spp.) downs and flats (Curtis et al., 2012). The Night Parrot drinks regularly at waterholes.	Suitable habitat exists on site and throughout the local region. This species could potentially occur on site. However, this species is extremely rare and the probability of its occurrence on site is low.
Poephila cincta cincta	Black-throated Finch (southern)	E	E	The southern subspecies inhabits open woodland, scrubby plains and Pandanus flats with deep cover of grasses. Its habitat is never far from water. It is known to occur south of Townsville, particularly around Townsville and Charters Towers (DoE, 2014).	The Black-throated Finch is not known from the local area. It is therefore unlikely to occur on site.
Pristis pristis	Freshwater Sawfish	V	NL	Juveniles and sub-adult Freshwater Sawfish predominantly occur in rivers and estuaries, while large mature animals tend to occur more often in coastal and offshore waters up to 25 m depth. In northern Australia, this species appears to be confined to freshwater drainages and the upper reaches of estuaries (DoE, 2014).	Highly unlikely to occur on site as there are no large permanent waterbodies present.
Elseya lavarackorum	Gulf Snapping Turtle	E	V	Currently known only from rivers and creeks draining into the Gulf of Carpentaria. Inhabits slow-flowing freshwater rivers and streams (Curtis et al., 2012).	Highly unlikely to occur on site as there are no permanent rivers or creeks present.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Emydura subglobosa worrelli	Diamond Head Turtle	NL	NT	The Diamond Head Turtle inhabits larger rivers and permanent lakes and lagoons in the Gulf and Cape York regions (Cogger, 2000).	Highly unlikely to occur on site due to the absence of rivers and permanent lakes.
Stictonetta naevosa	Freckled Duck	NL	NT	In Queensland, this species is found in the south-east and south-west of the state. Occasional visitor to northern Queensland. Inhabits large, well-vegetated swamps (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Rostratula australis	Australian Painted Snipe	E Mi Ma	V	This species inhabits shallow inland wetlands, either permanent or temporary, including palustrine wetlands (gilgais), billabongs and man-made dams throughout eastern and northern Australia (DoE, 2014).	Unlikely to occur on site due to lack of suitable wetland habitat.
Migratory Species					
Acrocephalus australis	Australian Reed-warbler	Ma, Mi	SL	Widespread throughout eastern Australia and coastal parts of western Australia. Inhabits aquatic vegetation over water, crops, bamboo, gardens and willows (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Actitis hypoleucos	Common Sandpiper	Ma, Mi	SL	Edges of rivers and streams, dams, lakes, mangroves, mudflats, beaches and urban areas. Found from coastal to inland areas (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Anseranas semipalmata	Magpie Goose	Ma	NL	Inhabits northern Australia, including eastern Queensland and the northern ends of Western Australia and the Northern Territory. It occurs in rush and sedge-dominated swamps, as well as floodplains and rice crops (Simpson and Day, 2010).	Unlikely to occur on site due to lack of suitable habitat.
Apus pacificus	Fork-tailed Swift	Ma, Mi	SL	A migratory species that inhabits Australia in the summer months. Known to appear and forage for aerial insects over any habitat (Pizzey and Knight, 2007).	Species is strictly aerial when visiting Australia. May potentially occur over site. Development on site is unlikely to affect this species as it is strictly aerial remaining high above ground. Rarely if ever comes into contact with vegetation or land.
Ardea alba	Great Egret	Ma, Mi	SL	Common throughout Australia except in most arid areas. Known to prefer shallow water, particularly when flowing, but may be seen in any wetland area, including inundated grasslands (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Ardea ibis	Cattle Egret	Ma, Mi	SL	Common throughout Australia except in the most arid areas. Prefers damp grasslands, particularly where cattle are abundant, but may be seen in any wetland area (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Arenaria interpres	Ruddy Turnstone	Ma, Mi	SL	Occurs mostly in coastal areas. Prefers rocky shores or beaches (DoE, 2014).	Unlikely to occur on site, as it is a coastal species.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Calidris acuminata	Sharp-tailed Sandpiper	Ma, Mi	SL	Lagoons, swamps, lakes and pools near the coast, and dams, waterholes, soaks, bore drains and bore swamps, saltpans and hypersaline saltlakes inland (DoE, 2014).	A very small amount of potentially suitable habitat for this species occurs in the waterholes of the site. Suitable habitat for this highly mobile species will remain in undisturbed areas of the site and in the local area. No significant impact is expected.
Calidris ferruginea	Curlew Sandpiper	Ma, Mi	SL	In Queensland, this species occurs mainly in coastal areas, with scattered inland records. Mainly occurs on intertidal mudflats in sheltered coastal areas, and also around non-tidal swamps, lakes and lagoons near the coast, saltworks and sewage farms. Inland they occur around ephemeral and permanent lakes, dams, waterholes and bore drains (DoE, 2014).	A very small amount of potentially suitable habitat for this species occurs in the waterholes of the site. Suitable habitat for this highly mobile species will remain in undisturbed areas of the site and in the local area. No significant impact is expected.
Calidris ruficollis	Red-necked Stint	Ma, Mi	SL	Recorded in all coastal regions, and found inland when conditions are suitable. Also inhabit saltworks and sewage farms, saltmarsh, and ephemeral or permanent shallow wetlands (including lagoons, lakes, swamps, riverbanks, waterholes, bore drains, dams, soaks and pools in saltflats) (DoE, 2014).	A very small amount of potentially suitable habitat for this species occurs in the creeks and waterholes of the site. Suitable habitat for this highly mobile species will remain in undisturbed areas of the site and in the local area. No significant impact is expected.
Calidris subminuta	Long-toed Stint	Ma, Mi	SL	Inhabits shallow freshwater or brackish wetlands including lakes, swamps, river floodplains, streams, lagoons and sewage ponds. The species is also found in areas of muddy shoreline and reservoirs (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Charadrius mongolus	Lesser Sand Plover	Ma, Mi	SL	Occurs mainly in coastal areas. Seldom recorded away from the coast, at margins of lakes, soaks and swamps associated with artesian bores (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Charadrius ruficapillus	Red-capped Plover	Ma	NL	Occurs throughout Australia on beaches, saline wetlands and lakes, saltmarsh, mudflats, and occasionally in shallow freshwater wetlands (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Charadrius veredus	Oriental Plover	Ma, Mi	SL	Migratory species that spends a few weeks in coastal areas before moving further inland. They usually inhabit flat, open, semi-arid or arid grasslands, where the grass is short and sparse, and interspersed with hard, bare ground, such as claypans, dry paddocks, playing fields, lawns and cattle camps, or open areas that have been recently burnt. At the onset of the wet season, some may move into lightly wooded grasslands (DoE, 2014).	There is little suitable habitat on site for this species. It is unlikely to occur on site.
Chlidonias leucopterus	White-winged Black Tern	Ma, Mi	SL	Non-breeding migrant to Australia, where it is widespread and common along south-western, northern and central-eastern coasts. Inhabits tidal wetlands, such as harbours, bays, estuaries and lagoons, and their associated tidal sandflats and mudflats. Also inhabits terrestrial wetlands, including swamps, lakes, billabongs, rivers, floodplains, reservoirs, saltworks, sewage ponds and outfalls (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat and its preference for coastal areas.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Cuculus optatus	Oriental Cuckoo	Ma	SL	An uncommon regular migrant to coastal northern and eastern Australia. Inhabits monsoon forest, rainforest, river flats, roadsides, mangroves and islands (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat and its preference for coastal areas.
Gallinago hardwickii	Latham's Snipe	Ma, Mi	SL	A non-breeding visitor to south-eastern Australia, travelling through northern Australia to reach non-breeding areas located further south. They usually inhabit open, freshwater wetlands with low, dense vegetation (e.g. swamps, flooded grasslands or heathlands around bogs and other water bodies), as well as habitats with saline or brackish water, in modified or artificial habitats, and in habitats located close to humans or human activity (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Gallinago megala	Swinhoe's Snipe	Ma, Mi	SL	There are few records of this species in Australia. Found in swamps, billabongs, river pools, small streams and sewage ponds (DoE, 2014).	A very small amount of potentially suitable habitat for this species occurs in the creeks and waterholes of the site. Suitable habitat for this highly mobile species will remain in undisturbed areas of the site and in the local area. No significant impact is expected.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Glareola maldivarum	Oriental Pratincole	Ma, Mi	SL	Inhabits open plains, floodplains or short grassland (including farmland or airstrips), often with extensive bare areas. They often occur near terrestrial wetlands, such as billabongs, lakes or creeks, and artificial wetlands such as reservoirs, saltworks and sewage farms, especially around the margins. The species also occurs along the coast (DoE, 2014).	There is very little suitable habitat available on site for this species. It is unlikely to occur on site.
Haliaeetus leucogaster	White-bellied Sea-eagle	Ma, Mi	SL	Common throughout Australia except in the most arid areas. Prefers areas of permanent, deep or flowing water, where prey (fish and birds) is abundant (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Himantopus himantopus	Black-winged Stilt	Ma	NL	Large inland waterbodies and estuarine or coastal habitats such as river deltas, coastal lagoons and shallow freshwater or brackish pools with extensive areas of mudflats, salt meadows, saltpans, coastal marshes and swamps (BirdLife International, 2012).	Unlikely to occur on site due to lack of suitable habitat.
Hirundo rustica	Barn Swallow	Ma, Mi	SL	Widespread in the northern hemisphere and winters in the southern hemisphere. Inhabits open country in coastal lowlands, often near water, towns and cities. Also in or over freshwater wetlands, paperbark Melaleuca woodland, mesophyll shrub thickets and tussock grassland (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat and its primarily coastal distribution.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Hydroprogne caspia	Caspian Tern	Ma, Mi	SL	Widespread in coastal and inland habitat. Inhabits sheltered coastal embayments (harbours, lagoons, inlets, bays, estuaries and river deltas), near-coastal or inland terrestrial wetlands, especially lakes, waterholes, reservoirs, rivers and creeks. They also use artificial wetlands, including reservoirs, sewage ponds and saltworks (DoE, 2014).	A very small amount of potentially suitable habitat for this species occurs in the creeks and waterholes of the site. Suitable habitat for this highly mobile species will remain in undisturbed areas of the site and in the local area. No significant impact is expected.
Limosa lapponica	Bar-tailed Godwit	Ma, Mi	SL	Widespread in coastal areas, with regular inland movements. Inhabits intertidal sandflats, banks, mudflats, estuaries, inlets, harbours, coastal lagoons and bays, sewage farms, saltworks, saltlakes and brackish wetlands near coasts, sandy ocean beaches, rock platforms and coral reef-flats. Occasionally inhabits inland wetlands or areas of short grass, such as farmland, paddocks and airstrips (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Limosa limosa	Black-tailed Godwit	Ma, Mi	SL	Found in coastal areas throughout Australia. There are a few inland records, from shallow lakes, swamps, dams and bore-overflows (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Numenius minutus	Little Curlew	Ma, Mi	SL	Widespread in coastal regions of northern Australia. Found in grasslands, floodplains, mudflats, fields and sewage ponds (Pizzey and Knight, 2007).	Unlikely to occur on site, as it is a coastal species and little suitable habitat occurs on the site.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Numenius phaeopus	Whimbrel	Ma, Mi	SL	Found mainly in coastal regions throughout Australia. It is often found on the intertidal mudflats of sheltered coasts. There are a small number of inland records from saline lakes and canegrass swamps (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Pandion cristatus	Eastern Osprey	Ma, Mi	SL	This cosmopolitan species is found in coastal areas. It inhabits a range of coastal habitats and larger river systems (DoE, 2014).	Unlikely to occur on site, as it is a coastal species and there is no suitable habitat on the site.
Phalaropus lobatus	Red-necked Phalarope	Ma, Mi	SL	Irregular summer migrant to Australia. Inhabits shallow pools, saltfields, mudflats, beaches, saltmarsh and wetlands (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Plegadis falcinellus	Glossy Ibis	Ma, Mi	SL	Widespread throughout northern and eastern Australia. Inhabits fresh water marshes at the edges of lakes and rivers, lagoons, floodplains, wet meadows, swamps, reservoirs, sewage ponds, rice-fields and cultivated areas under irrigation. Occasionally found in coastal locations such as estuaries, deltas, saltmarshes and coastal lagoons (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Pluvialis fulva	Pacific Golden Plover	Ma, Mi	SL	Widespread in coastal areas of Australia. Inland it is known from major river systems and wetlands (DoE, 2014).	Unlikely to occur on site due to lack of suitable habitat.
Recurvirostra novaehollandiae	Red-necked Avocet	Ma	NL	Occurs in estuaries, mudflats, swamps, lakes, claypans and sewage ponds across much of Australia (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.

Scientific Name	Common Name	Conservation Status		Habitat	Notes/Likelihood of Presence on Site
		EPBC Act	NC Act		
Stiltia isabella	Australian Pratincole	Ma	NL	Inhabits northern and inland Australia. Found near water on plains, claypans, swamp margins and sparse stony shrubland (Pizzey and Knight, 2007).	Unlikely to occur on site due to lack of suitable habitat.
Tringa glareola	Wood Sandpiper	Ma, Mi	SL	Found mainly in north-western Australia, with scattered records elsewhere. Inhabits swamps, billabongs, lakes, pools and waterholes (DoE, 2014).	A very small amount of potentially suitable habitat for this species occurs in the waterholes of the site. Suitable habitat for this highly mobile species will remain in undisturbed areas of the site and in the local area. No significant impact is expected.
Tringa nebularia	Common Greenshank	Ma, Mi	SL	Found in a range of coastal and inland wetland habitat throughout Australia (DoE, 2014).	Unlikely to occur on site due to lack of suitable wetland habitat.
Tringa stagnatilis	Marsh Sandpiper	Ma, Mi	SL	Inhabits coastal and inland wetlands throughout Australia (DoE, 2014).	Unlikely to occur on site due to lack of suitable wetland habitat.
Xenus cinereus	Terek Sandpiper	Ma, Mi	SL	Found in coastal areas throughout Australia. Inhabits mudflats, estuaries, islands and coastal swamps (Pizzey and Knight, 2007).	Unlikely to occur on site, as it is a coastal species.
Crocodylus johnstoni	Freshwater Crocodile	Ma	NL	Freshwater rivers, creeks and billabongs in northern Australia (Wilson, 2005).	Unlikely to occur on site due to lack of permanent rivers, creeks and billabongs.

E – Endangered
V – Vulnerable
NL – Not listed
NT – Near Threatened
Mi – Migratory
Ma – Marine
SL – Special Least Concern

5.7.8 Declared Pests

No declared pest species were observed in the aquatic areas of the Investigation Area during the surveys. The scats and tracks of the Feral Pig (*Sus scrofa*) and Wild Dog (*Canis familiaris*), both Class 2 declared pest species under the LP Act, were noted at several of the survey sites. Landholders are responsible for the control of Class 2 pests on their land.

Feral Pigs are omnivores, which feed on a range of native flora and fauna. Their feeding and bathing behaviour promotes erosion, bed degradation and weed spread in riparian areas. Feral Pigs can also pose a risk to human health, as they carry a range of diseases.

Wild Dogs prey on native fauna and livestock and compete with native predators such as quolls and raptors. Wild Dogs pose a risk to human health and safety.

The non-declared Cane Toad (*Rhinella marina*) was heard calling in several areas of the Project site and observed at AQ1 in the dry season. Canes Toads are highly toxic aquatic pests that feed on a variety of small native wildlife and may also compete with native frog species.

Control measures for these three pest species are outlined in Section 6.2.

6.0 CONCLUSIONS, IMPACTS AND RECOMMENDATIONS

The aquatic ecology surveys identified a range of environmental values for the waterways of the Investigation Area:

- Habitat for a range of flora and fauna species, including two threatened species;
- Areas of RE 1.3.7b, which has a Biodiversity Status of Endangered and is a Category B ESA;
- Semi-permanent and permanent waterholes;
- Drinking water for a range of terrestrial animals;
- Dry season refugia for a range of terrestrial animals;
- Nesting and roosting habitat for bird and bat species;
- Breeding habitat for a small number of amphibian species; and
- Habitat for macroinvertebrates and a small number of fish and crustacean species.

Many of these values are located primarily in areas outside the Project disturbance footprint. The Project will impact on only a small portion of the riparian habitat located in the Investigation Area.

The waterhole at AQ8 is the most significant aquatic habitat in the Investigation Area. It is the largest and deepest waterhole and is likely to be permanent. It is an important dry season and drought refuge for the fauna of the Investigation Area. AQ8 is located outside the Project disturbance footprint and outside the catchment in which Project activities will be conducted. It is therefore unlikely that the Project will impact on the environmental values of this site.

The AUSRIVAS habitat assessment found that all survey sites provided moderate to good aquatic habitat. Some areas of erosion and impacts from cattle grazing were observed at the survey sites.

Stream sediments were found to contain a high proportion of coarse particles (i.e. gravel and sand). Metal concentrations in stream sediment were generally low. Copper and nickel levels above the low ISQG were recorded at a small number of sites. All results fell below the high ISQG.

Water quality at the survey sites was generally poor. Results for pH, conductivity, DO, total nitrogen, total phosphorus, copper and aluminium exceeded the applicable guideline levels at many sites. These results are reflective of the stagnant, ephemeral nature of the waterbodies sampled and natural mineralisation in the area.

Macroinvertebrate diversity, abundance and PET richness were generally low. SIGNAL scores were correspondingly low, but were consistent with the expected results for ephemeral streams. The majority of sites fell within Quadrant 3 of the SIGNAL biplot, indicating poor habitat and water quality for macroinvertebrates in the ephemeral creeks of the Investigation Area.

The riparian areas of the Investigation Area were found to provide habitat for 153 species of plants and 67 species of animals. Two threatened fauna species, one Migratory species, five Marine species, 13 weed species and four introduced fauna species were recorded. Areas of RE 1.3.7b (River Red Gum woodland on channels and levees) were recorded along many of the waterways in the Investigation Area.

Aquatic fauna diversity and abundance were found to be low. This is thought to be due to the Project's location in the upper reaches of the catchment and the highly ephemeral nature of the Project waterways.

6.1 POTENTIAL IMPACTS

A total of approximately 6.5 ha of riparian vegetation will be removed as part of Project development. Clearing of riparian vegetation may lead to injury or mortality of resident fauna. Clearing of riparian vegetation will also remove a small portion of potential habitat for the Golden-backed Honeyeater. Impacts on the Golden-backed Honeyeater are discussed in detail in the Barbara Copper Project Terrestrial Flora and Fauna Assessment (AARC, 2014).

A small portion (approximately 1.8 ha) of the riparian vegetation to be removed to construct the new access road is classified as RE 1.3.7b (River Red Gum Riparian Woodland), which has a Biodiversity Status of Endangered. Clearing of this vegetation will lead to a small reduction in the extent and connectivity of this vegetation community. Currently there is approximately 75 ha of this vegetation community within the Investigation Area.

The removal of vegetation from the Project Area will expose large areas of topsoil, which if improperly managed may be eroded and washed into surface waters, causing increased turbidity and suspended solids levels as well as siltation of creek channels. Changes in water quality may impact aquatic biota.

Development of the north pit will require the diversion of a small first-order drainage feature around the western edge of the pit. Construction of the diversion will alter stream morphology and hydrology, and could potentially result in accelerated erosion and decreased water quality in the waterway. These potential impacts are unlikely to be significant, as this minor drainage feature does not hold water, and flows only after prolonged heavy rainfall, which occurs infrequently in the Project Area.

Construction of the Project haul roads and access road will require the establishment of creek crossings in both first-order drainage features and the larger third-order drainage feature in the southern part of the Investigation Area. Construction and usage of creek crossings may lead to impacts such as vegetation clearing and fragmentation, erosion and siltation, with associated impacts on aquatic biota.

The Project will generate stormwater runoff and site waste water. This contaminated water could potentially enter site waterways if not managed effectively, with potential to cause harm to aquatic fauna and flora.

The Project Area is located approximately 17 km upstream of Lake Julius. Lake Julius is a lacustrine wetland and water source for the city of Mount Isa. There is the potential for sediment, stormwater runoff, sewage, waterborne pollutants (such as hydrocarbons) and mine affected water (which is acidic, saline and contains sulphides and metals) from the Project Area to enter Lake Julius in extreme climatic conditions if not effectively managed, particularly in the wet season. It should be noted that any discharges made due to extreme weather will be diluted by the large amounts of uncontaminated rainwater runoff present in the catchment.

Construction and operation activities will require the storage, handling and use of minimal hazardous substances (i.e. diesel, oil, grease), which have potential to be released into waterways by spill or overflow, with adverse impacts on the health of aquatic fauna and flora.

The development of the Project will increase the amount of open area, tracks, water sources and waste on the Project Area. This may improve the suitability of the Project Area for weed and pest species, which are known to thrive in these conditions. Increased vehicle movement in the Project

Area also poses a risk of spreading weeds and introducing new weed species into the Project Area. This could result in an increase in weed abundance in riparian areas, with a consequent reduction in the integrity of riparian communities.

Measures to manage and mitigate these potential impacts are discussed below.

6.2 RECOMMENDED MITIGATION AND MANAGEMENT MEASURES

The Project layout has been designed to avoid riparian areas and areas of RE 1.3.7b where allowable by topographical constraints. The layout minimises clearing of riparian vegetation to the smallest practical extent.

At the end of project life, cleared areas should be revegetated and rehabilitated. In order to restore the existing regional ecosystems, rehabilitation works should utilise those species found in the relevant communities (refer to Appendix D). Native grass species are recommended for use in rehabilitation. Topsoil from disturbed areas should be stockpiled for use in the rehabilitation works.

Clearing of riparian vegetation should be conducted in a staged manner, to allow fauna to migrate to adjacent habitat areas, with minimal fragmentation of existing habitat and the preservation of existing vegetation corridors where possible. All large trees should be inspected for fauna prior to removal (particularly hollows). If animals are detected then clearing must cease until they move on or are relocated by an experienced spotter-catcher. Trees with hollows should be lowered gently to the ground with the hollows facing up to minimise risk of fauna injury. Hollow bearing trees or tree sections with hollows should be placed outside the disturbance area and adjacent to creeks. Any Golden-backed Honeyeater nests encountered during site clearing works should not be disturbed. Detailed mitigation measures for Project impacts on the Golden-backed Honeyeater are provided in the Barbara Copper Project Terrestrial Flora and Fauna Assessment (AARC, 2014).

A vehicle washdown bay should be installed on site and used by all vehicles that have come into contact with weeds. A Weed Management Plan should be developed to limit the spread of weed species on the Project Area. Staff should be informed of the species of weed likely to be encountered on the Project Area, the location of known weed infestations, and how to report the presence of new infestations as part of the site induction. The Weed Management Plan should include a weed control program. Weed control should focus on Mimosa Bush, Rubber Vine and any new weed species that are detected in riparian areas.

Two Class 2 pests, the Feral Pig and Wild Dog, are known to be present in the Project Area. Landowners are expected to take reasonable steps to keep land free from Class 2 pests. It is recommended that a Pest Management Plan be developed to reduce pig and dog numbers in the Project Area and prevent the introduction of other Class 2 pests into the Project Area. Control strategies outlined in the Pest Management Plan should be in-line with the local shire council pest control strategies, and the strategies suggested within the Pest Fact Sheets in Appendix G. Recommended pest control strategies are outlined briefly below.

The Queensland Government recommends 1080 (sodium monofluroacetate) baiting as the most economic and effective method for controlling feral predator species (DAFF, 2012; State of Queensland, 2013). Baits should be buried to prevent consumption by non-target species. Ideally the baiting program should be conducted in the dry season and target watering points. Poisoned grain is the recommended bait for Feral Pigs. Pigs should be pre-fed with unpoisoned bait before commencement of baiting. Fresh meat baits should be used to target dogs. Any pest animals that survive the baiting program can then be targeted by a trapping and/or shooting program (State of Queensland, 2013). Detailed information on pest management is provided in Appendix G.

Once construction of the Project commences, erosion and sediment controls (such as hessian fences, ground-cover mats or blankets and sand-bags) should be installed to prevent sediment deposition in waterways and associated water and sediment quality impacts. Clean water should be diverted around disturbed areas to prevent pollution and maintain natural flows.

Chemicals and hazardous substances used during construction and operation should be stored in sealed, bunded areas in accordance with the Material Safety Data Sheet and applicable Australian Standards. A Spill Emergency Response Procedure should be developed to outline the response to any chemical spills. Spills must be promptly contained and cleaned up as they have the potential to contaminate surface water, leading to adverse impacts on aquatic flora and fauna. EHP must be informed of any spills into waterways.

Waterway crossings should be designed to minimise erosion potential and avoid the impediment of natural flows. The materials used in construction of the crossings should be resistant to erosion, to prevent materials being washed away and deposited downstream. Disturbance of the bed and banks of watercourses should be avoided wherever possible.

The creek diversion should be designed to mimic the hydrology of the existing channel. Diversion works should be conducted in the dry season to minimise impacts on water quality. The diversion will be designed to allow natural flows back into the creek at a downstream location of the watercourse. The banks of the engineered diversion channel should be planted with native flora species from the Project region. Planting of trees should ensure that the integrity of the engineered channel is not compromised.

A segment of the Staff Induction Program should be allocated to informing staff of the Spill Emergency Response Procedure, vegetation clearing requirements, correct chemical handling and storage procedures and Pest and Weed Management Plans. Staff should also be trained in the appearance and basic ecology of the Purple-necked Rock-wallaby and Golden-backed Honeyeater and reporting requirements for sightings of these species.

6.3 ENVIRONMENTAL MONITORING

It is recommended that water and sediment quality monitoring should be continued at the survey sites to gather additional baseline data, capture natural variability and confirm the findings of the initial monitoring. It is recommended that site-specific guidelines be developed for those parameters that consistently failed to comply with the applicable guidelines (i.e. pH, conductivity, DO, copper, aluminium, nutrients).

A Receiving Environment Monitoring Program (REMP) should be developed and implemented for the Project. The REMP should include monitoring of upstream and downstream sites for water quality, sediment quality, macroinvertebrates, erosion and vegetation diversity and condition. Monitoring of the receiving environment will allow the detection of any impacts on waterways downstream of the Project Area.

6.4 ENVIRONMENTAL OFFSET REQUIREMENTS

The Queensland Environmental Offsets Policy requires environmental offsets to be delivered where a prescribed activity will create significant residual impacts on particular matters of National, State or Local environmental significance (referred to as prescribed environmental matters). The prescribed environmental matters relevant to the Project are threatened species habitat (discussed in the AARC Terrestrial Flora and Fauna Assessment, 2014) and remnant regional ecosystems intersecting waterways shown on the Vegetation Management Watercourse Map. The potential for offsetting remnant regional ecosystems intersecting waterways is currently being investigated further.

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 17/06/14 15:49:26

Buffer: 100.0Km

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Areas:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	10
Listed Migratory Species:	19

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place and the heritage values of a place on the Register of the National Estate.

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	1
Commonwealth Heritage Places:	None
Listed Marine Species:	26
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Commonwealth Reserves Marine	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

Place on the RNE:	11
State and Territory Reserves:	1
Regional Forest Agreements:	None
Invasive Species:	27
Nationally Important Wetlands:	2
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat may occur within area
Erythrura gouldiae Gouldian Finch [413]	Endangered	Species or species habitat known to occur within area
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat likely to occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Mammals		
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Pseudantechinus mimulus Carpentarian Antechinus [59283]	Vulnerable	Species or species habitat known to occur within area
Sminthopsis douglasi Julia Creek Dunnart [305]	Endangered	Species or species habitat may occur within area
Reptiles		
Acanthophis hawkei Plains Death Adder [83821]	Vulnerable	Species or species habitat known to occur within area
Elseya lavarackorum Gulf Snapping Turtle [67197]	Endangered	Species or species habitat known to occur

Name	Status	Type of Presence within area
Sharks		
Pristis pristis Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Migratory Wetlands Species		
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat likely to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]		Species or species habitat known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat known to occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Species or species habitat known to occur within area
Numenius phaeopus Whimbrel [849]		Species or species habitat known to occur

Name	Threatened	Type of Presence
		within area
Pluvialis fulva Pacific Golden Plover [25545]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Tringa glareola Wood Sandpiper [829]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Species or species habitat known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Name
Defence - MT ISA TRAINING DEPOT

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Anseranas semipalmata Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat likely to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]		Species or species habitat known to occur within area
Charadrius ruficapillus Red-capped Plover [881]		Species or species habitat known to occur

Name	Threatened	Type of Presence
		within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat known to occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat known to occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Himantopus himantopus Black-winged Stilt [870]		Species or species habitat known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Species or species habitat known to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Species or species habitat known to occur within area
Numenius phaeopus Whimbrel [849]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Species or species habitat known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Stiltia isabella Australian Pratincole [818]		Species or species habitat known to occur within area
Tringa glareola Wood Sandpiper [829]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Species or species habitat known to occur within area
Reptiles		
Crocodylus johnstoni Freshwater Crocodile, Johnston's Crocodile, Johnston's River Crocodile [1773]		Species or species habitat may occur within area

Extra Information

Places on the RNE [Resource Information]

Note that not all Indigenous sites may be listed.

Name	State	Status
Natural		
Fountain Range	QLD	Registered
Indigenous		
Battle Mountain	QLD	Indicative Place
Frank Creek Site	QLD	Indicative Place
Little Brumby Creek Site	QLD	Indicative Place
Bower Bird Area	QLD	Registered
Lake Moondarra Quarry 1 Area	QLD	Registered
The Granites Area	QLD	Registered
Historic		
Casa Grande	QLD	Indicative Place
Mount Isa Underground Hospital	QLD	Indicative Place
Cloncurry Courthouse	QLD	Registered
Tent House	QLD	Registered

State and Territory Reserves [Resource Information]

Name	State
Bullen Bullen	QLD

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Frogs		
Bufo marinus Cane Toad [1772]		Species or species habitat likely to occur within area
Rhinella marina Cane Toad [83218]		Species or species habitat likely to occur within area
Mammals		

Name	Status	Type of Presence
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Camelus dromedarius Dromedary, Camel [7]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Acacia nilotica subsp. indica Prickly Acacia [6196]		Species or species habitat may occur within area
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Cryptostegia grandiflora Rubber Vine, Rubbervine, India Rubber Vine, India Rubbervine, Palay Rubbervine, Purple Allamanda [18913]		Species or species habitat likely to occur within area
Cylindropuntia spp. Prickly Pears [85131]		Species or species habitat likely to occur within area
Eichhornia crassipes Water Hyacinth, Water Orchid, Nile Lily [13466]		Species or species habitat likely to occur within area
Jatropha gossypifolia Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Lantana camara Lantana, Common Lantana, Kamara Lantana, Large-leaf Lantana, Pink Flowered Lantana, Red Flowered Lantana, Red-Flowered Sage, White Sage, Wild Sage [10892]		Species or species habitat likely to occur within area
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Parthenium hysterophorus Parthenium Weed, Bitter Weed, Carrot Grass, False Ragweed [19566]		Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Prosopis spp. Mesquite, Algaroba [68407]		Species or species habitat likely to occur within area
Salvinia molesta Salvinia, Giant Salvinia, Aquarium Watermoss, Kariba Weed [13665]		Species or species habitat likely to occur within area
Tamarix aphylla Athel Pine, Athel Tree, Tamarisk, Athel Tamarisk, Athel Tamarix, Desert Tamarisk, Flowering Cypress, Salt Cedar [16018]		Species or species habitat likely to occur within area
Vachellia nilotica Prickly Acacia, Blackthorn, Prickly Mimosa, Black Piquant, Babul [84351]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus Asian House Gecko [1708]		Species or species habitat likely to occur within area

Nationally Important Wetlands [Resource Information]

Name	State
Lake Julius	QLD
Lake Moondarra	QLD

Coordinates

-20.4224 139.83871

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World Heritage and Register of National Estate properties, Wetlands of International Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

For species where the distributions are well known, maps are digitised from sources such as recovery plans and detailed habitat studies. Where appropriate, core breeding, foraging and roosting areas are indicated under 'type of presence'. For species whose distributions are less well known, point locations are collated from government wildlife authorities, museums, and non-government organisations; bioclimatic distribution models are generated and these validated by experts. In some cases, the distribution maps are based solely on expert knowledge.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

-Department of Environment, Climate Change and Water, New South Wales

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

This product is projected into GDA 1994 MGA Zone 54

Note:
This map shows the location of wetland protection areas which are defined under the Environmental Protection Regulation 2008. Within wetland protection areas, certain types of development involving high impact earthworks are made assessable under Schedule 3 of the Sustainable Planning Regulation 2009.

The Department of State Development Infrastructure and Planning is the State Assessment Referral Agency (SARA) under Schedule 7 of the Sustainable Planning Regulation 2009 for assessable development involving high impact earthworks within wetland protection areas. The Department of Environment and Heritage Protection is a technical agency.

The policy outcome and assessment criteria for assessing these applications are described in the State Development Assessment Provisions (SDAP) *Module 11: Wetlands and wild rivers*.

This map is produced at a scale relevant to the size of the lot on plan identified and should be printed at A4 size in portrait orientation. Consideration of the effects of mapped scale is necessary when interpreting data at a large scale.

For further information or assistance with interpretation of this product, please contact the Department of Environment and Heritage Protection at www.ehp.qld.gov.au or email planning.support@ehp.qld.gov.au.

Note:
This map shows the location of wetlands on the Map of Referable Wetlands which are defined under the Environmental Protection Regulation 2008.

Wetlands are assessed for ecological significance using the environmental values for wetlands in section 81A of the Environmental Protection Regulation 2008. Wetlands are considered either High Ecological Significance (HES) or of General Ecological Significance (GES) for the purposes of the environmental values.

This map is produced at a scale relevant to the size of the lot on plan identified and should be printed at A4 size in portrait orientation. Consideration of the effects of mapped scale is necessary when interpreting data at a large scale.

For further information or assistance with interpretation of this product, please contact the Department of Environment and Heritage Protection at <www.ehp.qld.gov.au> or email <planning.support@ehp.qld.gov.au>

Water bodies and wetland regional ecosystems

Water bodies	Wetland regional ecosystem	
		Marine system (e.g. open ocean) Open ocean extending to the Queensland 3nm coastal limit. Includes shallow coastal indentations or bays without appreciable freshwater inflows, and coasts that are exposed to oceanic waves and currents. Water regimes are determined primarily by oceanic tides.
		Estuarine system (e.g. mangroves, salt flats and estuaries) Includes wetlands with oceanic water that are significantly diluted with freshwater derived from land drainage.
		Riverine system (e.g. river and creek channels) Wetlands and deepwater habitats contained within a channel. Due to scale constraints these areas may include fringing palustrine vegetation.
		Lacustrine system (e.g. lakes) Wetlands and deepwater habitats situated in a topographic depression or a dammed river channel. Includes areas where emergent perennial vegetation has less than 30% areal coverage and total waterbody area exceeds 8ha.
		Palustrine system (e.g. vegetated swamps) Wetlands dominated by persistent emergent vegetation or where water in deepest part of the basin is less than 2m, active wave formed shores or bedrock features are lacking.
		Wetland point features (e.g. springs, rockholes)
		Riverine system (drainage lines)

Areas that may include wetlands

Remnant regional ecosystem 51–80% wetland (mosaic units)

Remnant regional ecosystem 1–50% wetland (mosaic units)

The above descriptions are an abbreviated version of the full descriptions in the Wetland Mapping and Classification Methodology www.wetlandinfo.ehp.qld.gov.au

Wetlands

For the purposes of mapping and classification, wetlands are:
areas of permanent or periodic/intermittent inundation, with water that is static or flowing , fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed 6m. To be a wetland the area must have one or more of the following attributes:

i. at least periodically the land supports plants or animals that are adapted to and dependent on living in wet conditions for a t least part of their life cycle, or
ii. the substratum is predominantly undrained soils that are saturated, flooded or ponded long enough to develop anaerobic condit ions in the upper layers, or
iii. the substratum is not soil and is saturat ed with water, or covered by water at some time.

Other Feature

- Towns
- Roads
- Cadastral boundaries (>0.5km² area)
- Built-up areas of Queensland
- Ocean outside 3nm limit
- Land at least 1km outside of Queensland

Kilometres

Scale 1:100,000 at A1 size

Further information on wetland mapping (including methodology and digital data) is available from www.wetlandinfo.ehp.qld.gov.au

Accuracy information: The positional accuracy of wetland data mapped at a scale of 1:100,000 is +/-100m with a minimum polygon size of 5ha or 75m wide for linear features, except for areas along the east coast which are mapped at the 1:50,000 scale with a positional accuracy of +/-50m, with a minimum polygon size of 1ha or 35m wide for linear features. Wetlands smaller than 1ha are not delineated on the wetland data. Consideration of the effects of mapped scale is necessary when interpreting data at a larger scale, e.g. 1:25,000. For property assessment, digital linework should be used as a guide only. The extent of wetlands depicted on this map is based on rectified 2009 Landsat ETM+ imagery supplied by Statewide Landcover and Trees Study (SLATS), Department of Science, Information Technology, Innovation and the Arts (DSITIA). The extent of water bodies is based on the maximum extent of inundation derived from available Landsat imagery up to and including the 2009 imagery.

Data sources: Water body mapping derived from satellite imagery, DSITIA; regional ecosystem mapping, DSITIA; drainage mapping, Geoscience Australia (GA), Department of Defence and DSITIA; Roads, MapInfo Australia Pty Ltd, 2006; Towns and Built-up areas, GA, 2003; Coastline, GA, 2004; Queensland 3NM Limit, Australian Maritime Boundaries Information System (AMBIS), GA, 2001; Digital Cadastral Database (DCDB), Department of Natural Resources and Mines, July 2011; Springs database, Queensland Herbarium, 2011; SRTM 90m DEM, USGS/NASA, 2006. Landsat ETM+ imagery supplied by the Australian Centre for Remote Sensing (ACRES), Australian Surveying and Land Information Group (AUSLIG), Canberra. The satellite imagery used in this product has been pre-processed by SLATS, DSITIA.

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. All pages of this report have been checked and approved for release.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting

- **EA150H: Soil Particle Density required for Hydrometer analysis according to AS 1289.3.5.1-2006 was not requested by the client. Typical sediment SPD values used for calculations and consequently NATA endorsement does not apply to hydrometer results.**
- **EG094 (Metals in Freshwater by ORC): It is recognised that EG094T (Total Metals by ORC) is less than EG094F (Dissolved Metals by ORC) for some samples. However, the difference is within experimental variation of the methods.**
- **Ionic balances are within acceptable limits as detailed in the 21st Ed. APHA "Standard Methods for the Examination of Water and Wastewater".**
- **It is recognised that EG020T (Total Metals) is less than EG020F (Dissolved Metals) for some samples. However, the difference is within experimental variation of the methods.**
- **TDS by method EA-015 may bias high due to the presence of fine particulate matter, which may pass through the prescribed GF/C paper.**

Signatories

This document has been electronically signed by the authorized signatories indicated below. Electronic signing has been carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	Position	Accreditation Category
Greg Vogel	Laboratory Manager	Brisbane Inorganics
Hamish Murray	Supervisor - Soils	Newcastle - Inorganics
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics
		WB Water Lab Brisbane

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. All pages of this report have been checked and approved for release.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

NATA Accredited Laboratory 825

Accredited for compliance with ISO/IEC 17025.

WORLD RECOGNISED ACCREDITATION

Signatories

This document has been electronically signed by the authorized signatories indicated below. Electronic signing has been carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Andrew Epps	Senior Inorganic Chemist	Brisbane Inorganics
Andrew Epps	Senior Inorganic Chemist	WB Water Lab Brisbane
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting

- **It is recognised that EG020-T (Total Metals by ICP-MS) is less than EG020-F (Dissolved Metals by ICP-MS) for some samples. However, the difference is within experimental variation of the methods.**
- **It is recognised that EG094-T (Total Metals in Freshwater) is less than EG094-F (Dissolved Metals in Freshwater) for some samples. However, the difference is within experimental variation of the methods.**

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. All pages of this report have been checked and approved for release.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

NATA Accredited Laboratory 825

Accredited for compliance with ISO/IEC 17025.

WORLD RECOGNISED ACCREDITATION

Signatories

This document has been electronically signed by the authorized signatories indicated below. Electronic signing has been carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Andrew Epps	Senior Inorganic Chemist	Brisbane Inorganics
Hamish Murray	Supervisor - Soils	Newcastle - Inorganics
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting

- **EG005T (Total Metals) Sample EB1416456-011 shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.**
- **This report has been amended and re-released to allow the reporting of additional analytical data. Fe and Ag results have now been included on the report.**

Methods

Data receipt and post-processing

Bat call data were recorded over four nights using two Song Meter SM2BAT detectors (Wildlife Acoustics, USA). The detectors were programmed to operate between sunset and sunrise and to record the acoustic data as full-spectrum sound files (.WAV format).

Data received for analysis included the following:

Detector name	Recording dates	Site	Number of WAV files recorded
SM5	Nights of 2/7/14 and 3/7/14	AQ1	260
	Nights of 4/7/14 and 5/7/14	AQ6	388
SM10	Nights of 2/7/14 and 3/7/14	AQ4	47
	Nights of 4/7/14 and 5/7/	AQ8	501

All WAV files were post-processed with Wildlife Acoustics' *Kaliedoscope Version 2.0.3* to generate call sequence files in Anabat zero-crossing analysis (ZCA) format. This process yielded a total of 1552 sequence files for the four sites.

Bat call identification

All sequence files were analysed using *AnalookW* (Corben 2014) and a subset of files containing representative samples of all call types recorded at each site were selected for identification. Species identification was achieved manually by comparing the *AnalookW* call sonograms with those of regionally-relevant reference calls and with published call descriptions (e.g. Reinhold *et al.* 2001; Milne 2002; Pennay *et al*. 2004).

Species' identification was also guided by considering their probability of occurrence based on general distribution information (Churchill 2008; van Dyck *et al.* 2013) and/or database records obtained from Wildlife Online (http://www.ehp.qld.gov.au/wildlife/wildlife-online/index.html) and/or the Atlas of Living Australia (http://www.ala.org.au).

Reporting standard

The format and content of this report follows Australasian Bat Society standards for the interpretation and reporting of bat call data (Reardon 2003), available on-line at http://www.ausbats.org.au/.

Species nomenclature follows van Dyck *et al.* (2013).

Results & Discussion

The ZCA conversion process generated 1552 sequence files, more than half of which (911 files) were recorded at Site AQ8. The majority of recorded calls were produced by just a few species, so only 15% (228) of the sequence files were needed for identification.

At least seven species were recorded during the Barbara dry season survey; however a number of calls could not be reliably identified to species level due to similarities between call characteristics of some species that probably occur in the study area.

The seven positively identified species included six vespertilionids and one molossid (see Table 1). Another two vespertilionid species were possibly also present but not reliably identified. These unresolved species included:

- several brief and weak calls with steep linear pulses terminating around 35-40 kHz, which were possibly attributable to a *Nyctophilus* species (*N. arnhemensis, N. bifax* and *N. geoffroyi* all potentially occur in the study area); and
- a number of calls with steep FM-qCF pulses and characteristic frequency at 57-59 kHz, which may have been from *Vespadelus caurinus* (similar pulse shape but slightly higher frequency than the many calls with Fc=54-56 kHz that were more readily attributable to *V. finlaysoni*). However, the nearest records for *V. caurinus* are in the Boodjamulla National Park area, so these calls may simply be *V. finlaysoni* calls at the extreme upper limit of its frequency range.

The dry season survey (this report) failed to record a number of bats that were recorded during the wet season survey (Balance! Environmental report dated 26 May 2014), including one molossid (*Chaerephon jobensis*), three emballonurids (*Saccolaimus flaviventris, Taphozous georgianus* and *T. troughtoni*) and the dusky leaf-nosed bat (*Hipposideros ater*). It did, however, add a further two species (*Vespadelus baverstocki* and *V. finlaysoni*) to the total bat inventory for the survey area.

Glossary

Technical terms used in this report are described in the following table.

Approach phase	The part of a bat *call* emitted as the bat starts to home in on a detected prey item; a transitional series of *pulses* between the *search phase* and *feeding buzz*, that become progressively steeper and shorter in duration.
Call	Refers to a single bat call, made up of a series of individual sound *pulses* in one or more *phases* (*search, approach, feeding buzz*).
CF (=Constant Frequency)	A type of *pulse* in which the dominant component consists of a more-or-less 'pure tone' of sound at a Constant Frequency; with *shape* appearing flat on the sonogram. Often also contains a brief *FM* component at the beginning and/or end of the CF component (*viz.* FM-CF-FM).
Characteristic frequency (Fc)	The frequency of the flattest part of a *pulse*; usually the lowest frequency reached in the *qCF* component of a pulse. This is often the primary diagnostic feature for species identification.
Duration	The time period from the beginning of a *pulse* to the end of the pulse.
Feeding buzz	The terminal part of a *call*, following the *approach phase*, emitted as the bat catches a prey item; a distinctive, rapid series of very steep, very short-duration pulses.
FM (=Frequency Modulated)	A type of *pulse* in which there is substantial change in frequency from beginning to end; *shape* ranges from almost vertical and linear through varying degrees of curvature.
FC range	Refers to the range of frequencies occupied by the *characteristic frequency* section of *pulses* within a call or set of calls.
Frequency sweep or "band-width"	The range of frequencies through which a *pulse* sweeps from beginning to end; Maximum frequency (Fmax) – minimum frequency (Fmin).
Knee	The transitional part of a *pulse* between the initial (usually steeper) frequency sweep and the *characteristic frequency* section (usually flatter); time to knee (Tk) and frequency of knee (Fk) can be diagnostic for some species.
Pulse	An individual pulse of sound within a bat *call*; the *shape*, *duration* and *characteristic frequency* of a pulse are the key diagnostic features used to differentiate species.
Pulse body	The part of the *pulse* between the *knee* and *tail* and containing the *characteristic frequency* section.
Pulse shape	The general appearance of a *pulse* on the sonogram, described using relative terms related to features such as slope and degree of curvature. See also *CF, qCF* and *FM*.
qCF (=quasi Constant Frequency)	A type of *pulse* in which there is very little change in frequency from beginning to end; *shape* appears to be almost flat. Some pulses also contain an *FM* component at the beginning and/or end of the qCF component (*viz.* FM-qCF).
Search phase	The part of a bat *call* generally required for reliable species diagnosis. A consistent series of *pulses* emitted by a bat that is searching for prey or and/or navigating through its habitat. Search phase pulses generally have longer duration, flatter slope and more consistent shape than *approach phase* and *feeding buzz* pulses.
Sequence	Literally, a sequence of *pulses* that may be from one or more bats; but generally refers to a *call* or part (e.g. *phase*) of a call.
Tail	The final component of a *pulse*, following the *characteristic frequency* section; may consist of a short or long sweep of frequencies either upward or downward from the Fc; or may be absent.

Biosecurity Queensland

Fact sheet

DECLARED CLASS 2 PEST ANIMAL

July 2014

Feral pig

Sus scrofa

Pigs (*Sus scrofa*) were introduced to Australia by early settlers. Subsequent accidental and deliberate releases resulted in the wild (feral) population establishing throughout Australia.

Feral pigs cause environmental and agricultural damage, spread weeds and can transmit exotic diseases such as leptospirosis and could spread foot-and-mouth disease.

Declaration details

Feral pigs are declared Class 2 pest animals under Queensland legislation. Declaration requires landholders to control declared pests on land under their control.

Description and general information

Feral pigs are typically smaller, leaner and more muscular than domestic pigs with well developed shoulders and necks, and smaller, shorter hindquarters.

The body is usually covered in sparse, coarse hair and they have a longer, larger snout, longer tusks, a straighter tail and narrower back than domestic pigs. Feral pigs are mostly black, buff-coloured or spotted black and white.

Growth potential is similar to domestic pigs, although harsh environmental conditions tend to stunt development. Adult female feral pigs usually weigh 60–75 kg, while males usually weigh 90–110 kg. Older boars (razorbacks) can have massive heads and shoulders and a raised and prominent back bone that slopes steeply down to small hams and short hind legs. Some boars develop a crest or mane of stiff bristles extending from their neck down the middle of their back.

Feral pig wallow

Feral pig rooting

Map 1. Distribution of feral pigs in Queensland

Habitat and distribution

Feral pigs are found in all habitat types in Queensland. The greatest concentrations of feral pigs are on the larger drainage basins and swamp areas of the coast and inland. In hot weather, pigs need to remain near water.

Population estimates can be achieved by spotlighting, aerial survey or the use of motion cameras.

Evidence of feral pigs includes fresh digging or rooting of the ground, tracks and faeces on and off pads, mud or hair at holes in fences where pigs have pushed through, wallows, tusk marking and mud rubs on trees and fence posts and nests in vegetation made by sows before farrowing.

Biology and behaviour

Female and juvenile pigs usually live in small family groups with a home range of 2–20 km^2. Adult males are typically solitary, with a home range of 8–50 km^2. Range size varies with season, habitat, food availability and disturbance. Herds of 400 pigs have been recorded in Cape York.

Feral pigs are generally nocturnal, spending daylight hours sheltering in dense cover. Pigs are omnivorous, eating plants and animals and are extremely opportunistic feeders, exploiting any temporarily abundant food.

They prefer green feed and will eat grains, sugarcane and other crops, fruit and vegetables. They root extensively for tubers, worms and soil invertebrates.

Feral pigs have relatively high energy and protein requirements, particularly during pregnancy and lactation and often move to other parts of their home range during pregnancy.

Life cycle

Under good seasonal conditions, breeding occurs all year and sows can produce two litters per year. Adult females have a 21–day oestrus cycle, with a gestation period of about 113 days, producing a litter of 4–10 piglets. Sows can make nests of available vegetation just before farrowing. Nests sometimes have a domed roof and are usually less than 2 km from available water. Piglets normally spend the first 1–5 days of life inside the nest, with the sow nearby. Weaning occurs after 2–3 months. Sexual maturity is reached when sows weigh about 25 kg, usually around six months of age.

Mortality of juveniles is high if the mother's dietary protein intake is low (up to 100% mortality in dry seasons). Adult mortality does not vary as much with seasonal conditions, but few animals live more than five years.

Impacts

Pigs can damage almost all crops from sowing to harvest, starting with uprooting seed and seedlings to feeding on or trampling mature crop.

They feed on seed, sugar cane and grain crops (except safflower), fruit (especially banana, mango, papaw, macadamia and lychee) and vegetable crops. Research has shown feral pigs can take up to 40% of lambs.

Pastures are damaged by grazing and rooting and pigs can also transport weeds. Wallowing pigs damage and foul the water in tanks and bore drains and silt up troughs. They can also damage fences and dam walls.

Pig activity degrades water quality and the habitat for small terrestrial and aquatic animals. It also creates erosion and allows exotic weeds to establish. Predation of native fauna does occur and examination of faeces has shown remains of marsupials, reptiles, insects, and ground-nesting birds and their eggs.

Feral pig damage to river banks

Feral pig damage to sugar cane

Diseases and parasites

Feral pigs can carry many infectious diseases and internal and external parasites. Some are endemic (already present), while others are exotic to Australia.

Many of the diseases can spread to domestic pigs, other livestock and humans. Feral pigs can transmit sparganosis, melioidosis, leptospirosis, Q fever and brucellosis to humans.

To prevent contracting these diseases it is advisable to either avoid handling feral pigs or use suitable protective clothing (mask, goggles, strong rubber gloves and plastic apron and boots) to minimise contamination with blood, urine and faeces. Rare or undercooked meat should not be eaten; thoroughly cook meat to avoid contracting pathogens.

Control

Feral pigs are difficult to control because they are primarily nocturnal, breed rapidly, are generalist omnivores and have large home ranges and thus control programs need to be conducted over a wide area (often including several properties) to be effective.

Effective control requires an integrated, collaborative approach where all stakeholders participate in planning, implementation and evaluation of the actions taken.

Trapping

Trapping is an important technique that is most useful in populated areas, on smaller properties (‹5000 ha), and where there are low pig numbers. Trapping can be particularly useful in 'mopping up' survivors from baiting programs. It is most successful when food resources are limited.

Trigger mechanisms for pig traps can be made pig-specific and therefore pose little danger to wildlife or domestic animals.

Advantages

- This is the safest form of control and can be safely undertaken on closely populated areas.
- It's flexible and can be incorporated into routine property activities, making economical use of labour and materials.
- Carcasses can be safely disposed.
- Traps can be moved and re-used; good trapping makes use of opportunities as they arise.
- Normal pig behaviour is not altered, which allows a greater number of the total population in an area to be targeted.
- More humane to pigs and non-target species.
- The number of animals removed can be easily monitored.

Disadvantages

- Can be time consuming and expensive to construct and maintain.
- Must be checked regularly.
- Not practical for large-scale control.
- Some pigs are trap shy.

Tips

- Stop all activities that will disturb normal feeding (i.e. do not undertake any shooting or dogging).
- Pre-feeding (i.e. ensure that pigs are visiting trap and consuming bait) prior to activating traps is an essential part of successful trapping.
- Feeding sites should be placed where feral pigs are active (i.e. water points, holes in fences, areas containing old carcasses on which pigs have been feeding).
- Bait for traps must be food that pigs usually eat in that area. Pigs feeding on one crop (e.g. sugarcane) will often not take to alternative foods. However, new, novel baits are sometimes attractive (e.g. fermented grains).
- The trap can be built around the feeding site, with feeding within the trap undertaken for several nights before it is set.
- Set the trap every night and check each day. If the trap cannot be checked daily then shade and water must be provided.
- Continue to trap until no more pigs are caught. A change of bait can be tried. Again, feed for one or two nights before re-setting the trap.
- Traps may be left permanently in locations used by pigs and can be utilised when fresh signs of pigs appear.
- If the trap is to be moved, start feeding at the new site before re-locating the trap.

Design

There are several trap designs but all are principally an enclosed area with one-way gates (see Figure 1).

The main area of the trap can be any shape and be made from materials on the property. The best material is steel mesh with a grid 100 × 100 mm, with a minimum height of at least 1.5 m. Star pickets need to be placed no more than 1.5 m apart and imbedded far enough to ensure that adult pigs cannot push them over or lift them up out of the ground.

Alternative trap entrances

Funnel entrance

Formed by the two ends of the mesh forming a funnel, the ends are tied together at the top with wire or rope. The pig moves through the funnel forcing the bottom of the mesh ends apart and once it is in the trap the ends spring back together (see Figures 1 and 2).

Figure 1. Alternative trap entrances – funnel entrance

Figure 2. Silo trap with funnel entrance (14 m of silo mesh diameter about 4.5 m

Figure 3. Pig-specific trigger

Figure 4. Close up of pig-specific trigger

Feral pig trap

Trapped feral pigs

Hog hopper – pig specific bait station

Tripped gate entrance

A side-hinged gate is pulled shut by springs and is held open by many systems that can be triggered to allow the gate to swing shut. Often trip wires or other systems are used; most of these systems are not selective for feral pigs and can be triggered by any animal attracted to the bait. Once triggered the trap is no longer effective in trapping pigs.

Pig-specific trigger

By far the simplest and most effective trigger system has the gate held open by a bar (often a branch or piece of wood) which is hooked over the wire on the gate and on the side panel (see Figure 3). For a close up of the pig specific trigger (see Figure 4).

Pigs rooting for feed in the trap lift the bar allowing the gate to swing shut. The specific feeding habit of pigs insures they are the only animals that lift the trigger bar.

The gate may be latched to prevent pigs from opening the door once triggered. However, this will prevent more pigs pushing their way in to join those inside.

Poisoning

Poisoning is the most effective control method available that can quickly reduce a pig population.

Sodium fluoroacetate (1080) can only be supplied by people approved under the Health (Drugs & Poisons) Regulation 1996 for the purpose of controlling declared pest animals. Your local government office should be able to assist you.

Pre-feeding is the most important step in ground-based poisoning operations. Free feeding with non-poisoned bait should be performed for several days prior to laying poisoned baits.

By selecting bait wisely, landholders can be species-selective in their poisoning program and avoid many of the unintentional effects of secondary poisoning.

Bait material such as fermented grains are very attractive to pigs. It is a good idea to establish a free feeding routine so that pigs are the only animals feeding, which helps to keep other non-targets away from the feeding site.

Other options (like pig-specific feeders) are now commercially available, and can assist in reducing non-target species access to bait. Other options include burying baits; feral pigs are one of the few animals that will dig up bait.

Aerial poisoning is also available and typically used for broadscale control in western and northern regional areas. Bait is distributed from an aircraft. This is particularly useful for covering large, remote, areas or restricted ground access. Aerial poisoning is a proven and cost-effective method for reducing pig populations.

A phosphorous-based poison is also available for use in Queensland.

Shooting and the use of dogs

Shooting pigs by helicopter is effective in areas where pigs exist in reasonable numbers and are observable from the air.

Ground shooting is not effective in reducing the pig population unless intense shooting is undertaken on a small, isolated and accessible population of pigs.

Dogs may be used to remove the few remaining pigs left after poisoning and trapping campaigns. Dogs are able to locate and flush pigs out of areas of thick cover. Dogs must not be used to hold or attack pigs.

Do not use dogs or shoot in areas before or during poisoning or trapping operations.

Fencing

Though an expensive option, fencing can offer successful pig control especially for high value crops grown on small areas. Research has indicated that the most successful pig-proof fences are also the most expensive.

The most effective pig-proof fences use fabricated sheep mesh held close to the ground by plain or barbed wire and supported on steel posts.

Electrifying a conventional fence greatly improves its effectiveness if used before pigs have established a path through the fence.

Pigs will often charge an electric fence and unless the fence incorporates fabricated netting they often successfully breach the fence.

For crop protection or to avoid lamb predation, pig-proof fences need to be constructed before the pigs become a problem. Once pigs have adjusted to feeding on grain or lambs in a particular paddock fencing may be ineffective.

Fertility control

There are currently no available means to deliver fertility control to feral pigs. Such a technique is likely to remain unavailable for practical use given the lack of suitable contraceptives, suitable delivery mechanisms, and concerns with non-target species.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland (call 13 25 23 or visit our website at www.biosecurity.qld.gov.au).

Visit www.biosecurity.qld.gov.au to download a copy of the feral pig control manual.

Fact sheet

DECLARED CLASS 2 PEST ANIMAL

July 2014

Wild dog control

Canis familiaris

The term wild dog refers collectively to purebred dingoes, dingo hybrids and domestic dogs that have escaped or been deliberately released.

Wild dog control methods include baiting, trapping, shooting, fencing, and the use of guardian animals to protect stock. A planned strategy using a combination of these methods that also considers wild dog behavior will enable effective management.

Declaration details

Wild dogs are a declared Class 2 pest animal under Queensland legislation. As such, all landholders in Queensland are required to reduce the number of wild dogs on their properties.

Management strategies

To increase wild dog control effectiveness, it is essential that control programs are coordinated among adjoining properties.

Queensland research has shown that in some situations wild dogs can quickly re-colonise baited areas due to a number of factors including inconsistent bait programs which do not provide comprehensive wild dog control across the landscape. Such programs may alter the dynamics of wild dog populations in the area. To prevent livestock attacks and enhance wild dog management, it is important for producers to work together using a variety of control methods.

Wild dog ecology and seasonal variations can also influence the likelihood of wild dogs coming into contact with a control tool. The timing of control should consider seasonal variations and the availability of water (where water is restricted) and then target watering points. Many land owners bait using 1080 twice a year to target wild dogs during peaks in activity associated with breeding (March/May) and then again in September/November to target pups and juveniles. However, baiting and trapping is recommended at all times when wild dogs are active.

Control

Baiting

Poison baits are the most economic, efficient and effective method of controlling wild dogs, especially in inaccessible or extensive areas. Baits can be laid quickly by hand, from vehicles and from aircraft.

Currently there are two poisons legally available for wild dog control. These are 1080 (sodium fluoroacetate) and strychnine.

Subject to restrictions, 1080 baits, either manufactured or prepared from fresh meat can be obtained through people approved under the Health (Drugs & Poisons) Regulation 1996. A permit from the Queensland Department of Health is required for land owners to purchase strychnine. Strychnine can be used both in baits and on traps. The use of both 1080 and strychnine require adherence to the associated conditions of supply.

The use of poison baits will control some but not all wild dogs. Baits should be used in conjunction with all other control tools and not be relied on as a total control method.

Meat baits are attractive both to wild dogs and a range of non-target species. When using meat baits, they can be strategically positioned as wild dogs' keen sense of smell enables them to find baits intentionally buried in sand or otherwise hidden under bushes or in hollow logs. Meat baits may also be tied to prevent their loss to non-target species.

These meat bait placement techniques help to:

- reduce the risk of poisoning non-target species
- increase wild dog contact, hence receiving a lethal dose
- minimise bait removal by non-target scavengers
- deter ants (ant-covered baits are believed to be less attractive to wild dogs).

Heavy rain within two weeks of baiting can leach 1080 from baits, but baits may still remain toxic for a considerable time.

Trapping

A key success to trapping wild dogs (using foot-hold traps) depends on the skill of the operator. Visit www.feral.org.au to watch a PestSmart video on best practice techniques for wild dog trapping.

For humane reasons and to prevent escape, poisoning traps with strychnine is recommended to quickly kill captured wild dogs. A properly poisoned trap becomes a lethal device rather than a holding device.

A mixture of dog faeces and urine is a popular lure used by trappers. Attractiveness of lures varies with seasons and locations. No single lure has yet been found that is consistently attractive to all wild dogs and repeated use of one lure can lead to aversion amongst remaining dogs.

Traps are best placed in areas of high wild dog activity (known as leads). Here the wild dog is most likely to find and investigate the decoy/odour.

A wild dog scent post (an area where urine or faeces have been deposited) can be found by walking with a domestic dog on a lead along a known pad. Trap placement in relation to the scent post can be optimised by observing the domestic dog's behaviour as it approaches. Factors to consider are:

- where on the bush it smells
- placement of feet while urinating/defecating/sniffing
- how it approaches and where it scratches in relation to the pad and scent post.

Padded, laminated or offset foot-hold traps, in a well tuned and functioning state are recommended.

Shooting

Shooting is an opportunistic method, mostly used for control of small populations or individual problem animals.

Fencing

Property fencing suitable to exclude wild dogs is expensive to build and requires continual maintenance to repair damage caused by fallen timber, fire, floods, feral and domestic animals, as well as vegetation regrowth. However, a properly maintained fence can restrict movement into an area where wild dogs have been controlled.

Electric fences suitable for wild dogs have been developed. Electrifying a fence creates a fear of the fence itself and deters wild dogs from approaching.

For property fencing to be successful, the fence must be maintained in good order and ongoing wild dog control conducted within the protected area to limit livestock impacts.

Fencing is the most effective method of protecting livestock and pets from wild dog attack on small acreage blocks.

A fence can also be a good area to place baits and traps when wild dogs are active.

Livestock guardian animals

Livestock guardian animals have been used to protect livestock from predators in Europe, Asia and America. Some producers in Queensland have decreased predation on sheep and goats using this method. The use of trapping and poisoning in conjunction with guardian animals must be well planned and managed to ensure guardian animal safety.

PEST ANIMAL
PA21 December 2013

Cane toad

Bufo marinus

The cane toad is not a declared pest in Queensland, so there is no legal requirement to control them.

Their original introduction in 1935 was to control agricultural pests, but they proved ineffective.

For the past 60 years, cane toads have been expanding their territory in Australia, and are capable of colonising at least four of the mainland Australian states.

As the toad's geographical range continues to expand, concern has increased about their detrimental environmental effects, particularly on the wetlands of the Northern Territory.

Studies into the feasibility of biological control have commenced.

History of introduction and spread

The cane toad or giant toad is an amphibian, native to Central and South America. Cane toads have been introduced throughout the world as a biological control for insect pests of agriculture, most notably sugarcane.

A consignment of cane toads from Hawaii was released into Queensland cane fields in 1935. The introduction was surrounded by controversy as to the potential costs and benefits to Australia.

It was hoped that the toad would control Frenchi and greyback beetles—pests of economic importance to the sugarcane industry.

By 1941, however, it had become evident that the cane toad was exerting only limited control over its intended prey. There were two main reasons for this:

- Greyback beetles are only rarely in contact with the ground and Frenchi beetles invade cane fields at a time when the toads are absent due to a lack of protective cover.
- The cane toad has a wide-ranging and indiscriminate diet, and it was not solely dependant upon its intended prey.

The unlimited food source, suitable environment and low rates of predation allowed dynamic reproduction and spread. Toads were recorded in Brisbane only 10 years after release. The toad continues to thrive and has now invaded the Northern Territory and New South Wales (see Map 1).

Map 1. Distribution of the cane toad in Australia

The cane toad's advance is only limited by environmental factors, such as the availability of water for breeding, tolerable temperatures, suitable shelter and availability of food.

Toads at the frontier of their range of expansion may be larger than those in established populations. This is most probably due to greater food supply, combined with a lower incidence of disease.

Description and general information

In comparison with native frog and toad species, adult cane toads have a distinctive head and face, and are large and heavily built creatures (adults may grow to 20 cm).

Following their aquatic larval stages (eggs and tadpoles), cane toads are generally encountered at night near any source of light. Cane toads are ground-dwelling—they are poor climbers and unable to jump very high.

A definite visor or awning extends over each eye and a high angular bony ridge extends from the eyes to the nose.

The parotid glands (see Figure 1) are perhaps the most characteristic feature of the adult cane toad. These glands are large, protuberant, and are situated on the head behind each ear. These glands carry a toxin.

Map 2. Distribution of the cane toad in Queensland

Figure 1. Distinguishing features of the cane toad

The cane toad's hands and feet are relatively small and lack discs at the tips of the digits. Webbing is absent between the fingers but is distinct and leathery between the toes.

Colouring on the dorsal (upper) surface may be brown, olive-brown or reddish-brown. The ventral (under) surface varies from white to yellow and is usually mottled with brown.

Warts are present on all cane toads; however, males possess more than females. Warts are dark brown at the caps.

Mating

Mating can occur at any time of the year and depends only on available food and permanent water. The mating call is a continuous purring trill that sounds like a running motor.

In situations where females are scarce or absent, male cane toads may have the ability to undergo a sex change to become fertile females; however, this has not been proved.

Eggs

Both cane toads and native frogs spawn in slow-moving or still water, but their eggs can be easily distinguished.

Cane toad eggs are laid in long, gelatinous 'strings' with the developing tadpoles appearing as a row of small black dots along the length. The strings are unique to cane toads, generally appearing as blobs of jelly attached to water plants or debris. Native frogs generally produce egg clusters as mounds of foam floating on the water surface.

Compared with native species, cane toad egg production is dynamic and a single clutch can contain up to 35 000 eggs. Remove any cane toad eggs found in the water and allow to dry out.

Figure 2. Drawing of toad spawn from *Wildlife of greater Brisbane*

Tadpoles

The cane toad is the only species in Australia that has a pure black tadpole. Native frogs have lighter-coloured undersides with a great range of colours and markings—cane toad tadpoles may turn paler colours to almost transparent at night.

Cane toad tadpoles are small and usually congregate in vast, slow-moving shoals. This 'shoaling' behaviour is uncharacteristic of most native species.

Unlike cane toad tadpoles, native species develop lungs at an early stage and periodically rise to the surface in order to exchange their lung gasses. Large groupings of tadpoles that do not break the water surface for air indicate cane toads.

Young toads

Following emergence from the water, the young toadlets usually congregate around the moist perimeter of the water body for about a week before they eventually disperse.

Young toads are very difficult to distinguish from the native *Uperoleiea* species, which also have parotid glands, but all *Uperolelea* species have bright red patches in the groin area.

Under ideal conditions toadlets may reach adult size within a year.

Toxicity

Bufo marinus produce venom in glands occurring in most of the skin on their upper surface. The venom is concentrated in the parotid glands as a creamy-white solution, which is released when the animal experiences extreme provocation or direct localised pressure (e.g. grasped by the mouth of a predator).

The parotid solution is highly toxic and when ingested it produces drastic acceleration of the heartbeat, shortness of breath, salivation and prostration. It is extremely painful if accidentally rubbed into the eye.

Ingestion of toads by domestic and most native animals can result in death. In some recorded cases, death has occurred within 15 minutes.

Field observations suggest that some predatory Australian species have learned how to feed safely on cane toads.

Birds have been observed flipping toads over to avoid the parotid glands. Predatory reptiles may have more trouble adapting, being unable to remove a toad from the mouth once they start feeding.

Effects on wildlife

The cane toad is poisonous at all stages of its life cycle and most native frog larvae and many aquatic invertebrates are dramatically affected by their presence.

Cane toads are voracious feeders that consume a wide variety of insects, frogs, small reptiles, mammals and even birds. Perhaps the only limiting factor to the prey taken is the width of the cane toad's mouth.

It has been suggested that cane toad competition for food and breeding grounds has been responsible for reducing the populations of some native frogs. However, many native frogs are arboreal (tree-dwelling) and occupy different niches. Cane toads don't have the native frogs' ability to 'shut down' during dry seasons when resources are limited.

Pressure from cane toads may displace native animals (frogs and other species) where they are already suffering due to manipulation of their habitat by humans and grazing animals. Animals that use waterholes as retreat sites during the dry season are especially vulnerable—toads will congregate here in large numbers.

Public health

Cane toads readily eat animal and human faecal material and, in areas of poor hygiene, they have been known to transmit disease such as salmonella.

Control

Control of cane toads is not enforced as there is currently no available effective broad scale control. Individuals and community groups have carried out removal campaigns to decrease numbers and slow the invasion front.

Fencing is recommended to keep toads out of ponds intended for native fish and frogs; a height of 50 cm is sufficient. Bird wire with 1 cm holes may keep toads out of an area.

Research indicates that spread can be delayed in semi-arid areas by blocking access to water holes.

Individual toads may be killed relatively humanely using a commercial spray available from hardware stores or may be stunned and decapitated (only by experienced operators). The removal of eggs from small water bodies such as frog ponds can be effective

Researchers have successfully mitigated impacts in recently colonised areas by 'training' predators however, large scale application of this technique is difficult.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland (call 13 25 23 or visit our website at www.biosecurity.qld.gov.au).

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture, Fisheries and Forestry (DAFF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAFF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

1.0 Introduction

Environmental Geochemistry International Pty Ltd (EGi) was commissioned by joint venture partners CopperChem Ltd and Syndicated Metals Ltd (hereafter referred to as the Joint Venture) to carry out an assessment of waste rock geochemistry for the Barbara Copper Project, located in north-west Queensland, approximately 50 km east of Mount Isa. The main purpose of the assessment was to identify any geochemical characteristics that potentially could adversely impact the quality of waste dump drainage and therefore will have implications for the management of waste rock at the site.

The Barbara Copper Project will involve open pit development of the Barbara copper resource comprising approximately 800,000 tonnes grading 0.5 %Cu. The resource also has trace concentrations of gold, silver and cobalt. The mineralisation is structurally controlled by the Barbara Shear Zone and occurs as a series of sulphide lodes hosted within a package of rhyodacitic volcanic rocks intruded by dolerite dykes. Sulphide mineralisation comprises semi-massive pyrrhotite/pyrite with chalcopyrite and chalcopyrite stringer veins.

The footprint of the mined area will be about 18 ha and will comprise two adjoining open pits located along the N-S trending strike of the resource that extends over a distance of approximately 900 m. The North pit will have a maximum depth of about 50 m, and the South pit will reach a depth of about 130 m. The two pits will be mined concurrently over a period of approximately two years. A conceptual layout for the Barbara site is given in Figure 1.

The resource will be developed as a conventional bench mining operation using drill, blast, excavation, and dump truck haulage to run-of-mine (ROM) ore stockpiles. Excavated ore will be crushed on-site then transported off-site by road train for processing at either Copperchem's Great Australia Mine in Cloncurry or another third party processing facility in the region.

In addition to ore, the open pit will produce approximately 7.5 Mtpa of waste rock which will be placed in a stable land form adjacent to the open pit. The Joint Venture expect the majority of waste will be low sulphur rock, primarily high Ca+Mg basalts and mafics, low Ca+Mg felsic volcanics, and pedogenic carbonates. However, some sulphide rich waste zones occur immediately adjacent to the ore zone, primarily on the footwall, which may be mined as fresh waste or left in the end walls of the pit. Such material is considered high risk in relation to its potential for generation of acid rock drainage (ARD) if exposed to atmospheric conditions.

The geochemical assessment carried out by EGi involved analysis of drill core samples representing the range of waste rock lithologies that will be intersected during open pit mining of the Barbara copper resource. The main objectives of the geochemical assessment were as follows:

- To define the geochemical characteristics of waste rock and ore grade materials and provide sufficient data for a preliminary assessment of the likelihood of occurrence of acid generating rock types.
- To assess the forms and reactivities of the sulphide mineralisation within ore and waste rock, and to assess the likely time frames for any materials that are potentially acid forming (PAF) to acidify.

- To assess the forms and reactivities of the carbonate mineralisation within waste rock, and to assess the usefulness of these materials for control or mitigation of ARD generation, if required.
- To identify any elemental enrichments that could be environmentally significant, and to assess the potential for mobilisation of elements that could adversely impact drainage quality.

This report presents the results and findings of the geochemical assessment, and the implications for waste rock handling and management, and drainage water quality at the Barbara Copper Project.

FIGURE 1: *Conceptual mine layout for the Barbara site*

2.0 Selection and Preparation of Drill Core Samples

A total of 121 drill core samples from 14 diamond drill holes were included in the geochemical assessment. The holes were drilled in February-March 2014 and were identified with the prefix BADD. The hole ID numbers: 015, 021, 023, 033, 034, 035, 036, 038, 042, 043, 045, 046, 049 and 080.

Each sample typically represented a 1 m interval of core, and a semi-regular sampling pattern was used to provide judicious spatial coverage of the northern and southern mining zones. Figure 2 shows a schematic of sample intervals that were tested, and a location plan for the drill hole collars is given in Figure 3.

FIGURE 2: *Down hole depths of core samples selected for geochemical assessment*

FIGURE 3: *Drill collar plan for the Barbara site*

The distribution of samples between rock types[1] was as follows:

Porphyritic Rhyolite (VFRD)	87 samples	Dolerite (IMD)	4 samples
Rhyolite (VFR)	3 samples	Mafic intrusive (IMO)	2 samples
Biotite Schist (XSB)	15 sample	Basalt (VMB)	2 samples
Biotite Chloritic Schist (XSBH)	1 sample	Psammite (XMO)	2 samples
Schist (XSO)	4 samples	Gossan (RZO)	1 sample

Most of the samples had low copper concentrations and were representative of material that will likely be mined as waste. The distribution of samples between waste and ore based on the current mine plan and a copper cut-off of 0.5 %Cu was as follows:

- Waste 94 samples
- Ore 27 samples

Three samples (8101, 8055, 8040) designated ore* in Appendix B were slightly below grade but were located within the ore zone and therefore would likely report as ore. Another sample (8068) designated ore** in Appendix B was a relatively minor interval of core with above grade copper located within the waste zone. It is possible such materials could report as waste or ore depending on actual mine planning.

3.0 Geochemical Assessment Methodology

3.1 Sample Preparation

Sample preparation was carried out by SGS Australia Pty Ltd in Townsville. Each sample was provided as a pulp (minus 75 µm) and as coarse residue (minus 3.35 mm).

Approximately half of the samples (primarily from zones of mineralisation) had previously been prepared and assayed for copper and a range of other elements by SGS as part of the Joint Venture's resource drilling program. These samples were despatched directly from SGS to EGi's laboratory in Sydney. The remaining samples (from non-mineralised zones) were sub-sampled by Joint Venture personnel from cores retained on site within the core storage facility. These samples were despatched to SGS for preparation, then pulps and coarse residues were forwarded to EGi for geochemical characterisation.

[1] A complete listing of rock type, mineral and weathering codes used by the Joint Venture is provided in Appendix A.

3.2 Laboratory Program

The static testing of each sample initially included analysis of the following acid-base parameters:

- Existing pH
- Electrical conductivity (EC)
- Total sulphur content
- Maximum potential acidity (MPA)
- Acid neutralising capacity (ANC)
- Net acid producing potential (NAPP)
- Net acid generation (NAG) capacity

Following review of the acid-base results, some samples were selected for more detailed analysis, which included one or more of the following:

- Solids multi-element analysis - 26 samples
- Water extractable elements - 26 samples
- Peroxide extractable elements - 12 samples
- Sequential NAG tests - 15 samples
- Kinetic NAG tests - 5 samples
- Sulphur Speciation - 5 samples
- Acid buffer characteristic curves - 5 samples
- Carbon Speciation - 5 samples

Most assays were carried out on pulp sub-samples. The only exception was the water extraction test where coarse residue was used.

3.3 Analytical Methods

Existing pH and Conductivity

The existing pH and salinity of each sample were determined by measuring the pH and EC of a suspension comprising 50 g of pulp sample in 100 mL of deionized water after a minimum of 1 hour of equilibration.

Sulphur and Carbon Analyses

Sulphur and carbon analyses were carried out by Australian Laboratory Services (ALS) in Brisbane, which is a NATA registered laboratory. This involved determination of the following:

- *Total sulphur* - Measured using a Leco sulphur analyser
- *Sulphate sulphur* - Samples were leached with hot HCl to remove acid-soluble sulphates. The amount of sulphate within the leachate was then determined by inductively coupled plasma atomic emission spectrometry (ICPAES).
- *Sulphide sulphur* - Calculated as the difference between Total-S and Sulphate-S values.
- C*hromium Reducible Sulphur* - Inorganic sulphur was reduced to H_2S by hot acidic $CrCl_2$ solution and the evolved H_2S gas trapped in zinc acetate solution as ZnS. the concentration of ZnS was subsequently quantified by idiometric titration. This method is designed to be selective for pyritic-sulphur, but may also include some elemental sulphur if present in a sample.
- *Total carbon* - Measured using a Leco carbon analyser
- *Organic-carbon* - Samples were digested with hot HCl to remove any acid soluble carbonates, then rinsed with distilled/deionised water to remove residual chloride. The acid-insoluble carbon remaining in the residue (which is predominantly organic-carbon) was then measured by Leco.
- *Inorganic-carbon* - Calculated as the difference between Total-C and Organic-C values.

Acid Neutralising Capacity

The ANC of a sample was determined using a modified Sobek Method. This method provides a direct measurement of the amount of acid that can be consumed by carbonate and other gangue minerals within a sample. A fizz test was initially carried out to provide a qualitative indication of the magnitude of neutralisation capacity. The fizz test involved addition of a few drops of acid to a small sub-sample of sample. A fizz rating was then assigned on the basis of the degree of fizzing, and based on the fizz rating, a known amount of acid was added to a known weight of pulverised material to produce a suspension with a pH in the range 1 to 2. The suspension was allowed to react for approximately 1 to 2 hours and then it is gently heated to complete the reaction. The amount of acid remaining after the reaction stage was determined by back-titration with sodium hydroxide. The amount of acid consumed by the sample (expressed in terms of kg H_2SO_4/t) was then determined by difference.

Maximum Potential Acidity

The MPA is the amount of acid that theoretically can be generated by a sample if all the sulphur occurs as reactive pyrite and there is complete oxidation of the pyrite according to the following reaction:

$$FeS_2 + 15/4\ O_2 + 7/2\ H_2O \Rightarrow Fe(OH)_3 + 2\ H_2SO_4$$

MPA is expressed in units of kg H_2SO_4/t. For the test samples the MPA values were calculated using the total sulphur contents as follows:

MPA (kg H_2SO_4/t) = Sulphur-%S x 30.6

Net Acid Producing Potential

The NAPP is the amount of acid that potentially can be produced by a sample after allowance for any ANC that the samples may also have. The NAPPs were calculated by subtracting the ANC values from the MPA values, with the results expressed in units of kg H_2SO_4/t.

Net Acid Generation (NAG) Test

The NAG test is a direct oxidation procedure for estimating the acid forming potential of a sample. The NAG test involved reaction of a 2.5 g sub-sample of pulverised material with 250 mL of 15% hydrogen peroxide, which acted as an oxidant to any sulphides present. The samples were allowed to react overnight to provide sufficient time for oxidation to occur. The reaction flasks were then gently heated for approximately 1 hour to decompose any residual peroxide. After cooling, the liquor pHs were recorded As both acid generation and acid neutralisation can occur simultaneously during a NAG test, the end result represents a direct measurement of the net amount of acid that a sample can generate. A sample is considered to be acid forming if the pH after reaction is less than pH 4.5. For such samples, the actual amount of acidity generated (expressed as kg H_2SO_4/t) is also determined by back-titration of the mixture to a pH 7 end-point.

Sequential NAG Test

With high sulphur samples (*i.e.* typically greater than 2 %S) the oxidation of sulphides is often not completed in a single-stage NAG test, and a sequential multi-stage procedure may be required to ensure all sulphides are fully oxidised. In the sequential NAG test, a 2.5 g sub-sample of pulverized material is reacted several times with successive 250 mL aliquots of 15% hydrogen peroxide. At the end of each stage, the sample is filtered to separate the solids and NAG liquor. The NAG liquor is then assayed for pH and acidity, as per a standard NAG test. The solids are recovered and the oxidation process continued by the addition of another aliquot of hydrogen peroxide. The overall NAG capacity of a sample is then determined by summing the individual acid capacities from each stage.

Kinetic NAG Tests

The kinetic NAG test provides an indication of the reactivity of the sulphides present in a sample, and in the case of a PAF sample it also provides an indication of the likely lag period for acid generation to occur under oxidising conditions. The kinetic NAG test is essentially the same as the standard NAG test, except that the kinetics of the peroxide oxidation reaction are indirectly monitored via continuous measurements of the pH and temperature of the NAG solution.

Acid Buffer Characteristic Curve

An acid buffer characteristic curve was produced by slowly titrating a sub-sample of pulverised material with dilute hydrochloric acid over a period of 16 to 24 hours. This titration method provides a far less aggressive treatment of a sample than that applied in the ANC method and hence provides a measure of the buffering provided by more soluble carbonates within a sample.

Multi-Element Analysis of Solids

Elemental analysis of solids was carried out by ALS. Samples were digested by multi-acid addition (*i.e.* hydrofluoric, nitric, perchloric and hydrochloric acids) and the digests were analysed using inductively coupled plasma mass spectrometry (ICPMS) for the following suite of elements: Al, As, Ba, Be, Bi, Ca, Cd, Co, Cr, Cu, Fe, Hg, K, Li, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Sn, Sr, Th, U, and Zn. Mercury was also assayed but an aqua regia digestion was used to ensure minimal volatilisation followed by analysis using ICPMS.

Water Extractable Elements

The water-soluble components within the four waste rock sample were determined by EGi by extraction of a 150 g sub-sample of coarse residue (minus 3.35 mm) in 300 g of deionised water for 24 hours. The extractions were carried out in Teflon containers, which were slowly rotated on an end-over-end shaker throughout the equilibration period. At completion, the pH and EC of each extract were recorded then the liquor fractions were filtered through 0.45 micron membrane filters and preserved with a few drops of high purity HNO_3 acid. The filtered extracts were despatched to ALS for multi-element using a combination of ICPMS, and ICP atomic emission spectrometry (ICPAES).

Peroxide Extractable Elements

Elements that may be mobilised as a consequence of sulphide oxidation were determined by EGi by reacting a 2.5 g sub-sample of pulverised material with 250 mL of 15% hydrogen peroxide, as per the single-stage NAG test procedure described above. After completion of the oxidation reaction, the NAG liquor was re-adjusted to 250 mL with deionised water. A 100 mL sub-sample was then taken for determination of NAG pH, and a second 100 mL sub-sample was filtered through a 0.45 micron membrane filter, preserved with a few drops of high purity HNO_3 acid, and sent to ALS for multi-element analysis.

4.0 ARD Characteristics

The acid forming characteristics of the 121 drill core samples are tabulated in Appendix B. Most samples representing waste had low sulphur contents and were non-acid forming (NAF) but there were some waste samples from close to mineralised zones that had elevated sulphur contents and were potentially acid forming (PAF). As expected, ore samples had high sulphide contents and approximately half of the ore samples tested were PAF. Summaries of specific geochemical characteristics are given below.

4.1 Existing pH

All samples were naturally circum-neutral or slightly alkaline. The existing pHs of all samples were greater than 6, and all but five samples were greater than pH 7.5. Figure 4 shows a statistical summary of the existing pHs for each rock type. Overall the results suggest that initial drainage from run-of-mine waste rock will be circum-neutral or slightly alkaline.

	IMO	RZO	VFR	VFRD	VMB	XAO	XSB	XSBH	XSO
max	9.1	8.4	8.8	9.9	8.5	9.5	9.2	8.8	8.3
median	8.7	8.4	8.3	8.7	8.4	8.7	8.4	8.8	8.0
min	7.8	8.4	8.0	6.8	8.3	7.9	6.1	8.8	7.5

FIGURE 4: *Statistical summary of the existing pHs of Barbara drill core samples split by rock unit*

4.2 ARD Classifications

Both NAPP and NAG results were used to assign an ARD classification to each sample. As the NAG test is completely independent of the NAPP approach, the combination of the NAPP and NAG results provides greater certainty to the assessment of ARD potential. The ARD classification criteria were as follows:

- *Non-Acid Forming (NAF)* - negative NAPP and NAG=0 (or NAGpH≥4.5)
  Although sulphides may be present in such samples, the inherent ANC should be sufficient to neutralise any acid that might have been produced by sulphide oxidation.

- *Potentially Acid Forming (PAF)* - positive NAPP and positive NAG (or NAGpH<4.5)
  The exposure of such a material to atmospheric conditions is likely to result in sulphide oxidation, which in turn could result in acidification.

- Uncertain *(UC)* - when there was a disparity between the NAPP and NAG results and a definitive classification could not be assigned. For such samples column leach testing may be required to assign an ARD classification.

The ARD classifications assigned to the Barbara drill core samples are included in Appendix B. The distribution of samples between ARD classifications was as follows:

Waste Rock Samples (total=94)

- NAF 83 samples (89% of waste samples)
- PAF 7 samples (7%)
- UC 4 samples (4%)

Ore Samples (total=27)

- NAF 12 samples (44% of ore samples)
- PAF 15 samples (56%)

It should be noted that the percentages of NAF and PAF as given above apply to the dataset for this geochemical investigation and do not necessarily reflect the percentages of NAF and PAF waste or ore that will be mined. The actual volumes of NAF and PAF waste rock will need to be estimated by the Joint Venture by block modelling of the proposed pit. Notwithstanding this qualification, the results of the drill core testing program suggest that the majority of waste rock should be NAF, but some waste with the potential to generate ARD occurs within the Barbara mining shell. Most of the PAF waste samples were located within the northern mining zone.

The results also confirm that a significant percentage of ore is likely to be PAF, as would be expected for chalcopyrite/pyrite ore. However, it is worth noting that just under half of the ore samples tested, despite having high sulphur contents, were NAF due to the mineralised rock also having high to very high ANC.

4.3 Acid-Base Account Plot

Figure 5 shows a plot of ANC versus sulphur content for the drill core samples. This type of plot is commonly referred to as an acid-base account plot. Figure 5a shows all samples whilst Figure 5b is the same acid-base account plot with expanded scales to highlight samples that contained less than 3 %S and had ANCs less than 150 kg H_2SO_4/t.

The Figure 5 plots clearly illustrate the preponderance of drill core samples representing NAF waste, which plot above the NAPP=0 line shown in Figure 5. These samples have negative NAPPs and therefore theoretically have an excess of ANC over the acid potential of any contained sulphides. In most cases the waste NAF samples had low sulphur contents and also moderate to high ANCs, resulting in substantial negative NAPPs.

However, a small percentage of waste samples plot below the NAPP=0 line shown in Figure 5, suggesting that there may not be sufficient ANC in these samples to negate the acid potential of the contained sulphides. Similarly, approximately half of the ore samples clearly plot below the NAPP=0 line, most of which have high to very high acid potentials.

4.4 ARD Classification Plot

Figure 6 shows an ARD classification plot for the Barbara drill core samples. This type of plot illustrates the concurrence of the NAPP and NAG test results. Samples classified as NAF plot in the upper left quadrate of Figure 6. This quadrate denotes samples with a negative NAPP that also produce a negative response under NAG test conditions (*i.e.* the samples remained above pH 4.5 when oxidised). PAF samples plot in the lower right quadrate, which corresponds to positive NAPP and NAG test results. Again, most waste samples plot in the NAF quadrate, whereas the ore samples are distributed between the NAF and PAF quadrates.

There were four waste samples (8002, 8004, 8017 and 8031) that had low sulphur contents (0.10 to 0.26 %S) and small negative NAPPs (-1 to -6 kg H_2SO_4/t) that produced positive results when oxidised with peroxide in the NAG test in that they acidified to less than the pH 4.5. These four samples plot in the lower left "uncertain" quadrate. The positive NAG results suggest that some of the ANC in these samples may be only sparingly reactive under circum-neutral and weakly acidic conditions. Notwithstanding that the NAG results were positive, the amounts of acid generated were relatively minor (2 to 5 kg H_2SO_4/t) in comparison to other PAF samples. Column leach testing will be required to confirm whether the materials they represent are actually NAF or PAF.

It should be noted that sequential NAG testing was required to quantify the total acid generating capacities of samples with high to very high sulphur contents. As noted in Section 3.3, with high sulphur samples (*i.e.* typically greater than 2 %S) the oxidation of sulphides is often not completed in a single-stage NAG test, and a sequential multi-stage procedure may be required to ensure all sulphides are fully oxidised. Sequential NAG tests were run on 15 samples, with up to seven stages required for some samples. The results for each stage are tabulated in Appendix C, and the NAG results included in Appendix B that are based on the sequential method are marked with asterisks.

4.5 Sulphur versus NAGpH

The relationship between sulphur content and NAG pH is shown in Figure 7. With the exception of the four "uncertain" waste samples all other waste and ore samples with sulphur contents less than 0.3 %S maintained a NAG pH greater than the 4.5 criterion for NAF when oxidised with peroxide. Furthermore, 12 of the 15 samples containing between 0.3 and 1.0 %S also had NAG pHs greater than 4.5.

FIGURE 7: *Plot of NAG pH versus sulphur content for Barbara drill core samples containing less than 5 %S (Note: there were five ore samples containing more than 5 %S which had NAG pHs less than 4.5)*

4.6 NAPP versus NAG

The relationship between NAPP and NAG results is shown in Figure 8. Overall there was reasonable agreement between the magnitude of the NAG results based on direct oxidation of samples, and the NAPP values based on sulphur contents and ANCs. With the exception of the four *uncertain* samples, samples with negative NAPPs had zero NAG capacities, samples with positive NAPPs generated approximately the equivalent amount of acid when oxidised under NAG test conditions. The close agreement of positive NAPP and NAG values for samples with elevated sulphur contents is consistent with most of the sulphur occurring as sulphide, presumably as either chalcopyrite and/or pyrite.

FIGURE 8a: *Plot of NAG versus NAPP for Barbara drill core samples - all samples*

FIGURE 8b: *Plot of NAG versus NAPP for Barbara drill core samples - expanded scales*

4.7 Reactivity of PAF Rock

Kinetic NAG tests[2] were carried out on two ore and three waste samples to assess the reactivity of the sulphides present and to provide a qualitative assessment of the likely lag period for acid generation to occur under oxidising conditions. The acid-base characteristics of the five samples selected for kinetic NAG testing were as follows:

- Ore #8050 BADD035: 49-50m VFRD 3.59 %S, ANC=14 kg H_2SO_4/t, NAPP=96 kg H_2SO_4/t
- Ore #8112 BADD021: 139-140m XSB 5.37 %S, ANC=42 kg H_2SO_4/t, NAPP=122 kg H_2SO_4/t
- Waste #8066 BADD045: 27-28m XSB 0.73 %S, ANC=15 kg H_2SO_4/t, NAPP=7 kg H_2SO_4/t
- Waste #8092 BADD050: 39-40m VFRD 1.85 %S, ANC=21 kg H_2SO_4/t, NAPP=35 kg H_2SO_4/t
- Waste #8072 BADD046: 26-27m VFRD 1.47 %S, ANC=34 kg H_2SO_4/t, NAPP=11 kg H_2SO_4/t

The kinetic NAG test involves a similar procedure to the standard NAG test where a sample is oxidised using hydrogen peroxide, but with the addition that the pH and temperature of the NAG liquor are constantly recorded during the reaction phase of the test. The reaction kinetics are then extrapolated to the field situation using correlations previously derived from an extensive database comprising results of kinetic NAG tests, leach column tests, and field observations across a wide range of rock types.

Whilst kinetic NAG testing is not a replacement for column leach tests, the profiles obtained by the accelerated procedure provide a qualitative estimate of the lag period[3] to the extent that acidification of PAF rock is likely to occur rapidly (weeks to months), within the short term (many months to one or two years), or medium to long term (many years).

The individual kinetic NAG reaction profiles for the five samples are given in Appendix D, and a compilation of the NAG pH profiles for all five samples is given in Figure 9.

Ore Sample #8050

This sample had a below average ANC for ore and the kinetic NAG profile indicated rapid rates of sulphide oxidation and acid generation. The sample acidified to less than pH 4 within approximately 20 minutes of the peroxide being added, and to pH 3 after 40 minutes. The rapid acidification in the kinetic NAG test confirms the reactive nature of the sulphides present and suggests that any lag stage preceding acidification will be relatively short for ore with low ANC as represented by the test sample *i.e.* possibly weeks to months rather than years. The temperature of the NAG solution also provides an insight into sulphide reactivity (see Appendix D-1). The temperature of the NAG liquor increased markedly as the pH approached 3, reaching

2 The kinetic NAG test is an accelerated laboratory procedure which markedly differs to conventional kinetic methods such as column leach test where reactions occur in real time as a consequence of exposure to atmospheric oxygen.

3 The lag times provided in this report should be used as a guide only and are based on correlations previously derived by EGi from comparison of kinetic NAG profiles with results from real time testing of the same materials (*e.g.* leach column tests) and field observations at actual mine sites.

boiling point after about 50 minutes. Some of the initial temperature rise maybe attributed to the oxidation of pyrite, which is an exothermic (heat generating) process. However, as the oxidation process continues, there is an increasing tendency for the hydrogen peroxide to catalytically decompose, a process that is also exothermic. This markedly accelerates the heating of the NAG solution. The main catalyst for peroxide decomposition is usually dissolved iron that is released during pyrite oxidation.

FIGURE 9: *Kinetic NAG pH profiles for Barbara drill core samples*

Ore Sample #8112

In contrast to the low ANC ore sample discussed above, sample #8112 took considerably longer to acidify under NAG test conditions, consistent with its higher ANC of 42 kg H_2SO_4/t. Although there was clear visual evidence of the peroxide reacting with the sample (*i.e.* strong fizzing), the pH remained circum-neutral for approximately three hours. During this lag phase the acid generated from sulphide oxidation was immediately neutralised by the inherent ANC of the sample. As a rule, such a slow response generally extrapolates to a lag time under field conditions of at least a year and possibly several years. This sample did eventually acidify to less than pH 3 (consistent with it being PAF) and as with the other ore sample the acidification was accompanied by a rapid increase in temperature (see Appendix D-2), albeit after approximately four hours of reaction.

Waste Sample #8066

The sulphur content and ANC for this sample were toward the lower ends of the respective ranges[4] for PAF waste. At the start of the test the pH initially increased slightly from around 6 up to 7, then very gradually decreased as sulphides were oxidised. It took more than 6 hours for the pH to reach 5, and the pH was 4.3 when the test was terminated after approximately 18 hours. No temperature change was detected for this sample. The reaction kinetics during the NAG test suggest that waste rock as represented by this sample would likely react only slowly if exposed to atmospheric conditions and remain circum-neutral for at least a year and probably several years.

Waste Sample #8092

The sulphur content of this waste sample was higher at 1.85 %S, but it also exhibited a long lag phase during the kinetic NAG test. The pH at the start of the test was 7.6, and the pH was buffered above 6 for more than three hours. The pH eventually decreased to approximately 3 after six hours, at which point the temperature increased sharply (see Appendix D-4). Again, the slow reaction kinetics observed in the NAG test suggest that such a long lag for material under field conditions, probably in the order of several years.

Waste Sample #8072

Although this sample had a significant sulphur content (1.47 %S) and was classified as PAF, it did not acidify to any significant extent during the kinetic NAG test, with the pH remaining at between 6 to 7. It was only when the sample was boiled[5] at the completion of the monitored reaction phase that the pH decreased to 4.5. The extended plateau exhibited in the kinetic NAG test is consistent with the presence of an above average ANC for waste of 34 kg H_2SO_4/t. Again, the reaction kinetics for this sample suggest that waste rock as represented by this sample would likely react only slowly if exposed to atmospheric conditions and remain circum-neutral for at least a year and probably several years.

4.8 Sulphur Forms

The five samples that were included in the kinetic NAG testing program were also submitted to ALS for determination of sulphur forms. The speciation scheme involved determination of total sulphur (by Leco), sulphate-sulphur (by hot HCl leach), sulphide-sulphur (by difference), and chromium reducible sulphur. The method used for chromium reducible sulphur is reportedly selective for pyritic-sulphur, but may also include some elemental sulphur if present in a sample.

The results of sulphur speciation are presented in Table 1. With all five samples there was only minimal sulphate present (*i.e.* between 0.03 to 0.19 %S). Consequently, it can be assumed that almost all of the sulphur in the test samples was sulphidic, and the chromium reducible concentrations were virtually identical to the sulphide values determined by difference from the total-S and sulphate-S results.

---

4 The average ANC for PAF waste samples was 25 kg H_2SO_4/t and the range was 13 to 49 kg H_2SO_4/t.

5 The NAG liquor is boiled following the reaction phase of the NAG test to ensure complete oxidation of sulphides and to decompose any residual peroxide prior to final measurements of pH and acidity.

***TABLE 1**: Sulphur speciation results for PAF samples in the kinetic NAG testing program*

EGi id	Hole_ID	Interval (m)	Rock Type	Total Sulphur	Repeat Total-S	Sulphate Sulphur	Sulphide Sulphur	Cr-Red-S	ARD Class
				(%S)					
8050	BADD035	49-50	VFRD	3.59	3.53	0.19	3.34	3.46	PAF
8066	BADD045	27-28	XSB	0.73	0.76	0.03	0.73	0.76	PAF

* The repeat total sulphur assay was a component of the sulphur speciation scheme

4.9 Acid Neutralisation Capacity

The inherent neutralisation capacity of each sample was quantified using the Sobek procedure, which is the most widely used measure of neutralisation capacity for mine waste materials. Figure 10 shows a statistical plot of the ANC results for ore and waste samples split by ARD classifications.

	NAF ORE	PAF ORE	NAF WASTE	PAF WASTE	UC WASTE
25 percentile	75	26	13	15	
minimum	26	14	3	13	8
maximum	387	127	165	49	10
75 percentile	131	87	45	31	
median	98	47	23	21	9

***FIGURE 10:** Statistical summary of the ANCs of Barbara drill core samples split by ARD classification*

The ANCs of ore samples were typically in the moderate to high range. The median ANC for the NAF ore samples was particularly high at of 98 kg H_2SO_4/t, which equates to approximately 10 %$CaCO_3$ equivalent.

The median for the PAF ore samples was lower but still substantial at 47 kg H_2SO_4/t. In the latter case the ANCs were (by definition) less than the acid potentials of the contained sulphur, but they would be expected to produce long lag periods (i.e. delay to acid generation) if ore is exposed to atmospheric conditions. The median ANC of 47 kg H_2SO_4/t is sufficient to neutralise the acid that can be produced from oxidation of approximately 1.5 %S as pyrite or chalcopyrite, which would typically take in excess of a year to occur under field conditions. Furthermore, it is expected that the mixing of higher ANC NAF ores with PAF ores within ROM ore stockpiles would enhance the lag phase.

The ANCs of samples representing waste rock were typically lower than for ore. The ANCs of the relatively small numbers of PAF waste samples identified in this study ranged from 13 to 49 kg H_2SO_4/t and the median was 21 kg H_2SO_4/t. Although lower than for ore, the results of the kinetic NAG tests on three PAF waste samples (see Section 4.7) suggest that the ANC should still provide a reasonable lag if the rock is exposed to conditions conducive to sulphide oxidation.

4.10 Carbon Forms and Reactivity of Neutralising Capacity

Five samples with high ANCs were selected to assess carbon present speciation and to determine the reactivity of the carbonate mineralisation responsible for the ANC. They included our NAF waste samples and one sample representing PAF ore as follows:

- NAF Waste #8007 BADD034: 79-80 m VFRD ANC=165 kg H_2SO_4/t
- NAF Waste #8114 BADD038: 99-100 m XSB ANC=135 kg H_2SO_4/t
- NAF Waste #8080 BADD043: 59-60 m XSB ANC=134 kg H_2SO_4/t
- NAF Waste #8078 BADD042: 69-70 m VFRD ANC=76 kg H_2SO_4/t
- PAF Ore #8056 BADD033: 64-65 m VFRD ANC=95 kg H_2SO_4/t

Carbon Speciation

The speciation of carbon within the drill core samples involved measurements of total carbon and organic carbon. The difference between these two measurements was assumed to be inorganic carbon occurring in the form of carbonate, which typically accounts for most of the neutralisation capacity in samples with moderate to high ANCs. The carbon speciation results are tabulated in Table 2. The total-C concentrations ranged from 0.57 to 1.53 %C, virtually all of which occurred as inorganic carbon. These results confirm the presence of significant carbonate mineralisation within waste and ore grade materials with high ANCs.

***TABLE 2**: Carbon speciation and Carbonate Neutralising Values for Barbara drill core samples*

EGi id	Hole_ID	Interval (m)	Rock Type	Total Carbon (%C)	Organic Carbon (%C)	Inorganic Carbon (%C)	CNV	ANC	ARD Class
8080	BADD043	59-60	XSB	1.16	0.02	1.15	94	134	NAF
8078	BADD042	69-70	VFRD	0.57	0.02	0.56	46	76	NAF
8056	BADD033	64-65	VFRD	0.81	0.02	0.8	65	95	PAF
8007	BADD034	79-80	VFRD	1.53	0.03	1.5	123	165	NAF
8114	BADD038	99-100	XSB	1.14	0.02	1.14	93	135	NAF

Key
CNV = Carbonate Neutralising Value (kg H_2SO_4/t)
ANC = Acid Neutralising Capacity (kg H_2SO_4/t)

Carbonate Neutralising Value

The carbonate neutralising value (CNV) is an indirect measure of the inherent buffering capacity within a sample based on the inorganic carbon content. The CNV determination assumes that all inorganic carbon occurs as reactive carbonate, and it was calculated by multiplying the inorganic %C by 81.67. Figure 11 shows a plot of CNV versus ANC for the five drill core samples.

***FIGURE 11:** Comparison of ANC and CNV for Barbara drill core samples*

Overall, there was good agreement in the neutralisation potentials determined by the two methods, albeit that the ANCs were consistently higher for these samples. The source of the difference has not been determined. The correlation of CNV and ANC suggests that a relatively simple total carbon assay could be useful for operational differentiation of rock with moderate to high neutralisation capacity that would be suitable for use in mitigating the acid potential of PAF waste within the waste rock dump.

Acid Buffer Characteristic Curves

The buffer curves for the five samples were produced by recording the pH of sample suspensions titrated with dilute H_2SO_4 over a period of about 18 to 24 hours. The titration method provides a far less aggressive treatment of a sample than that applied in the ANC method (which involves reaction at around pH 1 to 2) and hence provides a measure of the buffering provided by more soluble carbonates within a sample. This type of buffering is typically characterised by a plateau at around circum-neutral pH at the start of the titration curve, and the extent of the plateau can be used as an indicator of the fraction of ANC that would likely be available to maintain pH neutral conditions, which is usually required if the material is to be used for ARD mitigation when it is essential to maintain low metal solubilities.

The buffer curves for individual sample are presented in Appendix E, together with buffer curves for reference samples representing limestone, dolomite, ferroan dolomite, magnesite and siderite. A compilation of the buffer curves for all five samples is also shown in Figure 12.

FIGURE 12: *Acid buffer curves for Barbara drill core samples with high ANCs*

All five samples produced well-defined buffer plateaus at between pH 6 to 8 that were characteristic of the buffering provided by limestone or dolomitic rock[6]. The curves suggest that most of calcareous minerals within the samples were reactive and would be readily available for pH buffering under circum-neutral conditions.

There is no definitive method of quantifying the fraction of ANC that is readily available, but a useful guide adopted by EGi is the amount of acid that is required to acidify a sample to pH 5, as this generally coincides with the point where the buffer curves begin to decline sharply. Table 3 gives the "readily-available" neutralising capacities (expressed as kg H_2SO_4/t) for the five samples based on the pH 5 criterion. The percentage of ANC that was readily available typically ranged from 70 to 93% of the ANCs measured using the Sobek method.

Overall, the results suggest that most of the neutralising capacity in rock with moderate to high ANC should be readily-available. It is therefore expected that NAF waste with similar characteristics to the test samples would be suitable for use in mitigating the ARD potential of PAF waste should it be encountered. This could include blending with PAF waste to negate its acid potential and/or construction of NAF layers encapsulating PAF waste within the dump. Further discussion on utilisation of carbonate rock for ARD control at Barbara is provided in Section 6.2.

***TABLE 3**: Readily-available neutralising capacity based on acid buffer characteristic curves*

EGi id	Hole_ID	Interval (m)	Rock Type	CNV	ANC	Readily Available ANC*	Percent Readily Available
8080	BADD043	59-60	XSB	94	134	118	88%
8078	BADD042	69-70	VFRD	46	76	71	93%
8056	BADD033	64-65	VFRD	65	95	82	86%
8007	BADD034	79-80	VFRD	123	165	116	70%
8114	BADD038	99-100	XSB	93	135	107	79%

Key
CNV = Carbonate Neutralising Value (kg H_2SO_4/t)
ANC = Acid Neutralising Capacity (kg H_2SO_4/t)
* Readily available based on tiration to pH 5

6 Calcite and limestone are usually readily available for neutralisation and can maintain a plateau at circum-neutral pH up until almost all of the ANC is consumed. Dolomite is also usually reactive, however the reactivity may decline when there is significant iron substitution, such as with ferroan dolomite. In contrast, magnesite and siderite are usually poorly reactive at circum-neutral pH, and significant dissolution of these carbonates often only occurs under laboratory conditions when the pH drops below about 4.

5.0 Elemental Characteristics of Waste Rock

5.1 Elemental Composition of Solids

Twenty-six samples from across the deposit were selected for multi-element analysis. The samples included 19 samples representing waste rock and seven representing ore grade materials. The distribution of samples between rock types was as follows:

Waste

- VFRD 14 samples (9 NAF / 2 UC / 3 PAF)
- VFR 1 sample (NAF)
- IMD 1 sample (NAF)
- XSB 1 sample (PAF)
- XAO 1 sample (NAF)

Ore

- VFRD 3 samples (1 NAF / 2 PAF)
- IMD 1 sample (NAF)
- XSB 2 samples (1 NAF / 1 PAF)
- XSO 2 samples (1 NAF / 1 PAF)

The analysis of the drill core samples included the following suite of elements: Al, As, Ba, Be, Bi, Ca, Cd, Co, Cr, Cu, Fe, Hg, K, Li, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Sn, Sr, Th, U, and Zn

The elemental compositions of the 26 samples are tabulated in Appendix F, and statistical box plots of the results for waste and ore samples are given in Figures 13 and 14, respectively.

5.2 Geochemical Abundance Indices

To provide some relativity to the multi-element data, the compositions of the solids were compared to typical concentrations reported for soil in non-mineralised areas. The purpose of this comparison was to highlight any elements that were significantly enriched, especially elements that are generally regarded as environmentally important. The comparison is expressed as a Geochemical Abundance Index (GAI), which relates enrichment to the median soil abundance value using the formula:

$$GAI = \log_2 [C / (1.5*S)]$$

where C is the concentration of the element in the sample and S is the median soil[7] content for that element. It should be noted that median soil contents are based on typical values for soils from non-mineralised areas, and do not represent the actual soils occurring at the Barbara project area.

[7] References for median soil data were: (1) Bowen, H.J.M. (1997) Environmental Chemistry of the Elements. Academic Press, London. (2) Berkman, D.A. (1976) Field Geologists' Manual, The Australian Institute of Mining and Metallurgy, Parkville, Victoria, Australia

***FIGURE 13**: Box plot of elemental concentrations in Barbara drill core samples representing waste*

***FIGURE 14**: Box plot of elemental concentrations in Barbara drill core samples representing ore*

GAIs are truncated to integer increments (0 through to 6, respectively) where a GAI of 0 indicates the element is present at a concentration similar to, or less than, median soil abundance and a GAI of 6 indicates approximately a 100-fold, or greater, enrichment above median soil abundance.

The enrichment ranges for the GAI are as follows:

Little or No Enrichment
GAI = 0 < 3 times median soil

Minor Enrichment
GAI = 1 (3 to <6 times) or GAI=2 (6 to <12 times)

Significant Enrichment
GAI = 3 (12 to <24 times), 4 (24 to <48 times), 5 (48 to <96 times) or 6 (≥ 96 times)

The GAIs for the Barbara samples are given in Appendix G, and Figures 15 and 16 provide graphical summaries of the frequency of enrichment factors for each element for waste samples and ore samples, respectively.

Ore Samples

As would be expected, all of the ore samples assayed were significantly enriched (GAI≥3) with copper and sulphur, and most were significantly enriched with selenium, bismuth and cobalt. One of the seven ore samples (8112) was also significantly enriched with arsenic (114 mg/kg), and some samples exhibited minor enrichment (GAI of 1 or 2) with nickel.

Waste Rock Samples

Some waste rock samples were also significantly enriched with copper, sulphur and selenium relative to concentrations typically reported for background soil. In the case of copper the concentrations in the waste samples were generally markedly less than in ore, but high in comparison to soil in non-mineralised areas.

There was also evidence of minor enrichment (GAI of 1 or 2) of some waste samples with bismuth and cobalt, but otherwise the results suggest that other environmentally important elements typically occurred at concentrations approximating background soil. They included antimony, arsenic, cadmium, chromium, lead, manganese, mercury, nickel, tin and zinc.

***FIGURE 15**: Frequency distribution plot of GIAs in Barbara drill core samples representing waste*

***FIGURE 16**: Frequency distribution plot of GIAs in Barbara drill core samples representing ore*

5.3 Salinity

The ECs of all drill core samples were measured as part of the initial acid-base characterisation to provide an indirect measure of content of soluble salts with freshly mined rock, and to assess the potential for development of saline drainage if the material is exposed to atmospheric conditions. The ECs were measured on 1:2 (w/w) suspensions of pulp samples equilibrated for at least one hour. Figure 17 shows a statistical plot of the EC values for different Barbara rock units.

***FIGURE 17**: Summary of the EC values for Barbara drill core samples split by rock unit*

For VFRD, which is the dominant waste unit, the ECs were generally indicative of low concentrations of dissolved salts. Approximately 72% of the 87 samples from this unit had ECs of less than 400 µS/cm, which generally signifies that a sample is *non-saline*. A further 21% had ECs between 400 and 800 µS/cm which signifies that a sample is *slightly saline*. These results, together with the existing pH results discussed in Section 4.1, suggest that drainage from freshly mined, run-of-mine waste rock will be circum-neutral or slightly alkaline and have relatively low concentrations of soluble salts.

Thirteen of the 121 drill core samples tested did have ECs exceeding 800 µS/cm, suggesting that materials as represented by those samples could initially leach some soluble salts if exposed to atmospheric conditions. All but one of the 13 samples were representative of ore with high to very high sulphur contents. The samples with ECs exceeding 800 µS/cm were from the VFRD (1 waste and 5 ore samples), XSO (3 ore samples), XSB (3 ore samples), and IMD (1 ore sample) rock units.

5.4 Water Extractable Elements

The elemental assays discussed above provide an indication of elements that are enriched within the solids relative to concentrations typically found in non-mineralised soil. However, a significant GAI does not necessarily mean that an element will be a concern for water quality, and similarly, a low GAI value does not necessarily mean that an element will not be of environmental concern.

The potential for leaching of metals, metalloids and other elements of environmental interest was assessed using two leaching procedures. The first was batch extractions with deionised water to provide insights into solutes that might be released from freshly mined NAF and PAF materials immediately following exposure to atmospheric conditions, and hence provide an indication of the quality of drainage that might ensue a rainfall event.

The second leaching test involved extraction with hydrogen peroxide. The peroxide extractions were focused on PAF materials and the aim was to provide an indication of drainage quality from sulphidic rock after prolonged exposure resulting in significant sulphide oxidation and potential acidification. The results of the peroxide extractions are discussed in Section 5.5.

Water extraction tests were carried out on the same selection of 26 samples that were assayed for multi-elements, which included 18 samples representing waste rock and 8 samples representing ore grade materials. The tests water extractions were carried out on crushed coarse residue (minus 3.35 mm) at a solid:water ratio of 1:2. The use of deionised water meant that extraction occurred at the existing pH of a sample. The analysis of the water extracts included the following suite of elements: Ag, Al, As, B, Ba, Be, Ca, Cd, Cl, Co, Cr, Cu, F, Fe, Hg, K, Mg, Mn, Mo, Na, Ni, P, Pb, Sb, Se, Sn, SO_4, Sr, Th, U, and Zn.

The results of the water extraction tests are provided in Appendix G, and statistical box plots of the results for waste and ore samples are given in Figures 18 and 19, respectively. The main findings of the water extraction tests involving waste rock and ore grade samples were as follows:

Waste Rock Samples

- The water extracts of all of the 18 waste samples were slightly alkaline, with pHs ranging from 8.6 to 9.0 and the median was 9.0.
- The ECs were low, with values ranging from 78 to 645 µS/cm and a median of only 200 µS/cm. This again indicates that drainage from freshly mined waste rock as represented by the test samples will have low concentrations of soluble salts.
- For the majority of waste samples the dominate ions released into solution were potassium (median 25 mg/L), sodium (median 11 mg/L), sulphate (median 13 mg/L) and chloride (median 13 mg/L).
- Sulphate concentrations for PAF waste were, on average, slightly higher than for NAF waste. Other differences were relatively minor.

***FIGURE 18**: Box plot of elemental concentrations in water extracts of Barbara drill core waste samples*

***FIGURE 19**: Box plot of elemental concentrations in water extracts of Barbara drill core ore samples*

- There were trace concentrations of aluminium in most extracts (median 0.19 mg/L), but the concentrations of copper and other environmentally important elements were low, and in most cases the concentrations were close to, or below, the analytical detection limits.
- The median concentrations of environmentally important elements in the water extracts of waste samples were as follows:
  - ≤ 0.0001 mg/L Hg, Cd
  - ≤ 0.001 mg/L Cr, Co, Mn, Ni, Pb, Sb, Sn
  - ≤ 0.002 mg/L As, Cu
  - ≤ 0.005 mg/L Mo, Zn:
  - ≤ 0.01 mg/L Se
- The low concentrations of soluble copper (and other metals) are consistent with the alkaline pH of waste rock samples, as the solubilities of most metals are highly pH dependent and typically are only sparingly soluble at circum-neutral or slightly alkaline pH.

Ore Samples

- Although the ore samples had significant sulphur contents and four of the eight were PAF, the compositions of the water extracts were in most respects similar in composition to the extracts of the waste rock samples, the only real difference being higher concentrations of sulphate (median 380 mg/L versus 13 mg/L for waste) and magnesium (median 18 mg/L versus 1 mg/L for waste). The higher concentrations of sulphate and calcium are consistent with the higher ECs reported for some ore samples as discussed in Section 5.3.
- Otherwise, all the ore extracts were slightly alkaline and the concentrations of environmentally important elements were low, with the possible exception of manganese which for the ore samples exhibited a median concentration of 0.16 mg/L compared to 0.001 mg/L for the waste samples.

The composition of a water extract basically represents a state of chemical equilibration between the liquor and solids phases at the natural pH of the material. The results are therefore generally applicable to the same material in the field when freshly mined. This being so, the results of the water extractions tests suggest drainage from freshly mined waste rock will typically be slightly alkaline and have low concentrations of soluble salts, and metals.

Similarly, it is expected that the drainage from stockpiles of recently mined ROM ore would be alkaline and have low concentrations of dissolved metals, but there could be some leaching of sulphate from high grade ores.

5.5 Peroxide Extraction Results

The purpose of the peroxide extractions was to provide indicative data on any metals or metalloids that might be released from sulphidic waste rock or ore grade materials as represented by the samples if there was prolonged exposure to atmospheric conditions leading to extensive sulphide oxidation and, in the case of PAF rock, development of acidic conditions. The potential for generation of ARD by some rock has

implications for the quality of pit water where sulphidic rock is exposed on final walls, and for the qualities of drainages from the waste rock dump or ROM ore stockpiles.

The peroxide extractions were based on the single-stage NAG test. As described previously in this report, the NAG test involves reaction of a sample with hydrogen peroxide to rapidly oxidise any sulphides that are present. Normally only the pH and acidity of the NAG solution are measured following the oxidation stage, but with these tests a sub-sample of the NAG solution was filtered and then assayed for multi-elements to discern the extent of any elemental releases from the samples as a consequence of sulphide oxidation. The peroxide extracts were assayed for the same suite of elements as the water extracts, namely: Ag, Al, As, B, Ba, Be, Ca, Cd, Cl, Co, Cr, Cu, F, Fe, Hg, K, Mg, Mn, Mo, Na, Ni, P, Pb, Sb, Se, Sn, SO_4, Sr, Th, U, and Zn.

Peroxide extractions were carried out on a selection of 12 samples that included six samples representing ore, all of which were classified PAF, and six samples representing waste, five of which were PAF and the classification of the sixth was uncertain (UC).

The compositions of the 12 peroxide extracts are tabulated in Appendix I.

All of the waste samples acidified to some extent during peroxide extraction, with the final pHs ranging from 3.0 to 4.6. With the ore samples, four acidified during peroxide extraction to pHs between 2.9 to 4.3. The other two ore sample (8039 and 8056) remained circum-neutral (pH 7.7 and 7.8), notwithstanding that both had high sulphide contents (4.28 and 3.77 %S) and were classified as PAF based on positive NAPP and NAG test results. The lack of acidification during the peroxide extraction tests can be attributed to the two samples having high ANCs (95 and 93 kg H_2SO_4/t). As was discussed in Section 4.1, such samples typically require a multiple sequential extractions to induce an acidic state.

Unlike the water extract results discussed in Section 5.4, the compositions of peroxide extractions are not directly meaningful for the field situation because they are a function of both the volume of peroxide used per unit weight of sample and the amounts of elements released from a sample as a consequence of sulphide oxidation. The 100 mL/g used for the peroxide extraction is high in comparison to leach rates typically used in long term, column leach tests. The leach rates for columns routinely run by EGi typically average around 50 to 100 mL/kg/week, which over a five year period equates to a ratio of around 20:1. Therefore, to provide some relativity of the data to the field situation and also "average" leachate quality that might be expected from the same samples under standard column leach test conditions, a 5-times scaling factor[8] was applied to concentrations reported for the peroxide extracts.

[8] This scaling factor is based on the premise that for typical mine rock containing (say) 1 to 2 %S as pyrite it typically takes several years to substantially complete the oxidation process under the typical leach column set-up used by EGi. Assuming a five-year period and an average leaching rate during that period of 75 mL/kg/week gives an effective ratio of liquor to solids after five years of approximately 20:1, which is about five-times lower than the ratio for the peroxide extraction test. Clearly, a single scaling factor will not be appropriate for all material types given that geochemical behaviour under column leach conditions depends on a number of variables including sulphide content, the extent of any lag period, and the reactivity of the sulphides present. From past experience, EGi has determined that concentrations in peroxide extractions carried out at a solid to liquor ratio of 1:100 are typically between 3 to 10 times lower than average concentrations typically recorded for leachates from the same materials in standard column leach tests. Therefore, peroxide extract concentrations typically need to be increased in the order of 5-times to provide a reasonable guide to what might be expected from column leach tests.

Figure 20 is a statistical box plot of the scaled compositions of the peroxide extracts for the 10 samples that did acidified (which includes both waste and ore), and Figure 21 gives the same type of plot for the two ore samples that remained circum-neutral.

As expected, the extracts of samples that acidified had high concentrations of sulphate, iron and aluminium, which are the major elements commonly observed in ARD from PAF rock. There were also high concentrations of dissolved copper. The median and maximum scaled concentrations for these elements for the 10 samples were approximately:

- sulphate 1700 mg/L median 4848 mg/L maximum
- copper 130 mg/L 790 mg/L
- iron 35 mg/L 635 mg/L
- aluminium 35 mg/L 74 mg/L.

There were also releases of other environmentally important elements, albeit at concentrations one or two orders of magnitude less than copper. For example:

- cobalt 1 mg/L median 10 mg/L maximum
- manganese 4 mg/L 16 mg/L
- nickel 3 mg/L 12 mg/L
- zinc 1 mg/L 2 mg/L.

There were also significant releases of calcium (median 138 mg/L) and magnesium (median 47 mg/L) that presumably resulted from the reaction of ANC by some of the acid produced by sulphide oxidation.

Elements that were not released to any significant extent in comparison to the metal mentioned above included:

- mercury median ≤0.0005 mg/L
- antimony, cadmium, lead & tin median ≤0.005 mg/L
- chromium median <0.01 mg/L
- arsenic median 0.02 mg/L
- selenium median 0.2 mg/L

The results for the two PAF ore samples that remained circum-neutral provide an indication of conditions that might apply during the lag phase, when the initial acid produced by sulphide oxidation is being neutralised by the inherent ANC of the material. Although results are available for two samples only, they indicate significant releases of sulphate (1580 & 1835 mg/L) and calcium (555 and 655 mg/L) consistent with acid generation then neutralisation by carbonate mineralisation. There was also some copper release (13 and 0.6 mg/L) but only low concentrations of iron and aluminium, consistent with the low solubilities of these two elements at circum-neutral pH.

FIGURE 21*: Box plot of elemental concentrations in non-acidic peroxide extracts of PAF Barbara drill core samples*

6.0 Summary and Implications for Waste Rock Management

6.1 Summary and Findings

This report presents the results from static testing of drill core samples for the Barbara Copper Project. The main aims of the geochemical testing program were to define the range of acid forming characteristics likely to be exhibited by waste rock and ore grade materials, and to assess the implications for the quality of mine drainage, with particular emphasis on the potential for generation of ARD and release of environmentally important elements from the waste rock dump and within the final pit void. The assessment program and the main findings were as follows:

Assessment Program

- The geochemical assessment was based on testing of a total of 121 drill core samples from 14 diamond drill holes.
- The samples were selected by EGi in consultation with the Joint Venture and were considered to be representative of the range of rock types that will be mined during the Barbara Project.
- The selection of samples included representative samples of waste and ore grade materials. Approximately three-quarters of the samples were waste and one-quarter ore.
- The dominant rock types were porphyry rhyolites (90 samples) and biotite schists (20 samples). There were also limited numbers of samples representing numerous minor rock units that included dolerite (4 samples), basalt (2 samples), mafic intrusive (2 samples), psammite (2 samples) and gossan (1 sample).
- It should be noted that the proportional representation of samples across different lithologies does not necessarily correspond with the relative amounts of these materials that will be mined as waste, or the relative amounts that will be exposed on pit walls within the final void. Such estimates will require a much greater sampling intensity than that carried out for this exploratory ARD assessment study.
- The acid forming characteristics of all samples were determined using standard static testing procedures. They included determination of existing pH, EC, sulphur content, ANC, MPA, NAPP, and NAG capacity. Other testing carried out on selected samples included sequential NAG tests, kinetic NAG tests, acid buffer curves, multi-element analysis, and water and peroxide extraction tests.

Geochemistry of Waste

- Although the Barbara Project will involve the mining and processing sulphidic ore, the results of this study suggest that the majority of waste rock will have a low sulphur content and will be NAF.

- Waste from the near-surface weathered zone will likely have little ANC and hence will essentially be barren with respect to both acid generation potential and acid neutralisation potential.
- Most other NAF waste rock should have moderate ANC that will be at least several times greater than any acid that might be produced from any contained sulphides. It is expected that drainage from run-of-mine NAF waste rock will be neutral to slightly alkaline and have low concentrations of soluble salts and environmentally important metals and metalloids.
- Approximately 20% of NAF waste samples had ANCs exceeding 50 kg H_2SO_4/t. Such material would be ideally suited to ARD mitigation measures if required, such as blending with, or encapsulation of, PAF waste.
- Some PAF waste samples with elevated sulphur contents (*i.e.* 0.71 to 4.27 %S) were identified in this study. At this stage there are insufficient samples to ascertain the overall occurrence of PAF waste for the proposed pit, but most of the PAF waste samples in this study were located in the northern mining zone and it is expected that most PAF waste will be localised and close to the ore zones and not widely distributed throughout the entire mining area.
- The results of the kinetic NAG tests suggest sulphide mineralisation in PAF waste is reactive and will oxidise if the material is exposed to atmospheric conditions. However, a lag period of at least a year, and possibly several years can be expected for typical PAF waste with an ANC of more than 20 kg H_2SO_4/t. During this lag period it is expected that any drainage resulting from exposure to atmospheric conditions would remain circum-neutral but would likely have elevated concentrations of sulphate and calcium. There may also be some release of copper, but only low concentrations of iron and aluminium would be expected commensurate with the low solubilities of these two elements at circum-neutral pH.
- In the event of long term exposure of PAF waste leading to development of acid conditions there would likely be significant increases in the concentrations of dissolved metals within drainage. In addition to copper, iron and aluminium, there would likely be significant concentrations of cobalt, manganese, nickel and zinc.

Geochemistry of Ore Grade Materials

- As would be expected, most of the 27 ore samples tested in this study had high to very high sulphide contents but only half were classified as PAF.
- The occurrence of NAF ore can be attributed to moderate to high ANC. The median ANC for the NAF ore samples close to 100 kg H_2SO_4/t, which equates to approximately 10 %$CaCO_3$ equivalent.
- Most of the PAF ore samples tested in this study also had significant ANC, with a median for the test samples close to 50 kg H_2SO_4/t. An ANC of this magnitude would be expected to significantly delay formation of acid conditions.
- Based on the results of this study a lag of at least a year would be expected for ROM ore. Given that ore will be trucked off-site for processing, it is expected that the residence times for ore stockpiles on site would be shorter than the expected average lag period for ROM ore.

- It is expected that the drainage from stockpiles of recently mined ROM ore will be alkaline and have low concentrations of dissolved metals, but there could be some leaching of sulphate from high grade ores.
- However, in the event that high sulphide ore is exposed long term there would be a significant risk of generation of low pH, high sulphate drainage with high concentrations of environmentally important elements. As such, from an environmental viewpoint it would be advisable to preferentially transport high sulphide ore off-site as soon as possible.

6.2 Operational Identification of PAF Waste

- The methods used in this study to assign NAF/PAF classifications provide the most accurate means of assessing the acid forming potential, and the results of this study provided an indication of the occurrence of materials with ARD potential. However, it is expected that the NAPP and NAG data currently available will not be sufficient for detailed block modelling of the Barbara resource in relation to NAF/PAF waste classification.
- Furthermore, implementation of a selective handling strategy will require development of protocols to ensure PAF rock can be identified prior to mining so that problematic waste can be handled and placed within the dump in a correct manner.
- A protocol based on total sulphur content may be sufficient for development of a preliminary waste schedule, and/or may be adequate for operational use. It is understood that a sulphur database of considerable size already exists that could be used for modelling and planning purposes.
- Based on the results of this study it is recommended that a sulphur cutoff value of 0.3 %S is initially used for NAF/PAF classification of waste rock.
- A cut-off of 0.3 %S will capture almost all rock with a significant ARD risk, and provide a degree of conservatism in that many of the samples in this study containing more than 0.3 %S were NAF.
- A few samples containing less than 0.3 %S did acidified slightly under NAG test conditions and their ARD classifications were uncertain. In the event that some waste containing less than 0.3 %S was PAF, the total amount of acid it could produce would be low, and most likely negated as a consequence of general mixing with run-of-mine NAF rock during excavation and dumping operations.
- During operations, additional samples for confirmation of sulphur content can be taken from grade control holes, blast holes, and/or channel and face samples from benches.

6.3 Implications for Waste Rock Management

- A detailed NAF/PAF waste schedule for the project is not yet available but preliminary block modelling of the Barabara deposit by the Joint Venture indicates that approximately 85-90% of total waste rock will have a total sulphur content of less than 0.3 %S. As noted above, a cutoff of 0.3 %S is considered to be conservative in relation to NAF/PAF classification, hence the preliminary indication is that less than 15% of waste rock will be PAF. The high ratio of NAF to PAF waste rock means problematic material can be accommodated within the core of the waste rock dump in a

manner that provides long-term geochemical stability, thereby limiting the potential for sulphide oxidation or metals leaching.

- Preliminary block modelling also indicates that most waste with a sulphur content exceeding 0.3 %S is localised around the ore zone, which will simplify operational identification of PAF material requiring selective handling and management.
- Notwithstanding these expectations, there will be a need for diligent management of any waste rock that is identified as PAF to obviate the ARD risk. The overall goal of waste rock management at the Barbara site must be to place all PAF waste rock within the final dump landform so that long-term generation of ARD from the PAF rock does not occur or is restricted to a rate that can be readily assimilated *in-situ* by the surrounding NAF material so the resultant dump seepage is of a quality that will not adversely impact the downstream environment.
- As most NAF waste rock is expected to have at least moderate ANC, there may be opportunities for blending of high ANC NAF waste with PAF waste to negate some or all of its acid potential. However, true blending is often difficult to achieve operationally, and to be effective there usually needs to be a considerable excess of carbonate mineralisation contained within the NAF material to ensure there is sufficient fines with reactivities to match potential acid generation rates of the finer fractions of PAF waste likely to be produced during mining, hauling and dumping. This generally means that the blending rate of high ANC NAF material needs to be at least several times greater than the amount theoretically needed to equal the acid potential of the PAF rock overall.
- It is therefore recommended that the management of PAF waste rock at Barbara is primarily based on segregation and selective placement of PAF rock within the dump in a manner that limits oxygen contact and leaching of PAF material within the dump, thereby limiting the exposure of PAF rock to conditions that are conducive to ARD generation processes. This is best achieved by placement of PAF waste in small compacted cells or lifts with encapsulating layers comprising compacted NAF waste.
- The design and scale of PAF cells will depend on the relative amounts of PAF and NAF rock, the NAF/PAF production schedule, and the ability to construct compacted cells or layers in a timely manner. Specific criteria for selective PAF waste placement can be developed when the production schedule for NAF/PAF waste rock becomes available.
- Cells of PAF rock can be constructed by running out the load or paddock dumping the waste rock. This approach requires a higher degree of effort, but rock generally needs to be leveled and compacted in small lifts to create cells that have a permeability that limits the transfer of oxygen.
- Although PAF waste is expected to exhibit a lag of a year or more it would be preferable from an environmental perspective to close out PAF cells as soon as possible, and prior to any expectation of seasonal rain.
- Ideally, higher ANC NAF material should be placed immediately over PAF cells to provide some additional alkalinity to any water that does leach down into cells, prior to further encapsulated by layers comprising compacted run-of-mine NAF waste.

- T o provided a high level of geochemical stability, high ANC NAF rock can be interlayered with PAF material in small lifts to produce a cell that, overall, is non-acid forming. An overall ANC/MPA ratio for each cell of greater than 3 is generally recommended.
- It is essential that no PAF waste rock is placed within the outer zones of dumps where convective transport of oxygen can occur. Also, PAF rock should be excluded from under final outer slopes as this will facilitate final closure by reducing the need for infiltration control on slopes.

6.4 Pit Water Quality

- The potential for exposure of some PAF rock around the pit shell has implications for pit water quality, especially late in mine life and closure. The current level of knowledge of Barbara pit geochemistry, geomorphology and hydrogeology is not sufficient for detailed modelling of pit water quality, but it seems likely that some sulphide mineralisation will be exposed on the final pit floor and footwall benches as these final surfaces will be close to ore zones.
- In the longer term, it is expected that exposed PAF rock will produce localised ARD during rainfall events, and that the resultant pit drainage could have elevated concentrations of sulphate, iron, aluminium and copper, and possibly other environmentally important elements.
- The impact on pit water quality overall will depend on the extent of PAF rock exposure relative to total pit area. If PAF rock represents only a small fraction of total pit wall area then it is likely that any ARD produced would be diluted and neutralised to some extent by the much larger volume of alkaline runoff from NAF rock around the pit.
- During operations, the use of high ANC waste for sheeting roads within the pit will also provide additional alkalinity to mine drainage to mitigate any ARD inputs.
- It is recommended that more detailed investigation of the geology and geochemistry of the final pit shell is carried out, with particular emphasis on the final pit floor and footwall benches. Such investigation should be carried out during the early stages of operations to allow sufficient time for mine planning to minimise the extent of exposure of PAF material in the final shell and/or for planning the management of PAF material within the waste rock dump.
- The prediction of pit water quality during operations and post mining will require development of a hydrogeochemical model that integrates geochemical processes such as pyrite oxidation, acid generation and metals solubility with hydrologic factors relating to surface water fluxes (rainfall and evaporation) and groundwater fluxes within the pit limits.

Key Lithology

IMD	Dolerite	**VMB**	Basalt
IMO	Mafic Intrusive	**XAO**	Amphibolite
RZO	Gossan	**XSB**	Biotite schist
VFR	Rhyolite	**XSBH**	Biotite-chlorite schist
VFRP	Porphyritic rhyolite	**XSO**	Schist

Key ARD Parameters

pH	Existing pH (1:2 extract)	**NAPP**	Net Acid Producing Potential (kg H_2SO_4/t)
EC	Electrical Conductivity (µS/cm))	**NAG**	Net Acid Generation capacity (kg H_2SO_4/t)
MPA	Maximum Potential Acidity (kg H_2SO_4/t)		(* signifies sequential NAG result)
ANC	Acid Neutralising Capacity (kg H_2SO_4/t)	**NAG pH**	pH of NAG liquor
Ratio	Ratio of ANC to MPA results		

Material Type

ore*	Below grade sample but sample occurs within the 0.5 %Cu halo
waste **	Waste sample that occurs on the edge of ore zone
waste ***	Small waste band within ore zone

Key ARD Classification

NAF	Non-Acid Forming
PAF	Potentially Acid Forming
UC	Uncertain

Appendix C

Sequential NAG Test Results for Barbara Drill Core Samples

Appendix D

Kinetic NAG Test Profiles for Barbara Drill Core Samples

APPENDIX D-1: Kinetic NAG test profiles for Barabara drill core sample BADD035: 49-50m
[Ore #8050, VFRD, 3.59 %S, ANC = 14 kg H_2SO_4/t, NAPP = 96 kg H2SO4/t]

APPENDIX D-2: Kinetic NAG test profiles for Barbara drill core sample BADD021: 139-140m
[Ore #8112, XSB, 5.37 %S, ANC = 42 kg H_2SO_4/t, NAPP = 122 kg H2SO4/t]

APPENDIX D-3: Kinetic NAG test profiles for Barbara drill core sample badd045: 27-28m
[Waste #8066, XSB, 0.73 %S, ANC = 15 kg H_2SO_4/t, NAPP = 7 kg H2SO4/t]

APPENDIX D-4: Kinetic NAG test profiles for Barbara drill core sample BADD050: 39-40m
[Waste #8092, VFRD, 1.85 %S, ANC = 21 kg H_2SO_4/t, NAPP = 35 kg H2SO4/t]

APPENDIX D-4: Kinetic NAG test profiles for Barbara drill core sample BADD046: 26-27m
[Waste #8072, VFRD, 1.47 %S, ANC = 34 kg H_2SO_4/t, NAPP = 11 kg H2SO4/t]

Appendix E

Acid Buffer Characteristic Curves for Barbara Drill Core Samples

APPENDIX E-1: Acid buffer characteristic curve for Barbara drill core sample BADD034: 79-80m
[NAF Waste #8007, VFRD, ANC = 165 kg H_2SO_4/t]

APPENDIX E-2: Acid buffer characteristic curve for Barbara drill core sample BADD038: 99-100m
[NAF Waste #8114, XSB, ANC = 135 kg H_2SO_4/t]

APPENDIX E-3: Acid buffer characteristic curve for Barbara drill core sample BADD043: 59-60m
[NAF Waste #8080, XSB, ANC = 134 kg H_2SO_4/t]

APPENDIX E-4: Acid buffer characteristic curve for Barbara drill core sample BADD042: 69-70m
[NAF Waste #8078, VFRD, ANC = 76 kg H_2SO_4/t]

APPENDIX E-4: Acid buffer characteristic curve for Barbara drill core sample BADD033: 64-65m
[PAF Ore #8056, VFRD, ANC = 95 kg H_2SO_4/t]

Appendix F

Elemental Compositions of Barbara Drill Core Samples

Berkman, D.A. (1976) Field Geologists' Manual, The Australian Institute of Mining and Metallurgy, Vic.

* Geochemical Abundance Indices (GAI)
GAI=0 represents <3 times median soil content
GAI=1 represents 3 to 6 times
GAI=2 represents 6 to 12 times
GAI=3 represents 12 to 24 times
GAI=4 represents 24 to 48 times
GAI=5 represents 48 to 96 times
GAI=6 represents more than 96 times

1 INTRODUCTION

The purpose of the Waste Rock Management Plan (WRMP) is to provide a framework for management of waste rock for the proposed Barbara Copper Project. The WRMP specifies how environmental issues related to identifying, handling and containment of waste rock will be managed during the mine life cycle. The WRMP also outlines the performance objectives and how these will be measured, monitored and reported.

This WRMP is based on the results of initial geochemical testing and classification of waste rock, and provides further details to general commitments made in the Plan of Operations related to waste rock management for inclusion in an environmental authority application.

The WRMP may be revised as required during operations as additional information becomes available such as those obtained through the monitoring procedures identified in this plan.

1.1 Objectives

The objective of the WRMP is to ensure environmentally safe and effective management of waste rock generated during mining operations. To achieve this objective, the WRMP details a practical basis whereby management measures can be part of the mine planning that includes:

- Waste rock characterisation
- Waste rock management
- Waste rock dump conceptual design
- Monitoring and reporting
- Decommissioning and closure.

2 SITE DESCRIPTION

2.1 Physical Setting

The Barbara Copper Project is located in the Shire of Mount Isa in northwest Queensland, approximately 60 kilometres (km) northeast of the town of Mount Isa. The region is characterised by thin rocky soil cover overlying bedrock. Rugged bedrock outcroppings are common. Vegetation is primarily spinifex with some shrubs and few trees.

The Barbara Copper Project straddles EPM19733 and EPM16112. The Barbara Copper Project will involve open pit development of the Barbara copper deposit, which also contains trace concentrations of gold, silver and cobalt. Mining will occur on two adjoining open pits (Barbara North Pit and Barbara South Pit) located along the North-South trending strike of the deposit, which extends over a distance of approximately 900 m. The two pits will be mined concurrently over a period of approximately 18 months.

Groundwater levels measured in 2014 within the BCP site ranged from 8.26m to 25.96m below ground surface (RLA, 2014). The nearest reading to the WRD was 25.96m bgs. No shallow aquifers were identified.

2.2 Climate

The regional climate in northwest Queensland is classed as hot semi-arid. Based on climate data collected at Mount Isa airport (Bureau of Meteorology 2014) from 1966 to 2014, the mean maximum and minimum temperature are 31.8 degrees Celcius (°C) and 17.2 °C, respectively. The mean annual rainfall is 459.3 millimetres (mm), with most rain falling between December and March. Throughout the year evaporation exceeds rainfall.

2.3 Geology

The Barbara deposit lies within the Mount Isa Inlier. The copper-gold-silver-cobalt mineralisation is structurally controlled by the Barbara Shear Zone and occurs as a series of sulfide lodes hosted within a package of felsic volcanic rocks intruded by dolerite dykes. Sulfide mineralisation comprises semi-massive pyrrhotite/pyrite with chalcopyrite and chalcopyrite stringer veins. Two phases of mineralisation occur with a low grade copper-cobalt phase overprinted with a later coarse grained, chalcopyrite-gold-silver phase which forms both hangingwall and footwall zones of higher grade mineralisation.

The majority of waste will be low sulfur rock, primarily high calcium/magnesium basalts and mafics, low calcium/magnesium felsic volcanics, and pedogenic carbonates. However, some sulfide rich waste zones occur immediately adjacent to the ore zone, primarily on the footwall, which may be mined as fresh waste or left in the end walls of the pit. This sulfide rich material can generate acid and metalliferous drainage (AMD) if exposed to atmospheric conditions.

3 WASTE ROCK CHARACTERISATION

A waste rock geochemical assessment has been completed (EGi 2014) that defines the geochemistry of waste rock materials associated with the proposed Barbara Copper Project. The assessment involved the analysis of 121 drill core samples from 14 diamond drill holes, representing the range of waste rock lithologies that will be intersected during open pit mining operations.

Each sample typically represented a 1 m interval of core, and a semi-regular sampling pattern was used to provide judicious spatial coverage of the North Pit and South Pit mining areas. The waste rock sample types analysed are shown in Table 3-1. Most of the samples had low copper concentrations and were representative of material that will likely be mined as waste. Based on the current mine plan and a copper cut-off of 0.3 % copper (Cu), thirty-one samples were classed as ore and 90 samples were classed as waste rock.

The waste rock assessment program focussed on predicting the:

- Acid generation due to the exposure of sulfide minerals in the waste rock to atmospheric oxygen and water, which can form sulfuric acid (H_2SO_4) and lead to acid drainage.
- Potential for waste rock to leach of metals (metalliferous drainage) and salts (saline drainage).

Table 3-1 Waste rock types analysed for

Lithology	Number of Samples
Porphyritic Rhyolite (VFRD)	87
Dolerite (IMD)	4
Rhyolite (VFR)	3
Mafic intrusive (IMO)	2
Biotite Schist (XSB)	15
Basalt (VMB)	2
Biotite Chloritic Schist (XSBH)	1
Psammite (XMO)	2
Schist (XSO)	4
Gossan (RZO)	1

The static geochemical testing of waste rock samples included:

- pH and electrical conductivity (EC) measurements based on a 1:2 solid to deionised water extraction
- Acid-base accounting to determine the net acid producing potential (NAPP) based on total sulfur concentrations, maximum potential acidity (MPA) and acid neutralising capacity (ANC) measurements.
- Total metal analysis of the bulk waste rock sample, and multi-element analysis of leachates generated by the 1:2 solid to deionised water extraction.
- Single stage net acid generation (NAG), and kinetic NAG measurements.

3.1 Waste Rock Geochemistry

The key findings of the EGi (2014) waste rock geochemical assessment include the following:

- Majority of waste rock will have a low sulfur content and will be non-acid forming (NAF). Eighty-seven per cent of waste rock samples were NAF and 13% PAF based on a total sulfur cut-off of 0.3%.
- Waste from the near-surface weathered zone will likely have little ANC and hence will essentially be barren with respect to both acid generation potential and acid neutralisation potential.
- Most other NAF waste rock should have moderate ANC that will be at least several times greater than any acid that might be produced from any contained sulphides.
- Drainage from NAF waste rock is expected to be neutral to slightly alkaline and have low concentrations of soluble salts and environmentally important metals and metalloids.
- Approximately 20% of NAF waste samples have ANC that exceed 50 kg H_2SO_4/t. Such material would be ideally suited to ARD mitigation measures if required, such as blending with, or encapsulation of, PAF waste.
- Some PAF waste samples with elevated sulfur contents (i.e. 0.71 to 4.27 % sulfur (%S)) were identified, with most of the PAF waste samples located in the northern mining zone and it is expected that most PAF waste will be localised and close to the ore zones and not widely distributed throughout the entire mining area.
- Sulfide mineralisation in PAF waste is reactive (based on kinetic NAG tests) and will oxidise if the material is exposed to atmospheric conditions. However, a lag period of at least a year, and possibly several years can be expected for typical PAF waste with an ANC of more than 20 kg H_2SO_4/t.
- During this lag period it is expected that any drainage resulting from exposure to atmospheric conditions during this lag period would remain circum-neutral, but likely to contain elevated concentrations of sulphate and calcium and copper.
- Significant increases in the concentrations of dissolved metals (Cu, iron (Fe), aluminium (Al), cobalt (Co), managanese (Mn), nickel (Ni) and Zinc (Zn)) within drainage is likely in the event of long term exposure of PAF waste leading to development of acid conditions.

3.2 Ore Geochemistry

The key findings of the EGi (2014) waste rock geochemical assessment include the following:

- Most of the ore samples tested in this study had high to very high sulphide contents, but only approximately 56% were classified as PAF. The remaining 44% were classified as NAF.
- Median ANC for the NAF ore samples close to 100 kg H2SO4/t, which equates to approximately 10 %CaCO3 equivalent.
- Median ANC for PAF ore was approximately 50 kg H_2SO_4/t. An ANC of this magnitude would be expected to significantly delay formation of acid conditions.
- Based on the results of this study a lag of at least a year would be expected for ROM ore. Given that ore will be trucked off-site for processing, it is expected that the residence

times for ore stockpiles on site would be shorter than the expected average lag period for ROM ore.

- Drainage from stockpiles of recently mined ROM ore is expected to be alkaline and have low concentrations of dissolved metals, but there could be some leaching of sulfate from high grade ores.
- Significant risk of generation of low pH, high sulfate drainage with high concentrations of environmentally important elements is expected in the event that high sulfide ore is exposed long term.

3.3 Geotechnical Properties

The NAF rock is primarily comprised of fresh, felsic to mafic volcanic rock. Although the waste rock has not been subjected to geotechnical testing, it is conservatively assumed the mined waste rock will be able to maintain an angle of repose of 37 degrees (°) on the working face of the waste rock dump.

3.4 Waste Rock Quantities

The estimated total amount of waste rock expected to be mined from the Barbara Copper Project is summarised in Table 3-2. The estimated mineral waste volumes were calculated based on the current final pit shell designs (19 September 2014) and the available mining block models.

The total amount of waste rock generated by the Barbara Copper Project is estimated at 8 million tonnes (Mt), with approximately 13% expected to be PAF based on total sulfur cut-off of 0.3%.

Table 3-2 Estimated waste rock volumes

Total Waste Rock (million tonnes)	Waste Rock Volume (million cubic metres)	Waste Type	Total Amount (Mt)	Total Volume (million cubic metres)
8	3.0 (in-situ) 3.9 (loose)	PAF	1.0	0.39 (in-situ) 0.51 (loose)
		NAF	7.0	2.64 (in-situ) 3.43 (in-situ)

The management of AMD will involve development of the mining waste schedule for life of the mining operation. The mining waste schedule identifies the volume and timing of extraction of NAF and PAF waste rock, and will be used to design the waste rock dump to limit its exposure to oxidation of PAF material during and post mining. Figure 3-1 shows the waste rock mining schedule during the life of the operation.

Figure 3-1 Waste rock mining schedule during the life of the mining operation

3.5 Waste Rock Geochemical Model

A waste rock block model has been developed to provide a basis for the initial mine planning for the proposed Barabra Copper Project. The waste rock block model was based on data compiled from 150 drill holes that form the resource definition database comprising 3906 total sulfur assays using a sulfur cut-off at <0.3%S.

Cross-sections through the Barbara ore deposit showing the distribution of the NAF and PAF waste and ore units are provided in Appendix A.

4 WASTE ROCK MANAGEMENT

Waste rock which will be placed in an out-of-pit waste rock dump located approximately 500m from the South Pit. NAF waste rock materials, with suitable geotechnical properties, will be used for construction of the ROM pad, access and haul roads, process areas and office areas. The remainder of the NAF will be used to encapsulate PAF waste in the waste rock dump.

There may be an opportunity to move some potentially acid generating waste rock into the Barbara North Pit; however, the feasibility of this management strategy is yet to be determined.

4.1 Waste Rock Classification

The proposed Barbara Copper Project waste rock classification system consists of two waste rock material types that are defined by the total sulfur concentrations (Table 4-1).

Table 4-1 Barbara Copper Project Waste Rock Classification System

Total Sulfur Concentration	Waste Description	Estimated Delay to Onset of AMD
≥ 0.3%	PAF	Approximately 1 year, and possibly several years
< 0.3%	NAF	-

4.2 Waste Rock Mining and Segregation

Based on the outcomes of the EGi (2014) geochemical assessment program, the recommended management of PAF waste rock for the Barbara Copper Project is mainly based on segregation and selective placement of PAF waste rock within the waste rock dump in a manner that limits its exposure to conditions (i.e. atmospheric oxygen and water) that are conducive to AMD generation and leaching processes.

The key to the success of this WRMP is to identify the various waste rock material types in the field and at the active mining face. This approach will require a material identification system, including:

- Survey control on a daily basis (or as required) based on material movement records.
- Maintaining an up to date waste rock block model.
- Mapping of pit walls and mined faces according to the lithological domains used on-site.
- Blasthole sampling and logging to assist in this waste characterisation.
- Visual inspections, sampling and field-based testing to differentiate NAF and PAF material.
- Confirmatory laboratory-based analysis of selected samples to support field-based testing.

Blast hole cuttings would be collected during blasting operations for analysis at the onsite laboratory or similar facility. A sample density of 1 in 10 blast holes is considered adequate to perform the required waste rock segregation, recognising that the number of blast hole samples collected would depend on the geologic conditions within the blast area and the blast hole pattern.

The blast hole samples would be subjected to field-based testing, with selected samples submitted for laboratory-based testing for NAPP and NAG testing (see Section 4.3). Based on the results, the material will be classified as one of the two waste rock material types (i.e NAF or PAF). The sampling and testing will be completed on the same schedule as ore determination (if practically possible) in order to be effectively included in the mine planning process.

Records of the type of waste rock material loaded into the haul trucks, the volume of each waste rock type mined during each shift, movement and its final destination will be kept. This methodology will provide control such that waste rock types are mined and delivered to the correct location within the waste rock dump.

All of the above information will be used to assist in updating the waste rock mining schedule and quantities, and the waste rock block model.

4.3 Waste Rock Monitoring and Reporting

The waste rock management strategy involving selectively handling and placement of NAF and PAF waste rock will not be solely dependent on a laboratory-based analysis as this is subject to significant delays, leading to the potential to misplace PAF waste rock within the waste rock dump. To this end, field-based testing of waste rock material during mining operations is critical to the success of the WRMP.

4.3.1 Field-Based Testing

The main field indicator for the selective handling of PAF waste rock is related to the ability of sulfide minerals within the waste rock to generate acid, thus the field test method is designed to predict the potential to generate acidity. This method is based on field procedures originally developed for acid sulfate soils in Queensland (Ahern *et al* 1998). The field-based methodology is provided in Appendix C.

It should be noted that the analysis of waste rock samples using the field based testing method will need to be calibrated against laboratory results prior to operational implementation.

4.3.2 Laboratory-Based Testing

Selected waste rock samples will be analysed at a National Association of Testing Authorities Australia registered laboratory for the following:

- NAPP (including total sulfur, MPA and ANC)
- Single stage NAG measurements

The results will be used as a quality control process to confirm and support field-based testing.

4.3.3 Visual Inspections

Suitably qualified mine geologists will carry out weekly visual inspections on each area of the waste rock dump to evaluate the performance and condition of the facility. The toes of the waste rock dump would be checked for seepage, and if seepage is observed, the specific location and flow rate will be recorded, and a sample would be collected for water quality analysis in accordance with the Environmental Monitoring Plan for the Barbara Copper Project. These inspections will also occur as soon as practicable (e.g. when conditions are safe) after significant rainfall events.

4.3.4 Reporting

The results of the visual inspections and all field-based and laboratory-based analysis will be recorded and documented in a suitable storage system developed for the Barbara Copper Project.

5 WASTE ROCK DUMP DESIGN

The waste rock dump is designed to be a permanent storage for waste rock mined from the Barbara Copper Project. The waste dump design is based on the mining waste schedule and involves selective mining and placement of waste rock to form a waste rock dump that encapsulates the PAF material with NAF waste. The key objective of the waste rock dump design is to ensure that the final landform is safe, stable and non-polluting.

The waste rock dump design features the following items:

- NAF base
- PAF cell
- Crowned covers
- Benched batters
- Surface drainage measures
- Containment of sediment and affected waters in a dam located at the downstream toe of the waste rock dump

The conceptual design of the waste rock dump, prepared by URS, is shown in drawings 42627360-001 and 42627360-002 provided in Appendix B. The conceptual design is based on the 3-D computer-aided design (CAD) of the waste rock dump prepared by AMC Consultants Pty Ltd. Detailed design of the WRD will be required prior to commencement of WRD construction.

5.1 Waste Storage

The waste rock dump is conceptually designed as a low-profile structure to encapsulate PAF in NAF. Based on a 30% swell factor, the waste rock dump is designed to contain 3.00 million lcm of NAF plus 0.36 million lcm of PAF, for a total of 3.36 million lcm. NAF used for construction materials outside the waste rock dump amount to 0.31 million lcm, which is separate from the 3.00 million lcm reporting to the waste rock dump. The waste rock dump is approximately 28m high (measured from the crest to lowest toe) and covers a footprint of 22.95 Ha.

Prior to placement of any PAF materials, the NAF base will be constructed to provide a platform upon which the PAF will be placed. The concept design considered the phasing of NAF and PAF generation from the mine, which indicates there will be sufficient NAF mined to build the NAF base prior to PAF being mined. The purpose of the NAF base is to elevate the PAF to limit exposure to waters that may enter the waste rock dump and percolate along the original ground surface. This is a reasonable measure as the NAF will not be capped to limit infiltration. The minimum required thickness of NAF base beneath the PAF cell is 5 m.

The entire waste rock dump footprint, including the NAF base, must be cleared of vegetation and stripped of topsoil for later use during rehabilitation. Topsoil will require careful stockpile management to limit damage to the topsoil and to protect against erosion. Foundation preparation is generally not required due to the thin soil cover and hard bedrock foundation.

Placement of PAF onto the NAF base may begin once the WRD Dam is commissioned. Surface waters that pass over or through the PAF must be managed to prevent discharge to the creeks, hence the inclusion of the WRD in the defence measures.

The external batters will be at the angle of repose. Each 10 m high lift will be stepped inward by 10m to create and overall batter of approximately 2.4H:1V.

5.2 Waste Rock Dump Dam

A dam positioned downstream of the waste rock dump footprint is specified for containment of surface runoff and sediment. The nominal capacity required is 40 ML, which is approximately 20% of the design storage allowance (DSA) storage requirement. The remainder of the DSA storage requirement will be available in other storages, including the mine pit. The nominal location of the waste rock dump dam is shown in Drawing 42627360-001 (Appendix B).

The waste rock dump will be located outside the annual exceedance probability (AEP) of 1 in 100 year flood extents of the drainage path that passes the toe of the waste rock dump. The waste rock dump Dam will be comprised of NAF waste rock and lined on the upstream face to prevent water from percolating through the structure. Details of the waste rock dump dam are not provided at this time, however the dam would likely be constructed from locally available materials such as rock fill fitted with an upstream impermeable liner.

5.3 Surface Water Management

Management of surface water runoff is required during operation and for the final landform. The NAF base is to be graded to shed water away from the PAF area during operation.

Once the waste rock dump reaches the ultimate height, the surface is to be crowned to promote direct surface water falling on the waste rock dump toward the edges. The crown of the surface follows the centreline of the PAF cell. The final surface will be capped with a material that will limit infiltration and promote water shedding. The PAF area will be capped with topsoil overlying growth medium overlying a Barrier Layer. The topsoil will be spread to mimic the existing natural soil profile; if the natural topsoil cover is sporadic then the WRD cover will be the same. The growth medium acts as a growth medium for roots to penetrate the Barrier Layer. The Barrier Layer is intended to limit infiltration and to resist erosion, and will be comprised of fine material selectively sourced from the NAF material. The Barrier Layer is not expected to be a clay material. The NAF cover is similar to the PAF cover minus the Barrier Layer.

Drainage ditches are specified along the edges of the waste rock dump to channel clean surface runoff and runoff from the waste rock dump cover toward the waste rock dump Dam via the drainage chutes.

5.4 Waste Rock Placement

Generally, it is anticipated that paddock tipping will be used initially. Once an area is built up to 10m, end tipping will progress to form each NAF lift. PAF waste rock may be placed by paddock or end tipping, but must be located within the central portion of the NAF base to keep the PAF Cell at least 5m from the crest of the WRD.

5.5 Construction Considerations

The waste rock dump construction is divided into three sequential phases: clearing and stripping, placement during operations, and closure capping. The following items need to be considered for construction:

- Construction materials from NAF need to be identified and quantified during planning and design stages.
- Waste rock identification management is required throughout the mine operation to ensure PAF is properly stored.
- Dumping schedules must consider the mine schedule to avoid the situation where PAF cell growth exceeds the NAF base capacity.
- Monitoring is required to ensure the waste rock lift heights agree with the dumping plan.
- Careful scheduling is required to prevent misplacement of PAF and to meet the design requirements.
- It is recommended to employ full-time management of the WRD operation during all stages of construction to ensure final closure requirements and objectives are met.
- Dump performance monitoring and documentation including stability, erosion, and consolidation.
- Environmental monitoring of conditions at the dump including seepage water, surface water, and waste rock identification are required to verify environmental performance objectives are met.

6 DECOMMISSIONING AND CLOSURE

The decommissioning and closure design includes armouring, capping and revegetation elements placed in a layered sequence to limit erosion and infiltration and promote growth of targeted vegetation, and a surface water management system to convey runoff. These design elements are intended to create a final landform that is safe, stable and non-polluting. To this end, the following items are included in the closure design:

- Capping system: specified to promote growth of endemic vegetation and water shedding.
- Surface water management: drainage ditches western flank, and potion of the eastern flank, and drainage chutes at the groin near the WRD toe to convey runoff and limit erosion.
- Reconfiguration of the WRD Dam into a sediment catchment dam to provide sediment collection but not to retain water.

8 LIMITATIONS

URS Australia Pty Ltd (URS) has prepared this report in accordance with the usual care and thoroughness of the consulting profession for the use of CopperChem Limited and only those third parties who have been authorised in writing by URS to rely on the report.

It is based on generally accepted practices and standards at the time it was prepared. No other warranty, expressed or implied, is made as to the professional advice included in this report. It is prepared in accordance with the scope of work and for the purpose outlined in the Purchase Order Terms and Conditions.

The methodology adopted and sources of information used by URS are outlined in this the Report.

Where this report indicates that information has been provided to URS by third parties, URS has made no independent verification of this information unless required as part of the agreed scope of work. URS assumes no liability for any inaccuracies in or omissions to that information.

This Report was prepared between August and October 2014. The information in this report is considered to be accurate at the date of issue and is in accordance with conditions at the site at the dates sampled. Opinions and recommendations presented herein apply to the site existing at the time of our investigation and cannot necessarily apply to site changes of which URS is not aware and has not had the opportunity to evaluate. This document and the information contained herein should only be regarded as validly representing the site conditions at the time of the investigation unless otherwise explicitly stated in a preceding section of this report. URS disclaims responsibility for any changes that may have occurred after this time.

This report should be read in full. No responsibility is accepted for use of any part of this report in any other context or for any other purpose or by third parties. This report does not purport to give legal advice. Legal advice can only be given by qualified legal practitioners.

This report contains information obtained by inspection, sampling, testing or other means of investigation. This information is directly relevant only to the points in the ground where they were obtained at the time of the assessment. The borehole logs indicate the inferred ground conditions only at the specific locations tested. The precision with which conditions are indicated depends largely on the uniformity of conditions and on the frequency and method of sampling as constrained by the project budget limitations. The behaviour of groundwater and some aspects of contaminants in soil and groundwater are complex. Our conclusions are based upon the analytical data presented in this report and our experience. Future advances in regard to the understanding of chemicals and their behaviour, and changes in regulations affecting their management, could impact on our conclusions and recommendations regarding their potential presence on this site.

Where conditions encountered at the site are subsequently found to differ significantly from those anticipated in this report, URS must be notified of any such findings and be provided with an opportunity to review the recommendations of this report.

Whilst to the best of our knowledge information contained in this report is accurate at the date of issue, subsurface conditions, including groundwater levels can change in a limited time.

Therefore this document and the information contained herein should only be regarded as valid at the time of the investigation unless otherwise explicitly stated in this report.

Except as required by law, no third party may use or rely on, this Report unless otherwise agreed by URS in writing. Where such agreement is provided, URS will provide a letter of reliance to the agreed third party in the form required by URS.

To the extent permitted by law, URS expressly disclaims and excludes liability for any loss, damage, cost or expenses suffered by any third party relating to or resulting from the use of, or reliance on, any information contained in this Report. URS does not admit that any action, liability or claim may exist or be available to any third party.

URS does not represent that this Report is suitable for use by any third party.

Except as specifically stated in this section, URS does not authorise the use of this Report by any third party.

It is the responsibility of third parties to independently make inquiries or seek advice in relation to their particular requirements and proposed use of the relevant property.

Any estimates of potential costs which have been provided are presented as estimates only as at the date of the Report. Any cost estimates that have been provided may therefore vary from actual costs at the time of expenditure.

APPENDIX C FIELD pH PEROXIDE TEST (pH_{FOX})

The procedure for the field pH peroxide test (pH_{FOX}) is outlined below:

1 Adjust the pH of the hydrogen peroxide to pH 4.5–5.5 before going into the field.
2 Calibrate battery powered field pH meter according to manufacturer's instructions.
3 Prepare the test tubes in the test tube rack. Make sure the rack is marked with the depths so there is not confusion about the top and bottom of the drill interval being assessed. It is important to use heat-resistant test tubes for the pH_{FOX} test as the reaction can generate considerable heat (up to 90 °C). It is recommended that a tall, wide tube be used for this test as considerable bubbling may occur, particularly on highly sulfidic or organic samples.
4 Conduct pH_{FOX} tests at intervals on the drill intervals of 1 m to a maximum of 5 m composite and at least one per rock unit whichever is lesser. Do NOT composite different lithologies.
5 Remove approximately 1 level teaspoon of sample from the fine grained blast hole or drill cuttings. Place approximately half teaspoon of the sample into the pH_{FOX} test tube for the corresponding depth test.
6 Add a few millilitres of 30% H_2O_2 (adjusted to pH 4.5–5.5) to the sample (sufficient to cover the sample with peroxide) using a plastic pipette and stir the mixture. Do NOT add the peroxide to the test tube in which the pHF test was conducted, that is, the pH_{FOX} test tube should not have any deionised water in it. Beakers can be used, however glass is usually easily broken when conducting field work, and when multiple tests are being conducted it is difficult to handle large beaker sizes efficiently. Do NOT add more than a few millilitres at a time. This will prevent overflow and wastage of peroxide. A day's supply of peroxide should be allowed to reach room temperature prior to use (cold peroxide from the fridge may be too slow too react).
7 Rate the reaction of soil and peroxide using a reaction scale (see Table C-1)
8 Ideally, allow approximately 15 minutes for any reactions to occur. If substantial sulfides occur, the reaction will be vigorous and may occur almost instantly. In this case, it may not be necessary to stir the mixture. Careful watch will be needed in the early stages to ensure that there is no cross contamination of samples in the test tube rack. If the reaction is violent and the sample peroxide mix is escaping from the test tube, a small amount of deionised water (or demineralised water; not tap water) can be added (using a wash bottle) to cool and calm the reaction. Usually this controls overflow. Do NOT add too much deionised water as this may dilute the mixture and affect the pH value. It is important to only use a small amount of soil otherwise violent reactions will overflow and the sample will be lost.
9 Steps 6 to 8 may be repeated until the sample peroxide mixture reaction has slowed. This will ensure that most of the sulfides have reacted. In the lab this procedure would be repeated until no further reaction occurs, however in the field, best judgement is recommended. Usually one or two extra additions of a few millilitres of peroxide are sufficient.
10 If there is no initial reaction, individual test tubes containing the sample peroxide mixture can be placed into a container of hot water (especially in cooler weather) or in direct sunlight. This will encourage the initial reaction to occur. When the sample starts to 'bubble', remove the test tube immediately from the hot water and replace into test tube rack.
11 Wait for the sample peroxide mixture to cool (may take up to 10 minutes). The reactions often exceed 90ºC. Placing an electrode into these high temperature situations may result

in physical damage and inaccurate readings. Check the temperature range of the pH meter and probe to see what temperature is suitable. Note that a more exact pH is achieved if a temperature probe is also used; however, this may be impractical in some field situations.

12 Use an electronic pH meter (preferred method) to measure the pH_{FOX}. Rinse probe in deionised water before placing in the solution. Place a spear point electrode into the test tube, ensuring that the spear point is totally submerged in the sample:peroxide mixture. Never stir the mixture with the electrode. This will damage the semi-permeable glass membrane.

13 Wait for the reading to stabilise and record the pH_{FOX} measurement.

14 All measurements should be recorded on a data sheet.

15 Rinse pH probe in deionised water.

16 Rinse thoroughly all test tubes and racks with copious quantities of water. Use a test tube brush to remove the residue in the tube. Always wear gloves and eye protection when washing out the test tubes.

Table-C-1 pH_{FOX} Reaction Rating Scale and Interpretation

Reaction Rating	Reaction Rating	Indicative pH After Oxidation (pH_{FOX})	Interpretation
0	No reaction	> 5.5	NAF
1	Slight reaction	5.0 to 5.5	PAF
2	Medium reaction	4.5 to 5.0	PAF
3	High reaction	3.0 to 4.5	PAF
4	Very vigorous reaction, gas evolution and heat generation commonly >80 °C	< 3.0	PAF

GOVERNMENT OIL & GAS INFRASTRUCTURE POWER INDUSTRIAL

URS is a leading provider of engineering, construction, technical and environmental services for public agencies and private sector companies around the world. We offer a full range of program management; planning, design and engineering; systems engineering and technical assistance; construction and construction management; operations and maintenance; and decommissioning and closure services for power, infrastructure, industrial and commercial, and government projects and programs.

EXECUTIVE SUMMARY

This report presents the results and findings of column leach tests involving waste rock and ROM oxide samples from the Barbara mine site. The columns were laboratory scale and leaching of the test samples was carried out under controlled conditions. There were six column tests, one involving waste rock that was potentially acid forming (PAF), three representing non-acid forming (NAF) waste rock, and two representing ROM Oxide. The characteristics of the test materials were as follows:

- **PAF1** - PAF waste rock with elevated copper (0.79%Cu) and high sulphur (2.49 %S). Also some ANC (17 kg H_2SO_4/t) likely to delay the onset of acidification.
- **NAF1** - NAF waste rock with low copper content (0.02%Cu) and low sulphur (0.05 %S).
- **NAF2** - NAF waste rock with low copper content (0.02%Cu) and low sulphur (0.1 %S).
- **NAF4** - NAF waste rock with high copper content (1.05%Cu), high sulphur content (1.32 %S) and high ANC (75 kg H_2SO_4/t).
- **ROM1** - ROM oxide with high copper (0.53 %Cu) but low sulphur (0.05 %S) and classified NAF.
- **ROM2** - ROM oxide with high copper (0.95 %Cu) but low sulphur (0.1 %S) and classified NAF.

Five tests (PAF1, NAF1, NAF2, ROM1 and ROM2) ran continuously for 12 months. The sixth test initially involved a sample representing low sulphur NAF waste (referred to as NAF3) but to expand the geochemical range of test materials this sample was replaced after 8 weeks with a sample representing high sulphur NAF waste (NAF4). The subsequent leaching of NAF4 extended for 12 months. The main findings were as follows:

High Sulphur PAF Waste Rock as Represented by PAF1

The PAF1 sample representing PAF waste rock did not acidify during the 12 months test period, confirming a lag period of at least a year for this type of material. There was no evidence of significant leaching of copper or other environmentally important elements, with concentrations in leachate typically close to, or less than the limits of analytical detection. However, there was significant release of sulphate, indicating sulphide oxidation did occur during the test at a moderate rate. Over the 12 month test period the total release of sulphur was equivalent to approximately 0.03 %S. Assuming the sulphur occurred in the sample as pyrite, the release of sulphur equates to an acid generation potential of 0.9 kg H_2SO_4/t. Whilst significant, this amount of acid generation represents only a small portion of the MPA of PAF1 of 75 kg H_2SO_4/t. Therefore, after 12 months of leaching the PAF1 sample was still in the early stages with respect to sulphide oxidation and acid generation/neutralisation. As there was no evidence of any decrease in leachate pH or alkalinity during the test, and the original ANC of 17 kg H_2SO_4/t was only depleted by 5% during the 12 month period, it is likely that the lag period for waste rock as represented by PAF1 would extend for several years. During this lag period it is expected that leaching of copper would remain limited as the solubility of copper is pH-dependent. Under alkaline conditions, most of the copper released as a consequence of the oxidation of chalcopyrite should continue to re-precipitate as copper oxy-hydroxide onto waste rock surfaces. It is expected significant copper release will only occur from this type of waste rock toward the end of the lag phase when the pH of the material begins to decrease below about 6.

High Sulphur NAF Waste Rock as Represented by NAF4

The NAF4 sample represents high sulphur rock that also has moderate to high ANC and is overall NAF. The column leach test on this sample confirmed generation of alkaline drainage during the 12 month test period. There was evidence of a moderate rate of sulphide oxidation but, notwithstanding an ore-grade copper content of 1.06%Cu, there was only limited leaching of copper, with concentrations in leachate of around 0.2 to 0.4 mg/L. Given the solubility of copper is pH-dependent, there is no reason to expect any significant increase in the rate of copper leaching from this type of waste rock over the longer term, assuming the material remains circum-neutral. Apart from some copper, there was no evidence of leaching of environmentally important elements such as arsenic, cadmium, mercury, lead, zinc.

Low Sulphur NAF Waste Rock as Represented by NAF1 and NAF2

Samples NAF1 and NAF2 represent typical low sulphur, NAF waste rock at the Barbara site. In most respects, these waste rock samples can be considered geochemically benign in that the sulphide-sulphur contents were negligible and the neutralising capacities were low. Copper was slightly elevated in comparison to typical background soil, as was arsenic in NAF2, but otherwise there were no significant (GAI≥2) elemental enrichments of environmental importance.

The results of the column leach tests were consistent with the benign nature of this type of NAF waste rock. Leachates from both these columns were circum-neutral and there were only low rates of leaching of sulphate. Although copper contents were slightly elevated, there was no evidence of significant copper release, with concentrations in leachates typically less than 0.005 mg/L. However, there was minor leaching of arsenic from NAF2, with concentrations typically around 0.03 mg/L in leachates collected during the latter half of the test. And, as with other samples, the concentrations of other environmentally elements were typically close to, or less than the respective analytical detection limits.

Low Sulphur/High Copper ROM Oxide as Represented by ROM1 and ROM2

In most respects the geochemical characteristics of the samples representing ROM Oxide were similar to low sulphur NAF waste, the only difference being the copper contents of the ROM oxide samples were much higher at approximately 0.53 and 0.95%Cu, respectively. Given the low sulphur contents it can be assumed most, and probably all, of the copper occurred in oxide forms. There was some leaching of copper during the column leach tests, with concentrations in leachate typically varying between 0.1 to 1.0 mg/L. Given the weathered nature of ROM Oxide and the likelihood that the solubility of copper in such waste will be pH-dependent, it is reasonable to assume the leaching of copper from material as represented by ROM1 and ROM2 over the long term would remain much the same as the chemistry of leachate from the column tests, that is slightly alkaline, low in soluble salts, and apart from some copper, have only trace concentrations of other environmentally important elements including antimony, arsenic, cadmium, cobalt, mercury, lead, selenium and zinc.

1. INTRODUCTION

This report presents the results and findings of a column leach test program involving samples representing waste rock and ROM oxide at the Barbara Copper Project, located in north-west Queensland, approximately 50 km east of Mount Isa. The column test program was commissioned by Round Oak Minerals to better understand the geochemical behaviours of different types of waste rock and ROM oxide when exposed to atmospheric conditions. The program was co-ordinated by Environmental Geochemistry International Pty Ltd (EGi) and involved a series of six laboratory-scale, leach columns setup at EGi's geochemical laboratory in Sydney.

The column leach test is a kinetic based procedure in which samples are exposed to atmospheric conditions and allowed to react at naturally occurring rates, thereby providing data on geochemical behaviour that can be applied to analogous field situations. The exposure and drainage conditions imposed in the column test method are intentionally conducive to sulphide oxidation, and the rate of leaching is standardised so that the chemical behaviours of materials with different geochemical characteristics can be directly compared. Because of the kinetic nature the column tests, they are commonly run for a year or more to allow sufficient time for oxidation reactions and other chemical processes to become fully established.

The primary objectives of the Barbara column leach program were to quantify:

- the reactivities of sulphide mineralisation within waste rock when exposed to atmospheric conditions;
- rates of acid generation by potentially acid forming (PAF) samples under atmospheric conditions;
- the duration of lag periods preceding acidification; and
- the potential for leaching of environmentally significant elements from all types of waste rock and ROM oxide.

The column leach tests commenced on 30 August 2019, with leaching extending over 12 months during which a total of thirteen leachate collections were made. This report describes the geochemical characteristics of the test samples and the results of the column leach tests during the 12 months of testing.

2. SAMPLE COLLECTION AND DESCRIPTIONS

Six samples were initially collected by Round Oak personnel from within the South pit in July 2018 and were despatched to the EGi laboratory in Sydney for testing late. The samples were tentatively labelled by Round Oak as PAF1, PAF2, NAF1, NAF2, ROM Oxide1 and ROM Oxide2. These labels reflected the material types they were judged to represent.

Following the initial geochemical characterisation of the six samples by EGI, the PAF2 sample was re-labelled as NAF3 as it was found to have a low sulphur content and was definitively classified as non-acid forming (NAF).

Subsequently, another two samples were despatched to EGi in November 2019, one of which contained visible sulphide mineralisation and was selected for column leach testing as a replacement for the low sulphur NAF3 sample to expand the range of material types is the column leach program. Geochemical characterisation of this additional sample confirmed it had a high sulphide content, but it also had a significant acid neutralising capacity (ANC) and overall was NAF. It was therefore labelled NAF4.

Sample descriptions and location plan as provided by Round Oak for the original six samples are presented in **Table 1** and **Figure 1**, respectively.

Table 1: *Descriptions of Barbara waste rock and ROM oxide samples*

Material Class	Location	Northing	Easting	Depth in Pit	Geological Description
PAF1	South Pit	380252	7741437	330 RL	Oxidise sample quartz sericite schist, minor secondary copper.
NAF1	South Pit	380184	7741440	330 RL	Biotite schist
NAF2	South Pit	380122	7741495	325 RL	Biotite schist
NAF3 (previously PAF2)	South Pit	380193	7741549	325 RL	Oxidise sample quartz sericite schist with secondary copper, malachite and azurite.
NAF4	South Pit	na	na	na	na
ROM Oxide1	South Pit	380298	7741497	325 RL	Sample collected at the southern end of the shear zone and outside the ore zone. Very oxidised samples with minor secondary copper, malachite and azurite.
ROM Oxide2	South Pit	380224	7741519	325 RL	Sample collected from the hanging wall of the shear zone. Mainly oxidised schist, with secondary copper, malachite and azurite.

Figure 1: *Sample location plan for Barbara waste rock and ROM oxide samples*

3. SAMPLE PREPARATION

Each sample comprised approximately 10 kg of rock pieces. Following inspection of the samples they were despatched to International Resource Laboratories (IRL) Services for sample preparation, which involved crushing to minus 4 mm size for use in the column leach tests. A sub-sample of crushed sample was also pulverised for initial geochemical characterisation analyses.

4. GEOCHEMICAL CHARACTERISATION METHODOLOGY

The geochemical characterisation of the Barbara samples included analysis or calculation of the following parameters using standard methods[1] commonly used to define the geochemical properties of mine waste materials. Sulphur and carbon assays and multi-element scans were carried out by Australian Laboratory Services (ALS). All other assays were carried out by the EGi Laboratory.

Total sulphur

Measured by direct high temperature combustion, oxidation and infra-red detection using Leco induction furnace.

Sulphate-sulphur

A 2 g sub-sample of pulverised material was batch extracted for one hour with 80 ml of 1M KCl solution that was purged with argon gas for 30 minutes prior to use. The extract was filtered and the filtrate analysed for dissolved sulphate.

Sulphide-sulphur

Calculated as the difference between Total-S and Sulphate-S values.

Chromium Reducible Sulphur

Inorganic sulphur was reduced to H_2S by hot acidic $CrCl_2$ solution and the evolved H_2S gas trapped in zinc acetate solution as ZnS. The concentration of ZnS was subsequently quantified by idiometric titration. This method is designed to be selective for pyritic-sulphur, but may include some elemental sulphur if present.

Total Carbon Content

Total carbon content was measured using a Leco carbon analyser.

Maximum Potential Acidity

The MPA is the amount of acid (expressed as kg H_2SO_4/t) that theoretically can be generated by a sample when all sulphur occurs as reactive pyrite and there is complete oxidation of the pyrite to acid (H_2SO_4) and ferric hydroxide according to the following reaction:

$$FeS_2 + 15/4\ O_2 + 7/2\ H_2O \Rightarrow Fe(OH)_3 + 2\ H_2SO_4$$

Based on the stoichiometry of this reaction, the one mole of pyrite (or two moles of sulphur) will produce two moles of sulphuric acid. This means, for example, a sample containing 1 %S as pyrite could potentially produce 30.6 kg H_2SO_4/t with complete oxidation of the pyrite. MPA is commonly calculated using a total sulphur content, however if a significant portion of the sulphur occurs as sulphate the MPA will be over-estimated as sulphate does not contribute to acid forming potential. For the column test samples more accurate estimates of MPA were obtained by multiplying the sulphide-sulphur contents (as %S) by a factor of 30.6.

Acid Neutralising Capacity

ANC was determined using a modified Sobek Method[2]. This method provides a direct measurement of the amount of acid that can be consumed by carbonate and other gangue minerals within a sample. A fizz test was initially carried out to provide a qualitative indication of the magnitude of neutralisation capacity. This involved the addition of one or two drops of 1:3 HCl (approximately 8% HCl) to approximately 0.5 g of pulverised sample. The degree of "fizzing" was assessed and a fizz rating between 0 and 5 was assigned, where 0 signifies no visible reaction and 5 signifies very strong reaction. The fizz rating was then used to determine the strength and amount of acid required in the Sobek method to produce a suspension with a pH in the range 1 to 2. These ranges from 4 mL of 0.5 M HCl for a fizz rating of zero up to 60 mL of 1.0 M HCl for a fizz rating of 5. The suspension was allowed to react for approximately 1 to 2 hours, then the flask placed on a hot-plate and the suspension heated to 80 to 90°C for another 1 or 2 hours to complete the reaction. The amount of acid remaining after the reaction stage was determined by back-titration with sodium hydroxide. The amount of acid consumed by the sample (expressed in terms of kg H_2SO_4/t) was then determined by difference.

Carbonate Neutralising Value

The carbonate neutralising value (CNV) is an indirect measure of the neutralisation capacity within a sample based on the carbon content of a sample. The calculation assumes the carbon occurs exclusively as carbonate, and CNV is commonly expressed in terms of the amount of sulphuric acid that theoretically could be neutralised by the carbonate within a sample per unit weight (kg H_2SO_4/t). The calculation of CNV is based on the stoichiometry of the following reaction:

$$CaCO_3 + H_2SO_4 \Rightarrow Ca^{2+} + SO_4^{2-} + H_2O + CO_{2\,(g)}$$

where the main reaction products are calcium, sulphate, water and carbon dioxide gas. This reaction indicates that the one mole of carbon (as carbonate) will neutralise one mole of sulphuric acid. This means for a sample containing 1 %C as carbonate the CNV will be approximately 81.67 kg H_2SO_4/t. A total carbon assay is commonly

---

2 The most widely used method for assessing the inherent acid neutralising capacity (ANC) of a sample is the modified Sobek method (*Sobek, A.A., W.A. Schuller, J.R. Freeman, and R.M. Smith (1978). Field and Laboratory Methods Applicable to Overburdens and Minesoils. U.S. Environmental Protection Agency 600/2-78-054, Washington DC*).

used to calculate CNV although for materials where significant carbon occurs in organic forms the use of an inorganic-carbon contents should be used.

Net Acid Producing Potential

The NAPP is the amount of acid (kg H_2SO_4/t) that potentially could be produced by a sample after allowance for any ANC that the sample has. The NAPP of each sample was calculated by subtracting the ANC from the MPA value.

Net Acid Generation (NAG) Test

The NAG test is a direct oxidation procedure for estimating the acid forming potential of a sample. The NAG test involved reaction of a 2.5 g sub-sample of pulverised material with 250 mL of 15% hydrogen peroxide, which acted as an oxidant to any sulphides present. The samples were allowed to react overnight to provide sufficient time for oxidation to occur. The reaction flasks were then gently heated for approximately 1 hour to assist with decomposition of any residual peroxide. After cooling, the liquor pHs were recorded. As both acid generation and acid neutralisation can occur simultaneously during a NAG test, the end result represents a direct measurement of the net amount of acid that a sample can generate. A sample is considered to be acid forming if the pH after reaction is less than pH 4.5. For such samples, the actual amount of acidity generated (expressed as kg H2SO4/t) was also determined by back-titration of the mixture to a pH 7 end-point.

Monitored NAG Tests

A monitored NAG test was carried out on sample PAF1. The monitored NAG test provides an indication of the reactivity of the sulphides present in a sample, and in the case of a PAF sample it also provides an indication of the likely lag period for acid generation to occur under oxidising conditions. The monitored NAG test is essentially the same as the standard NAG test, except that the kinetics of the peroxide oxidation reaction are indirectly monitored via continuous measurements of the pH and temperature of the NAG solution.

Acid Buffer Characteristic Curve

An acid buffer characteristic curve was produced for sample NAF4 by slowly titrating a sub-sample of pulverised material with dilute hydrochloric acid over a period of 16 to 24 hours. The incremental additions of acid range from 0.1 mL of 0.1 M HCl per 60 seconds for samples with low ANC, and up to 0.1 mL of 0.5 M HCl per 60 seconds for samples with ANCs exceeding 100 kg H_2SO_4/t. This titration method provides a far less aggressive treatment of a sample than that applied in the ANC method and hence provides a measure of the buffering provided by more soluble carbonates within a sample.

Multi-Element Analysis of Solids

Samples were digested by multi-acid addition (*i.e.* hydrofluoric, nitric, perchloric and hydrochloric acids) and the digests were analysed using inductively coupled plasma mass spectrometry (ICPMS) for the following suite of elements: Al, As, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, Hg, K, Li, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Sn, Sr, Th, U, and Zn. Mercury was also assayed but an aqua regia digestion was used to ensure minimal volatilisation followed by analysis using ICPMS.

5. GEOCHEMICAL CHARACTERISTICS OF TEST SAMPLES

5.1. Acid Forming Characteristics

Table 2 presents the acid forming characteristics of each sample. Acid-base account and ARD classification plots are also presented in **Figure 2** and **Figure 3**, respectively. The main findings are as follows:

PAF1

The sample labelled PAF1 had a high sulphur content (2.49 %S), most of which was present as sulphide. It also had some ANC (17 kg H_2SO_4/t), albeit relatively low and significantly less than the acid potential of the sulphide present. The NAPP was definitively positive (58 kg H_2SO_4/t) and the sample acidified to pH 3.4 under NAG test conditions. The ANC has potential to delay the onset of acidification of this material type when exposed to atmospheric conditions, but the positive NAPP and NAG test results suggest such material would likely generate acidic drainage in the longer term.

NAF1

The results for sample NAF1 were consistent with it being NAF. It had a low sulphur content (0.05 %S), relatively low ANC (15 kg H2SO4/t) and negative NAPP and NAG test results.

NAF2

The results for sample NAF2 were similar to NAF1. The sulphur content was low (0.1 %S), as was the ANC (15 kg H_2SO_4/t). The NAPP was negative NAPP and the sample did not acidify under NAG test conditions.

NAF3

Similarly, the sulphur content of sample NAF3 was negligible (0.02 %S), the ANC relatively low (11 kg H_2SO_4/t), and both the NAPP and NAG were negative.

NAF4

In contrast, sample NAF4 did have a significant sulphur content (1.32 %S), almost all of which was sulphidic. This sample also had a high copper content (1.06 %Cu) and it is likely that most of the sulphur was present as copper sulphide. Notwithstanding the high sulphide content, NAF4 also had a moderate to high ANC (75 kg H_2SO_4/t), which exceeded the acid potential of the sulphide present and consequently produced a negative NAPP (-36 kg H_2SO_4/t). The NAG test result was also consistent with this sample being NAF.

ROM1 & ROM2

There were only trace concentrations of sulphur in the two ROM Oxide samples, and both samples had negative NAPP and NAG test results. The ANCs were also low (7 and 10 kg H_2SO_4/t). Overall the results suggest both samples are essentially benign with respect to acid potential and neutralisation potential, which is consistent with their oxide descriptions.

Abbreviations

CNV = Carbonate Neutralising Value
ANC = Acid Neutralising Capacity
MPA = Maximum Potential Acidity
NAPP = Net Acid Producing Potential
(MPA and NAPP values calculated using Sulphide-S)
NAG = Net Acid Generation capacity
NAGpH = pH of NAG liquor
NAF = Non-Acid Forming
PAF = Potentially acid forming

Methods

Total sulphur - Measured using a Leco sulphur analyser

Sulphate-sulphur - Sample leached with hot HCl to remove acid-soluble sulphates. The amount of sulphate within the leachate is then determined by ICPAES.

Sulphide-sulphur - Calculated as the difference between Total-S and Sulphate-S values.

Cr Reducible S - Sample reacted with hot acidic CrCl2 to reduce (non-sulphate) inorganic sulphur forms to H_2S which are trapped in zinc acetate solution and determined.

Total carbon - Measured using a Leco carbon analyser

Organic-carbon - Hot HCl to remove any carbonates, then rinsed with distilled water. The residual carbon in the residue (i.e. acid-insoluble carbon) then measured by Leco.

Inorganic-carbon - Calculated as the difference between Total-C and Organic-C values.

Figure 2: *Acid-base account plot for Barbara waste rock and ROM oxide samples*

Figure 3: *ARD classification plot for Barbara waste rock and ROM oxide samples*

5.2. Sulphur Speciation

The test samples were analysed for total sulphur and also sulphur forms, which allowed differentiation of the sulphur between sulphide that has acid potential, and sulphate which does not contribute to acid forming potential. Two samples, PAF1 and NAF4, had significant sulphur contents, and with both samples most of the sulphur was sulphidic. Also, both samples had elevated copper contents suggesting the presence of significant copper sulphide mineralisation. **Figure 4** shows the estimated distribution of sulphur in PAF1 and NAF4 based on the sulphur speciation and copper assays.

Figure 4: *Sulphur speciation in column leach test samples*

PAF1 had a copper content of 0.79 %Cu. Assuming all the copper was present as chalcopyrite ($CuFeS_2$) the amount of sulphur associated with the chalcopyrite would be 0.80 %S. This represents approximately one-third of 2.45 % sulphide-%S content of PAF1. Pyrite likely accounted for the remaining 1.69 %sulphide-S.

Copper mineralisation was also evident in NAF4 (see **Figure 5**), which had a copper content of 1.05 %Cu. This equates to 1.06 %S as chalcopyrite. With NAF4 the sulphide-sulphur content was only slightly higher at 1.32 %S, hence potentially most of the sulphide in NAF4 occurred as chalcopyrite, with only 0.22 %S present as pyrite.

Figure 5: *Photograph showing sulphide mineralisation in sample NAF4*

5.3. Sulphur Reactivity

The monitored NAG test was used to provide an indication of the reactivity of sulphides in the PAF1 sample (**Figure 6**). The monitored NAG test is an accelerated procedure which, in addition to sulphide reactivity, provides an indication of the likely lag period for acid generation to occur under oxidising conditions. The monitored NAG test is similar to the standard NAG test where a sample is oxidised with hydrogen peroxide, but with the added feature that the pH and temperature of the NAG liquor are constantly recorded during the reaction phase of the test.

The pH at the start of the monitored NAG test on PAF1 was 5.0, and it remained close to pH 5 for approximately 20 minutes. The initial pH plateau represents a lag in acidification that can be attributed to the sample having an ANC of 17 kg H_2SO_4/t. During this lag most of the acid generated from sulphide oxidation was neutralised. Over the next 90 minutes the pH steadily decreased to around pH 3. During this phase there was noticeable "fizzing" of the NAG liquor produced by the reaction of peroxide with sulphides exposed on particle surfaces. As the pH decreased there was a concurrent increase in the temperature of the NAG liquor, which effectively reached boiling point after approximately 115 minutes of reaction time. Some of the temperature rise can be attributed to the oxidation of pyrite, which is an exothermic (heat generating) process, but most is associated with catalytic decomposition of the peroxide, a process that is also exothermic[3]. The catalyst for the decomposition reaction is typically dissolved iron released during pyrite oxidation, although other metals such as copper can also contribute. As such, the occurrence of a temperature peak is often a further indication of sulphide reactivity in that it reflects increasing concentrations of reaction products.

Figure 6: *Monitored NAG pH profiles PAF waste rock and low-grade ore samples*

[3] The temperature spike recorded in this and other monitored NAG tests is primarily an artefact of the test procedure as most heat is generated by the decomposition of the peroxide. Under field conditions the oxidation of sulphides involves atmospheric oxygen, and the rates of oxidation are typically orders-of-magnitude slower than in the NAG test where rates are highly accelerated by use of peroxide. Under field conditions the heat generated by the exothermic oxidation of pyritic material can be dissipated throughout a larger rock mass, which typically limits temperature rise. However, it can be the case that self-heating of highly sulphidic materials can occur within a waste rock dump if conditions are conducive to oxidation, especially if the generation of heat promulgates convective air movement through outer zones of the dump. If the material has a very high sulphide content and is also carbonaceous then spontaneous combustion can also occur under some situations.

Overall, the monitored NAG profile for sample PAF1 indicates the sulphidic mineralisation within the sample was reactive, however the 20 minute lag at the start of the test suggests that acidification of such material would likely take some time to occur (many months and possibly years) under field conditions.

5.4. Carbonate Neutralising Value

The capacity of a sample to inherently neutralise any acid that might be generated by the oxidation of pyrite and other sulphides is usually quantified using the Sobek ANC method which involves the addition of acid to a sample and measurement of the amount of acid consumed. As the ANC of a sample is commonly associated with the presence of carbonate mineralisation, the inorganic carbon content of a sample can also provide a secondary measure of neutralisation potential. With this alternate approach the result is commonly referred to as the carbonate neutralising value (CNV). **Figure 7** shows a comparison of the ANC and CNV results for the samples included in the column leach test study.

Figure 7: *Comparison of CNV and ANC results for column leach test samples*

For the Barbara samples the CNVs were consistently smaller than the corresponding ANCs, but overall there was reasonable agreement when considered over the range of values exhibited by the samples. This suggests carbonate mineralisation (e.g. calcite, limestone or dolomite) was a significant contributor to the neutralising capacity of most of the samples, and particularly NAF4 which had the highest ANC. However, for samples with very low ANCs some neutralisation could derive from of other gangue minerals such as silicates.

5.5. Acid Buffer Characteristics

The only sample in the column test program with a significant ANC was samples NAF4, which also had a high copper sulphide content. An acid buffer curve for NAF4 is shown in **Figure 8**. The acid buffer curve provides an indication of the reactivity of mineralisation providing neutralisation capacity with a sample. The titration method used to produce a buffer curve is not as aggressive in terms of acid addition as the standard ANC method, and hence it provides a measure of the buffering provided by more soluble carbonates within a sample. This can be important for NAF samples that also have high sulphide contents, as differential reactivities of sulphide and carbonates may result in leachate chemistries that are inconsistent with NAPP values.

Figure 8: *Acid buffer characteristic curve for sample NAF4 with an ANC of 75 kg H_2SO_4/t*
(reference standards also have ANC equivalent of 75 kg $H2SO_4$/t)

For comparison purposes, Figure 8 also includes buffer curves for reference samples representing limestone, dolomite, ferroan-dolomite, magnesite and siderite. Limestone (or calcite) is usually readily available for neutralisation and can maintain a plateau at circum-neutral pH up until almost all of the ANC is consumed. Dolomite is also usually reactive, however the reactivity may decline when there is significant iron substitution, such as with ferroan dolomite. In contrast, magnesite is usually poorly reactive at circum-neutral pH, and significant dissolution of magnesite often only occurs under laboratory conditions when the pH drops below about 4. The buffer curve for NAF4 follows closely that of ferroan-dolomite.

5.6. Multi-Element Analysis of Solids

Elemental analysis of solids was carried out by ALS. Samples were digested by multi-acid addition (*i.e.* hydrofluoric, nitric, perchloric and hydrochloric acids) and digests were analysed using inductively coupled plasma mass spectrometry (ICPMS) for the following suite of elements: Al, As, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, K, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Sn, Sr, U, and Zn. Mercury was also assayed but an aqua regia digestion was used to ensure minimal volatilisation followed by analysis using ICPMS. The multi-element composition of each sample is given in **Table 3,** together with corresponding Geochemical Abundance Indices (GAI)**.** The purpose of GAIs is to identify elements that occur at concentrations significantly greater than median background soil abundance values, where:

- GAI of 0 indicates the element is present at a concentration similar to, or less than, median soil abundance,
- GAI of 1 or 2 represent minor enrichment of an element, and
- GAI of 3 to 6 represent significant enrichment above median soil abundance.

As might be expected, copper was enriched to varying extents in all samples. The copper contents of PAF1 (7,880 mg/kg), NAF4 (10,550 mg/kg), ROM oxide1 (5,320 mg/kg) and ROM oxide2 (9,470 mg/kg) were particularly high. The copper contents of NAF1 (194 mg/kg) and NAF2 (223 mg/kg) were much lower, but still relatively high in comparison

with typical background soil with a median of only 30 mg/kg. The analyses of solids also indicate enrichments of some other elements that may be potentially important environmentally:

	Significant (GAI≥3)	*Minor (GAI 1 or 2)*
PAF1	Cu, Co, Se, S	As, Mg, Ni
NAF1	-	Cu
NAF2	-	Cu, As, Co, Cr, Mg
NAF3	Cu	Co, Mg
NAF4	Cu, S	Co, Mg, Se
ROM Oxide1	Cu	Co, Mg, Se
ROM Oxide2	Cu	Co, Mg, Se

6. COLUMN LEACH TEST METHODOLOGY

6.1. Column Setup and Leaching Regime

The setup of the column leach tests was similar to that which was used for previous samples from Round Oak's Wallace North Project. Each column comprised 2.0 kg (dry weight) of solids housed within a plastic Buchner funnel measuring 174 mm in diameter and 100 mm in height. The funnel configuration provides a free-draining condition and a relatively high exposure area per unit mass of sample, thereby providing conditions amenable to sulphide oxidation.

The column setup at the EGi laboratory is shown in **Figures 9 to 11.** The columns were positioned on a rack beneath heat lamps that maintained a surface temperature of about 30 to 35 ºC for approximately 8 hours each day. The purpose of the lamps was to enhance drying of the samples between water additions to ensure there was air-filled porosity within the samples into which atmospheric oxygen could diffuse, thereby providing conditions amenable to sulphide oxidation.

Figure 9: *Photograph of column leach test setup - side view*

Figure 10: *Photograph of column leach tests - top view*

Figure 11: *Photograph of column housing with crushed sample*

6.2. Leaching Regime

Immediately following setup, each column was flushed with 800 mL of deionised water and first-flush leachates were collected three days later for analysis. Thereafter, the columns operated on a four-week leach cycle. During the first three weeks of each cycle the samples were moistened by a once weekly addition of deionised water at a rate equivalent to 100 mL/kg/week, with almost all the water initially retained by the samples, then lost via evaporation. On the fourth week of each cycle the samples were flushed with deionised water at a rate equivalent to 400 mL/kg/week, and leachates collected over the following few days in plastic containers positioned beneath the columns. The weight of leachate collected was recorded (typically around 500 mL for a 2 kg column) and subsamples then taken for analysis.

6.3. Leachate Analysis

The analysis of leachates included measurements of pH, electrical conductivity (EC), and acidity or alkalinity. A subsample of each leachate was also filtered (0.45 µm Millipore membrane) and preserved prior to despatch to ALS for elemental analysis. Leachates from all columns were analysed for Ag, Al, As, B, Ba, Be, Ca, Cd, Cl, Co, Cr, Cu, F, Fe, Hg, K, Mg, Mn, Mo, Na, Ni, P, Pb, Sb, Se, Si, Sn, SO_4, Sr, Th, Tl, U and Zn.

7. COLUMN LEACH TEST RESULTS

Leach column testing commenced on 30 August 2019. The initial six samples included NAF3, but the column leach test involving NAF3 was stopped after the leachate collection on Week 8, and replaced by a new column comprising NAF4 which commenced on 29 November 2019. The decision to replace NAF3 with NAF4 provided greater variation in the rock types being tested in that NAF4 had high sulphur, high ANC and high copper content, whereas NAF3 had a low sulphur content similar to NAF2.

7.1. First Flush

The chemistries of the first-flush leachates are given in **Table 4**. The concentrations of sulphate in the initial leachates from PAF1 and NAF4 were significantly higher than for the other samples, consistent with these two samples having much higher sulphur contents than the other samples in the test program (i.e. 61 mg/L for PAF1 and 113 mg/L for NAF4, compared to 2 to 19 mg/L for other samples). Otherwise the chemistries of the first-flush leachates were similar in that they were:

- alkaline (pHs ranging between 7.7 and 8.5 and alkalinities between 28 and 68 mg $CaCO_3$/L),
- low in soluble salts (ECs of 109 to 278 µS/cm),
- had only trace concentrations of aluminium (0.2 to 0.5 mg/L), iron (0.2 to 0.5 mg/L), and manganese (0.01 to 0.07 mg/L), and
- the concentrations of most other dissolved metals and metalloids were typically close to, or below the limits of analytical detection. This included arsenic (≤0.006 mg/L), cadmium (<0.0001 mg/L), chromium (<0.001 mg/L), lead (<0.001 mg/L), mercury (<0.0001 mg/L) and zinc (≤0.008 mg/L).

7.2. Weeks 4 to 52

Leachate assay data for the Barbara column leach tests are tabulated in **Appendix A**. Also, time series plots for leachate pH, EC, acidity/alkalinity, sulphate, calcium, magnesium, iron, aluminium, arsenic, copper, cobalt, manganese and zinc are presented in **Appendix B.** The main findings were as follows:

7.2.1. PAF1 Column

- The pH of leachate from PAF1 remained circum-neutral during the 12 months of testing, signifying the sample was still in the lag phase. This lag is consistent with the findings of the monitored NAG test. The pH fluctuated between 6.8 and 7.7 during the test, and the median was 7.4. Although the pH remained circum-neutral, the alkalinity of leachate was relatively low, fluctuating between 11 to 19 mg $CaCO_3$/L during the 12 month test period.

Table 4: *Composition of initial flush from Barbara column leach tests*

* NAF3 - Initially labelled PAF2 when sampled at site but subsequently classified as NAF

** *Alkalinity and acidity expressed as mg CaCO3/L*

*** *Underline indicates concentration is less than the limit of analytical reporting*

- The release of sulphate from PAF1 also remained relatively low during the 12 months, varying between 155 and 334 mg/L, and averaging 233 mg/L. The average sulphate release rate (SRR) for the 12 month was approximately 16 mg/kg/week, which correspond to an intrinsic oxidation rate for sulphide in the column of approximately 2.5×10^{-8} kg O_2/m^3/sec. This represents a relatively slow rate of sulphide oxidation, notwithstanding that the sample contained 2.47 %S almost exclusively as sulphide.
- Even though pyrite oxidation occurred to some extent during the test, albeit at a slow rate, there was no evidence of leaching of iron which, together with sulphate, are the main reaction products from pyrite oxidation. After the initial flush the concentrations of iron in leachate were typically less than the 0.05 mg/L analytical detection limit. Given the sample remained circum-neutral, it can be expected that any iron that was released as a consequence of oxidation of pyrite or chalcopyrite would have re-precipitated within the column as iron oxy-hydroxide, most likely as coatings on particle surfaces.
- Similarly, there was little leaching of copper despite the sample containing significant chalcopyrite and having a total copper content of 7,880 mg/kg. The concentrations of copper in leachate fluctuated between 0.03 to 0.13 mg/L and averaged 0.05 mg/L. The relatively low copper concentrations may partly reflect the low rates of sulphide (chalcopyrite) oxidation during the test period, but the low concentrations are also consistent with the fact that copper, like iron, exhibits very low solubility under circum-neutral and alkaline conditions. Therefore, even though it is likely chalcopyrite was oxidising to some extent it is also likely most of the copper released from the chalcopyrite re-precipitated as copper oxy-hydroxide onto particle surfaces in the column. It is expected much higher copper concentrations would occur in leachate from PAF1 if the test was extended beyond the lag phase and the pH decreased below about 6.
- Other significantly enriched elements in PAF1 include cobalt and selenium, and there was minor sample enrichment with arsenic and nickel. During the 12 month test period the concentrations of arsenic in leachate were less than the analytical detection limit of 0.001 mg/L, and only trace concentrations were recorded for cobalt (average 0.01 mg/L), nickel (average 0.01 mg/L) and selenium (average 0.02 mg/L). Similarly, there was only minor leaching of manganese (average 0.05 mg/L) and aluminium (average 0.05 mg/L).
- The concentrations of other environmentally important metals also remained low, and in most cases the concentrations were less than the analytical detections limits. Such was the case for cadmium (≤0.0002 mg/L), mercury (<0.0001 mg/L), lead (<0.001 mg/L), antimony (<0.001 mg/L), chromium (<0.001 mg/L) tin (<0.001 mg/L), and zinc (<0.005 mg/L).

7.2.2. NAF1 and NAF2 Columns

- Samples NAF1 and NAF2 produced leachates during the 12 month test period that were essentially the same. Leachate from both these columns were slightly alkaline, with pHs typically between 7.3 to 7.6, and alkalinities around 20 to 30 mg $CaCO_3$/L.
- Sulphate concentrations were low, with NAF1 leachate averaging only 20 mg/L and NAF2 only slightly higher at 47 mg/L. The average sulphate release rate for NAF1 was only 2 mg/kg/week, and the corresponding IOR was 3.0×10^{-9} kg O_2/m^3/sec, which is effectively negligible. Similarly, for NAF2 the average sulphate release rate was only 4 mg/kg/week, and the IOR was 5.7×10^{-9} kg O_2/m^3/sec. These results indicate that sulphide oxidation was essentially non-existent in NAF1 and NAF2.
- The major cation in leachates from NAF1 and NAF2 was calcium, averaging 11 mg/L for NAF1 and 21 mg/L for NAF2.
- Although the copper contents of the NAF1 and NAF2 samples were slightly elevated in comparison to typical background soil, there was no evidence of significant copper release, with concentrations in NAF1 leachates

typically less than the detection limit of 0.001 mg/L. With NAF2 the concentrations in leachate typically ranged from 0.001 to 0.005 mg/L.

- Similarly, although the cobalt and chromium contents of NAF2 were slightly elevated compared to background soil there was no evidence of significant leaching of these two metals, with the concentrations in leachate consistently less than the analytical detection limit of 0.001 mg/L.
- However, there was minor leaching of arsenic from NAF2, with concentrations in leachate trending slightly higher during the first six months of testing, then stabilising at around 0.03 mg/L during the second six months.
- The concentrations of other environmentally elements were typically close to, or less than the respective analytical detection limits, including cadmium (<0.0001 mg/L), mercury (<0.0001 mg/L, and lead (0.001 mg/L).

7.2.3. NAF4 Column

- As noted above, the leach test involving NAF3 was terminated after 8 weeks and was replaced by NAF4. This change meant that the leach test on NAF4 trailed the other five column tests by 12 weeks.
- Sample NAF4 differed from NAF1 and NAF2 in that it had much higher contents of sulphur (1.32 %S) and copper (1.05 %Cu). Based on copper content, the NAF4 sample was likely more representative of ore grade material than typical waste rock.
- Like all other samples, the pH of leachate from NAF4 remained slightly alkaline during the 52 weeks of testing, with the pH ranging from 7.1 to 7.6 and the alkalinity remaining relatively steady at between 19 to 30 mg $CaCO_3$/L.
- Although NAF4 remained slightly alkaline, there was significant release of sulphate during the test consistent with sulphide oxidation occurring. Between weeks 4 to 52 the average concentration of sulphate was 452 mg/L, and the average sulphate release rate was 32 mg/kg/week. This corresponds to an IOR of 4.8×10^{-8} kg O_2/m^3/sec, which is in the moderate range for sulphidic rock.
- As well as sulphate there was also significant leaching of calcium, with the concentrations in leachate averaging 146 mg/L during the 52 week test period. The release of calcium likely reflects carbonate minerals within the NAF4 sample reacting with the acidity generated by sulphide oxidation. This process is consistent with NAF4 having a relatively high ANC of 75 kg H_2SO_4/t and a CNV of 61 kg H_2SO_4/t (see Section 5.1). There was also some magnesium release (average 29 mg/L), suggesting the carbonate mineralisation in NAF4 may have been partially dolomitic. This is supported by the acid buffer curve for NAF4 which indicated reactivity consistent with dolomite (see Section 5.5).
- Although NAF4 had a high copper content, the concentrations of copper in leachate were relatively minor at around 0.01 to 0.04 mg/L. The relatively low concentrations of soluble copper can likely be attributed to the circum-neutral pH, with any copper released from oxidation of chalcopyrite being reprecipitated as copper oxy-hydroxide within the column.
- Similarly, there was virtually no leaching of iron. Like copper, any iron released from oxidation of chalcopyrite (or pyrite) would have reprecipitated as iron oxy-hydroxide in-situ under the prevailing circum-neutral pH condition of the test material.
- There was some leaching of manganese (typically around 0.2 mg/L) but otherwise no significant leaching of other environmentally important metals or metalloids, with concentrations in leachate close to, or less than, the analytical limits.

7.2.4. Oxide ROM1 and ROM2 Columns

- The two ROM oxide samples also had high copper contents (0.53 and 0.95 %Cu, respectively), but unlike NAF4 the sulphur contents were low (0.05 and 0.16 %S, respectively). Therefore it can be assumed that the copper occurred in oxide forms, hence the description of these two samples as ROM oxide.
- Both samples remained circum-neutral during the 12 months of testing. The pHs of leachates from both samples fluctuated between 7.3 to 8.0, and the alkalinities averaged at 24 and 34 mg $CaCO_3$/L, respectively.
- There was some release of sulphate during the first few months, but concentrations in leachate decreased with time. Overall, there was only minimal leaching of sulphate from ROM1 (average 23 mg/L), consist with the very low sulphur content of this sample. Sulphate concentrations in leachate from ROM2 were slightly higher (average 62 mg/L), but still relatively low in comparison to what typically occurs with acidic drainage from PAF rock.
- The average sulphate release rate for ROM1 between weeks 4 to 52 was only 1.5 mg/kg/week and the corresponding IOR was only 2.3×10^{-9} kg O_2/m^3/sec. These values are consistent with sulphide oxidation being negligible. The values for ROM2 were only slightly higher at 4.0 mg/kg/week and 6.1×10^{-9} kg O_2/m^3/sec, respectively.
- There was evidence of some leaching of copper, with concentrations in leachate typically varying between 0.1 to 1.0 mg/L. As the copper in ROM1 and ROM2 was probably present in oxide forms, the results for these two samples likely indicate pH-dependent solubility control for copper release. If that was the case, the leaching of copper from ROM Oxide as represented by ROM1 and ROM2 over the long term should not vary significantly above the range exhibited during the test, assuming the pH remains circum-neutral, which would be expected given the low sulphur content and NAF classification.
- Although both ROM oxide samples exhibited minor enrichment with cobalt compared to background soil, there was no evidence of significant leaching, with cobalt concentrations in leachate remaining less than 0.01 mg/L.
- Similarly, there was no evidence of significant leaching of arsenic with concentrations ranging from 0.002 to 0.006 mg/L, and concentrations of cadmium, mercury, lead, and zinc were consistently less than the limits of analytical detection.

8. SUMMARY AND IMPLICATIONS

This report presents the results and findings of column leach tests involving waste rock and ROM oxide samples from the Barbara mine site. The columns were laboratory scale and leaching of the test samples was carried out under controlled conditions. There were six column tests, one involving waste rock that was PAF, three representing NAF waste rock, and two representing ROM oxide. Five tests (PAF1, NAF1, NAF2, ROM1 and ROM2) ran continuously for 12 months. The sixth test initially involved a sample representing low sulphur NAF waste (NAF3) but to expand the geochemical range of test materials this sample was replaced after 8 weeks with a sample representing high sulphur NAF waste (NAF4). The subsequent leaching of NAF4 extended for 12 months. The main findings were as follows:

High Sulphur PAF Waste Rock as Represented by PAF1

The PAF1 sample representing PAF waste rock did not acidify during the 12 months test period, confirming a lag period of at least a year for this type of material. However, there was significant release of sulphate, indicating sulphide oxidation did occur during the test. The lag phase exhibited by PAF1 was consistent with the reaction profiles exhibited by the sample in the monitored NAG test.

Over the 12 month test period the total release of sulphur was equivalent to approximately 0.03 %S. Assuming the sulphur occurred in the sample as pyrite, the release of sulphur equates to an acid generation potential of 0.9 kg H_2SO_4/t. Whilst significant, this amount of acid generation represents only a small portion of the MPA of PAF1 of 75 kg H_2SO_4/t.

The amount of ANC depleted during the test can also be estimated based on leachate alkalinity and the release of calcium and magnesium. These parameters equate to a loss of ANC of 0.9 kg H_2SO_4/t, the same as the acid potential of reacted sulphide.

Therefore, it can be concluded that after 12 months of leaching the PAF1 sample was still in the early stages with respect to sulphide oxidation and acid generation/neutralisation. As there was no evidence of any decrease in leachate pH or alkalinity during the test, and the original ANC of 17 kg H_2SO_4/t was only depleted by 5% during the 12 month period, it is likely that the lag period for waste rock as represented by PAF1 would extend for several years.

It is expected that leaching of copper would remain limited throughout the lag period as the solubility of copper is pH-dependent. Under alkaline conditions, most of the copper that is released as a consequence of oxidation of chalcopyrite will continue to re-precipitate as copper oxy-hydroxide onto waste rock surfaces. It is expected significant copper release will only occur toward the end of the lag phase when the pH of the material begins to decreased below about 6.

High Sulphur NAF Waste Rock as Represented by NAF4

The NAF4 sample represents high sulphur rock that also has moderate to high ANC and is overall NAF. The column leach test on this sample confirmed generation of alkaline drainage during the 12 month test period. There was evidence of a moderate rate of sulphide oxidation but, notwithstanding an ore-grade copper content of 1.06%Cu, there was only limited leaching of copper, with concentrations in leachate around 0.1 to 0.4 mg/L. Given the solubility of copper is pH-dependent, there is no reason to expect any significant increase in the rate of copper leaching from this type of waste rock over the longer term, assuming the material remains circum-neutral. Apart from some copper, there was no evidence of leaching of environmentally important elements such as arsenic, cadmium, mercury, lead, zinc.

Low Sulphur NAF Waste Rock as Represented by NAF1 and NAF2

Samples NAF1 and NAF2 represent typical low sulphur, NAF waste rock at the Barbara site. In most respects, these waste rock samples can be considered geochemically benign in that the sulphide-sulphur contents were negligible and the neutralising capacities were low. Copper was slightly elevated in comparison to typical background soil, as was arsenic in NAF2, but otherwise there were no significant (GAI≥2) elemental enrichments of environmental importance.

The results of the column leach tests were consistent with the benign nature of this type of NAF waste rock. Leachate from both these columns were circum-neutral and there were only low rates of leaching of sulphate. Although copper contents were slightly elevated, there was no evidence of significant copper release, with concentrations in leachates typically less than 0.005 mg/L. However, there was minor leaching of arsenic from NAF2, with concentrations typically around 0.03 mg/L in leachates collected during the latter half of the test. And, as with other samples, the concentrations of other environmentally elements were typically close to, or less than the respective analytical detection limits.

Low Sulphur/High Copper ROM Oxide as Represented by ROM1 and ROM2

The geochemical characteristics of two samples representing ROM oxide were similar to low sulphur NAF waste, except for copper contents which were much higher at approximately 0.53 and 0.95%Cu. Given the low sulphur contents it can be assumed most, and probably all, of the copper occurred in oxide forms. There was some leaching of copper during the column leach tests, with concentrations in leachate typically varying between 0.1 to 1.0 mg/L. Given the weathered nature of ROM Oxide and the likelihood that the solubility of copper in such waste will be pH-dependent, it is reasonable to assume the leaching of copper from material as represented by ROM1 and ROM2 over the long term would remain much the same as the chemistry of leachate from the column tests. That is, slightly alkaline, low in soluble salts, and apart from some copper, have trace concentrations of environmentally important elements including antimony, arsenic, cadmium, cobalt, mercury, lead, selenium and zinc.

1 INTRODUCTION

This Air Quality Monitoring Program (AQMP) has been designed specifically for the Barbara Copper Project (the Project) by Round Oak Minerals Pty Ltd (ROM). The AQMP was prepared to provide guidance for the management of the site and to help meet the Projects environmental conditions set in the Environmental Authority (EA) EPML02840015.

The Project is located approximately 40 kilometres (km) north east of Mt Isa. It is located within the Mt Isa City Council area. The main objective for the AQMP is to ensure that emissions from the Project do not cause unacceptable impacts to the surrounding community and environment. This will be accomplished by establishing an air quality monitoring protocol to evaluate compliance against relevant criteria. As the Project progresses the AQMP will be updated as necessary.

1.1 PURPOSE

The overall purpose of the AQMP Is to:

- Manage and minimise the impact of dust emissions from the Project on the community and environment;
- Establish an air quality monitoring program to assess the impacts of mining construction and operations on surrounding sensitive receptors against the specific air quality criteria set out in Schedule B of the Project's approval conditions (the EA);
- Investigate complaints relating to dust in a timely manner and devise mitigation measures that deal effectively with the causes of legitimate complaints;
- Detail actions and responsibilities in the event of an exceedance of a dust trigger level or a legitimate complaint; and
- Outline investigation, reporting and management requirements in respect to air quality management.

1.2 SCOPE

The AQMP contains the management of air quality characteristics during, exploration, construction and operation of the Project. It has been designed to comply with conditions B1 and B2 of the projects EA:

B1 *The activities must not cause an exceedance of the air quality objectives specifie in Table B1 beyond the boundaries of any mining lease/s listed on this environmental authority*

B2 *Prior to commencing the mining activity, the environmental authority must ensyre that an air quality monitoring program is developed and implemented by an appropriately qualified person that is capable of determining compliance with condition B1 of this environmental authority.*

1.3 ROUND OAK DOCUMENT LIBRARY

INX InTuition® shall be used as the Round Oak Minerals Document Library for controlling standards, procedures, guidelines, forms and other controlled documents in accordance with the Document and Record Management Procedure.

InTuition® provides workers including Round Oak Minerals employees, contractors and visitors access to the latest controlled versions of documents.

All documents controlled on InTuition® will be reviewed based on the frequency assigned to the document to ensure currency of information.

2 AIR QUALITY CRITERIA

2.1 LEGISLATION AND STANDARDS

The relevant legislation required for addressing all aspects of the AQMP for the Project are:

- Environmental Protection Act 1994 (EP Act) and
- Environmental Protection (Air) Policy 2008 (EPP (Air)).

The EP Act places emphasis on managing Queensland's environment within the principles of ecological sustainable development. The EP Act imposes a 'General Environmental Duty' on all individuals and organisations, requiring them to take reasonable measures to avoid environmental harm.

The EPP (Air) identifies environmental values that should be protected under the EP Act and provides starting indicators and air quality objectives that can be employed to protect the particular environmental values. The EPP Air also contains a framework for making consistent and informed decisions about the air environment.

Guidelines considered in the AQMP included Model mining conditions (DEHP, 2013) and the Good Practise guide for assessing and managing the environmental effects of dust emissions (NZME, 2001).

2.2 ENVIRONMENTAL AUTHORITY TRIGGER LEVELS

The relevant trigger levels are shown in Table 1 below. If dust emissions cause environmental nuisance at a sensitive receptor and trigger a complaint, the EA holder must provide evidence that particulate emissions due to mining activities from the mine are not exceeding the EA trigger levels. Should particulate emissions be proven to be above EA trigger levels during an investigation following a complaint, the holder is subject to a non-compliance with the EA.

Table 1: Air Quality Trigger Levels

PARAMETER	MEASUREMENT PERIOD	AIR QUALITY OBJECTIVE
Arsenic and it's compounds as arsenic	Average over annual calendar period	Must not exceed background levels 250 µm/m^2/day
Cadmium and its compounds as cadmium		
Copper and its compounds as copper		
Lead and its compounds as lead		
Dust deposition (total insoluble matter)		120 µm/m^2/day
Arsenic and it's compounds as arsenic		Must not exceed background levels

3 AIR QUALITY MANAGEMENT

3.1 AIR QUALITY IMPACT ASSESSMENT

The only significant potential air quality impact is dust from mining activities, particularly wheel generated dust emissions at peak production. In any earthworks, dust is a potential contaminant of air quality. Oxides of carbon, nitrogen and sulphur would also be emitted in vehicular emissions; however, these emissions

are expected to be minor. The amount, composition and size of the Project's dust emissions will be influenced by a number of factors, including the nature of the source materials disturbed or handled, the intensity of on-site activities, the climatic conditions being experienced and the degree of dust mitigation measures being applied during the operation.

Mining activities with the potential to generate significant airborne particulate matter during the Project's operation include:

- Wheel generated dust emissions from vehicle movements on unsealed roads;
- Dust from clearing activities;
- Dust generated from exposed soil in disturbed area;
- Dust from blasting and mining of open cut pits, and
- Dust from materials handling, crushing, dumping on the leases.

3.2 DUST MITIGATION MEASURES

Dust mitigation measures proposed by ROM were considered when estimating the extent of dust emissions from the Project.

3.2.1 Trafficable Areas

Trafficable areas that are in frequent use will be monitored for the generation of excessive dust and where required maintained sufficient to prevent the generation of dust. This applies to:

- Haul roads for ore and overburden;
- The precinct of the ROM;
- Areas where loaders are operating;
- Maintenance areas; and
- Other major roads (heavy equipment roads) on the mine site.

Vehicles will remain within identified trafficable areas unless there is a valid reason to travel 'off road'. Under normal circumstances, dust that carries higher than the height of the tray of a dump truck is unacceptable and additional dust control measures should be implemented.

Vehicles will be operated at speeds which avoid the generation of excessive dust, 20 km/hr at administration and 40km/hr around site where sign posted.

Any spilt ore or copper concentrate shall be graded off the road surface as soon as possible, so as to minimise the chance of fines and dust being generated. Graded ore should be pushed into a heap where it can be recovered.

3.2.2 Disturbed Areas

Disturbance areas void of cover systems will be kept to a minimum. Vegetation clearing and topsoil stripping is to be conducted immediately before overburden stripping begins.

As far as possible:

- Vegetation clearing and topsoil stripping will be avoided when wind conditions and low moisture promote the generation of dust;
- Bulldozers, loaders and haul trucks will be operated in a manner that will minimise generation of dust;
- Cleared vegetation will be windrowed to reduce surface wind speeds; and
- A water cart will be deployed where practicable to dampen dusty areas.

Dust control measures will include the use of water sprays, minimising drop heights when handling soil and waste rock and avoiding double handling of materials wherever practicable.

Topsoil stockpiles will be located, formed and vegetated to minimise the generation of dust. Alternatively, topsoil will be placed directly on to rehabilitation areas where possible.

Rehabilitation of disturbed areas will be performed when practicable. The forming of final surfaces will be avoided during dry and windy weather. During topsoil stripping haul roads, reclamation and spreading sites will be watered as required to minimise airborne dust. Topsoil operations will be assessed prior for wetting down of the impacted areas prior to topsoiling activities being undertaken.

3.2.3 Loader / Shovel Operations

Loader and shovel operators will avoid the generation of excessive dust by:

- Minimising drop heights placing material into haul trucks; and
- Avoiding overloading haul trucks to limit spillage during transit.

3.2.4 Mining Equipment

Persons operating trucks, earthmoving or loading equipment shall ensure the cab windows are closed so cab dust (air con) filter systems can operate effectively during operations as appropriate to the machine.

Maintenance of vehicle cab dust filter systems shall be done regularly to ensure the system remains effective. Vehicle operators shall report defective cab dust filter systems in accordance with a preventative maintenance schedule.

Truck drivers shall remain within the dust filtered cab whenever the truck is being loaded or discharging a load.

3.2.5 Drilling

Drilling rigs will be fitted with effective dust control and collection equipment. Dust curtains, water sprays and air extraction systems will be employed wherever practicable.

Drill cuttings, including dust cones, should be wetted down to prevent dust generation. Care should be taken when moving drilling equipment not to disturb drill cuttings.

Wetting down of drill pads and adjacent hardstand areas will assist in reducing airborne dust.

In the event of defects that prevent the effective operation of a drill rig dust suppression system the drill rig operator shall cease operations until the defect is rectified.

3.2.6 Stemming and Blasting

Blasting will be carried out in accordance with the Drill and Blast Procedure to control dust. In particular, blasting will not be conducted during weather conditions that are inconsistent with corporate guidelines for blasting or likely to impact adversely on sensitive receivers.

3.2.7 Waste Rock Dump

Disused roads shall be windrowed off as appropriate to prevent vehicular access and the production of airborne dust. Access roads, traffic, tip and work areas of active waste rock dumps shall be wet down as required to minimise the production of airborne dust.

Waste rock tipping operations at an elevated height, exposed to strong winds shall be scheduled to minimise the amount of airborne dust produced. Waste rock dump rehabilitation shall be programmed as an integral part of the mining operation to minimise sources of airborne dust.

The estimated reduction in dust emissions achieved by the application of the control measures are presented in Table 2.

Table 2: Control Measures included in Emission Estimations

ACTIVITY / AIR EMISSION SOURCE	CONTROL MEASURE	REDUCTION
Exposed Areas	Rehabilitation	60%

ACTIVITY / AIR EMISSION SOURCE	CONTROL MEASURE	REDUCTION
Haul Roads - Sealed and Unsealed	Dust suppression watering	75%
Crusher	Watering at both ends	50%

4 AIR QUALITY MONITORING

4.1 DUST DEPOSITION GAUGES

Dust deposition gauges will be implemented during all stages of mining at various locations around the Barbara Copper Project. The monthly dust deposition monitoring program will measure dust deposition (fall out) data for the management of nuisance based air quality issues in accordance with *AS/NZS 3580.10.1:2016: Methods for sampling and analysis of ambient air: Determination of particulate matter - Deposited matter - Gravimetric method*. This will be achieved by sampling dust particulate matter at the designated dust deposition monitoring locations every 30 days following the methodology outlined below.

The dust deposition gauges will provide deposited dust samples (total solids) in g/m^2/month. The analysis of samples will be undertaken at a NATA accredited laboratory. Samples will also be analysed for ash content, combustible matter, total soluble matter and total insoluble matter to assist in determining possible contamination and dust sources.

Dust deposition monitoring is currently being undertaken at three locations around Barbara Copper Project. Monitoring of dust deposition will be continued at these locations throughout the duration of the Project. The locations of the dust deposition monitoring stations are outlined in Table 3.

If considered necessary, due to an irregular event or as part of complaint management, additional dust deposition gauges can be installed at other sensitive receptors to manage the circumstance.

Table 3: Passive Dust Gauge Monitoring Locations

SITE ID	LATITUDE (GDA94 Z54)	LONGITUDE (GDA94 Z54)	LOCATION DESCRIPTION
BDG01	-20.4252	139.8711	East of Mining Lease
BDG02	-20.4307	139.8596	Near Site Administration
BDG03	-20.4040	139.8382	North-west of Infrastructure Area

4.1.1 Depositional Dust Monitoring

AS/NZS 3580 identifies the equipment to use in collecting a dust sample and how to use it. The key equipment is a deposit gauge, which comprises a 150 ± 10mm diameter funnel inserted into a glass bottle (at least 4L in size) through a rubber stopper (see Figure 1). Note the NATA accredited laboratory will provide the bottles. Replacement rubber stoppers can be purchased from the laboratory as well.

Set up the deposit gauge and stand so that the height of the top of the funnel is 2m ± 0.2m above the ground level of the immediate surrounding area.

The glass bottle may also collect rainwater and other material such as bugs and leaf litter, etc. This does not contaminate the sample and should not be removed in the field. However, it is recommended that the type of any contamination be noted for each sample on a piece of paper at the time of collection (for example, note the presence of bird droppings, leaf litter, sticks, spider webs, Christmas beetles, etc. or whether the bottle was broken). This record may help explain unusual results (such as high insoluble matter) during laboratory analysis.

- After 30 days ± 2 days, wash any deposited matter in the funnel into the glass bottle using distilled water;
- Remove the funnel and seal the glass bottle with a lid;
- Identify the glass bottle with a label showing site location, the date sampling began and ended, and the funnel diameter to the nearest millimetre; and
- Insert a clean funnel into a fresh glass bottle.

Figure 1: Typical Depositional Dust Bottle

Figure 2: Dust bottle in Stand and (2) Bottles for change out

4.2 GRAVIMETRIC DUST MONITORING

This method determines average dust concentrations and comprises the collection of dust by drawing a constant flow rate of ambient air through a filter. Data is usually collected over a 24 hour period and results are expressed in $g/m^3/24hr$ (i.e. mass of dust per volume of air per 24 hrs). A selective inlet may be fitted to a high volume sampler to restrict the particle size being sampled (for example, to ensure only PM_{10} particles are sampled).

When coupled with a wind direction vane or matched with records of wind data, this method enables determination of dust levels from a particular event or source. It also gives an indication of the potential health effects of the dust because it allows measurement of fine and very fine particles in the atmosphere.

Should gravimetric dust sampling become a requirement for the site technical experts will be contacted in the first instance to develop and implement a sampling program.

4.3 COMPLIANTS MANAGEMENT

A legible record of all concerns made by the public will be kept on site by Round Oak Minerals. Each concern received in relation to the Project will be formally documented and a record of the following information will be maintained for legal and compliance purposes.

- The date and time of concern;
- The nature of concern (e.g. dust);
- The method by which the concern was received (e.g. telephone);
- The name and title of the person who receives the concern;
- The personal details of the complainant, if made available, or if no details were provided, a note to that effect;
- The action taken in relation to the concern, including any follow-up contact, the outcome of investigations and any required on-going actions;
- Reasoning for why no action was taken; and
- The final status of the concern (e.g. resolved, continuing or unresolved).

Follow up actions taken by an environmental consultant in relation to air quality (dust) concerns may include depending on circumstances:

- A site inspection of the complainant's residence;
- An investigation of meteorological conditions at the time of the incident;
- An investigation of potential dust generating sources in the vicinity of the complainant's residence; and
- If the complainant's residence is outside the Project's proactive air quality monitoring network, installation of an applicable monitoring station at the complainant's residence (e.g. dust deposition gauge); and
- If required, engagement of an air quality specialist to assist the concerns investigation process.

5 PEOPLE

5.1 ORGANISATIONAL STRUCTURE AND ACCOUNTABILITY

Round Oak has a process for establishing and maintaining an organisational structure with clear roles, responsibilities, authorities, and expectations. The Organisational structure provides clear accountability for deliverables.

Employees have written job descriptions and those descriptions are communicated to them.

5.1.1 Structure

Round Oak operates from its head office located in Brisbane, Queensland. At the Group level, the HSEC Manager has overall responsibility for HSEC functions.

At operational level, the assigned Site Manager (e.g. General Manager/SSE/Registered Mine Manager) has overall responsibility for HSEC performance. In addition, HSEC site personnel have a line responsibility to the Site Manager and a reporting function to the HSEC Manager.

The responsibility and authority pertaining to HSEC performance of key personnel, specialists and sub-contractors is described below. These responsibilities are categorised in relation to relevant positions and will be issued as part of the site induction.

5.1.2 Responsibilities

Responsibilities of key positions are described within Position Descriptions and the Management Structure Management Plan. Some selected responsibilities for positions are provided below.

Site Manager / Site Senior Executive (SSE)

The SSE is responsible for:

- Approve procedure and revisions;
- Provide adequate resources to ensure that effective dust control processes are used and that all identified hazards and risks are effectively controlled; and
- Ensure that the risk to persons and the environment from operations generating dust is at an acceptable level.

Corporate HSEC Team

The Corporate HSEC Team is responsible for:

- Informing site management of any changes to legal and other requirements;
- Providing advice for training and awareness programs;
- Providing HSEC management system standards and associated documents;
- Providing HSEC support.

Environmental Advisor

The Environmental Advisor Officer has direct reporting line to the Group HSEC Manager and a functional reporting link to the SSE and is responsible for the following:

- Ensuring data collected/reported and associated records maintained;
- Consulting with the SSE/Site Manager on air quality matters;
- Assisting with site inspections and audits;
- Liaising with workers on air quality management measures;
- Facilitating the implementation of environmental improvements and initiatives where practicable; and
- ensuring non-conformances and environmental incidents are identified, reported and suitable corrective actions are determined and completed.

Supervisors

Supervisors are responsible for:

- Utilise processes to identify hazards which may impact on the health and safety of the employees, the environment and the local community;
- Communicate the dust control procedures, process and potential effects to staff and to seek feedback;
- Staff are adequately trained, qualified and competent to perform duties;
- Actively participate in decisions involving the procurement of new plant and equipment; and
- Ensure that all identified hazards and risks are effectively controlled.

General Responsibilities of all Workers

All workers have a general environmental duty. Workers must not carry out any activity that causes, or is likely to cause, environmental harm unless the person takes all reasonable and practicable measures to prevent or minimise the harm. All Workers are responsible for:

- Utilise processes to identify hazards and control risks associated with assets;
- Communicate issues or concerns as appropriate; and
- Hazard / Near miss reporting.

6 RISK IDENTIFICATION AND ASSESSMENT

Generation and ineffective control of environmental dust pose a risk to:

- Health of workers and surrounding neighbours (sensitive receptors);
- Smothering of surrounding vegetation and contaminated run-off entering receiving waters; and,
- Environmental nuisance to public amenity.

7 REPORTING

7.1.1 Monthly Reporting

A monthly review of all air quality monitoring results will take place to ensure best practice management and compliance with air quality criteria. The data collected will contribute to the Project's internal monitoring and reporting system and be reported to the Project's management team on a regular basis.

In the event that a complaint regarding dust emissions is made to ROM by a sensitive receptor, and/or monitoring indicates the air quality criteria have been exceeded, an investigation would be undertaken (in accordance with the TARP) to identify the cause of the exceedance. If the exceedance is found to be

attributed to mining activities, Round Oak Minerals will implement dust mitigation measures so that dust emissions generated by the mining activities do not exceed criteria

7.1.2 Air Quality Management Plan Review

The Environmental Management Plan shall will be reviewed in response to events, changes in legislation, change in operations, findings of inspections and audits and management reviews.

8 CHANGE MANAGEMENT

The Change Management process includes the consideration for safety and health risks arising from significant changes to process, equipment, people, work environment, work conditions and work hours.

Change shall be managed in accordance with the Change Management Procedure.

Evidence showing consideration of safety and health risk assessment and management shall be maintained. As a minimum, this can be demonstrated through the following processes and records:

- Development, completion and review of JSA, work procedures and processes;
- Completion of Change Management Form or event in InControl®;
- Communication of relevant information between affected parties through meeting minutes, newsletters, emails, memos, notifications, inductions and orientations;
- Review of feedback; and
- Review of key documents such as management plans, structural and layout drawings, location maps showing changes affecting safety and health.

1 INTRODUCTION

This Groundwater Management Plan (GWMP) was developed for the Barbara Copper Project (BCP) to meet the requirements of conditions E16-18 of the Barbara Environmental Authority (EA) EPML02840015, dated 3 February 2020.

1.1 BACKGROUND

The conditions of the Barbara EA state the following:

E16 A Groundwater Management Program must be developed, documented and implemented by appropriately qualified persons

E17 The Groundwater Management Program required by Condition E16 must:

a) Identify potential sources of contamination to groundwater from the activity; and

b) Ensure that all potential groundwater impacts due to the activity are identified, monitored and mitigated;

c) Documented sampling and monitoring methodology; and

d) Ensure that adequate groundwater monitoring and data analysis is undertaken to achieve the following objectives:

i. Detect any impacts to groundwater levels due to the activity;

ii. Detect any impacts to groundwater quality due to the activity;

iii. Determine compliance with condition E11 and E12; and

iv. Determine trends in groundwater quality; and

e) Include an appropriate quality assurance and quality control program; and

f) Include a conceptual site model; and

g) Include a review process to identify improvements to the program that includes and addresses any comments provided by the administering authority.

This document serves to meet the requirements of these conditions.

1.2 OBJECTIVE

This GWMP has been prepared to monitor and manage the potential impacts on groundwater at and surrounding the Barbara Copper Project. It outlines the groundwater monitoring plan and associated groundwater impact criteria that will trigger further assessment and groundwater impact management.

The document has been prepared based on the potential impacts to groundwater identified in the Barbara Plan of Operations (2019) and Barbara Groundwater Assessment Report (2014).

2 PROJECT AND SITE CHARACTERISTICS

2.1 PROJECT OVERVIEW

The Barbara Copper Project is wholly owned by Round Oak Minerals and is located approximately 60km north-east of Mount Isa in North West Queensland. The Project operates within mining lease (ML) 90241, which covers approximately 1,761 hectares (ha) and targets copper ore and trace gold through open cut mining. The ore is transported offsite be processed at a third-party processing facility in the region.

Onsite activities commenced in February 2019 and will continue until approximately December 2020.

The site layout and mining infrastructure is outlined in **Figure 1.**

2.2 CLIMATE

The semi-arid to arid Mount Isa region is described as having a tropical continental climate (Bureau of Meteorology, Australia – Koppen Australian climate classification scheme). The wet season extends from December to March and delivers most of the yearly rainfall. Dry season months are characterised by relatiely low rainfall.

Climate data for the Barbara Copper Project were taken from the Bureau of Meterology (BoM0. The nearest BoM meteorological station to the operation is Mt Isa Airport (Station 029127). Based on the available data, the average maximum temperature varies from 24.9°C in July to 37.3°C in December, whereas average minimum temperature ranged from 8.7°C in July to 23.8°C in January (Error! Reference source not found.).

3 GEOLOGICAL AND HYDROGEOLOGICAL SETTING

3.1 HYDROLOGY AND TOPOGRAPHY

The Barbara Groundwater Assessment Report (2014) describes the topography and drainage characteristics of the Barbara area as containing three main landform types. These are erosional hills, ridges and plateaus and colluvial footslopes and alluvial channels. The area is dominated by exposed and subcropping Proterozoic rocks forming the hills and plateaus that dominate the landscape. Small areas of proximal colluvium are found as footslopes flanking the sides of the ridges and at the base of scarps. Minimal alluvial sediments are found in immature drainage systems.

The are no major watercourses in the vicinity of the operation although there are several minor, ephemeral tributaries that traverse the mining lease. Drainage channels tend to flow to the northwest, down gradient from the steeper hills located in the southern and central sections of the mining lease area. The deposition of alluvium within drainage systems is minimal.

3.2 GEOLOGY

3.2.1 Regional Geology

The Barbara Copper Project orebody is hosted within the Leichardt Metamorphics. At the operation, the Leichardt Metamorphics are steeply dipping at angles of up to 70 degrees and highly sheared. The orebody is located within what is informally termed as the Barbara Shear Zone. The area is structurally complex with structural repetition of stratigraphic units and wrench faulting common.

3.2.2 Local Geology

The Barbara Groundwater Assessment Report (2014) describes the local geology in the Barbara areas as comprising Proterozoic rocks of the Mount Isa Inlier. Rock types at Barbara include Felsic Volcanics (forming in the hills), dolerite/amphibolite (in the drainages/valleys) and basalt (forming plateaus). The Felsic Volcanics dip at 60 degrees towards the northeast and the dolerites are sub-vertical within the project area. These three rock types are resistant to weathering and extensive outcrop occurs throughout the area.

3.2.3 Geochemistry

An assessment of geochemical characteristics of waste rock and ore material at Barbara was conducted by the Environmental Geochemistry International Pty Ltd (EGI). A total of 121 drill core samples from 14 locations were analysed. Most samples representing waste had low sulphur contents and were non-acid forming (NAF) but there were some waste samples from close to mineralised zones that had elevated sulphur contents and were potentially acid forming (PAF). Ore samples had high sulphide contents and approximately half of the ore samples tested were PAF.

The Australian Standard Leaching Procedure testing on waste rock samples showed that all of the freshly mined waste rock is expected to be alkaline, with pH values ranging between 8.6 -9.0.

Sulphate concentrations for PAF waste were, on average, slightly higher than for NAF waste. Other differences were relatively minor. There were trace concentrations of aluminium in most extracts (median 0.19 mg/L), but the concentrations of copper and other environmentally important elements were low, and in most cases the concentrations were close to, or below, the analytical detection limits.

The Australian Standard Leaching Procedure testing on ore material recorded that all samples were slightly alkaline and that the concentrations of environmentally important elements were low, with the possible exception of manganese which for the ore samples exhibited a median concentration of 0.16 mg/L compared to 0.001 mg/L for the waste samples (EGI, 2014).

3.3 HYDROGEOLOGY

3.3.1 Aquifer characteristics

Occurrence and Extent

The primary aquifer at the Barbara Copper Project occurs within the Leichardt Metamorphics, generally at the base of the weathered zone. There is very little regolith across the project area and no regolith aquifer was identified. Alluvial deposits within drainage systems in the project vicinity are recorded as minimal.

Groundwater level measurements recorded in exploration drill holes during 2013 indicated that the median depth to groundwater at the Barbara deposit was approximately 12m below ground surface. Aquifer intervals and airlift yields for six bores in the Barbara project area indicate that groundwater is mainly found below the regolith (**Table 1**).

Table 1 - Aquifer intervals and airlift yields (RLA, 2014)

Bore	Total depth (m)	Aquifer intervals (m)	Airlift yield (l/s)	Total airlift yield (l/s)
BAWB01	104	22-23	0.6	1.1
		34-35	0.3	
		43-44	0.2	
BAWB02	104	No aquifer intervals encountered	-	-
BAWB03	104	No aquifer intervals encountered	-	-
BAWB04	100	No aquifer intervals encountered	-	-
BAWB05	102	39-40	0.2	0.3
		49-51	0.1	
BAWC071	146	19-22	0.5	0.8
		108-109	0.3	

Hydrogeological parameters

Given the arid climate and skeletal soils at the Barbara Copper Project, rainfall infiltration is considered to be minimal, with the vast majority of water lost by evaporation and transpiration. From exploration drilling logs and data recorded during the construction of groundwater monitoring bores in 2014, it is considered that direct rainfall recharge mechanism to the Leichardt Metamorphics aquifer at BCP is episodic recharge via lineaments aligned with watercourses (RLA, 2014).

Hydraulic conductivity values were first obtained through slug (falling head) tests conducted at four monitoring bores. Hydraulic conductivity values are regarded as extremely low to locally high (**Table 2**).

Table 2 - Hydraulic conductivity values calculated from slug tests at Barbara monitoring bores (RLA, 2014)

Bore	Hydraulic conductivity (m/d)	Hydraulic conductivity (m/s)	Qualitative description
BAWB01	8.00E+02	9.26E-03	Locally high
BAWB02	1.93E-05	2.23E-10	Extremely low
BAWB04	1.98E-03	2.29E-08	Very low

BAWB05	6.86E-04	7.94E-09	Very low

3.4 HYDROGEOCHEMISTRY

Chemical groundwater analysis conducted at the Barbara deposit indicated that the groundwater in the Barbara monitoring bores is predominantly of calcium bicarbonate and mixed calcium sodium bicarbonate type.

There is no indication of high sulphate content in the groundwater, even in the groundwater from bore BAWB02, which is in the Green Zone orebody, or from bores BAWB07 and BARC071, which are in the Barbara orebody (WMV, 2019).

3.5 GROUNDWATER FLOW

The contours and potentiometric surface profile (**Figures 1** and **2**) show that, providing there is hydraulic continuity throughout Leichardt Metamorphics, groundwater flow will be from south-west to north-east within the project area. There is also considered to be little or no potential for the development of alluvial aquifers within the project area (RLA, 2014).

3.6 SURFACE WATER INTERACTIONS

There is little regolith at the Barbara Copper Project site and no regolith aquifers have been identified. Groundwater levels at the Barbara Copper Project occur at minimum of 8m below surface level. The drainage features at BCP are immature and only incised to a shallow depth. None of the drainage incision reaches 8m depth. Therefore, there can be no groundwater to surface water interactions within the project area (RLA, 2014).

3.7 ENVIRONMENTAL VALUES

Environmental values (EVs) for water are those qualities that allow a waterbody or groundwater aquifers to support aquatic ecosystems and human water uses (EHP, 2014). The EVs of a system require protection from anthropogenic effects to ensure healthy aquatic ecosystems and waters are safe for community use (EHP, 2014). The *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* (EPP Water) was designed to provide guidance in achieving the objectives of the *Environmental Protection Act 1994* with respect to water and wetlands. The EPP Water provides a framework for the identification of EVs of Queensland waters, in order to protect the water environment while allowing for ecologically sustainable development. The EPP Water notes that EVs and water quality objectives (WQOs) are being progressively determined for different areas in Queensland. WQOs define objectives for physical, chemical and biological characteristics of water. The Project falls within the Southern Gulf Catchments region as relevant to the EPP Water, for which specific water and wetland EVs attribution and water quality planning is currently under development. The EPP Water defines EVs for waters and wetlands as:

a) for high ecological value waters—the biological integrity of an aquatic ecosystem that is effectively unmodified or highly valued; or

b) for slightly disturbed waters—the biological integrity of an aquatic ecosystem that has effectively unmodified biological indicators, but slightly modified physical, chemical or other indicators; or

c) for moderately disturbed waters—the biological integrity of an aquatic ecosystem that is adversely affected by human activity to a relatively small but measurable degree; or

d) for highly disturbed waters—the biological integrity of an aquatic ecosystem that is measurably degraded and of lower ecological value than waters mentioned in paragraphs (a) to (c); or

e) for waters from which aquatic foods intended for human consumption are taken—the suitability of the water for producing the foods for human consumption; or

f) for waters that may be used for aquaculture—the suitability of the water for aquacultural use; or

g) for waters that may be used for agricultural purposes—the suitability of the water for agricultural purposes; or

h) or waters that may be used for recreation or aesthetic purposes—the suitability of the water for—

   (i) primary recreational use; or

   (ii) secondary recreational use; or

   (iii) visual recreational use; or

i) for waters that may be used for drinking water—the suitability of the water for supply as drinking water having regard to the level of treatment of the water; or

j) for waters that may be used for industrial purposes—the suitability of the water for industrial use; or

k) the cultural and spiritual values of the water.

As specific environmental values are "currently under development" within the Gulf region, the following are deemed most relevant to the site:

- aquatic ecosystems (slightly-moderately disturbed systems);
- agriculture uses (stock water);
- secondary recreation;
- visual recreation;
- cultural and spiritual values.

Stygofauna has been detected in groundwater, with relatively low abundance and diversity at the family level (AARC, 2014). Post-mine land use is expected to be low-intensity grazing. Based on these observations, it is considered groundwater has environmental values for aquatic ecosystems protection (due to the presence of stygofauna) and for livestock drinking (due to the proposed grazing land use).

4 POTENTIAL IMPACTS

4.1 NATURE AND EXTENT OF ACTIVITIES

As per the *Plan of Operations* (BCP, 2019), the major activities that will be conducted on the Barbara mining lease are as follows:

- Open-cut mining using conventional drill and blast, load and haul;
- Dewatering of groundwater to allow mining and reuse on-site; and
- On-site out-of-pit waste rock dump.

4.2 POTENTIAL IMPACTS ON GROUNDWATER LEVELS

Groundwater levels surrounding the Barbara project can be potentially impacted by the removal of water from the mined open pit area. It is anticipated that as a result of pit dewatering there will be a cone of groundwater level depression that will extend approximately 1km along the Barbara Shear Zone from the centre of the pits (RLA, 2014). The nearest privately-owned stockwatering bore (RN 70146) is located approximately 1.5km from the North Pit. Considering the lack of groundwater use within the area, this presents a very low overall risk to the groundwater resources in the area.

4.3 POTENTIAL IMPACTS ON GROUNDWATER QUALITY

Groundwater quality can be potentially impacted due to:

4.3.1 Infiltration through Waste Rock Dump

Characterisation of the waste rock dump indicates that rainwater encountering waste rock will most likely be non-acid forming (NAF) with low sulphur content (EGI, 2014).

83 of the 94 waste rock samples tested were classified as non-acid forming and recorded low sulphur concentrations (EGI, 2014). The absence of potentially acid-forming material and the negligible amount of sulphur in most waste rock samples implies that oxidation reactions should be minimal.

The Australian Standard Leaching Procedure test on waste rock samples showed that some waste rock samples were significantly enriched with copper, sulphur and selenium relative to concentrations typically reported for background soil (EGI, 2014). It is expected that drainage from NAF waste rock will be neutral to slightly alkaline and have low concentrations of soluble salts and environmentally important metals and metalloids.

In the event of long-term exposure of PAF waste leading to development of acid conditions there would likely be significant increases in the concentrations of dissolved metals within drainage. In addition to copper, iron and aluminium, there would likely be significant concentrations of cobalt, manganese, nickel and zinc. Given, the high ratio of NAF to PAF waste rock at the Barbara project, problematic material is accommodated within the core of the waste rock dump in a manner that provides long-term geochemical stability and limits the potential for sulphide oxidation or metals leaching.

4.3.2 Storage of mine-affected water

The two open pits are proposed to remain as open final voids. Therefore, after the completion of mining, the pits are expected to store water. It is expected that evaporation rates in these pit lakes will exceed the rate of inflow and, as a result, the water level in the pits will always remain lower than the surrounding groundwater table (RLA, 2014).

There is also a sediment dam onsite. The likelihood of seepage from this dam is very low, as it has been HDPE lined. This dam will be retained to evaporate stormwater runoff from the rehabilitated waste rock dump. Water quality monitoring will be ongoing to determine the quality of the water in the pits and sediment dam prior to decommissioning.

5 CONCEPTUAL SITE MODEL

A summary of groundwater modelling is provided below:

- The groundwater flows towards the centre of the mining lease towards the location of the South and North pit. The contours and the potentiometric surface profile show that, providing that the hydraulic continuity exists through the Leichardt Metamorphics, groundwater flow will be from south-west to north-east within the Barbara Shear Zone (RLA, 2014).
- The central segment is the approximate location of the North and South pits. The positioning of the bores is such that groundwater will flow generally towards this central segment from each bore.
- The groundwater level data from the Barbara deposit highlighted that the depth of groundwater is a minimum of and that the potentiometric surface contours flow away drainage systems and towards the location of the pits.

- No groundwater-surface water interaction is expected in the alluvium due to the large thickness of the confining unit.
- Potential impacts to the groundwater aquifer include drawdown. The distance to the nearest privately-owned stockwater bore is approximately 1.5km, which is beyond the radius of drawdown influence (approximately 1km).

Figure 1 - Potentiometric contours at Barbara Copper Project (RLA, 2014)

Figure 2 - Potentiometric surface profile from BAWB02 to BAWB05 (RLA, 2014)

6 GROUNDWATER MONITORING AND MANAGEMENT PROGRAM

6.1 OVERVIEW

The GWMP for the Project includes procedures and processes required to assess the potential impacts of mining activities on groundwater resources. The establishment and implementation of the GWMP will evolve and respond to the various stages of the mining project. It will be reviewed to ensure the program remains reflective of the different project phases, including operations and post-closure activities.

The GWMP has been developed for the Project to detect any changes to groundwater quantity or quality due to mining activities. The GWMP has been developed by taking into consideration the current suitability of groundwater for agricultural use, aquatic ecosystems protection (due to the presence of stygofauna) and for stock water drinking. In accordance with the regulatory requirements specified in condition E17 of the EA, the GMP must:

- Identify potential sources of contamination to groundwater from mining activities.
- Ensure that all potential groundwater impacts due to the activity are identified, monitored, and mitigated.
- Document sampling and monitoring methodology.
- Ensure that adequate groundwater monitoring and data analysis is undertaken to achieve the following objectives:
    - Detect any impacts to groundwater levels due to the activity.
    - Detect any impacts to groundwater quality due to the activity.
    - Determine compliance with condition E11 and E12 of the EA.
    - Determine trends in groundwater quality.
- Include an appropriate quality assurance and quality control program.
- Include a conceptual groundwater model.
- Include a review process to identify improvements to the program.

6.2 EXISTING MONITORING NETWORK

There are eighteen monitoring bores included in the EA monitoring framework for the Project (**Table 3**), comprising ten compliance bores and eight seepage monitoring bores.

Table 3 - Barbara groundwater monitoring criteria

Monitoring Point	Location (GDA94, Zone 54)		Surface RL (m)	Total Depth (mbgl)	Screened Interval (mbgl)	Monitoring frequency	
	Easting	Northing				Standing water level	Groundwater quality
Compliance bores							
BAWB05	380948	7740252	377.32	102	35-102	Monthly	Quarterly

Seepage bore 4b	380711	7740800	355.11	16	5-15		

6.3 MONITORING AND SAMPLING METHODOLOGY

As per condition E10 of the EA, the groundwater quality and standing water levels (SWLs) must be monitored:

- At the locations specified in Table E5 of the EA (Error! Reference source not found.);
- At the frequencies specified in Table E5 (Error! Reference source not found.); and
- For the quality characteristics identified in table E6 of the EA.

Groundwater monitoring and sampling will be conducted by a suitably qualified and experienced professional in accordance with the Queensland Department of Environment and Science (DES) Monitoring and Sampling Manual (DES, 2018; or subsequent updated versions), the Geoscience Australia Groundwater Sampling and Analysis – A Field Guide (Sundaram et al. 2009), and the Australian/New Zealand Standard (AS/NZS) 5667.11:1998 for water quality – sampling Part 11 guidance on sampling groundwater.

As per condition A5 of the EA, all monitoring activities, records, and reports required by this environmental authority or related to environmental management of the activities must be:

- Carried out by an appropriately qualified person;
- Kept for a period of not less than five years; and
- Provided to the administering authority in the specified format within 10 business days of a request.

6.4 MONITORING DATA MANAGEMENT

The data gathered from the groundwater monitoring will be collated into a database which will include:

- A site plan showing sampling location;
- Periodic photos from sampling locations during sampling event;
- Tabulated results of the monitoring compared with applicable background levels;
- All data collected during each monitoring round;
- A record of the chain of custody of the samples from sampling through to analysis; and
- Laboratory analysis certificates.

6.5 QUALITY ASSURANCE AND QUALITY CONTROL

The DES Monitoring and Sampling Manual (DES, 2018) provides guidance on the types of quality control measures and the frequency of collection of quality control samples.

The following quality assurance and control measures are proposed for its GWMP:

- Field blank (one per trip or one per 20 samples)
- Blind duplicates (one per 10 samples)

Field blanks are used to estimate the contamination of a sample during the collection procedure. They are prepared in the field in the same manner as the sample. The sample will be taken from MilliQ water. For example, if a sample is field filtered, the field blank will also be filtered. It is recommended that water is supplied by the testing laboratory.

Blind duplicates are to be taken at the same time as the sample. It is recommended that the same bottle type be collected one after the other. The date and time of the sample should not be disclosed to the laboratory. Interpretation is based on the reproducibility assessment method, which provides a measure of precision. The analytical values from the original sample and its duplicate are compared by calculating the relative per cent difference (RPD) for each parameter as follows:

$$RPD(\%) = [\frac{Sample - Duplicate}{Mean\ of\ sample\ and\ Duplicate}] * 100$$

The RPD then uses the limit of reporting (LOR) to identify thresholds for valid reproducibility. These include:

- Mean of sample and duplicate <10 times LOR: There is no RPD limit (i.e. reproducibility is valid)
- 10 times LOR < Mean of sample and replicate < 20 times LOR: The RPD range limit is 0%-50% for a valid duplicate
- Mean of sample and replicate > 20 times LOR: The RPD range limit is 0% - 20% for a valid duplicate.

If the RPD exceeds the threshold percentage, the results are considered unreliable and require further investigation. Only one duplicate sample is needed to be collected per sampling event.

7 GROUNDWATER IMPACT TRIGGERS AND INVESTIGATION PROTOCOLS

7.1 GROUNDWATER EXCEEDANCE NOTIFICATION

Groundwater quality limits (as Limit A and Limit B) are discussed in Table E6 of the EA. As per condition E11 and E12 of the EA, groundwater measured from any compliance bore specified in Table E5 must not exceed the corresponding Limit A specified in Table E6 on any five consecutive sampling occasions, and Limit B specified in Table E6 on any three consecutive sampling occasions.

Condition E13 states "*If groundwater measured from any compliance bore specified in Table E5 exceeds the corresponding Limit B specified in Table E6 on any one sampling occasion the environmental authority holder must resample the groundwater within the compliance bore for all exceeding parameters within ten business days of receipt of results.*"

Condition A9 of the EA states that the environmental authority holder must notify the administering authority within 24 hours of becoming aware of any emergency, incident, sample result or event which does or may contravene a condition of this environmental authority.

It is recommended that the administering authorities should be notified in accordance with condition A9 if groundwater measured from any compliance bore specified in Table E5 exceeded the corresponding Limit A specified in Table E6 on any five consecutive sampling occasions, and Limit B specified in Table E6 on any three consecutive sampling occasions.

Condition E13 states that if groundwater measured from any compliance bore specified in Table E5 exceeds the corresponding Limit B in Table E6 on any one sampling occasion the environmental authority holder must resample the groundwater within the compliance bore for all exceeding parameters within ten business days of receipt of results.

7.2 GROUNDWATER QUALITY TRIGGERS AND LIMITS

Groundwater contaminant limits have been set based on the following:

- Default ANZG (2018) guideline values for freshwater aquatic ecosystems for 95% species protection for slightly to moderately disturbed ecosystem.
- Site-specific values based on 80th and 95th percentiles.

The shallow groundwater trigger levels and water quality objectives outlined in Table E6 of the EA have been set based on the following:

- ANZECC (2000) value for 95% species protection, Table 3.4.1, measured as 'dissolved' metals.
- Derived from site-specific values, based off dissolved concentration of metals (80th percentile).
- Derived from site-specific values, based off dissolved concentration of metals (95th percentile).
- Based off ANZECC (2000) low reliability metals and metalloids, Section 8.3.7.1

7.3 GROUNDWATER LEVEL TRIGGERS

No condition outlining triggers for groundwater level is included in the EA. However, SWL will be monitored monthly for interpretation purposes only in accordance with condition E10 of the EA.

7.4 GROUNDWATER INVESTIGATION PROCEDURES

Condition A10 of the EA states that *"Within 10 business days following the initial notification of an emergency or incident, or receipt of monitoring results, whichever is the latter, further written advice must be provided to the administering authority, including the following:*

a) Results and interpretation of any samples taken and analysed

b) Outcomes of actions taken at the time to prevent or minimise unlawful environmental harm; and

c) Proposed actions to prevent a recurrence of the emergency or incident."

Exceedances notified to the administering authorities must be investigated as per condition A10 of the EA for monitoring bores listed in Table E5 of the EA.

Condition E13 also states that if the concentration of a contaminant measured at a compliance bore or seepage bore exceeds any trigger level specified in Table E6 on any one sampling occasion, the holder of this environmental authority must resample for all exceeding parameters within ten business days of receipt of the initial results.

8 REVIEW AND IMPROVEMENT PROCESS

8.1 GROUNDWATER MONITORING PROGRAM REVIEW

In accordance with Condition E18, the GWMP will be reviewed on an annual basis by an appropriately qualified person to determine whether the program continues to meet the requirements stated in Condition E17 of the EA. The review process may include the following:

- An assessment of the outcome of the GWMP against the objectives outlined in the Barbara EA;
- A review of the adequacy of the monitoring locations, sampling frequency and groundwater quality triggers specified in the Barbara EA;
- Recommendations for any required variations to the extent of monitoring program and any required increase in monitoring bore locations off-lease to monitor quality impacts adequately;
- Revision of monitoring parameters and sampling frequency; and
- Expanding the existing groundwater monitoring network over time to enable ongoing groundwater impact evaluations.

This GWMP may be updated as required or revised based on the outcomes of the review process. The administering authority will be consulted in relation to any significant changes proposed to the GWMP. The document will be made readily available to the administering authority on request.

8.2 BORE REPLACEMENT AND DECOMMISSIONING

The Barbara Copper Project will proactively maintain the groundwater monitoring network, replacing any bores as necessary and will use the review of monitoring data to inform the location of any additional monitoring bores if required.

Bore construction and decommissioning will be undertaken in accordance the Minimum Construction Requirements for Water Bores in Australia (NUDLC, 2011) and in accordance with Condition E14, must be undertaken in a manner that:

- Prevents contaminants entering the groundwater;
- Ensures the integrity of the bores to obtain representative groundwater samples from the target aquifer; and
- Maintains the hydrological environment within the aquifer.

For all existing monitoring bores and new monitoring bores being installed, a bore drill log must be kept in accordance with requirements specified in condition E15 of the EA (including bore location, construction details, and hydrogeological and stratigraphic information).

1 INTRODUCTION

The Barbara Copper Project (BCP) is located approximately 60km northeast of Mt Isa in north-western Queensland, within the Leichhardt River Basin. The site operates under Environmental Authority (EA) EPML02840015 (Effective Date – 30 October 2019), issued by the Department of Environment and Science (DES, 2019a). Development of the project site commenced in March 2019. The key water management features incorporated in the water management system at the project includes the following:

- North Pit;
- South Pit;
- Waste Rock Dump (WRD) Sediment Dam; and
- Diversion drains and bunds.

Round Oak Minerals Pty Ltd (Round Oak) has engaged ATC Williams Pty Ltd (ATCW) to update the Water Management Plan (WMP) for the site. A WMP was originally developed by URS (now known as AECOM) in 2014 during the conceptual stage of the project. That WMP was updated by ATCW in 2018 (ATCW, 2018) during the detailed design phase.

Construction of the WRD Sediment Dam was completed in August 2019, with both the North Pit and South Pit under excavation. In September 2019, excavation of the North Pit was temporarily halted to allow it to be used for water storage during the upcoming wet season. This WMP updates the 2018 WMP (ATCW, 2018), with the as constructed structure details as at October 2019. The expected life of mine (LoM) is less than 2 years (March 2019 – November 2020).

1.1 Purpose of the Water Management Plan

The purposes of this WMP document are listed below.

(i) Comply with the licence conditions under the EA.
(ii) Outline the control measures to be implemented to prevent detrimental impact on receiving waters.
(iii) Provide site personnel with a guide to ensure effective water management.

The scope has been prepared to satisfy the conditions outlined in the DES (2012) guideline *Preparation of Water Management Plans for Mining Activities*. The WMP includes the following:

(a) Contaminant Source Study (Section 3);
(b) A study of the Environmental Values and Water Quality Objectives (Section 3);
(c) Site Water Balance and Model (Section 4);
(d) Water Management System (Section 3,4,5,6);
(e) Saline and Metalliferous, Drainage Prevention and Management Measures (Section 3);
(f) Acid Rock Drainage Prevention and Management Measures (if applicable) (Section 3);
(g) Emergency and Contingency Planning; (Section 8); and
(h) Monitoring and Review (Section 7).

1.2 Report Structure

The structure of this report, to address the scope of the WMP, is as follows:

Section 2.0	-	Provides a description of the project in the context of the site water management strategy and the site setting, including the climatic and hydrological conditions.
Section 3.0	-	Presents an overview of expected site water quality and contaminant types. It includes details the water management strategy for the site as well as identification of potential Environmental Values.
Section 4.0	-	Outlines hydraulic license conditions regarding the Design Storage Allowance, Extreme Storm Storage and Mandatory Reporting Level.
Section 5.0	-	Presents details of site water balance modelling carried out for the site, including a review of overall hydrological performance based on the adopted water management layout.
Section 6.0	-	Details site water monitoring and review requirements.
Section 7.0	-	Provides an overview of the Emergency and Contingency procedures for the site.

2 PROJECT BACKGROUND

2.1 Project Development

The BCP is located approximately 60km northeast of Mt Isa in north-western Queensland. Primary access to the site comprises a 10km unsealed access track, via Lake Julius Road. Mining operations and construction commenced in March 2019, incorporating conventional open cut and excavation methods. It is understood that no processing is to occur at the site, with extracted ore to be transported by road train to processing sites at Malaco's Mt Cuthbert Mine and Glencore's Mt Isa Mine. Consequently, the site development includes a run-of-mine (ROM) pad and haul road infrastructure, but does not include processing or a tailings storage facility. The location of the BCP in a regional context is shown on **Plate 1**.

Plate 1
Site Location

Source: Google Earth Satellite (accessed 6 November 2018)

2.2 Site Infrastructure

The general layout of the site is depicted in **Figure 001**. The BCP incorporates the following key infrastructure:

- North Pit;
- South Pit;
- Waste Rock Dump (WRD);
- Waste Rock Dump Sediment Dam (WRD Sediment Dam);
- Light Infrastructure Area (LIA);
- Run-of-Mine (ROM) Pad, which includes the Road Train Loading Area (RTLA); and
- Magazine.

Other elements include:

- Haul roads and tracks
- Diversion drains
- Sewage treatment facility

The configuration of key site infrastructure is listed in the following sections. Pit geometry elevations were supplied by Round Oak in Mine Datum (AHD +1000m). The elevations listed below have been translated to reflect Australian Height Datum (AHD), by subtracting 1,000m. Refer also to **Table 2** (Section 3.3) for maximum licenced areas of disturbance.

The general layout of the site is depicted in **Figure 001**.

2.2.1 North Pit

The open-cut pit is located downstream of the rest of the site, with two diversion channels (ATCW, 2019) to redirect flows around the pit extents. The current configuration of the pit, as at 22 October 2019 is summarised below:

- Pit rim elevation — RL 316 m
- Approx. pit depth — 16 m
- October 2019 constructed pit rim capacity — 129.1 ML
- Pit extents — 1.5 ha
- Catchment area — 3.3 ha

A 1ML nominal sump is located at the base of the North Pit to collect rainfall that reports to the pit. The water is this sump is used for dust suppression.

2.2.2 South Pit

The open-cut pit is located to the east of the main creek alignment. The South Pit has a diversion drain on its east side to collect and convey clean surface flows from the adjacent hills to an alternative creek to the north of the pit. Site impacted catchment runoff from the ROM Pad/RTLA and the eastern portion of the WRD that flows along the haul road is diverted into the South Pit. The configuration of the pit as at 22 October 2019 is summarised below:

- Pit Rim Elevation — RL 334m
- Approx. Pit Depth — 34m
- Ultimate Pit Rim Storage Capacity — Approx. 3.3GL
- October 2019 Constructed Pit Rim Capacity — 995.4ML
- Pit Extents — 6.4ha
- Catchment Area — 21.0ha

A 1ML nominal sump is located at the base of the South Pit to collect rainfall that reports to the pit from the ROM Pad/RTLA and the haul road. It is expected that under extreme rainfall conditions the sump volume of 1ML will be exceeded, and thus water will spill into the South Pit. Round Oak have advised that operations will cease during inundation of the South Pit. Water from the South Pit sump is pumped to the North Pit.

2.2.3 WRD Sediment Dam

The WRD Sediment Dam is located directly downstream of the WRD and acts as a collection point for any surface runoff from the WRD. In previous documentation, the WRD Sediment Dam has been referred to as the 'WRD Dam'. The original dam was proposed as an earthen fill embankment lined with a Bituminous Geomembrane (BGM) liner. The constructed structure comprises two earthen fill embankments lined with a geomembrane and cushioning geotextile. The configuration of the dam is summarised below.

- Embankment Crest Elevation — RL 338.3m AHD
- Full Supply Level — RL 337m AHD
- Maximum Storage Capacity — 131.9ML
- Sediment Dam Extents — 3.0ha
- Catchment Area — 29.4ha

2.2.4 Light Infrastructure Area

The LIA is located south-east of the South Pit. The location is utilised as a general purpose area for mining plant, storage of equipment and materials. Runoff from the LIA is contained locally through bunding. Round Oak have advised that under extreme rainfall conditions, runoff will be conveyed to the South Pit via a surface drain alongside the haul road.

2.2.5 ROM Pad and Road Train Loading Area

The ROM Pad and RTLA are located adjacent to the South Pit. This location is utilised for temporary storage of excavated ore and waste prior to classification and haul/disposal. Runoff from the area drains to the South Pit.

2.2.6 Magazine

The explosives magazine is located to the north-west of the North Pit. The magazine area is bunded and is not included in the surface water transfer system.

2.3 Site Schedule

The site development timeline, as specified by Round Oak, is listed in **Table 1.**

Table 1
Site Development Schedule

Estimated Timing	Actual Timing	Infrastructure
Jan – Feb 2019	Jan – Feb 2019	Site access road, raw water tank installation
		Haul roads
		Topsoil stripping & stockpiling
		Surface water diversion features around site
		Diversion channel west of North Pit
		WRD preparation
		WRD Sediment Dam
		ROM pad & road train loading area
		Light infrastructure area & sewage treatment facility
		Explosives magazine
		Pump transfer network
Feb 2019	Feb 2019	Operations commence – South Pit
Jul 2019	Sep 2019	Operations commence – North Pit
Sep 2019	Oct 2019	Operations suspended – North Pit*
Oct 2019	Oct 2019	North Pit prepared for mine water storage for wet season
Jan 2020		North Pit operations resume
Sep 2020	-	Operations cease – South Pit
Oct 2020	-	Discontinue pumped transfers of site water, gravity flows commence to south pit
Oct 2020	-	Progressive rehabilitation

*At October 2019, the North Pit has reached a total volume of 129.1ML out of a design volume of 193.9ML.

2.4 Hydrological Characteristics and Topography

2.4.1 Regional Context

The BCP is situated within the Leichhardt River Basin (refer **Plate 2**). The Leichhardt River is formed in the Selwyn ranges at an approximate elevation of RL 405 m, falling over its 630km length to discharge into the Gulf of Carpentaria to the north. Julius Dam is located some 30km downstream of the project, at the confluence of the Leichhardt River and Paroo Creek. Lake Julius has a capacity of approximately 107.5GL and is listed in the Commonwealth's Directory of Nationally Important Wetlands.

Plate 2
Leichhardt River Basin Catchment Map

Source: Google Earth Satellite (accessed 6 November 2018)

2.4.2 Site Context

The topography and drainage characteristics of the local area surrounding the BCP has been described by Syndicated Metals Ltd (2014), and for the purposes of this plan is reproduced below.

"There are three main landform types in the Barbara area. These are: erosional hills, ridges and plateaus, colluvial foot slopes and alluvial channels. The area is dominated by exposed and sub cropping Proterozoic *rocks forming hills and plateaus. Small areas of proximal colluvium are found as foot slopes flanking the sides of ridges and at the base of scarps. Minimal alluvial sediments are found in immature drainage systems.*

There are no major [drainage or riverine features] *in the Barbara area; however, there are several minor, ephemeral tributaries which run through the site. Drainages tend to drain to the northwest, down from the steeper hills found in the south and through the Barbara area. Deposition of alluvium within drainage systems is minimal and there are no palaodrainages present in the area."*

The network of local ephemeral watercourses within the BCP region are depicted on **Plate 3**.

Plate 3
Local Watercourses in the Barbara Area

Source: Google Earth Satellite (accessed 6 November 2018)

2.4.3 Climatic Conditions

Located in north-western Queensland, the BCP is subject to a semi-arid tropic environment. The nearest meteorological weather station to the site, with greater than 2 years of rainfall records, is the Bureau of Meteorology's (BoM) West Leichhardt weather station (No. 029121) located some 25km to the south-west of the site. The average annual rainfall in the region is approximately 432mm. The West Leichhardt station does not have long term evaporation data – a key factor in the assessment of surface water management. Therefore, for the purposes of this assessment evaporation data has been sourced from a SILO Data Drill specific to the site location. The average total annual evaporation for the site is 2,971mm. **Plate 4** summarises the average rainfall and evaporation for all months of the year for the site. From the SILO Data Drill series, only data ranging from 1970 to 2019 was plotted, as Class A evaporation pan data is only available in the region for this period.

Plate 4
Mean Rainfall and Evaporation

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Rainfall	122	110	74	16	13	12	7	4	7	18	34	75
Evaporation	287	241	258	235	190	155	167	212	262	323	321	320

Plate 4 indicates that evaporation potential exceeds mean monthly rainfall throughout the entire year. On an average monthly basis, maximum evaporation occurs later in the year (October to December). During the dry season months, evaporation is significantly lower, with the lowest monthly total typically occurring in June.

The climate at the site is associated with highly variable rainfall conditions. Mean values indicate a distinct pattern with lower rainfall conditions associated with the winter months, and higher values associated with the summer months. The wet season occurs between December and March, with 77% of mean annual rainfall occurring during these months, peaking in January, as shown on **Plate 4**.

2.4.4 Hydrogeology

Site characterisation of site hydrogeology has been undertaken by Rob Lait & Associates, with documentation under *Barbara Copper Project – Hydrogeological Report* (RLA, 2014).

The predominant landforms in the area comprise erosional topographic features, colluvial foot slopes and alluvial channels. Fractured rock aquifer systems are located at variable depths, typically where mineralisation / veins occur. Airlift testing conducted at the site suggests variable depletion rates (RLA, 2014).

Productive aquifer systems at the site intersect mineralised zones.

3 INTERGRATED WATER MANAGEMENT STRATEGY

3.1 Objective

An objective of this Plan is to maintain the biological integrity of surface water and groundwater at the BCP and to ensure the quality of water does not adversely affect environmental values or the health, welfare and amenity of people and land users by meeting statutory requirements and acceptable standards.

3.2 Environmental Values and Beneficial Users

Schedule 1 of the *Environmental Protection (Water) Policy 2009* (EPP Water) (DES, 2018) defines waters which are managed pursuant to the *Environmental Protection Act 1994* (EP Act) (Qld Parliament, 2018). Under this policy, Environmental Values (EV's) are defined, with Water Quality Objectives (WQO's) developed in accordance with the downstream values and users.

Review of Schedule 1 indicates that the Leichhardt Basin (Gulf of Carpentaria drainage division) does not currently have gazetted and mapped EV's or WQO's. Notwithstanding, generalised assessment under the EPP Water can be based on the nature of the receiving environment.

Based upon the hydrological domains downstream of the BCP location and potential downstream users, classification of the Environmental Values (EV's) for the downstream environment may include (Sustainable Minerals Institute, 2012):

- Aquatic Ecosystems;
- Stock Water;
- Irrigation;
- Recreation and Aesthetics;
- Fishing;
- Water Sports;
- Drinking Water; and
- Cultural and Spiritual Values.

Drainage paths downstream of the site location are described in **Section 2**, with principal features including:

- **Minor Drainage Paths**
  A series of minor drainage paths convey waters from the site location to a confluence point with the Leichhardt River, located some 10km to the west of site (as measured longitudinally in the invert of the drainage path). These drainage paths are unmapped on the Queensland Government Watercourse Identification Map (WIM).

- **Leichhardt River**
  The source of the Leichhardt River is located some 15km to the south of Mount Isa with the headwaters forming at the base of the Selwyn Mountain range. The Leichardt River is dammed at Mt Isa by the Moondarra Dam. Downstream of the Moondarra Dam, the Leichhardt River flows east, then north. The longitudinal distance between the Moondarra Dam wall and the Minor Drainage Paths-Leichardt River confluence point is some 40km. The Leichhardt River contributes to the Lake Julius Dam reservoir, some 15km to the north (longitudinally) of this confluence.

The Leichhardt River is an ephemeral Gulf river, and flow behaviour is dependent on rainfall conditions. Rainfall is typically heaviest in the summer period, as illustrated on Plate 4.

- **Lake Julius**
  Lake Julius has been formed by a concrete dam structure, featuring a series of arches and buttresses. The lake was formed by the damming of the Leichhardt and Paroo Rivers. The capacity to Full Supply Level is some 107.5GL. The owner/operator of Lake Julius and the Julius Dam is SunWater.

  Lake Julius is considered the practical end-point of the downstream environment. The large volume of the lake dilutes and allows for sedimentation of many contaminants, and so limits their potential to be mobilised further downstream.

  Downstream of the Julius Dam, the Leichhardt River continues north. A series of lesser Gulf rivers join the Leichhardt River as it flows towards the Gulf of Carpentaria, discharging in the vicinity of Burketown.

Additionally, areas downstream of the BCP are defined as slightly-moderately disturbed through historical and current mining and stocking activities. For example, the Leichhardt River has a significant history of contamination upstream of the site location, with riverine tailings discharge occurring at Mt Isa in the 1940's and discharge of process water continuing throughout the 1950's and 1960's (Sustainable Minerals Institute, 2012). Although river-bed sediment removal programs have significantly improved the amenability of the Leichhardt River, a slightly-moderately disturbed classification is considered appropriate.

3.3 Water Management Areas

The operation of the BCP is expected to include the following activities and infrastructure, much of which is relevant to Water Management, as detailed in **Table 2**.

Table 2
Water Management Areas

Defined Water Management Area	Name of disturbance area	Maximum licenced area of disturbance (ha)	Purpose
Active Mining Area	Run-of-mine (ROM pad)	3.5	Temporary storage, crushing and handling of ore
Active Mining Area	Road train loading area	1	Loading of ore for transport off-site
*Active Mining Area	North Pit	1.5	Mining of ore and site water management. Note: The North Pit is a regulated dam.
Active Mining Area	South Pit	6	Mining of ore and site water management. Note: The South Pit is a regulated dam.
Active Mining Area	Waste Rock Dump (WRD)	23	Storage and disposal of waste rock
NA	ROM pad dam	0.6	*NA - no longer part of project*
Non-Mining Area	WRD Sediment Dam	4	Water management for stormwater runoff from the WRD area
Non-Mining Area	Diversion drain	0.5	Water management to prevent stormwater runoff entering mine workings
Non-Mining Area	Topsoil stockpiles	2.5	Storage of topsoil for site rehabilitation works
Non-Mining Area	Access Road, Haul Roads and tracks	20.5	Site access
Non-Mining Area	Light Infrastructure Area: including Administration buildings, Fuel storage, Power facility and Workshop area	2.5	Site administration, Fuel Storage and power generation, Maintenance and storage
Non-Mining Area	Sewage treatment facility	0.5	Treatment of sewage
Non-Mining Area	Explosives magazine	0.5	Storage of explosives (not relevant to water management)

Table 2 is adapted from Table A1 of EPML02840015 (Date Effective: 30 October 2019)
*Operations of the North Pit have been temporarily suspended to provide wet season storage. The North Pit will resume operations in 2020.

3.4 Potential Contaminant Sources

The BCP predominantly involves two open cut pit developments, disposal of overburden waste rock material, handling of extracted ore and subsequent transportation offsite. Accordingly, the principal contaminant sources on site are the extracted waste rock and ore material from the North and South Pit.

Potential secondary contaminant sources are associated with secondary activities and infrastructure, such as road infrastructure, fuel storage and drainage work.

3.4.1 Waste Rock and Ore Geochemical Characterisation

Characterisation of the material to be extracted from the pits and described in this section has been taken from the following key reference:

- EGi (2014), *Barbara Copper Project – Assessment of Waste Rock Geochemistry*, Environmental Geochemistry International Pty Ltd, October 2014 (D/N 4405/1113)

EGi (2014) details a geochemistry investigation conducted in February and March 2014, involving 121 drill core samples obtained from 14 drill holes. The drill holes were located across the footprint of the North and South Pit.

EGi noted that a mining block model was not available to map geochemistry results to specific mining units. The pit development has changed significantly since EGi's 2014 assessment.

Standard geochemical analyses of drill samples were undertaken by EGi, with outcomes categorised based upon a 0.5% Copper (Cu) grade cut-off threshold for ore. In total, 27 samples were classified as ore, and 94 samples were classified as waste.

3.4.1.1 Initial Drainage

Initial drainage tests were also performed by EGi, to provide an indication of the pH level expected from runoff reporting from waste and ore surfaces. The test method is designed to emulate 'first flush' runoff water quality, based upon a short duration contact time between rainwater and waste/ore.

The initial drainage analyses undertaken indicate that first flush surface runoff was expected to be circum-neutral to slightly alkaline (pH generally ≥ 7.5). It was concluded that the acidity/alkalinity of the initial drainage was not considered to be a significant water quality issue.

3.4.1.2 Acid Mine Drainage

Characterisation of Net Acid Producing Potential (NAPP) and Net Acid Generation (NAG) properties of the samples was undertaken to examine the potential for Acid Mine Drainage (AMD). AMD is the process by which sulphides oxidise when in contact with water and oxygen and form sulphuric acid. AMD is generally released over the longer term and is considered separately to 'first flush' runoff water quality. Some materials may exhibit both the capacity to generate acid, and to neutralise acid (Acid Neutralising Capacity, or ANC), with the final classification based on the overall properties of the sample (rather than sulphide content independently).

Based upon the analyses undertaken, the samples were classified by EGi as being:

- Non-Acid-Forming (NAF)
  The sample is not expected to generate acid in excess of the available ANC.
- Potentially-Acid-Forming (PAF)
  The sample may form sulphuric acid when in prolonged contact with water and oxygen.
- Uncertain (UC)
  The sample may or may not form acid.

Based upon the acid forming properties, water which remains in contact with material for medium-long term durations, may exhibit acid mine drainage.

The determined classifications, based upon the NAPP and NAG testing, are detailed in **Table 3**.

Table 3
Waste Rock Classifications

Waste / Ore	Classification	Number of Analyte Results	Proportion
Waste Rock (Cu ≤ 0.5% Grade)	PAF	7	7%
	NAF	83	89%
	UC	4	4%
Ore (Cu > 0.5% Grade)	PAF	15	56%
	NAF	12	44%

Plate 5
AMD Characterisation of Barbara Copper Project Samples - EGi (2014)

Reproduced from Figure 6a, EGi (2014)

Additional kinetic NAG analyses were conducted for five samples (three waste, two ore), to provide an indication of the lag time before significant acid generation occurs. Accordingly, the five samples analysed were PAF samples. The determined outcomes are presented in **Table 4**.

Table 4
AMD Samples – Acid Generation Lag Time

Sample	Final pH	Lag Time
Ore #8050	3.1	Weeks to months
Ore #8112	2.7	At least a year to several years
Waste #8066	4.7	At least a year to several years
Waste #8092	3.0	Several years
Waste #8072	6.3	At least a year to several years

Reproduced from EGi (2014)

Overall, lag times for samples classified as PAF were significant, and likely to exceed a year.

Of the two analysed PAF ore samples, one was highly reactive (Ore #8050), with generation of acid expected to occur within weeks of being exposed to atmospheric conditions (water and oxygen).

NAF waste rock materials were analysed to exhibit limited ANC, so that blending of NAF and PAF samples may not result in significant changes to acid generation characteristics of the blended material, compared to the PAF material alone.

3.4.1.3 Elemental Characterisation

Characterisation of the elements within each sample was undertaken using a geochemical abundance index approach (GAI). Under this approach, the abundance of minerals within a sample is compared to reference materials (which do not feature abundance or enrichment of specific elements).

The elements analysed included: Al, As, Ba, Be, Bi, Cu, Cd, Co, Cr, Cu, Fe, Hg, K, Li, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Sn, Sr, Th, U and Zn.

Elements which were considered to be minor enriched or greater by EGi (2014), are listed in **Table 5** and **6**.

Table 5
Elemental Ore Characteristics

Material	Element	Abundance (Ratio of Sample : Reference Material)	GAI	Description
Ore	Copper	≥24	≥3	Abundant
	Sulphur	≥24	≥3	Abundant
	Selenium	12 - 24	3	Significant enrichment
	Bismuth	12 - 24	3	Significant enrichment
	Cobalt	12 - 24	3	Significant enrichment
	Arsenic	12 - 24	3*	Significant enrichment
	Nickel	6 - 12	2**	Minor enrichment

*1 of 7 ore samples was classified as having a GAI of 3 for Arsenic, with 6/7 samples classified as having a GAI of 0 (Little to no enrichment)
**2 of 7 ore samples were classified as having a GAI of 2 for Nickel, with 5/7 samples classified as having a GAI of 0 (Little to no enrichment)

Table 6
Elemental Waste Characteristics

Material	Element	Abundance (Ratio of Sample : Reference Material)	GAI	Description
Waste	Copper	12 - 24	3	Significant enrichment
	Sulphur	12 - 24	3	Significant enrichment
	Selenium	12 - 24	3	Significant enrichment
	Bismuth	6 - 12	2	Minor enrichment
	Cobalt	6 - 12	2	Minor enrichment

3.4.1.4 Saline Drainage

Analyses of Electrical Conductivity (EC) were performed to provide an indication of the expected salinity of water coming into contact with waste and ore materials, with the following outcomes determined:

- 72% of analyses, generally comprising the predominant waste unit (Porphyritic Rhyolite), resulted in an electrical conductivity of less than 400 µS/cm, representative of 'non-saline water'.
- 21% of analyses resulted in an EC between 400 and 800 µS/cm, representative of 'slightly-saline water'.
- 13 of analyses conducted were classified indirectly as 'saline' (≥800 µS/cm). It is noted that 12 of the 13 analyses resulting in a 'saline' classification comprised high sulphur ore materials.

Based upon the EGi (2014) results, it was concluded that saline drainage was not considered a significant water quality issue, with respect to waste rock materials. Drainage from ore materials will be potentially saline.

3.4.2 Contaminants Associated with Non-Mining Areas

Contaminants associated with non-mining-areas, relevant to water management, include the following:

- **Gross Sediment & Suspended Sediment**
  A variety of mining activities have the capacity to result in mobilisation of sediment from shallow surfaces and sub-soils as a result of construction and disturbance authorised by the site EA.
  In general, water quality issues arising from sediment mobilisation relate to turbidity (water clarity).
  Sedimentation is a natural process, however mining activities have the capacity to cause erosion and mobilisation of sediment at increased levels.

- **Hydrocarbons**
  Hydrocarbons (diesel) will necessarily be stored and utilised on site to operate mining plant. Hydrocarbons stored at the LIA present a potential point source contaminant (i.e. they may impact a localised area).

- **Sewage**
  Any sewage generated onsite is to be kept separate from the water management system, with release in accordance with license conditions of the site EA.

3.4.3 Ore Processing / Beneficiation

Chemical processing/beneficiation of ore is not licensed for the BCP. Accordingly, there are no processing-based contaminant sources stored or used on-site.

3.4.3.1 Summary of Potential Contaminants

3.4.3.1.1 Waste Rock

Potential contaminants at the BCP predominantly relate to the mineral extraction activities within the North and South Pit.

Based upon the geochemistry investigation conducted by EGi (2014), potential water quality issues and contaminants relating to waste rock material may include the following:

- Copper, Sulphur, Selenium
  - Significantly Enriched
- Bismuth, Cobalt
  - Enriched
- Acid Generation
  - Most samples tested were NAF, however approximately 10% of samples tested were classified as PAF. Lag times for significant acid generation to occur (based on 3 samples) are expected to exceed one (1) year.

Suspended sediments from runoff generated from the WRD are likely to be elevated compared to non-mine impacted waters.

3.4.3.1.2 Ore

Water quality issues may relate to the ore streams extracted from the North and South Pit developments, as follows:

- Copper, Sulphur
  - Abundant
- Selenium, Bismuth, Cobalt, Arsenic
  - Significantly Enriched
- Nickel
  - Minor enrichment
- Acid Generation
  - Some 56% of the ore samples tested were classified as PAF. Lag times for significant acid generation (based on two samples) varied from 'weeks' to 'years'.

3.5 Water Management Strategies

3.5.1 Classification of Mined Material

Based upon the potential contaminant sources present at the BCP, materials classified as ore streams by EGi (2014) typically exhibit a greater capacity to produce contaminants, compared to waste rock materials. Furthermore, ore streams were generally classified as Potentially-Acid-Forming (PAF), whereas waste streams were generally classified as Non-Acid-Forming (NAF).

Processing of ore and disposal of ore by-products will not occur at the BCP, with processing instead occurring at Malaco's Mt Cuthbert Mine and Glencore's Mt Isa Mines.

Strategies for classifying and managing extracted material will comprise the following:

- **Initial Classification**
  Noting that significant acid formation may occur from PAF ore materials within a week of exposure to rainfall and oxygen, analysis of material upon extraction is to occur within 3 days, to allow sufficient time for appropriate disposal and management.

- **Ore**
  Management of extracted ore material within the BCP will comprise temporary storage with the ROM Pad and Road Train Loading Area, prior to haulage. Ore stockpiles should be assumed to contain PAF materials, with acid generation possible within a week of exposure to rainfall. Accordingly, water expressing from any ore stockpile is required to be contained. Ore material, once removed from the Mining Lease, are considered out of scope of this Water Management Plan.

- **Waste Units**
  Based upon a 0.3% Sulphur content threshold, EGi estimated that some 15% of the tested samples would be classified as PAF. Waste material extracted from the pits require classification into PAF and NAF units, with additional disposal requirements relating to PAF material.

  The classification of waste material is to occur based upon a developed block model assigned to mining material, or analysis of material upon extraction. Significant acid formation may occur within a year of exposure to atmospheric conditions. Therefore, sufficient disposal is considered to comprise dumping within an encapsulated PAF cell,

constructed within the WRD. PAF Waste material are to be disposed of within an encapsulated cell within 6 months of initial extraction.

3.5.2 Water

Based upon the potential contaminants, and downstream EV's, the following water types have been defined for the BCP:

- **Mine Affected Water (MAW)**
  - **Description of Expected Water Quality Issues**
    Water potentially impacted by exposure to mine waste and ore.
    MAW may contain elevated concentrations of Copper, Sulphur, Selenium, Bismuth, Cobalt, Arsenic and Nickel.
    Quantities of suspended sediments are potentially elevated.
    Acid generation from PAF extracted mining units may impact MAW.

    Defined Locations & Origins
    North Pit, South Pit, ROM Pad, Road Train Loading Area, WRD, WRD Sediment Dam, LIA (primarily hydrocarbons and sediment, refer below and Section 3.5.3.1)

    Management
    MAW is to be conveyed, via safe, effective and non-eroding hydraulic controls, to authorised containment structures within the BCP (WRD Sediment Dam, South Pit and North Pit).
    MAW inventories will be managed by evaporative losses from the North Pit, South Pit and WRD Sediment Dam.

- **Sediment Affected Water (SAW)**
  Description of Expected Water Quality Issues
  Water potentially impacted by elevated suspended sediments and associated water quality issues.

  Defined Location & Origins
  Magazine, roads and any other disturbed areas not defined as an active mining surface.
  Any area identified during operation as impacted by erosion or scour.

  Management
  SAW management will primarily revolve around the implementation of an effective Erosion and Sediment Control Plan, as mandated by the site EA, condition E17, to reduce the potential for erosion and promote the settlement of suspended sediments prior to discharge to downstream environments via safe, effective and non-eroding hydraulic controls.
  Management of SAW is predominantly expected to comprise the implementation of Erosion and Sediment Control (ESC) measures and activities such as silt fencing, compaction, remediation of scour locations, seeding, rock armouring and level spreaders.

- **Clean-Water**
  Description of Expected Water Quality Issues
  None – representative of natural conditions.

Defined Locations & Origins
Areas located upstream of the site, or site areas that are not disturbed (and do not report through a disturbed area).

Management
Clean Water is to be conveyed, via safe, effective and non-eroding hydraulic controls, to the downstream environment.
The principal goal of the water management strategy is to minimise the collection of Clean Water within site structures.
The principal management activity relating to Clean Water is the installation, inspection and maintenance of Clean Water drainage and diversionary infrastructure.

3.5.3 Other Contaminants

3.5.3.1 Hydrocarbons

Hydrocarbons represent a point source contaminant, with impacts typically arising from accidental spillage or leakage from containment tanks. Standard effective management for hydrocarbons involves the installation of a localised containment bund to retain hydrocarbons in the event of a tank leak.

3.5.3.2 Sewage and Sewage Effluent

Sewage and sewage effluent comprise another contaminant source.

It is noted that the release of sewage is conditioned within the EA under conditions C1 and C2. As the release of sewage is licensed, and sewage is not to be mixed with any site waters, it is considered that sewage does not comprise a contaminant with respect to the site regulated structures.

4 HYDRAULIC DESIGN ASPECTS

4.1 Regulated Structures

As required by Condition H1 of the EA, structures on-site which contain or control liquids (i.e. dams and related hydraulic infrastructure) require a Consequence Category Assessment (CCA), to determine whether the structure comprises a 'regulated structure' as defined by the "Manual for Assessing Consequence Categories and Hydraulic Performance of Structures" (the Manual) (DES, 2016).

The structures listed in **Table 6** are already licensed by the site EA, having been assessed during previous phases of the BCP development. The project no longer includes the ROM Dam because the South Pit sump now provides containment for runoff from the ROM Pad. When necessary, runoff from the ROM Pad can be managed through pump transfer to the North Pit and/or WRD Sediment Dam, to allow ongoing mining and mineral extraction within the South Pit.

Plate 6
Barbara Copper Project - EPML02840015 - Hydraulic Performance Criteria

Table H1 **Table H1 – Hydraulic performance criteria ('Table H1')**

Name of dam	Consequence category	Hydraulic performance criteria		
		Spillway capacity	Design Storage Allowance	Mandatory Reporting Level
North Pit	Significant	1:100 to 1:1000 AEP 72 hour duration storm event	1:20 AEP 2 month wet season	1:10 AEP 72 hour duration storm event
South Pit	Significant	1:100 to 1:1000 AEP72 hour duration storm event	1:20 AEP 2 month wet season	1:10 AEP 72 hour duration storm event
WRD Dam	Significant	1:100 to 1:1000 AEP72 hour duration storm event	1:20 AEP 2 month wet season	1:10 AEP 72 hour duration storm event
ROM Dam	Significant	1:100 to 1:1000 AEP72 hour duration storm event	1:20 AEP 2 month wet season	1:10 AEP 72 hour duration storm event

Reproduced from the site EA (EPML02840015).

Table H1 contains an error in specifying the spillway capacity performance criteria. For all dams, the criteria should read "1:100 to 1:1000 critical duration storm event".

4.2 Consequence Category Re-assessment

Should the function, geometry or contained contents of a regulated structure on-site materially change, reassessment of the CCA of site structures is required, as outlined in the EA (EPML02840015). There have been no material changes to any of the regulated structures since the EA was issued.

Additionally, any new structures onsite (such as dams or levees), which meet the definition of a structure, as defined by Structures which are dams or levees constructed as part of environmentally relevant activities (DES, 2017), will require assessment. No new regulated structures have been constructed at the site since the EA was issued.

4.3 Hydraulic Performance Criteria

4.3.1 Regulatory Requirement

Section 2.2.2.2 of the Manual outlines the process for Managing design storage allowance and extreme storm storage in integrated water management systems.

4.3.2 Design Storage Allowance

A key requirement of the Manual is the estimation of a Design Storage Allowance (DSA). DSA is defined as "*an available volume provided in a dam as at 1 November each year in order to prevent a discharge from that dam up to a specified annual exceedance probability (AEP).*" (DES, 2016).

The regulated structures requiring containment are listed within **Table 7**. It is noted that the DSA volume relating to some structures cannot be accommodated without transfer, necessitating consideration of DSA sharing via the installed pump and transfer system. The need to share DSA's triggers a requirement to prepare a system design plan (Refer Section 2.2.2.2 of the Manual). This is discussed further in **Section 5.2.2**.

Table 7
DSA Volumes for the Regulated Structures

Regulated Dam	North Pit	South Pit	WRD Sediment Dam	Total
DSA Criteria	Significant	Significant	Significant	
Critical Wet Period	2-Months	2-Months	2-Months	
Rainfall Total	677.2 mm	677.2 mm	677.2 mm	
Catchment Area	3.3 ha	21.0 ha	29.0 ha	
Runoff Coefficient	1.0	1.0	1.0	
DSA Volume	22.4 ML	142.2 ML	196.4 ML	361.0 ML
Capacity	129.1 ML	995.4 ML	131.9 ML	1256.5 ML
Capacity - DSA Vol	107 ML	823 ML	-64.5 ML*	895.5 ML

*The required DSA volume for the WRD Sediment Dam exceeds the design capacity of the storage. Pump transfer within the WBM indicates that the current pump transfer configuration is able to facilitate the DSA volume through transfer to other storages.

4.3.3 Mandatory Reporting Level

The site EA and the Manual define the level corresponding to the Extreme Storm Storage (ESS) as the Mandatory Reporting Level (MRL). Should the MRL be exceeded, in any circumstances, notification to DES is required, as per the site EA.

The location of the MRL must be clearly marked and be visible on each structure. The MRL's of each structure were confirmed during the inspections (16th October 2019) and associated reporting in *Barbara Copper Project - 2019 Annual Inspection of Regulated Structures* (ATCW, 2019). The determined 2019/2020 MRLs of the as constructed configuration for each structure are listed in **Table 8.**

Table 8
Mandatory Reporting Levels (MRLs)

Regulated Dam	North Pit	South Pit	WRD Sediment Dam
Consequence Category	Significant	Significant	Significant
Final Design Capacity	193.9 ML	3528.0 ML	131.9 ML
Total Catchment Area (incl. Extents)	3.3 ha	21.0 ha	29.0 ha
Runoff Coefficient	1.0	1.0	1.0
Extreme Storm Storage (ESS) Criteria	1:10 AEP 72 Hour Duration Storm Event	1:10 AEP 72 Hour Duration Storm Event	1:10 AEP 72 Hour Duration Storm Event
ESS Rainfall Depth	228.0 mm	228.0 mm	228.0 mm
Freeboard	0.3 m	0.4 m	0.3 m
Emergency Spillway Invert	RL 316.0 m	RL 334.0 m	RL 337.0 m
Adopted Mandatory Reporting Level	RL 315.6 m	RL 333.2 m	RL 334.3 m

4.3.4 Emergency Spillway Sizing

As specified by Table H1 of the EA (**Plate 6**), the site regulated structures require an emergency spillway for flood conveyance.

The emergency spillway geometries were designed utilising a simplified routing spreadsheet, which calculates flow rate according to the broad crested weir equation. The following parameters were utilised in sizing the spillways.

- Rainfall Data — BOM IFD (2016) Rare Estimates
- Catchment Losses — Nil (Catchment was assumed to be fully saturated Prior to design event)
- Coefficient of Weir Discharge — 1.45

The emergency spillway geometries are presented in **Table 9.**

Table 9
Regulated Structures - Minimum Emergency Spillway Geometry

Parameter	WRD Sediment Dam	South Pit	North Pit
Design Criteria	1:1000 AEP	1:1000 AEP	1:1000 AEP
Spillway Width	20.0 m	5.0 m	2.0 m
Spillway Elevation (AHD)	RL 337.0 m	RL 334.0 m	RL 316.0 m
Estimated Flow Depth	0.6 m	0.6 m	0.4 m
Dry Freeboard	0.4 m	0.4 m	0.3 m
Total Spillway Depth	1.0 m	1.0 m	0.7 m

The geometries of the spillways for the North Pit and South Pit allow for controlled releases rather than uncontrolled releases of excess stored waters.

4.4 Site Drainage

4.4.1 General

Control of the three water types, MAW, SAW and clean water, is required across the site. Clean water diversion drainage and containment drainage are illustrated on **Figure 001**.

4.4.2 North Pit Diversion Drains

There are several diversion drains around the North Pit. These are:

- A diversion drain and associated levee have been constructed to the west of the North Pit to convey the creek, including clean runoff from the WRD Sediment Dam, around the Pit.
- A diversion drain and associated levee have been constructed to the north of the Pit.
- A small diversion drain on the eastern side of the North Pit collects surface runoff from the eastern hills and conveys it to the diversion drain to the north of the Pit.

4.4.3 South Pit Diversion Drain

The South Pit diversion drain has been constructed to the east of the South Pit to divert clean surface runoff to the north of the South Pit, where it passes beneath the haul road and enters the creek diversion drain to the west of the North Pit.

4.4.4 WRD Sediment Dam Drainage

In the event of a spillway release form the WRD Sediment Dam, flows drain to the north, whereupon the enter the creek diversion drain to the west of the North Pit.

4.5 Pumped Transfer Lines

Pumped transfer lines from the WRD Sediment Dam to the North Pit and South Pit sumps have been installed. The relevant activation and deactivation levels and cease pumping logic are listed in **Table 12** and discussed in **Section 0**.

4.6 Erosion and Sediment Control Measures

As per condition E17 of the site EA, an Erosion and Sediment Control Plan is required for all stages of the mining plan.

5 WATER BALANCE MODEL

5.1 Objective

A Water Balance Model (WBM) has been developed to assess the performance of the site water management infrastructure and management systems, principally over the regulatory wet season.

Noting Table H1 of the EA (**Plate 6**), the Design Storage Allowance hydraulic performance criteria relating to each 'Significant' consequence regulated structure on site is the effective management of a 1:20 AEP 2 month wet season event (critical duration event). The principal measure output from a WBM is the modelled spill probability of a structure. Therefore, to measure the performance of regulated structures over the wet season, an equivalent probability to the DSA requirement was adopted for the spill probability criteria, as shown in **Table 10.**

Table 10
Adopted WBM Performance Criteria

DSA Hydraulic Performance Criteria – 'Significant' Consequence Structure	Equivalent WBM Performance Criteria
1:20 AEP, 2 month [critical duration] wet season	Equivalent Spill Probability ≤5% Measured over the regulatory wet season period.

5.1.1 Site Development and Simulation Staging

The WRD Sediment Dam and the North Pit function together to provide water storage for site impacted water. As at October 2019, the South Pit had reached an excavated volume of approximately 1GL of total available storage, out of a final design volume of 3.3GL. The final design volume will be available when excavation of the South Pit has been completed, which is estimated to be in October 2020.

The water balance model reflects the as constructed volumes in the North Pit, South Pit and WRD Sediment Dam. The model also reflects that there is no stored water in any structure at the start of the simulation (reflective of site conditions on 30 October 2019).

It has been assumed that during excavation of the pits, the respective pit is kept effectively empty of water, operating with an approximate 1ML sump for temporary, site impacted stormwater runoff storage.

5.1.2 Model Configuration

The water balance model was developed using GoldSim Pro, a dynamic probabilistic simulation program. The model uses a range of parameters to represent the catchment surface water flow system, being routed through a time series of daily rainfall data to estimate daily runoff.

The simulation for the WBM runs for a duration of 2 years. For the purpose of the WBM, it is assumed that all storages are empty (dry) at the commencement of the model, representative of the current site conditions.

5.1.3 Modelled Conditions

In order to define the water management strategy for the BCP, the current site configuration was adopted from the as constructed details provided in October 2019.

5.2 Input Data

5.2.1 Site Infrastructure

The site infrastructure listed in **Table 11** was modelled, with relevant data utilised within the model sourced from **Section 2**.

Table 11
Site Structures – WBM Input Data

Structure Data	Units	North Pit	South Pit	WRD Sediment Dam
Capacity	ML	129.1	995.4	131.9
Water Surface Area at Full Supply Level	ha	1.6	6.4	3.0
Full Supply Level	RL m	316.1	334.0	337.0
Initial Water Elevation	RL m	Empty	Empty	Empty
Pan Evaporation Factor	-	0.8	0.8	0.9
External Catchment Area	ha	1.8	14.6	26.4*

*While the WRD does not currently occupy the full 26.4 ha catchment, the model has assumed the entire catchment to be fully impacted by waste rock, which will occur as the WRD is extended during the mining operation.

5.2.2 Modelled Site Process Flow Configuration

The WBM was developed based on the site elements and interactions between storages, as advised by Round Oak. The connections and modelled transfers are depicted in **Plate 7.**

Plate 7
Site Water Management Strategy

The process flow configuration was provided by Round Oak, utilising the North Pit as the final site storage for transfer from the WRD Sediment Dam and South Pit. Should the dams spill, flows from the WRD Sediment Dam and South Pit would enter the diversion drain to the west of the North Pit. prior to reporting to the receiving environment.

Pumped transfer of site impacted stormwater runoff was based on the design configuration listed in the "Mine Infrastructure Site Layout Plan" (AECOM, 2019), provided in **Appendix A**. The current site configuration has the South Pit pump as a permanent structure. Having the south pit pump as a trailer mounted pump would provide the site with the capability to provide intermediate relief and redundancy under the failure scenario of other pumps being inoperable. The layout of the installed pump and pipeline transfer system has not changed from the design layout in **Appendix A**.

The adopted pumping levels and parameters for each storage are listed in **Table 12**. The Stage Storage Curves for the North Pit, South Pit and WRD Sediment Dam are contained in **Appendix B**.

Table 12
Site Structures - Modelled Pump Transfers

Structure Data	South Pit	North Pit	WRD Sediment Dam
Pump Configuration	HL110m Diesel Pump	90kW Pump	8kW Pump
Modelled Pump Flow Rate	20 L/s	100 L/s	20 L/s
Activation Level	Maintain Empty	RL 314m	RL 334m
Deactivation Level		RL 313m	RL 335m
Cease Pumping Logic	When water exceeds RL 315m AHD within the North Pit.	Risk of overtopping within South Pit	When water exceeds RL 315m AHD within the North Pit.
Operational Pump Destination	North Pit	-	North Pit
Contingency Pump Destination	-	South Pit (if required)	-

5.2.3 Input Climatic Data & Surface Runoff Model

Climatic input data (daily rainfall, evaporation and evapotranspiration) derived for the site location was obtained from the SILO Data Drill Program (DES, 2019), from 1889 to 2019. SILO Data Drills provide an uninterrupted climate record for modelling, derived from real weather station observations within the region. The sourced data utilised in the WBM is detailed in **Table 13.**

Table 13
Site Water Balance - Rainfall and Evaporation Input Data

Climate Data	Data Source	Comments
Daily Rainfall Rate (mm/day)	Rainfall data obtained from the SILO Data Drill Program for the Site Location (1889 - 2019)	Applied over dam surface areas, and as an input parameter for the estimation of surface runoff (AWBM).
Daily Evaporation Rate (mm/day)	Continuous record from SILO Data Drill formed by conjoining: CLIMARC estimates (1889 – 1957) and Class A Evaporation Data from proximate weather stations within the region (1889 – 2019).	Evaporation Data is scaled by evaporation factors for each site storage to reflect water storage conditions and expected water quality.
Daily Evapo-transpiration Rate (mm/day)	As calculated by the FAO short crop reference methodology, assuming a wind speed of 2 m/s.	PET is calculated based on temperature, vapour pressure and solar global exposure parameters derived from climatic data, and is adopted as a reasonable estimate of potential evapotranspiration losses from ground surfaces within the surface runoff model.

The Australian Water Balance Model (AWBM) was utilised to simulate daily runoff from rainfall generated within the various sub-catchment types that are present on the project site. **Plate 8** represents a schematic of the AWBM model, reproduced from Boughton (2009).

Plate 8
Schematic of the AWBM Rainfall-Runoff Model

Where:
C1 – C3 = Surface Storage Capacities
A1 – A3 = Partial Areas Represented by Surface Storages
BFI = Baseflow Index
K_b = Daily Baseflow Recession Constant
BS = Current Volume in Baseflow Store
K_S = Daily Surface Flow Recession Constant
S = Current Volume in Surface Store Routing

The catchment types and AWBM model parameters used to simulate these different catchment types and the average yields from these catchment areas are summarised in **Table 14.** Model parameters have been selected based on experience with similar water balance model studies, and are considered to be conservative in the context of this uncalibrated model.

Table 14
AWBM Model Parameters

AWBM Parameters	Split Areas (sum=1.0)			Storage Capacities (mm)			Ks (day-1)	BFI	Kb (day-1)
	A1	A2	A3	C1	C2	C3			
Natural	13.4	43.3	43.3	12	120	250	0	0	1
Hardstand	10	0	0	10	-	-	0	0	1
Waste	20	80	0	10	300	-	0	0	1
Open Cut	10	90	0	5	20	-	0	0	1

Site catchment areas were delineated based upon the following survey sources:

- Barbara Aerial Survey Lidar DTM (26/11/18) provided by Round Oak;
- As Constructed Survey data for the WRD Sediment Dam (19/08/19), North Pit (23/10/19) and South Pit (23/10/19); and,
- Shuttle Radar Topography Mission (SRTM) Hydro Enforced 1 Second DEM (Geoscience Australia, 2018)

The delineated catchment areas are depicted on **Figure 002** and detailed in **Table 15.**

Table 15
Site Structures - Catchment Areas

Structure Data	North Pit	South Pit	WRD Sediment Dam
Natural	-	2.0 ha	-
Hardstand	1.8 ha	5.9 ha	-
Waste	-	2.8 ha	26.4 ha
Open Cut	-	3.9 ha	-
Finished Surface Area	1.5 ha	6.4 ha	3.0 ha
Total Area	3.3 ha	21.0 ha*	29.4 ha

*Comprised of Catchments B, G, J and K from **Figure 002**.

5.2.4 Modelled Water Inflows

As advised by Round Oak, external inflows to site structures include surface runoff and groundwater inflow. The current excavations in the North and South Pits do not show evidence of infiltration from the groundwater table. Groundwater inflows previously adopted from RLA (2014) were not adopted for the modelling.

5.2.5 Modelled Water Outflows

With reference to the previous iteration of the Water Management Plan (URS, 2014), an average outflow rate exceeding 400m^3/day was utilised to represent dust suppression demands. In order to maintain a conservative assessment, dust suppression and washdown water usage was modelled at a rate of 200m^3/day on dry days (<5mm total rainfall depth).

5.3 Results

5.3.1 North Pit

Plate 9 indicates there are significant inflows to the North Pit as a result of pump transfer from the WRD Sediment Dam. It is noted that the storage within the pit could rise significantly, subject to prolonged or extreme rainfall conditions, however, these rainfall conditions exceed the site EA containment requirements.

Overall, the water balance of the North Pit is shown to increase the stored volume by a mean of approximately 48ML in the two years of the simulation.

Plate 9
North Pit - Modelled Storage Volume

5.3.2 South Pit

The South Pit is modelled to be effectively dewatered in rainfall events equal to the sites EA containment requirements, as can be seen in **Plate 10**. The higher percentile wet seasons result in some accumulation of water within the pit, primarily due to an inability to pump to the North Pit after it reaches the cease pumping level. This suggests that the pit sump capacity may be exceeded in extreme rainfall sequences. This may require operations in the South Pit to cease when the 1ML sump volume is exceeded. Once the stored volumes are contained within the 1ML sump, operations within the South Pit can re-commence.

Plate 10
South Pit - Modelled Storage Volume

5.3.3 WRD Sediment Dam

The WRD Sediment Dam is modelled to effectively contain runoff reporting from the WRD. The modelled pump configuration is set up to transfer water to the North Pit and maintain relatively low levels within the WRD Sediment Dam. This is to reduce the likelihood of a spill in a storm event due to the large upstream catchment reporting to the WRD Sediment Dam.

The net mean increase in stored volume at the end of the 2 year simulation is approximately 9ML, as shown in **Plate 11**.

Plate 11
WRD Sediment Dam - Modelled Storage Volume

5.3.4 Spill Probability

For the as constructed conditions detailed in **Table 11** and the operating conditions listed in **Table 12**, based upon the modelling undertaken, the adopted containment criteria for the regulated structures are met, as shown in **Table 16**.

Table 16
Modelled Scenarios - Spill Probabilities

	North Pit	South Pit	WRD Sediment Dam
Spill Probability	<1.0%	<1.0%	<1.0%

6 MONITORING AND REVIEW

Water quality monitoring at the BCP is required in accordance with the EA to identify any potential influence or threat to receiving waters. Monitoring requirements in relation to both clean (diverted) water and site water management systems are outlined in the EA.

6.1 Stored Water Quality Monitoring

Water quality monitoring is to occur within each water storage on site, with the data being reviewed against the contaminant limits outlined in the EA.

Stored water quality monitoring is to be undertaken to demonstrate compliance with defined contaminant limits. It is a requirement that these limits are achieved. If exceedance is recorded, practicable measures should be implemented to prevent access to stored water by all livestock and to minimise access by native fauna.

6.2 Surface Water Quality Monitoring

6.2.1 Release Water Quality Monitoring

Surface water monitoring requirements are specified in the EA under Conditions E5 to E7. Authorised release locations for the site are identified in the EA corresponding to the release locations of relevant site storages. Authorised release points are defined by Condition E2 (and Table E1) of the EA.

Surface water quality monitoring will be conducted for off-lease discharge events, i.e. each single or continuous event at which flow reports from each defined release site, with the monitoring frequency specified in the EA.

6.2.2 Receiving Water Quality Monitoring

Receiving water monitoring and downstream compliance monitoring sites and water quality limits associated with release events are outlined in the EA.

Round Oak is responsible for carrying out investigations into receiving water quality during and after any spill events in accordance with ANZECC methodology. This monitoring is to determine if there is any potential for environmental harm downstream of the site due to a release of potentially contaminated water.

6.3 Groundwater Quality Monitoring

Groundwater monitoring requirements are specified in the EA under Conditions E8 to E13. Groundwater quality triggers and monitoring bore locations are specified in Table E5-6 (of the EA).

Should an exceedance of a groundwater quality trigger contained within Table E6 of the EA occur, an exceedance investigation must be carried out, pursuant to Condition E11 of the EA.

6.4 Water Management Plan Review

In conjunction with annual Dam Safety Inspections, the hydraulic performance requirements for each structure are reviewed and updated to identify possible short-comings. This inspection is to be completed before 1 November each year.

The EA does not specify a formal frequency for review of the entire site Water Management Plan, however, reviews should be undertaken as deemed necessary to ensure measures, practices and procedures are carried out effectively to ensure minimal risk of environmental harm.

7 EMERGENCY CONTINGENCY PLAN

The following scenarios have been identified as potential events or incidents that would fall under this emergency and contingency management plan.

7.1 Extreme/Prolonged Rainfall

Rare rainfall events or prolonged conditions may cause a number of incidents to occur. In the event of an exceedance of the rainfall intensity and duration adopted to design the water management structures, the critical or "worst case" scenario would involve:

- overflow from the North/South Pit system or WRD Sediment Dam.

Under these conditions, failure and/or overtopping of water management structures may result in flooding of downstream areas within the flow path, as well as the release of contaminants to the receiving environment. In this event, a risk to any personnel working within the area would also be present. Any structures at risk of flooding would need to be evacuated and vital equipment removed from the area.

As detailed in Section 5.3, any spilling from structures on site would exceed the containment requirements of the EA.

7.2 Other Incidents Causing Environmental Harm

7.2.1 Spills or Leaks

Spills or leaks may occur from tanks, pipes or other mine infrastructure and instrumentation during any weather conditions, particularly under strong winds or other destructive conditions, where tanks can by propelled and pipes (above ground) can burst. The release of hydrocarbons is of particular concern to the receiving environment.

In the event of an incident, the assessment of potential environmental impact stemming from spills, leaks and their associated effects is to be made, irrespective of the volume of the spill occurring.

Notification to downstream stakeholders must occur for any degree of off-lease environmental impact. Notification and consultation with environmental authorities and specialists is an inbuilt feature of standard operating directives for spill incidents.

7.2.2 Erosion or Damage to Site Infrastructure

Water management infrastructure such as dams, embankments and drains may be subject to erosion, particularly during storm events or overtopping. Regular inspections are required to ensure infrastructure is operable and free of damage, with immediate remedial actions required should any damage be found.

7.2.3 Pumps

Back-up pumps and generators are to be made available in case of pump failure during extreme events. The additional pumps and generators are to be available while the failed pumps are being repaired.

7.2.4 Inability to access control and monitoring points in all weather conditions.

Four-wheel drive (4WD) vehicles are to be retained on site for the purpose of accessing control and monitoring points during and after storm events.

7.3 Responsibilities

It is the responsibility of the Site General Manager to ensure all elements of the water management plan are implemented. This includes ensuring all ongoing monitoring of the water management infrastructure is completed as outlined in the EA, and all required inspections, reviews and reporting are undertaken and submitted to DES in the specified and appropriate timeframes.

1.0 INTRODUCTION

AARC Environmental Solutions Pty Ltd (AARC) was commissioned by Round Oak Minerals Pty Ltd (ROM) to develop an Erosion and Sediment Control Plan (ESCP) for their Barbara Copper Project (the Project). This ESCP has been prepared in accordance with Environmental Authority (EA) No. EPML02840015 condition E17 as stated below.

> *An Erosion and Sediment Control Plan must be developed, documented and implemented by an appropriately qualified person for all stages of the mining activities to minimise erosion and the release of sediment to receiving waters.*

1.1 PURPOSE

The purpose of this document is to outline strategies to prevent and/or minimise erosion and the release of sediment into receiving waters, and the contamination of stormwater runoff.

1.2 SCOPE

The Project consists of a single Mining Lease (ML) in north-west Queensland; ML90241. The ESCP specifies erosion and sediment control measures appropriate for the construction and operational stages of the mine life. The process for developing the ESCP has included:

- The identification of areas of potential erosion risk arising from stormwater runoff for all Project stages;
- An assessment of the erosional risks related to the Project; and
- Nomination of appropriate erosion and sediment control measures applicable to the identified areas of erosion risk and having the objective of reducing the potential for Project to impact the receiving environment.

2.0 PROJECT DESCRIPTION

The Project is located within the Mt Isa local government area and can be accessed via Lake Julius / Kajabbi road from the Barkly Highway approximately 60 kilometres (km) to the north-east of Mt Isa. The current Plan of Operations is valid until 31 May 2022. The Project comprises two open cut pits that will target 818,000 tonnes of copper ore and trace amounts of gold over 18 months. Ore is mined and transported off-site via road train to a regional, third-party processing facility.

2.1 SITE BACKGROUND

2.1.1 Site Infrastructure

Major components of the Project's water management system as outlined in the ATC Williams (ATCW) Water Management Plan (WMP) include the North Pit, the South Pit and the Waste Rock Dump (WRD) Sediment Dam. Clean water diversion drains are used to reduce the volume of stormwater runoff accessing disturbed areas and requiring subsequent treatment.

2.1.2 Regional Context

The project is located within the Leichardt River Basin which flows from the Selwyn Ranges into the Gulf of Carpentaria. The Project site does not have any permanent surface water but includes a number of ephemeral drainage lines which exit the site to the north-west before joining the Leichardt River. The Leichardt River itself is an ephemeral river depending on rainfall conditions for flow events. The Lake Julius Dam, situated on the Leichardt and Paroo Rivers, approximately 25 km downstream from the Project site is the effective end-point of the downstream environment as any contaminants would be contained within the dam rather than moving further downstream.

Historically, the Leichardt river has experienced contamination upstream from the Project location and grazing and historical mining activities have resulted in disturbances to the downstream environment (Noller 2009).

2.2 LOCAL CLIMATE

The Project is located in north-west Queensland where the climate is described as 'tropical continental' being governed by latitude, elevation and distance from the coast environment. The nearest meteorological station is West Leichardt (209121), however this station does not contain records for long term evaporation. Given this, data from three stations near Mt Isa (29126, 29125, 29127) were used to determine monthly averages for rainfall and evaporation. The climate in this area is characterised by high variations of rainfall with a wet season typically between November and March. Mean annual rainfall when averaged across the three meteorological stations is 427 mm with approximately 80% of this falling during the wet season. Evaporation rates exceed rainfall throughout the year contributing to the semi-arid environment. Monthly rainfall and evaporation are shown in Figure 1.

Figure 1 Mean monthly rainfall and evaporation for Mt Isa (BOM stations 29126, 29125, 29127)

2.3 SOIL AND LAND SUITABILITY ASSESSMENT

AARC was previously engaged to undertake a Soil and Land Suitability Assessment (SLSA) at the Project site. The field survey found that the site was dominated by moderately undulating lands with rocky outcrops and quartz gravels dominated by shallow gravel strewn loam. Three main Soil Management Units (SMU) were identified as depicted in Table 1.

Table 1 Soil unit description

Soil Unit	Description
SMU1 – River Red Gum Sands	This soil unit consists of sandier soils with a high gravel and cobble content with finer soil material having been removed via alluvial action. These soils are often deep and well drained with some occasional occurrence in shallower areas near rocky outcrops. The areas have a sparse ground cover vegetation associated with river red gums and other riverine species.
SMU2 – Cloncurry Box Drainage Terraces	This soil consists of loamy to clayey sands present along terraces adjacent to drainage depressions in relatively flat topography (1-2%). This soil type typically has lower fine gravel content but larger (20-+60mm) sub-rounded to coarse fragments. There is evidence of minor gully erosion within the ephemeral watercourses, but soil chemistry suggests there is no strong predisposition to dispersion or erosion.
SMU3 – Snappy Gum Slopes	This soil unit is comprised of clayey sands to sandy clay loams with moderate to high levels of gravel content. The topography is made up of mostly steep low hills with extensive areas of rocky outcrop and steeper slopes.

Field surveys found little evidence of soil erosion within the Study Area and soil physio-chemical properties do not indicate an increased predisposition to dispersion. With the exception of one isolated data point within SMU2, soil chemical properties were non-sodic (ESP <6%), had favourable calcium magnesium ratios (>2) and were non-saline.

3.0 PROJECT LAYOUT

The Project has a number of water management areas which are intended to cater for the types of activities occurring on site, and the locations in which they occur. In general, these can be categorised as mining -related areas and non-mining related areas as described following.

3.1 MINING AREAS

The Run of Mine (RoM) pad, the North pit and South Pit, as well as the WRD are the principal active mining areas associated with the Project. Runoff from these areas is defined as mine affected water (MAW) as outlined in Section 4.0.

Management of RoM Pad runoff is achieved via bunding with all runoff directed towards the South Pit. Excess water from the South Pit is able to be pumped to either the North Pit or WRD Dam to allow for the continuation of mining.

In addition to mining operations, the North Pit will operate as a storage and evaporative facility in the event of large volumes of MAW requiring containment. The North Pit is a regulated dam and is planned to be available for water storage from October 2019. Water levels within the North Pit will be controlled via pumping between the South Pit and WRD Dam.

In addition to being the primary mineral extraction point, the South Pit is also a regulated dam and is able to be used for water management and runoff containment for other MAW sources. The levels within the South Pit will be controlled via pumping between the North Pit and WRD Dam.

Stormwater runoff from the WRD drains will drain to WRD Sediment Dam which will allow for settlement of suspended sediment.

3.2 NON-MINING AREAS

The WRD Dam is the primary holding facility for storm water runoff from the WRD and, in concert with the North and South Pits, facilitates the storage of water for the Project during the wet season.

The Light Infrastructure Area housing the administration offices, workshop, fuel storage, and power facility is bunded to divert stormwater runoff from surrounding areas and reduce the possibility of sediment release into the receiving environment.

The Access Road and Haul Road have been constructed with the intention of causing minimal impact from clearing and both utilise causeways where they intersect natural drainage lines. Activity on these roads is monitored and restricted in wet weather to reduce the potential for disturbance.

Non-mining areas also include diversions, drainage lines, the sewage treatment facility, the explosives magazine and access roads.

4.0 PROJECT WATER MANAGEMENT

The current WMP was developed by ATCW in 2019 (Appendix A) with the objective as stated below:

> *To maintain the biological integrity of water (surface or ground) at the Barbara Copper Project, and to ensure quality of waters do not adversely affect environmental values or the health, welfare and amenity of people and land users by meeting statutory requirements and acceptable standards.*

The following water types have been identified for the purposes of the WMP:

- Mine Affected Water (MAW); water potentially impacted via exposure to mine waste and ore;
- Sediment Affected Water (SAW); water potentially impacted by elevated suspended sediments and associated water quality issues;
- Clean Water; water that has not been affected by mine site activities.

The principles of water management at the Project site are to:

- Separate MAW from non-impacted water streams, with non-impacted water diverted and able to flow to the downstream environment;
- Retain MAW in structures that are designed to minimise the risk of release off site and/or reusing this water on site where possible.

Potential sources for contamination were identified as the waste rock and ore generated in construction and mining operations. Both the North and South Pit have been configured to hold water inflow via surface and groundwater ingress with the North Pit utilised as the final site storage for waters transferred from the South Pit and WRD Dam. The WMP nominates the Northern Pit, Southern Pit and WRD Sediment Dam as regulated water management structures for the Project.

Water is able to be re-used for dust suppression and plant and vehicle washdown facilities.

4.1 STORMWATER CONTROL STRATEGIES

The following stormwater management control strategies apply for the Project:

- Uncontaminated stormwater will be diverted around all areas where mining activities occur, or where contaminants or wastes are stored or handled;
- Within mining activity areas, contamination of stormwater will be minimised or prevented by utilising drains, bunds, and sediment traps and dams as appropriate;
- All stormwater contaminated by mining activities (past or present) will be captured and reused, or treated and released in compliance with the conditions of the EA;
- For disturbed and rehabilitated areas, sediment and erosion control infrastructure will be installed, to minimise erosion and prevent the contamination of waters;
- All existing and future water management infrastructure shall be designed, constructed and operated in accordance with the requirements of the EA; and

- Monitoring of the receiving environment shall be undertaken in accordance with the Project's EA to ensure stormwater is being effectively managed on the Project.

5.0 EROSION AND SEDIMENT CONTROL APPROACH

This section outlines the methods of control that will be utilised on the Project site to manage soil erosion and reduce the risk of release of pollutants off site.

5.1 SOURCES OF EROSION AND SEDIMENT

Operations within the Project site have the potential to alter the quality of surface water flow and patterns following clearing and land disturbance. Mining activities with potential to affect these parameters include:

- The construction and maintenance of haul and access roads and tracks;
- The movement of equipment within around the site;
- Land clearance in preparation for construction or mining;
- The RoM and WRD stockpiles;
- Land rehabilitation activities and areas awaiting rehabilitation.

5.2 CONTROL APPROACH

The control of erosion and sediment at the Project site will be developed with regard to the following guidelines:

- EPA Best Practise Urban Stormwater Management – Erosion and Sediment Control (Queensland 2008);
- Stormwater and environmentally relevant activities (Queensland Government 2014);
- Best Practice Erosion and Sediment Control (IECA 2008); and
- Environmental Protection (Water and Wetland Biodiversity) Policy 2019 (DES 2019).

ESC management will fall into three tiers with the first tier being the WMP as the basis for management of clean and mine affected water within the site. The control of erosion generating sources including rainfall and surface water runoff will form the second tier of control. Finally, the capture, treatment and reuse of MAW and SAW will limit impacts to downstream waters as defined in the EA.

5.3 OBJECTIVES AND TARGETS

The main objective of the ESCP is to reduce the potential for erosion and sediment discharge to maintain downstream environmental values and water quality objectives.

The objectives of this ESCP are defined in Table 2.

Table 2 ESCP objectives

Objectives	Targets	Indicators
Minimise erosion on site and in immediate surroundings	No reports of erosion incidents	Incident reports relating to instances of erosion
Minimise movement of sediment off-site	Retention of MAW and SAW on site	Incident reports of any uncontrolled releases from site
Ensure erosion and sediment controls are operating and maintained effectively	Regular checks of sediment control structures with accumulated sediment removed	Indicators for maximum allowable sediment storage and records of maintenance checks

6.0 EROSION RISK ASSESSMENT

This section of the report assesses the potential for soil loss on the Project site. This will assist in identifying appropriate control measures to reduce the potential for erosion and sediment loss across the site.

6.1 METHODOLOGY

The determination of potential soil loss for this project is based on the Revised Universal Soil Loss Equation (RUSLE) as described by the International Erosion Control Association (IECA). The RUSLE equation is::

$$A = R \times K \times LS \times C \times P, \text{ where:}$$

- A represents the soil loss rate in tonnes per hectare per year (t/ha/yr);
- R represents the rainfall erosivity potential of the area determined as a product of kinetic energy of storms;
- K is the soil erodibility factor as determined by soil studies determining the physical and chemical composition of soils present;
- LS is the estimation of the combined length and slope factor;
- C represents the vegetative ground cover and land management as per the equation

$$C = PLU \times CC \times SC \times SR; \text{ where:}$$

  - PLU is Prior Land Use;
  - CC is Crop Canopy;
  - SC is the surface or ground cover;
  - SR is the surface roughness;
- P represents the erosion control in place.

Through application of the RUSLE, soil loss rates have been determined and risk categories allocated in accordance with the IECA 2008 report as per Table 3.

Table 3 IECA erosion risk categories (2008)

Soil Loss (t/ha/year)	Risk Category
0 – 150	Very Low
150 – 225	Low
225 – 500	Moderate
500 – 1,500	High
>1,500	Extreme

6.1.1 Rainfall Erosivity

The R factor is calculated as a product of kinetic energy of a storm, times the maximum 30-minute storm depth as a sum of all storms in a year. This factor is representative of the driving inputs that cause sheet and rill erosion. The seasonal distribution of rainfall has an impact to the calculation of the R factor. Both the soil erodibility (K) and vegetative ground cover (C) change throughout seasons as the Project has defined wet and dry seasons. The Australian Soil Resource Information System (ASRIS) nominates an R factor for the site of 2701.8108.

6.1.2 Soil Erodibility

Soil erodibility is defined as the potential for soil to erode. Soils with high silt contents have a greater likelihood for erosion while higher sand and clay contents are more resistant to erosion. Erodibility factors are as described in Table 4. Based on the SLSA and data provided by ASRIS, the K factor for the site determined to be 0.0441.

Table 4 Soil erodibility (K)

Generalised Soil Characteristic	K	Description
High clay content	0.05 - 0.15	Resistant to detachment decreases erodibility
Course textured sandy soils	0.05 - 0.2	Though easily detached, these soils produce low runoff.
Medium textured silt loam soils	0.25 - 0.4	Moderately susceptible to detachment and produce moderate runoff.
High silt content	0.4-0.69	Highly erodible as easily detached while also prone to crusting surface which produces high runoff rates.

6.1.3 Length and Slope

From the ASRIS data, the L factor for the Project area has a maximum of 5.88, a minimum of 1.027 and a mean of 2.128. The S factor for the site has a maximum of 5.39, a minimum of 0.05 and a mean of 0.78. The S factor for the majority of the site rests between 0 and 1 with the higher values occurring in the northwest corner of the ML outside of active mining areas.

6.1.4 Ground Cover

The C factor ranges from 0.0001 where ground cover is dense and there is a canopy present such as within forests to 1 for unprotected bare earth. The ground cover factor at the site is determined from the data supplied by the State-Wide Landcover and Trees Study, the Normalised Difference Vegetation Index, Broad Vegetation Groups and satellite imagery. From this data, the C factor is estimated to fall between 0.25 for areas retaining the grazed low open woodland ecosystem (RE 1.11.2a) that was present onsite prior to mining operations and 1 for the heavily disturbed portions of bare earth present during mine operations.

6.1.5 Supporting Practises

Supporting practises are a measure of the effect of management practices on sediment loss control. Management controls may impact runoff velocity and flow paths. For the Project the P factor has been

assumed to be 1 as the Project has both disturbed areas that have erosion controls, and undisturbed areas that have no erosion control measures in place.

6.2 RESULTS

From the RUSLE factors determined above, risk ratings have been calculated for disturbed areas of the Project. When compared against IECA rates, the soil loss rate from site can be categorised as being of low risk.

Table 5 Risk assessment results

Description	Area (ha)	R	K	S (%)	L	P	C	A (t/ha/yr)	Risk Rating
North Pit Catchment	1.4	2701.8108	0.0441	0.78	2.128	1	1	197	Low
South Pit Catchment	14.7	2701.8108	0.0441	0.78	2.128	1	1	197	Low
WRD Dam	31	2701.8108	0.0441	0.78	2.128	1	1	197	Low
LIA	2.1	2701.8108	0.0441	0.78	2.128	1	1	197	Low

7.0 PROPOSED CONTROL MEASURES

7.1 CONSTRUCTION AND OPERATION PHASES

During the construction and operational stages of the Project, land clearing will be limited and progressive to ensure that disturbance areas at any point in time are minimised. Where possible, rehabilitation of disturbed areas will occur progressively to further reduce areas of disturbance.

7.1.1 Diversion of clean water

The South Pit east drain, North Pit east drain and WRD east drain are located upstream of disturbed sites and have been constructed to protect disturbed areas and reduce the total volume of MAW collected and requiring storage. These drains have been constructed in areas with a high composition of rock which will assist in retarding flow velocities and reducing erosion within the diversions. The drains have been designed to cater for the large flow events expected during the wet season.

In conjunction with upstream diversion drains existing clean water drainage lines throughout the site have been retained through the installation of under access roads and tracks. Figure 2 displays the location of diversion drains and culverts on site for separation of clean water and MAW.

7.1.2 Sediment Dam

The Sediment dam displayed in Figure 2 is proposed to be constructed to the North of the WRD with the purpose of receiving runoff from the WRD for settlement of suspended solids. Collected runoff water will either be evaporated or reused for dust suppression or other purposes. Water is able to be transferred to the South Pit and North Pit to balance the Projects water storage capacities and usage requirements.

The dam is proposed as an earthen fill embankment lined with a bituminous geomembrane liner. Dam sizing is such that a spillway release will only occur at less than a 1% annual exceedance probability.

7.1.3 Perimeter bunds

Perimeter bunding is implemented around all of the work areas and haul roads on the Project. These bunds direct surface water flow to storages on site and will contain any spills in work areas. Perimeter bunds play an additional safety role for areas adjacent to excavation sites and traffic control.

Bunding will be maintained to ensure integrity and non-impedance of natural drainage features.

7.1.4 Sediment fences & Coir logs

For short term disturbances sediment fences will be erected immediately downstream of land disturbances to capture sediment arising from storm events. Coir logs are an alternative that can be put in place downstream of worksites to capture disturbed sediment. Check dam traps are to be implemented in drains to supplement the major sedimentation controls and minimise erosion in drains.

During operation of the Project use of sediment fences will be reduced as they will be replaced with more permanent solutions such as bunding and diversion drains.

Figure 2 Project Water Separation

7.1.5 Traffic

Measures to minimise impacts from vehicle movement within the Project will include the following:

- Vehicles to be restricted to access tracks and designated haul roads;
- Erosion and sediment control measures installed on all haul roads, access tracks and roads with maintenance as required;
- Bunding alongside haul roads used by heavy vehicles on site;
- Speed limits to be observed by all machine operators;
- Cleaning and/or maintenance of vehicles or plant equipment to be undertaken within a work area that is able to capture and treat runoff.

7.2 REHABILITATION AND CLOSURE

The final landform design has as its objective the formation of a stable landform able to resist erosion caused by surface water runoff. Throughout the project progressive rehabilitation of areas will reduce the presence of bare earth areas. In accordance with condition G2 of the EA the Project will have in place a Post Mine Land-use Plan describing how rehabilitation objectives will be achieved.

Prior to germination of rehabilitated areas, activities to ensure maximum potential for revegetation of areas are to be undertaken. These measures include:

- Timing seeding activities to ensure best germination rates are achieved;
- Sediment fences and temporary perimeter banks for short term bare earth areas;
- Sediment and erosion control structures will not be removed until disturbed areas have been stabilised;
- Exposed surfaces will be ripped and left with sufficient surface roughness to minimise the potential for erosion;
- Bunds and check dams will be implemented across contours in order to capture and slow runoff; and
- Disturbed areas will be contoured to ensure all runoff is directed through erosion and sediment controls and onsite water management systems.
- Mulching and/or hydromulching, and/or temporary seeding of stockpiles will be utilised as appropriate for rehabilitation areas.

8.0 ADMINISTRATION

8.1 MONITORING AND MAINTENANCE

8.1.1 General

Regular monitoring of construction, operation and rehabilitation areas will be undertaken. Contractors conducting construction and rehabilitation works will be responsible for maintaining surface water diversion structures and erosion control measures.

Routine inspections of all Project areas will be undertaken until rehabilitation completion criteria have been satisfied. Inspection will be completed prior to expected rainfall events to ensure the performance of control measures.

Periodic inspections of site drainage systems will be undertaken, especially prior to the wet season and when any major change is implemented or planned. Amendments to the existing erosion and sediment controls and WMP will be undertaken as required.

8.2 CORRECTIVE ACTIONS

The following actions will be undertaken by ROM as required:

- Revision of construction, operation and rehabilitation activities as required;
- Maintenance and de-silting of erosion and sediment controls at a frequency determined by inspections undertaken monthly during the dry season and weekly during the wet season;
- Incident reports will be completed following any relevant non-compliance or erosion incidents;
- In the event of an environmental incident, appropriate responses to be implemented to minimise environmental harm;
- Close out any non-conformances as soon as practicable.

8.3 RECORDS

Records of inspections are to be stored in accordance with ROM document systems and physical copies of inspection checklists stored on site.

8.4 REPORTING

8.4.1 Internal

Incident reports will be utilised to inform of incidents and drive corrective actions. Incident reports are to be completed as soon as possible after becoming aware of an incident.

8.4.2 Regulatory Authority

The Mine Supervisor, or their delegate, will notify DES within 24 hours of becoming aware of an incident that has the potential to cause, or threaten to cause, material or serious environmental harm.

8.5 REVIEW

This document will be reviewed annually or earlier if required.

8.6 RESPONSIBILITIES

Roles and responsibilities are outlined below.

Table 6 Roles and responsibilities

Role	Responsibility
Site Supervisor or Delegate	Ensure resources are available to implement the contents of this plan Facilitate ESCP reviews Report incidents to DES
Senior Environmental Officer	Implement contents of this plan Train Staff in environmental awareness, issues and requirements of ESCP Facilitate monitoring of requirements in ESCP Report non-conformances to technical services Manage and ensure actions are closed out Advise on EA conditions Investigate environmental incidents and provide assistance with DES where necessary
Employees	Be familiar with contents of ESCP Undertake erosion and sediment control works Report visual degradation or apparent non-conformances with this ESCP within shifts as observed
Contractors	Undertake corrective actions as soon as practicable Report and non-conformance/environmental incidents within same shift as noticed Be familiar with contents of ESCP Prepare design and plan for construction,

Important note about your report

This Report is provided for the exclusive use of the Client pursuant to the Scope of Works dated on or about 21 February 2021, which requires us to provide Services relating to performing calibrated erosion modelling.

This Report is provided to the Client on the terms and conditions set out in the Standard Terms of SGM Environmental Pty Limited (SGME, we, us or our).

We derive data in this Report from information (or confirmation of the absence thereof) sourced from the Client and any subcontractors, designated laboratories and / or information that has been made available in the public domain at the time or times outlined in this Report. The passage of time, manifestation of latent conditions or impacts of future events may require further examination of the erosion modelling and subsequent data analysis, and re-evaluation of the data, findings, observations and conclusions expressed in this Report.

SGME has prepared this Report in accordance with the usual care and thoroughness of the consulting profession, for the sole purpose described above and by reference to any applicable standards, guidelines, procedures and practices outlined in the Scope of Works as at the date of issue of this Report. For the reasons outlined above, however, no other warranty or guarantee, whether expressed or implied, is made as to the data, observations and findings expressed in this Report, to the extent permitted by law.

This Report should be read in full and no excerpts are to be taken as representative of the findings. No responsibility is accepted by SGME for use of any part of this Report in any other context.

Reporting of the erosion modelling are based on a desktop assessment of data that has been measured by the Client and any subcontractors and other third parties.

SGME does not accept any Liability whatsoever for, or in respect of, any use of, or reliance upon this Report by any person contrary to the above or our Standard Terms.

1.0 Introduction

1.1 Background

SGM environmental Pty Limited (SGME) has been engaged by Round Oak Minerals Pty Limited (Round Oak) to complete a calibrated erosion model to assess the long-term stability of the final landform of the waste rock dump (WRD) (the final landform) at the Barbara Copper Project (the Mine).

1.2 Mine description

The Mine is a copper deposit located in north-western Queensland approximately (~) 65 kilometres (km) north-east of Mount Isa (Figure 1) and operates under environmental authority (EA) EPML02840015. Round Oak began operations in March 2019, incorporating conventional drill and blast / load and haul methods. The Mine operated until December 2020 and has now been placed in care and maintenance.

No processing of ore occurs at the Mine, with extracted ore being transported by road train to Glencore's Mount Isa processing facility for treatment. The Mine incorporates the following key infrastructure:

- north pit;
- south pit;
- WRD;
- WRD sediment dam;
- light infrastructure area;
- run-of-mine (ROM) pad;
- road train loading area; and
- magazine.

The final landform is located in the southern area of the Mine and was designed to store the waste rock produced from both the north and south pits. Waste rock is predominantly non-acid forming (NAF) and has low sulfur content. Post-closure, the runoff from the WRD will partially flow to the south pit via the haul road.

1.3 Scope

The reliability of an erosion model is based on a combination of the model's internal equations and the accuracy of the model's parameters. Using inaccurate erodibility parameters will result in inaccurate predictions which can lead to costly amendments due to a poorly designed landform.

The scope of this report is to complete rainfall and overland flow simulations to provide calibrated erodibility parameters for the cover material of the final landform. The calibrated parameters have been used for long-term erosion modelling of the final landform that meets the landform evolution modelling (LEM) requirements of the *Guideline: Progressive rehabilitation and closure plans (PRC plans)* (PRC plan guideline).

This report includes the following:

- desktop review of the landform design. including material properties (Section 2.0);
- rainfall and overland flow simulations to calibrate the erosion model (Section 3.0);
- calibrated erosion modelling to predict the long-term stability of the WRD (Section 4.0); and
- conclusions, limitations and assumptions of the rainfall simulation, overland flow simulation, erosion model and landform design (Section 5.0).

1.4 Link to the Progressive Rehabilitation and Closure Plan

The PRC plan guideline states that the *Progressive Rehabilitation and Closure Plan* (PRC plan) must include all supporting information required by the Department of Environment and Science (DES) to reach a decision on the 'soundness' of the rehabilitation strategies and delivery techniques to meet the approved land outcomes.

The objective of the final landform's design is to follow the Mine's rehabilitation objective outlined in EA EPML02840015. The post-closure objectives are to return the disturbed land to an agreed post-mining land use (PMLU) that is:

- safe (ie erosion gullies not presenting a danger to humans / animals);
- non-polluting (ie sediment runoff does not impede offsite assets);
- stable (ie stability does not compromise the PMLU or surrounding environment); and
- self-sustaining (ie the growth medium can support the PMLU).

2.0 Desktop review

2.1 Site conditions

2.1.1 Climate

The climate of the region that the Mine is located in is referred to as a local steppe climate. The region is classified as hot semi-arid climate (BSh) according to the Köppen-Geiger climate classification. These climates tend to have hot sometimes extremely hot, summers and warm to cool winters, with some to minimal rainfall. High variability in rainfall, temperature and evaporation are common in north-west Queensland. The average annual temperature is 25.2 degrees Celsius (˚C) and the average rainfall is ~ 396 millimetres (mm) per year.

2.1.2 Topography

The topography of the Mine is undulating hills with frequent outcropping of rocky ridgelines. The landforms surrounding the Mine include rugged hills and mountain ranges separated by undulating valleys to the east and the Leichardt River to the west. The surrounding mountain ranges typically rise to a maximum height of 400-500 metres (m) Australian Height Datum (AHD).

2.1.3 Hydrology

The Mine is located in the Leichardt River Basin. The Leichardt River Basin begins to the south of Mount Isa and drains via the Leichardt River to the Gulf of Carpentaria. The Mine contains several drainage lines and ephemeral tributaries that tend to drain north-west down the steeper hills into the Leichardt River.

2.2 Final landform design

A rainfall-shedding capping system (the capping) has been built over the final landform's footprint. A potentially acid forming (PAF) cell has been constructed to store all PAF waste rock in a stable and non-polluting manner. The capping contains a low permeability layer above and below the PAF waste rock, comprised of compacted NAF waste rock to prevent infiltration into the PAF cell and isolate it from the permeable NAF waste rock located beneath it. The overall performance objectives for the cover are to:

- promote a stable landform using vegetation growth where applicable;
- direct surface runoff to the WRD sediment dam via the exit ramp to the south pit; and
- prevent capillary rise of salt and other contaminants into the cap.

The final landform has a total disturbance footprint of ~ 23 hectares (ha). The side batters are at angle of repose (~ 37 degrees (°)) with a batter height of 10 m and a bench width of 12 m leading to an average batter slope of 1V:2.5H. The final landform is shown in Figure 2.

The natural rilling of the batters is expected to create natural rock armouring / outcropping that will provide potential habitat for the Purple-Necked Rock-Wallaby.

2.3 Cover material

2.3.1 Geochemistry

The final landform is mostly NAF waste rock (the cover material) with low sulfur content. Geochemical static characterisation of the Mine's waste rock was done by Environmental Geochemistry International Pty Limited (EGi) in 2014. In 2019 a kinetic leach column testing program was also done. The Kinetic column testing found that apart from limited leaching of copper, there was no evidence of leaching of environmentally important elements such as arsenic, cadmium, mercury, lead and zinc from either the cover material or the PAF samples (EGi 2020).

2.3.2 Stability

The structural stability of waste rock is heavily influenced by a combination of physical and chemical properties (eg exchangeable cations, electrical conductivity (EC) and organic matter (OM)).

Sodicity is the presence of a high proportion of sodium ions relative to other exchangeable cations. Waste rock is considered sodic when the exchangeable sodium percentage (ESP) is greater than six and highly sodic when the ESP is greater than 15.

High salt content can prevent the dispersion caused by sodicity. If the salinity falls below the requirement for stability, even a small amount of sodium can produce significant dispersion. The electrochemical stability index (ESI) is the ratio of EC and the ESP and is used to describe this relationship.

The Emerson aggregate test measures the stability of the waste rock structure when immersed in water and is used to predict slaking and / or dispersive behaviour.

OM content is representative of the structural condition and stability of the material. A high (greater than (>)3) percent (%) of OM can reduce erosion by increasing water infiltration and forming stable aggregates.

Closure studies were done by SGME in 2021 which included physical and chemical characterisation of the cover material. The findings from this study, with regard to erosion and landform stability, can be summarised as:

- ESP indicates the cover material has low sodicity (less than (<)6) and negligible risk of dispersion;
- ESI indicates the cover material should be stable;
- Emerson aggregate tests indicate the cover material is potentially dispersive (Class 3) when remoulded at the plastic limit (heavily trafficked); and
- OM content indicates the cover material has very poor structural condition and very low structural stability.

2.4 Target erosion rate

There is currently no broad agreement on what constitutes an 'acceptable' rate of erosion on a rehabilitated landform. The *Prediction of Sheet and Rill Erosion Over the Australian Continent: Incorporating Monthly Soil Loss Distribution* (Lu et al 2001) has previously reported that:

- the average Australian soil erosion rate is 6.3 tonnes per hectare per year (t/ha/y);
- a low rate of erosion is defined as <0.5 t/ha/y; and
- a high erosion rate is defined as >10 t/ha/y.

Landloch (2013) have shown that rehabilitated mine slopes have a low tendency to rill with an average erosion rate of <5 t/ha/y. The elimination of rilling will largely reduce the potential of channelised flow which can result in gully erosion. Therefore, avoiding rill formation will ensure landform stability and reduce the likelihood of excessive erosion.

It is important to note that erosion rates can vary from year to year depending on climatic conditions. Therefore, the maximum annual erosion rate will also be used as a secondary performance indicator.

Target average and maximum erosion rates of <5 t/ha/y and <10 t/ha/y have therefore been adopted for the WRD landform.

3.0 Rainfall and overland flow simulations

The studying of hydrological processes such as runoff, erosion and infiltration usually require the use of field plots under natural rainfall or field scale rainfall simulators. Laboratory scale rainfall simulators are a convenient and cost-effective method that has been proven to be effective in predicting hillslope erosion rates and deriving site-specific erodibility parameters for mining landforms (Evans et al 1997; Sheridan et al 2000; Landloch 2010; So et al 2018). These calibrated parameters can be used in conjunction with erosion models to assess the long-term stability of mining landforms.

3.1 Method

3.1.1 Equipment

3.1.1.1 Rainfall simulator

Mhaske et al (2019) provides a detailed design of the rainfall simulator used in this report. The simulator can be divided into four key parts (XXXX):

1. Water supply system connected to a pressurised full cone nozzle to produce simulated rainfall.
2. Supporting steel frame to mount water supply system and canvas windshields.
3. Hydraulic jack attached to a tilting table for slope adjustment.
4. Perforated plot to hold the sample to be tested and provide a means to capture runoff and infiltration.

a Water supply system and full cone nozzle

Irrigation pipes made of polyvinyl chloride (PVC) are used for the water supply system. A flow meter placed between two control valves is used to monitor and control the flow rate.

Full-cone spray nozzles constructed by Spraytech Systems Pvt Limited (Spraytech) are used to simulate rainfall. The spray angle of the nozzles is 45˚. Spray nozzles of four different orifice sizes are used to simulate different rainfall intensities:

- DA13.250 — 1.9 mm;
- DA13.350 — 2.2 mm;
- DA13.650 — 3.1 mm; and
- DA23.100 — 3.8 mm.

b Steel frame

A supporting steel frame was constructed to attach the water supply system and canvas wind shields. The frame is 3.0 m long, 2.0 m wide and 3.5 m high. The spray nozzle is attached centrally at the top of the frame to ensure adequate coverage (~ 3 m diameter spray area).

c Tilting table with hydraulic jack

A 1.2 m high tilting table was constructed to hold the erosion plot / overland flow flume and allow the adjustment of the slope angle. A manual hydraulic jack is fixed at the bottom of the table to lift the plot / flume to the desired slope angle.

d Erosion plot

A 0.5 m wide and 1.0 m long erosion plot secured to the top of the tilting table is used to hold the cover material and collect runoff and infiltration samples. The plot is divided into two sections by a perforated sheet that allows

the infiltration of water. The upper section holds the cover material and allows for runoff generation and collection, the lower section allows for infiltration through the plot and sample collection. This allows for both runoff and infiltration to be collected simultaneously.

e Calibration

Rainfall intensity is an important factor in accurate rainfall simulations. The rainfall simulator was calibrated using a flow meter and tipping bucket rain gauges. Four full cone nozzles with differing orifice sizes (Section 3.1.1.1a) were calibrated to achieve a variety of possible rainfall intensities. The nozzles have a 45° spray angle resulting in a spray area of ~ 2.50-3.00 m in diameter. Rain gauges were positioned at various places within the target area (0.5 square metres (m^2)) and averaged to calculate the rainfall intensity applied to the erosion plot.

3.1.1.2 Overland flow simulation

A 0.75 m wide and 2.00 m long flume was used to simulate overland flow and assess rill erosion. A hose was attached to the rainfall simulator's water supply system (to make use of the flow meter) and was discharged into a feeder tank that is located at the top of the flume to ensure a steady and even flow across the flume.

3.1.2 Experiments

NAF waste rock was collected by Round Oak staff from the final landform and transported in an intermediate bulk container to the SGME laboratory to be assessed. The cover material was uniformly mixed and placed into an erosion plot and an overland flow flume achieving a bulk density that is representative of a trafficked WRD (~ 1.5 tonnes per cubic metre (t/m^3)).

3.1.2.1 Rainfall simulation

Interrill erosion is measured by applying a simulated storm (ie 100 millimetres per hour (mm/h)) to a plot 0.50 m wide and 1.00 m long. The plot is set to a gradient of 20% and the storm event is run for 30 minutes. Rainfall is applied until steady state runoff is reached; then timed runoff and infiltration samples are collected at 5 minute intervals. The runoff samples collected after steady state is achieved are dried and weighed to measure the interrill erosion rate. Rainfall is measured by rain gauges and accounted for in the calculation of interrill erosion.

3.1.2.2 Overland flow simulation

Rill erosion is measured by applying various rates of overland flow to a flume 0.75 m wide and 2.00 m long. The flume is set to a gradient of 20% and consecutive rates of overland flow (measured with the flow meter) are applied for 3 minute intervals. Flow rates are increased until the maximum possible flow is achieved or until rills cut to the base of the flume. For each applied flow rate, three runoff samples are collected at 1 minute intervals. The samples are dried and weighed with the mean used to measure the rill erosion rate. No rainfall is applied during the overland flow simulation.

3.1.3 Calculations

In the *Water Erosion Prediction Project* (WEPP) model (the WEPP model) the erosion process is divided into interrill and rill erosion. These two processes are calculated in the model via a number of erodibility parameters (the parameters):

- interrill erodibility (K_I);
- rill erodibility (K_r);
- critical shear stress (τ_c); and
- effective hydraulic conductivity (K_e).

The parameters are derived from data collected during the rainfall and overland flow simulations and equations sourced from Liebenow, Elliot, Laflen & Kohl 1990, Sheridan, Loch & So 2000, Franco, Cassol, Pauletto & Pinto 2010 and Reichert & Norton 2013:

- K_i is calculated using the runoff samples obtained from the rainfall simulation and Equations 1-5 (Section 3.1.3.1);
- K_r and τ_c are calculated using the runoff samples obtained from the overland flow simulation and Equations 6-8 (Section 3.1.3.2); and
- K_e is calculated using the infiltration rates measured from the rainfall simulation.

3.1.3.1 Interrill erodibility

a Interrill erosion rate

$$E_i = \frac{Mss}{AD} \quad (1)$$

Where, E_i = interrill erosion rate (kilograms per squared metre seconds (kg/m^2 s)); Mss = soil dry mass (kilograms (kg)); A = plot area (m^2); D = time of sampling (seconds (s)).

Adjusted interrill erosion rate

$$E_{Ai} = (\frac{I_D}{I_M})^2 \times E_i \quad (2)$$

Where, E_{Ai} = adjusted interrill erosion rate (kg/m^2 s); I_D = design rainfall intensity (metres per second (m/s)); I_M = measured rainfall intensity (m/s).

b Interrill erodibility factor

Slope steepness factor

$$S_f = 1.05 - 0.85e^{-4sin\theta} \quad (3)$$

Where, S_f = slope steepness factor; θ = slope angle (radians).

Cover factor

$$C_f = e^{-2.5C} \quad (4)$$

Where, C_f = cover factor; C = rock (greater than (>) 2 millimetre (mm)) fraction.

Interrill erodibility factor

$$K_i = \frac{E_i}{IQS_fC_f} \quad (5)$$

Where, K_i = interrill erodibility factor (kilogram seconds per quartic metre (kg s/m^4)); Q = steady-state runoff rate (m/s).

3.1.3.2 Rill erodibility

a Rill erosion rate

$$E_r = \frac{Mss}{A_rD} \quad (6)$$

Where, E_r = rill erosion rate (kg/m^2 s); A_r = rill bed area (m^2); D = time of sampling (s).

b Hydraulic shear stress

Open channel flow (no rilling)

$$\tau = yds \tag{7}$$

Where, τ = hydraulic shear stress (pascals (Pa)); y = specific weight of water (9,806 kilograms per squared metre seconds ($kg/m^2 s^2$)); d = average water depth (m); s = hydraulic gradient (≈ flume slope angle (radians)).

Flow in rills

$$\tau = yrs \tag{8}$$

Where, r = hydraulic radius (m); s = hydraulic gradient (≈ rill slope angle (radians)).

c Rill erodibility factor and critical shear stress

Rill erosion rates (Equation 6) for all of the simulated flows is plotted against their corresponding hydraulic shear values (Equation 7 or 8) and a regression line is calculated. The slope of the regression line is the rill erodibility factor (seconds per metre (s/m)) and the intercept with the horizontal axis is the material's critical shear stress (Pa).

3.2 Results and discussion

3.2.1 Rainfall simulation

Interrill erosion was assessed by applying rainfall at an initial intensity of 112 mm/h to the erosion plot. The plot was set to a gradient of 20% and rainfall was maintained for 30 minutes. Timed (10-30 second) infiltration samples were collected at 5 minute intervals during the simulation. No runoff was observed for the initial intensity, so the simulation was repeated at ~ 400 mm/h (the maximum achievable intensity). Timed infiltration samples were collected at 5 minute intervals during the 30 minute simulation. No runoff was observed for the maximum achievable intensity.

Once steady state infiltration was achieved, the subsequent infiltration rates were averaged to derive the cover material's effective hydraulic conductivity (422 mm/hr). Interrill erodibility was not able to be calibrated from the rainfall simulation because no runoff was generated by any of the simulated storm events.

3.2.2 Overland flow simulation

Rill erodibility and critical shear were not calibrated from the overland flow simulation because no rilling was observed during any of the simulated flows.

4.0 WEPP modelling

4.1 The WEPP model

The WEPP model is a continuous simulation erosion prediction model, initially developed for agricultural purposes by the United States Department of Agriculture (USDA). The WEPP model integrates hydrology, vegetation science, hydraulics and soil mechanics to simulate the erosion process (both detachment and transport) at a two-dimensional hillslope scale.

The WEPP model is a daily time step model that simulates daily runoff and erosion for a given slope shape, based on initial waste rock hydrological conditions, characteristics of the rain event and waste rock erodibility and infiltration parameters on each day. The WEPP model can also be used to assess the erosion potential for extreme rainfall events.

The WEPP model has been used in the design of landforms for mines across Australia. Howard and Roddy (2012) have shown that observed cumulative erosion rates for mined landforms in Western Australia show good agreement with the WEPP model's predictions.

4.2 Method

The WEPP model was used to simulate final landform stability predictions for a 100 year period including data for rainfall, runoff, and sediment loss for the final landform. The WEPP model was also used to determine reductions in erosion rates from increasing groundcover.

4.2.1 WEPP model parameters

WEPP model inputs can be broken up into four key components: climate, material properties, topography and surface conditions.

4.2.1.1 Climate

A 100 year synthetic climate file was generated using the CLIGEN stochastic weather generator. CLIGEN has been widely used and validated in Australia (Yu 2003). The following data was imported into CLIGEN to generate this file:

- 121 years of patched daily temperature (maximum and minimum), rainfall and solar radiation sourced from the Bureau of Meteorology (BoM) SILO data drill (the SILO data drill); and
- 24 years of pluviograph (6-minute rainfall intensity) data from the BoM's Mount Isa Aero weather station (029127), located ~ 47 km south-west of the Mine.

Various parameters were then adjusted in the generated climate file to match the inputted data more closely. These include average rainfall on a wet day, maximum 30 minute rainfall intensity and time to peak rainfall intensity.

a Validation

The CLIGEN climate file has been compared to the SILO data drill to verify the accuracy of the WEPP model. The CLIGEN climate file and the SILO data drill show a high level of consistency in terms of both monthly rainfall totals (Figure 3) and design storm events (Figure 4). Therefore, the CLIGEN climate data file is considered appropriate for use in the WEPP model.

Figure 3 Average monthly rainfall comparison (CLIGEN and historical data)

Figure 4 Average recurrence interval comparison (CLIGEN and historical data)

4.2.1.2 Material properties

The WEPP model has been run using median values derived from laboratory physical and chemical data (SGME 2021). The NAF waste rock parameters inputted into the WEPP model are given in Table 1.

Table 1 Material parameters

Material type	Depth	Sand	Clay	Rock	OM	Cation exchange capacity (CEC)
	m	%	%	%	%	milliequivalents per 100 grams (meq/100g)
NAF waste rock	2.0	9.8	0.2	88.0	0.31	7.4

Effective hydraulic conductivity was derived from the maximum infiltration achieved during the rainfall simulator (422 mm/h). Interrill erodibility, rill erodibility and critical shear were calculated via the WEPP model since the parameters were not able to be derived from the rainfall simulation (no runoff achieved) or overland flow simulation (no rilling observed) and therefore could not be calibrated.

4.2.1.3 Topography

Three cross-sections that are considered representative of the WRD final landform were modelled. Table 2 and Figure 5 summarise the slope parameters used in the WEPP model. The slope gradient varies slightly around the final landform and includes a bench with a gentler gradient ~ halfway down, breaking the slope into sections.

Table 2 Slope parameters

Slope ID	Height	Section 1		Section 2		Section 3	
	m	Length (m)	Slope (%)	Length (m)	Slope (%)	Length (m)	Slope (%)
XS-1	19.0	14.7	74.8	12.5	8.0	11.9	67.2
XS-2	42.0	33.0	72.8	27.7	3.6	29.5	61.1
XS-3	32.0	343.9	9.6	-	-	-	-

4.2.1.4 Surface conditions

The WEPP model was run for a no vegetative groundcover scenario (worst-case). Vegetation development was also restricted during the WEPP model because vegetation growth rates for the area are not currently known.

Rill spacing was set to 0.5 m and surface roughness was set to 0.03 m, which is typical of a smooth surface that would develop after many rainfall events.

4.3 Results

The average and maximum annual erosion rates are given in Table 3.

Table 3 Annual erosion rate

Slope ID	Average	Maximum
XS-1	nil	nil
XS-2	nil	nil
XS-3	0.06	0.37

1. Units are in t/ha/y

4.4 Discussion

Table 3 shows that the final landform will experience negligible erosion rates (<0.6 t/ha/y) with the modelled cover and can be considered stable (unlikely to develop significant rilling). Similarly, the maximum erosion rates modelled (<0.37 t/ha/y) indicate that the final landform will be stable in the event of extreme rainfall.

The very low erosion rates predicted by the WEPP model can be attributed to the high effective hydraulic conductivity of the cover material which was derived from the rainfall simulation (Section 3.0). While the high hydraulic conductivity of the cover material will limit the potential for sheet and rill erosion, sediment may be transported through minor forms of tunnel erosion.

4.4.1 Limitations

The following limitations apply to the WEPP model:

- it does not predict deposition patterns;
- it does not adjust hillslope elevation in response to erosion;
- it does not consider gully and tunnel erosion; and
- it does not account for weathering, surface armouring and pedogenesis.

The effects of climate change on future rainfall event intensities, durations and / or frequencies may also affect the predictions made by the WEPP model.

5.0 Conclusions

5.1 Rainfall and overland flow simulations

Rainfall and overland flow simulations were done on NAF waste rock collected from the final landform in order to derive calibrated erodibility parameters. A rainfall simulator was used to study the interrill erosion process and calibrate the interrill erodibility factor and the effective hydraulic conductivity. An overland flow simulator was used to study the rill erosion process and calibrate the rill erodibility factor and critical shear stress.

5.1.1 Rainfall simulation

The effective hydraulic conductivity was derived from the infiltration rates measured during the rainfall simulation. However, interrill erodibility was not able to be calibrated from the rainfall simulation as no runoff was observed for any of the simulated storm events.

5.1.2 Overland flow simulation

Rill erodibility and critical shear were not able to be calibrated from the overland flow simulation as no rilling was observed for any of the simulated flows.

5.2 WEPP modelling

The WEPP model was run using desktop data, calibrated erodibility parameters and current landform designs to estimate the potential annual erosion rate (t/ha/y) for a 100 year period.

The WEPP model indicated that, given current landform designs, the final landform will experience negligible erosion (<0.37 t/ha/y) and can be considered stable with regard to the average and maximum rates of erosion (<5 t/ha/y and <10 t/ha/y respectively).

MB blank results are compared to the Limit of Reporting
LCS and MS spike recoveries are measured as the percentage of analyte recovered from the sample compared the the amount of analyte spiked into the sample.
DUP and MSD relative percent differences are measured against their original counterpart samples according to the formula : *the absolute difference of the two results divided by the average of the two results as a percentage.* Where the DUP RPD is 'NA' , the results are less than the LOR and thus the RPD is not applicable.

MB blank results are compared to the Limit of Reporting
LCS and MS spike recoveries are measured as the percentage of analyte recovered from the sample compared the the amount of analyte spiked into the sample.
DUP and MSD relative percent differences are measured against their original counterpart samples according to the formula : *the absolute difference of the two results divided by the average of the two results as a percentage.* Where the DUP RPD is 'NA' , the results are less than the LOR and thus the RPD is not applicable.

METHOD	METHODOLOGY SUMMARY
AN002	The test is carried out by drying (at either 40°C or 105°C) a known mass of sample in a weighed evaporating basin. After fully dry the sample is re-weighed. Samples such as sludge and sediment having high percentages of moisture will take some time in a drying oven for complete removal of water.
AN002/AN320/AN321	Soil sample is extracted in deionised water (1:2 or 1:5) and metals analysed by ICP OES, method AN320/AN321, with results reported on the dried sample basis.
AN012/AN320	Dried prepared soil is digested by oxidation with nitric acid and bromine followed by analysis of the digest by ICP OES.
AN014	This method is for the determination of soluble sulfate (SO4-S) by extraction with hydrochloric acid. Sulphides should not react and would normally be expelled. Sulfur is determined by ICP.
AN015	Soil sample is extracted in an end over end roller in 0.5 N sodium bicarbonate at pH 8.5 with the supernatant liquor analysed for Phosphorous. Orthophosphate anion (PO43-) is reacted with ammonium molybdate and potassium antimony tartrate in sulfuric acid solution. The resulting phospho-molybdate complex is reduced, using ascorbic acid, to an intense blue coloured complex Molybdenum Blue. The absorbance of this complex is measured at 880 nm by Discrete Analyser, and compared with calibration standards to obtain the concentration of orthophosphate in the sample. Based on Rayment & Higginson 9B1.
AN025/AN320	A chelating agent is used to complex metal ions in solution. The extracted elements are determined byICP OES.
AN101	pH in Soil Sludge Sediment and Water: pH is measured electrometrically using a combination electrode and is calibrated against 3 buffers purchased commercially. For soils, sediments and sludges, an extract with water (or 0.01M CaCl2) is made at a ratio of 1:5 and the pH determined and reported on the extract. Reference APHA 4500-H+.
AN103	pH in Soil Sludge Sediment and Water: pH is measured electrometrically using a combination electrode (glass plus reference electrode) and is calibrated against 3 buffers purchased commercially. For soils, an extract with water is made at a ratio of 1:5 and the pH determined and reported on the extract. Reference APHA 4500-H+.
AN106	Conductivity and TDS by Calculation: Conductivity is measured by meter with temperature compensation and is calibrated against a standard solution of potassium chloride. Conductivity is generally reported as µmhos/cm or µS/cm @ 25°C. For soils, an extract of as received sample with water is made at a ratio of 1:5 and the EC determined and reported on the extract, or calculated back to the as-received sample. Salinity can be estimated from conductivity using a conversion factor, which for natural waters, is in the range 0.55 to 0.75. Reference APHA 2510 B.
AN122	Exchangeable Cations, CEC and ESP: Soil sample is extracted in 1M Ammonium Acetate at pH=7 (or 1M Ammonium Chloride at pH=7) with cations (Na, K, Ca & Mg) then determined by ICP OES/ICP MS and reported as Exchangeable Cations. For saline soils, these results can be corrected for water soluble cations and reported as Exchangeable cations in meq/100g or soil can be pre-treated (aqueous ethanol/aqueous glycerol) prior to extraction. Cation Exchange Capacity (CEC) is the sum of the exchangeable cations in meq/100g.

METHOD	METHODOLOGY SUMMARY
AN122	The Exchangeable Sodium Percentage (ESP) is calculated as the exchangeable sodium divided by the CEC (all in meq/100g) times 100. ESP can be used to categorise the sodicity of the soil as below: ESP < 6% non-sodic ESP 6-15% sodic ESP >15% strongly sodic Method is referenced to Rayment and Lyons, 2011, sections 15D3 and 15N1.-
AN212	Samples are initially evaluated to determine the strength of reagents needed using a `'fizz' test. Samples are then subjected to an excess of hydrochloric acid followed by alkaline back titration to pH 7. Results are expressed in kg H2SO4/tonne or Kg CaCO3/tonne after correction for moisture content if applicable.
AN215	This is purely a calculation based on results obtained from Total Sulphur, Sulfate Method, and Acid Neutralisation Capacity Method (ME-AU-ENV-AN212). The negative value included as the LOR allows negative NAPP data to be reported in the LIMS, it is not the numerical LOR which would theoretically be 1kg H2SO4/tonne. The range of results is theoretically -980 to 1640kg H2SO4/Tonne.
AN216	Pulverised sub-sample of a waste rock or an as received sample of filter cake, soil or sludge is subjected to an oxidising digest with 15% hydrogen peroxide adjusted to pH 4.5. The pH and EC of the NAG suspension is recorded at various stages in the digest. The acid produced (if any) is titrated using standardised NaOH to pH 7.0. NAG results are reported to 0.5 kg H2SO4/tonne.
AN248	Nitrate / Nitrite in extract by Auto Analyser: In an acidic medium, nitrate is reduced quantitatively to nitrite by cadmium metal. This nitrite plus any original nitrite is determined as an intense red-pink azo dye at 540 nm following diazotisation with sulphanilamide and subsequent coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. Reference APHA 4500-NO3- F.
AN273	The sample is digested in Dichromate / Sulfuric Acid to oxidise the organic carbon. The determination is completed colourimetrically by Aquakem Discrete Analyser at 600 nm. Based on Rayment & Higginson 6B1.
AN274	Chloride by Aquakem DA following 1:5 or 1:2 DI water extraction: Chloride reacts with mercuric thiocyanate forming a mercuric chloride complex. In the presence of ferric iron, highly coloured ferric thiocyanate is formed which is proportional to the chloride concentration. Results reported on dry sample basis. Reference APHA 4500Cl-
AN277	Nitrite on the extract is determined as an intense red-pink azo dye at 540 nm following diazotisation with sulphanilamide and subsequent coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The original nitrite is determined. Reference APHA 4500-NO2- B.
AN281	The sample is heated in the presence of Sulphuric acid, K2SO4 and CuSO4 for two and half hours using a temperature controlled digestion block. Amino Nitrogen of many organic materials is converted to ammonium ion. Free ammonia also is converted to ammonium. The digest is cooled and placed on the Aquakem 250 discrete analyser for Ammonia determination.
SOL061	Soil sample is extrcated 1:10 in 1MKCl with aluminium determined by ICP OES.

FOOTNOTES

IS	Insufficient sample for analysis.	LOR	Limit of Reporting
LNR	Sample listed, but not received.	↑↓	Raised or Lowered Limit of Reporting
*	NATA accreditation does not cover the performance of this service.	QFH	QC result is above the upper tolerance
		QFL	QC result is below the lower tolerance
**	Indicative data, theoretical holding time exceeded.	-	The sample was not analysed for this analyte
***	Indicates that both * and ** apply.	NVL	Not Validated

Unless it is reported that sampling has been performed by SGS, the samples have been analysed as received.
Solid samples expressed on a dry weight basis.

Where "Total" analyte groups are reported (for example, Total PAHs, Total OC Pesticides) the total will be calculated as the sum of the individual analytes, with those analytes that are reported as <LOR being assumed to be zero. The summed (Total) limit of reporting is calcuated by summing the individual analyte LORs and dividing by two. For example, where 16 individual analytes are being summed and each has an LOR of 0.1 mg/kg, the "Totals" LOR will be 1.6 / 2 (0.8 mg/kg). Where only 2 analytes are being summed, the " Total" LOR will be the sum of those two LORs.

Some totals may not appear to add up because the total is rounded after adding up the raw values.

If reported, measurement uncertainty follow the ± sign after the analytical result and is expressed as the expanded uncertainty calculated using a coverage factor of 2, providing a level of confidence of approximately 95%, unless stated otherwise in the comments section of this report.

Results reported for samples tested under test methods with codes starting with ARS-SOP, radionuclide or gross radioactivity concentrations are expressed in becquerel (Bq) per unit of mass or volume or per wipe as stated on the report. Becquerel is the SI unit for activity and equals one nuclear transformation per second.
Note that in terms of units of radioactivity:

a. 1 Bq is equivalent to 27 pCi
b. 37 MBq is equivalent to 1 mCi

For results reported for samples tested under test methods with codes starting with ARS-SOP, less than (<) values indicate the detection limit for each radionuclide or parameter for the measurement system used. The respective detection limits have been calculated in accordance with ISO 11929.

The QC and MU criteria are subject to internal review according to the SGS QAQC plan and may be provided on request or alternatively can be found here: www.sgs.com.au/en-gb/environment-health-and-safety.

SGM Environmental Pty Limited (SGME) is a boutique consulting firm of experienced industry experts working with our clients and their stakeholders to develop and deliver innovative solutions to complicated challenges that create enduring value.

SGME was established to provide services in soil science, geochemistry, mine closure and Environmental management, planning & approvals cost efficiently. When you engage SGME you engage a partner to your business, priding themselves on:

Honest – Straight-up and no nonsense.

Trust – We say what we mean and we will deliver on our promises. We will advocate strongly for you.

Innovation – We will always look for new ways to help and create enduring value because that is what friends do when they work together.

Safety – We do it right so we all go home safely.

Dear Sarah

RE: MINE CLOSURE GEOTECHNICAL STUDY, BARBARA COPPER PROJECT

1. Introduction

This report presents the geotechnical assessment undertaken by PSM to inform the mine closure requirements for the Barbara Copper Mine on behalf of Round Oak Minerals, as per the Queensland Government Progressive Rehabilitation and Closure Plan Guideline (ESR/2019/4964)[1] . The assessment has been undertaken at the request of Peter Brown via email to Mr Greg Kennedy of PSM[2], with the agreed work package detailed in PSM2319-040L[3].

To complete the assessment, PSM have utilised the extensive experience gained by providing geotechnical advice for the Barbara Copper Mine since 2013 including initial Feasibility Design Studies through to the current operational geotechnical support since mining began in 2019. This report documents the background information, geotechnical model, adopted criteria and stability analyses used for the geotechnical assessment to assess requirements for mine closure.

2. Overview of Mining Footprint

The existing development comprises two open pits with ore mined using a conventional truck and shovel operation with out of pit dumps for stockpiling of overburden. Mining in the North pit has ceased at approximately 295 mRL, with pit access currently bunded off.

Open pit mining continues in the South pit and, at the time of reporting, is at approximately 240 mRL. The final pit depth is planned to 205 mRL. Figure 1 presents the location of both pits and shows the existing shape of the North pit and the latest final design shape of the South pit.

---

[1] Progressive Rehabilitation and Closure Plan Guideline (ESR/2019/4964), Queensland Government Department of Environment and Science

[2] RE: Address, email from Peter Brown of Round Oak to Greg Kennedy of PSM, received 18 September 2020

[3] PSM2319-040L Proposal for Closure Study, Barbara Copper Mine, issued 14 October 2020

3. Scope of Work

The scope of works for the Barbara closure study comprises:

1. Assessment of pit wall geotechnical stability, considering the effects of long-term erosion and weathering of the pit wall and the effects of significant hydrological events.
2. Proposed final slope angles of high wall, low wall and end walls of each final void, and used to determine the location of the abandonment bund beyond the final extent of potential failure.
3. Any mechanisms for achieving geotechnical stability to be detailed, and supervision, verification and auditing of engineering works carried out to achieve the post-closure void landform, to ensure construction is consistent with the geotechnical design.
4. Consideration of stability under rehabilitation goal of voids in Schedule G1 of the Environmental Authority (EA) for the mine[4].

The agreed work package to address items 1 to 4 above has been detailed in PSM2319-040L[5] and has been summarised in Section 4.

4. Approach

The geotechnical report requirements defined within the Queensland Government Progressive Rehabilitation and Closure Plans (PRC) for the void closure plan are set out within Section 3.6.3 of that document and include the following comments related to the required geotechnical report:

> *"A geotechnical report should focus on how the void will achieve post-closure slopes that will exhibit stability characteristics consistent with the planning and design of the post closure void"*

The long-term stability of the open pit void is dependent on several factors, the most important of which are:

- The presence and orientation of major geological structures (i.e. faults and shears) within the pit slopes
- The strength of the rock mass within the pit slope
- Variation in the strength of the rock mass with time (i.e. from stress relief and ongoing weathering)
- The depth and characteristics of soil or completely weathered rock in the upper pit walls, and their susceptibility to erosion over time
- The geometry of the pit wall
- The influence of groundwater and rainfall on slope stability
- The influence of seismic events.

The primary objective of the mine closure assessment is to identify the stable long-term crest location and nominate an exclusion zone around the perimeter of the final pit crest based on the predicted long-term slope stability. This is then used to plan the location of an abandonment bund to restrict access and manage public safety. To achieve this, PSM have taken the following approach, which has been illustrated schematically in Inset 1:

1. Identification of the long-term stable pit crest location by assessing the extent of the "potential maximum failure" using appropriate stability analyses methods, which in this case includes:
    a. Limit Equilibrium (LE) stability analyses, detailed in Section 7.1
    b. A geotechnical site inspection to identify potential structural failure mechanisms, detailed in Section 7.2

[4] Stable Rehabilitation Goal of Voids, Schedule G1 of Environmental Authority "*EPML02840015*"

[5] PSM2319-040L Proposal for Closure Study, Barbara Copper Mine, issued 14 October 2020

c. Use of approach as presented in the Western Australian guidelines for identification of a potentially unstable pit edge zone (DIR, 1997) – detailed in Section 7.3 but revised to take account of the long term landforms evident in weathered materials.

2. The "potential maximum failure" identifies the long-term post closure "potentially unstable zone" surrounding the void.
3. To ensure the long-term potentially unstable zone poses no risk to public safety, the zone is defined as an exclusion zone with a post closure abandonment bund/fence installed to restrict public access. An additional 10 m offset from the "potential maximum failure" boundary has been included for conservatism and that would allow maintenance of the bund if so required.

Inset 1: Schematic illustration highlighting long-term potential maximum failure, potentially unstable zone, abandonment bund and void.

The stable "void" is defined as the area within the abandonment bund/fence as illustrated in Inset 1. Long-term instability is not anticipated to impact areas outside of the recommended abandonment bund/fence location.

5. Data Sources

Existing data from previous work undertaken by PSM at the Barbara Operation was utilised for this study, and principally comprised data from the:

- Feasibility study undertaken for the open pits (PSM, 2014), and
- Quarterly geotechnical site inspections of the open pits (PSM, 2019a; 2019b; 2020a; 2020b).

Groundwater data was available from the preliminary groundwater assessment for the Barbara Operation conducted by Rob Lait and Associates (Pty) Ltd in 2013, which formed part of the feasibility study. Additionally, a hydrologic assessment of pit closure water levels is being undertaken by ATC Williams. A summary of their findings was provided to PSM via email[6].

The following three-dimensional (3D) surfaces (wireframes) were supplied by Round Oak Minerals (for this study as well as previous studies) and which included:

- Interpreted geological model (latest received - 03/08/2020)
- Digital elevation models (DEMs) of the North and South pit (22/10/2019), and the North pit only (18/10/2020), and
- South Pit Stage 2 Design V4B (20/08/2020).

[6] Email titled "*FW: Barbara Closure Water Balance for Voids*" from Gemma Brown, Round Oak Minerals to Greg Kennedy, Pells Sullivan Meynink (PSM), 23 October 2020.

6. Geotechnical Model

6.1 Rock Mass Units

The rock mass units (RMU's) are based on those adopted for the design of the open pits, with several RMU's having been defined for previous pit slope designs at the Barbara Operation (PSM, 2014). However, these can be simplified to three (3) RMU's as follows:

- Weathered rock (rhyodacite, amphibolite)
- Fresh rock (rhyodacite, amphibolite), and
- Mineralized zone (dolerite, schist, breccia), including the Barbara Fault Zone (BFZ).

Table 1 presents a simplified summary of the RMU's characteristics.

Table 1 – Summary of Typical Rock Mass Unit Characteristics

RMU	Field Strength	Weathering	RQD (%)	Defect Type	Defect Character
Weathered rock	R0 to R4/R5	Extremely to slightly weathered	10 - 100	Jointing	Closely to widely spaced, planar to irregular, smooth to rough, iron stained to chlorite or clay infill
Fresh rock	R5	Fresh	90 - 100	Jointing	Widely spaced, planar to irregular, smooth to rough, clean
Mineralised zone (BFZ)	R4 to R5	Fresh	90 - 100	Foliation and jointing	Widely spaced, planar to irregular, smooth to rough, clean or with chlorite veneer

The material properties adopted for the stability analyses for the rock mass units detailed in Table 1 are summarised in Table 2. The adopted material properties were based on those used by PSM in previous stability analyses for pit design purposes (e.g. PSM, 2014). However, lower bound Hoek-Brown parameter values were assigned to address long-term stability.

Groundwater levels for the analyses assumed that groundwater would be present at the pre-mining average level of 12 m below the surface and with hydrostatic conditions below the phreatic surface adopted in the analyses. Additionally, the pit closure water levels provided by ATC Williams were adopted for the study.

Table 2 - Adopted Rock Mass Shear Strengths

Rock Mass Unit	Hoek-Brown Parameters			
	UCS (MPa)	GSI	*mi*	*D*
Weathered Rock	25	35	25	0
Fresh Rock	80	55	25	0
Mineralised Zone (BFZ)	25	30	12	0

6.3 Structure

The structural model is based largely on the mapping completed by PSM and Round Oak within the South pit during the Quarterly Geotechnical Inspections. The existing structural database comprises data from field mapping undertaken by Round Oak, as well as field mapping and photogrammetric mapping undertaken by PSM.

The structural data shows:

- Major structures in the rock mass comprise foliation and faults / shears:
  - Foliation forms a predominant defect within the schist rock mass, comprising two splays of the BFZ, and is also present in localised zones of weakly foliated felsic volcanics adjacent to the schist
  - Sporadic faults and shears may also be present within the rock mass.
- Minor structures in the rock mass that are less continuous with jointing the main defect type.

Five (5) domains have been mapped over the south pit (PSM, 2020a; 2020b). The following summarises the structural model from the South pit:

- Domain 1 and Domain 2 (east wall of the South pit):
  - Most joint defects dip greater than 60° towards the west. Joints mapped in the north-east part of the East wall, Domain 2, are slightly rotated likely due to the proximity to the BFZ
  - Faults and shears are present in Domain 1 and Domain 2. These are generally moderately to steeply dipping (greater than 55°) but some moderately to shallow dipping faults and shears are also present.
- Domain 3, Domain 4, and Domain 5 (west wall of the South pit):
  - Most defects dip greater than 75° towards the east, except for a cluster of joints exposed in Domain 4 that dip between 30° and 50° towards north-northeast (NNE)
  - The shallow defect set dipping towards the NNE is evident within Domain 4, and typically have a persistence of less than 5 m.

Although the structural character is similar for the North pit, the following has been additionally noted (PSM, 2019a; 2019b):

- Joint sets form cubic blocks, resulting in a blocky to very blocky character
- Poorer structural conditions are associated with the BFZ, with dilation and poorer rock mass conditions occurring proximal to this zone.

6.4 Hydrogeology

Groundwater at the project site is primarily associated with the ore body. Groundwater exists in fractured rock aquifer systems in the rhyodacite, schist and amphibolite units. Monitoring in exploration holes in October 2013 (pre-mining) suggested a median depth to groundwater of approximately 12 m below the ground surface (Rob Lait & Associates, 2013).

It was noted at the pre-feasibility stage that the potentiometric surface is highly undulating suggesting there is variation in local permeability and compartmentalised by faults and shears. This compartmentalisation and variability in the level of saturation was observed during mining, whereby groundwater levels were noted as not being uniform across the pit floor (PSM, 2019a).

Pit lake water levels post-closure have been estimated by ATC Williams at approximately 303 mRL in the North pit and 290 mRL in the South pit.

7. Stable Long-Term Pit Slope Stability Assessment

7.1 Limit Equilibrium (LE) Analyses

Limit Equilibrium (LE) stability analyses have been completed using the Rocscience software program *Slide2* on representative cross sections through the North and South pits in the most geotechnically adverse location. These locations typically comprise the highest/steepest part of pit wall and where the lowest Factor of Safety (FoS) would be expected. The analyses provide the lowest FoS of the pit wall and the path of the surface for which the FoS is applicable (i.e. if failure where to occur it would be anticipated to occur along the path). The software also allows the user to query where alternative paths may form and for either a given FoS or range of FoS's. Based on experience the FoS increases with distance from the pit crest.

The analyses have been used to identify the location where a FoS of 1.5 is achieved beyond the pit crest and which defines the location of the stable long-term pit crest. A FoS of 1.5 is recommended as an appropriate value for defining long term stability as referenced within the Guidelines for Open Pit Slope Design[7].

The analyses have been completed using both non-circular and circular failure mechanisms with the rock mass strength parameters detailed in Section 6.1 and using the GLE-Morgenstern Price method.

Stability analyses were completed for Section A for the North Pit, and Section B and Section C for the South pit, with the respective locations shown in Figure 1. The results of the analyses are presented in Appendix A, with global Factor of Safety (FoS) summarised in Table 3.

Table 3 – Summary of the Global Factor of Safety (FoS) Obtained Per Failure Mechanism for Each Section

Section	FoS - Circular	FoS - Non-Circular
Section A	2.20	2.31
Section B	4.28	4.31
Section C	3.89	4.13

The results in Table 3 imply that a low risk of global instability impacting outside the final pit crests.

The results indicate that the current pit crests have a FoS of greater than 1.5 when considering only rock mass failure. As the majority of the rock mass within the Barbara open pits is high to very strength rock, global pit stability is controlled by geological structure (i.e. failure will occur along adverse defects), which has been assessed in Section 7.2.

7.2 Structural Failure and Current Pit Slope Performance

Structurally controlled failure mechanisms are the critical control for global pit slope stability for the majority of pit walls within the North and South pits.

Importantly, no global scale kinematically unstable structures or potential intersections of structures have been mapped or identified during mining. No signs of potential global instability, such as tension cracking beyond the pit crest, have been observed.

A prism pit slope monitoring system has been utilised since June 2020 with prisms installed along berms between 340 mRL and 280 mRL, with manual prism readings taken at regular intervals. To date, these prisms have shown no signs of pit slope movements which would indicate potential global pit slope failure.

Bench scale instability has been observed during mining with the following smaller-scale failures observed within the South pit:

[7] APA (6th ed.) Read, J., Stacey, P., & CSIRO (Australia). (2009). Guidelines for open pit slope design. Collingwood, Vic: CSIRO Publishing.

- North and East wall – bench-scale shallow wedge failures in the northeast, and planar failures in the east wall. Below the access ramp at 290 mRL and above the current mining floor at 240 mRL in the north wall, a south west dipping fault on the eastern margin of the BFZ has caused a shallow, multiple bench scale wedge failure. This structure has been mined out above 290 mRL and therefore does not pose risk of global pit slope instability beyond the current pit crest
- South wall – half-bench to bench-scale planar and wedge failures and zones of ravelling within the poorer rock mass associated with the Western Fault and Barbara Fault Zone
- West wall – bench-scale steep planar and one-sided wedge failures in the north-western area.

None of the failure mechanisms related to bench scale instability detailed above are expected to impact global pit slope stability beyond the current pit crest.

Unravelling of the very blocky rock mass proximal to the Barbara Fault Zone and progressive erosion of weak and weathered slope material may also occur due to water flow over time and has therefore been assessed using the approach as set out in WA guidelines detailed in Section 7.3 below.

7.3 WA Guidelines - Assessment of Maximum Area of Potentially Unstable Rock Mass

The Western Australian guidelines (DIR, 1997) provide a methodology for assessing the long-term slope stability following mine closure and identify an exclusion zone for the placement of an abandonment bund around the perimeter of the pits. This guideline has been developed primarily for pit slopes within deeply weathered profiles (primarily saprolite deposits) and is therefore considered to be conservative for the Barbara deposit.

The WA guidelines recommend the identification of a potentially unstable pit edge zone, with the abandonment bund location thereafter nominated 10 m (at minimum) outside of this zone to restrict access. The overall angle defining the maximum potentially unstable rock mass, is primarily dependant on whether the pit wall consist of weathered rock or unweathered (i.e. fresh) rock. The maximum potentially unstable pit edge zone for failure through each class of rock is defined by two separate design angles as follows:

- 25° for weathered rock, and
- 45° for unweathered (or fresh) rock.

Inset 2: presents a schematic section from DIR (1997) showing the placement of an abandonment bund 10 m beyond the potentially unstable pit edge zone.

Inset 2: Schematic cross-section presenting the recommended Western Australia guidelines for the placement of abandonment bunds from DIR (1997).

As the WA guidelines have been developed primarily from case studies of mine sites within saprolite, the recommended design angles in weathered and fresh rock may therefore be less appropriate for the rock mass at the Barbara as the rock mass is not significantly decomposed and has not undergone considerable weathering. As such, whilst the approach provided in Inset 2 was utilised, the adopted design angles for the bund location assessment were revised as follows:

- 25° in the Barbara Fault Zone – based on pit slope performance and observations within and proximal to the BFZ (i.e. ravelling)
- 30° in weathered rock – based on measured in-situ slope morphology angles from topographic features adjacent to the pits, Inset 3:
- 45° in unweathered (fresh) rock – unchanged from the Western Australian guidelines.

Inset 3: *In-situ* slope angles in weathered rock mass proximal to the North pit.

7.4 North Pit

The assessed potentially unstable pit edge zone for Section A is shown in Figure 2 and is located within 26 m behind the crest of the pit wall at this location. The minimum location of the abandonment bund at this location should therefore be 36 m behind the pit crest.

The assessed minimum location of the abandonment bund around the entire perimeter of the North pit is shown in Figure 3. The bund location typically varies from 15 m to 20 m around the perimeter, except in the south-east (Section A), where it is 36 m from the crest , due to a deeper weathering profile exposed in the pit walls.

The bund location behind the north-east pit crest traverses a diversion drain and the following options are recommended for the construction of the bund in this area:

- Follow the assessed bund location through the diversion drain and over the hill, but with the bund comprising a fence or highly permeable rock fill when located within the diversion drain. This will ensure that drainage can occur through the bund, whilst restricting access
- Alternatively, a waste rock buttress can be dumped below the regulated structure (on the access ramp, up to the nominal height of the regulated structure). This would ensure that the location of the required abandonment bund would coincide with the position of the regulated structure, and the existing regulated structure can therefore act as the abandonment bund.

7.5 South Pit

The assessed potentially unstable pit edge zone for Section B and Section C is shown in Figure 4 and Figure 5, respectively. The assessed potentially unstable pit edge zone is located within 4 m and 22 m behind the crest of the pit wall at these respective locations. The minimum location of the abandonment bund at these locations should therefore be 14 m and 32 m behind the pit crest, respectively.

The assessed minimum location of the abandonment bund around the entire perimeter of the South Pit is shown in Figure 6 and varies between 14 m to 32 m around the perimeter. The localised larger distances in the eastern and northern wall are due to a deeper weathering profile and presence of the Barbara Fault Zone, which are exposed in the pit walls at these locations.

7.6 Bund Location

For completeness the bund location for both pits was provided to Round Oak Minerals in electronic format, email of 20 November as a dxf file. Appendix B provides a figure of the dxf for completeness.

7.7 Bundwall Construction

The abandonment bund should be constructed as follows (DIR, 1997):

- Minimum dimensions of 2 m height and 5 m base width
- Where possible, from unweathered, freely draining, end dumped rockfill.

Should weathered rock only be available for the construction of the abandonment bund, the least weathered or hardest material should be used.

Suitable signs, clearly stating the risk to public safety and prohibiting public access, should be erected at appropriate locations around the safety bund wall. Shrub and/or tree planting at the outside edge of the bund wall should be implemented where practicable, to lessen the visual impact of the wall.

Where possible, it is recommended to utilise existing bunds and partially disturbed ground so long as the recommended minimum bund location is achieved.

8. Closure

We trust this report meets your immediate requirements. Please contact the undersigned if you have any queries or wish to discuss or clarify any aspect of the report.

TAILINGS.WATER.WASTE.

1. INTRODUCTION

1.1 Background

Aeris Resources (Aeris) owns and operates the Barbara Copper Project (BCP), located on mining lease ML90241 within the Mt Isa City Council. The BCP is located approximately 49 km northeast of Mt Isa and is accessed via Lake Julie Road from the Barkly Highway. The BCP is located at the upstream extents of an unnamed tributary of the Leichardt River. The unnamed tributary of Leichardt River and the Leichardt River are located in the Gulf Rivers Basin which discharges into the Gulf of Carpentaria. The location of the BCP relative to Mt Isa and Cloncurry is shown on **Diagram 1**.

DIAGRAM 1: SITE LOCATION

TAILINGS.WATER.WASTE.

1.2 Scope

The purpose of this report is to present findings of the post closure water management plan and water balance model (WBM) to assist in determining in the long term water levels within the North Pit, South Pit and Waste Rock Dump (WRD) Sediment Dam. This report should be read in conjunction with ATCW (2023) **[1]** detailing the outcomes of the geochemical assessment. Additional interpretive documents will be prepared by others to support the geochemical assessment. The BCP is currently in care and maintenance, with some preliminary remediation and rehabilitation works underway.

1.3 Methodology

The methodology adopted to achieve the scope of works for the PRCP inputs consists of the following tasks.

- Post Closure Water Management Plan and Water Balance Model (WBM). This will include:
  - Identification of water management infrastructure that is to be retained;
  - Calculate the spill risk from the North Pit, South Pit and WRD Sediment Dam.

1.4 Guidelines and Available Site Data

This assessment was undertaken against the following reference guidelines:

- Department of Environment and Science (2021), 'Guideline Progressive rehabilitation and closure plans (PRC plans)', ESR/2019/4964, March 2021, version 2.00. **[2]**

The following inputs were used in the preparation of this assessment:

- Department of the Environment and Science (2020), Environmental Authority EPML00715513 (Effective Date 3 February 2020), Queensland Government. **[3]**
- Surveyed Water Levels in the North Pit, South Pit and WRD Sediment. **[4]**
- PSM (2020), 'Mine Closure Geotechnical Study, Barbara Copper Project', Ref: PSM2319-041L Rev1, dated 14 December 2020. **[5]**
- Department of Industry and Resources, (1997), 'Safety Bund Walls Around Abandoned Open Pit Mines Guideline', Document Number ZMA048HA, Version 1.0. **[6]**
- The Long Paddock (2021), SILO Data Drill for Cell -20.40, 139.85, accessed 29 April 2022, https://www.longpaddock.qld.gov.au/silo/gridded-data/, Queensland Government. **[7]**

TAILINGS.WATER.WASTE.

1.5 Structure of Report

The structure of the report, to address the above scope of works, is as follows.

Section 2 Details the site layout and regional setting.

Section 3 Outlines the post closure passive management structures to be retained.

Section 4 Presents the inputs, assumptions, parameters and results on the post closure water balance model to determine the long-term water levels in the North Pit, South Pit and WRD Sediment Dam, as well as groundwater inflows and outflows.

Section 5 Provides a summary of the WBM and conclusions drawn from the results.

2. SITE LAYOUT AND REGIONAL SETTING

2.1 Site Layout and Drainage Features

The locations of the exiting site features (including diversion drains) are depicted on **DIAGRAM 2**.

DIAGRAM 2: SITE LAYOUT

The BCP is located on the western and eastern banks of the unnamed tributary of the Leichardt River, which runs in an approximate southeast to northwest direction. The route of this unnamed tributary was formalised by the construction of two permanent diversion drains. The most upstream (southerly) diversion is to the east of the WRD Sediment Dam and the most downstream (northerly) diversion is to the west of the North Pit. The two diversion drains and an associated levee at the North Pit were sized to convey flows up to and including the 1:1,000 AEP (0.1% AEP) design storm event.

The North Pit, South Pit, Run of Mine (ROM) Pad, Light Infrastructure Area (LIA) (including site offices and workshop area) are located on the eastern bank of the unnamed tributary of the Leichardt River. The WRD and WRD Sediment Dam are located on the western bank of the unnamed tributary of the Leichardt River. The WRD is to be capped with material from the rehabilitated ROM Pad, LIA area and excess access road material. The WRD Sediment Dam is to be retained for stockwater use by the landowner.

TAILINGS.WATER.WASTE.

2.2 Regional Watercourses

The unnamed tributary of the Leichardt River conveys flows to the Leichardt River approximately 9.5 km to the west-northwest of the BCP. All tributaries to the east of the Leichardt River within mine lease (ML) 90241 are unnamed. As such, when the unnamed tributary of the Leichardt River is henceforth referred to, it refers to the flow path through the BCP site and its continuing flow path to the Leichardt River.

Excluding the BCP, there are no dams or engineered structures on the unnamed tributary of the Leichardt River which might impact the characteristics of surface water runoff or flood behaviour. Approximately 35 km north of the confluence of the unnamed tributary with the Leichardt River, the Leichardt River is impounded by the Julius Dam. The location of the unnamed tributary, the Leichardt River, Julius Dam and the BCP mining lease are depicted on **DIAGRAM 3**.

DIAGRAM 3: REGIONAL WATERCOURSES

TAILINGS.WATER.WASTE.

3. POST CLOSURE PASSIVE WATER MANAGEMENT INFRASTRUCTURE

As part of the PRCP, Aeris propose to cease all active pumping between the North Pit, South Pit and WRD Sediment Dam which are currently included in the Care and Maintenance management measures **[11]**. As such, all drainage elements and water management on the site will be passive. A summary of the infrastructure that is to be decommissioned or retained are summarised in the following sections.

3.1 Decommissioned or Remediated Infrastructure

As part of the PRCP works, the following infrastructure is to be remediated or decommissioned:

- ROM Pad
- LIA
- Diversion drain to the west of the WRD Sediment Dam
- Diversion drain to the east of South Pit

The diversion drains to be retained (black lines) and decommissioned (red lines) are shown on **DIAGRAM 4**.

TAILINGS.WATER.WASTE.

DIAGRAM 4: DIVERSION DRAINS TO BE RETAINED AND REMOVED

The construction of the abandonment bunds, and the removal of the diversion drain west of the WRD Sediment Dam will impact the long-term water levels in the North Pit, South Pit and WRD Sediment Dam. Details of the catchments and WBM are included in **Section 4**.

3.2 Retained Infrastructure

As part of the PRCP works, the following infrastructure is to be retained:

- North Pit Residual Void (including an abandonment bund and fence) – The north wall of the North Pit is to be reduced from RL 316 m to RL 313 m to allow fresh water inputs to the North Pit for the catchment to the east.
- South Pit Residual Void (including an abandonment bund and fence)
- Diversion Drain (and Levee) to the west of the North Pit
- Rehabilitated WRD
- WRD Sediment Dam

TAILINGS.WATER.WASTE.

- Diversion Drain to the east of the WRD Sediment Dam

The configuration of the North Pit, South Pit and WRD Sediment Dam are detailed in **Table 1, Table 2** and **Table 3** respectively.

Volume of stored water*	23.5 ML
WRD Sediment Dam Extents	3.0 ha

*As at 16th September 2022 **[4]**

3.3 Abandonment Bunds and Fences

In 2020, PSM **[5]** proposed the location of the abandonment bunds around the North Pit and South Pit (shown in green on **DIAGRAM 5**).

Due to the long term assessed instability of the northern wall of the North Pit, it was concluded that the most suitable solution was to remove the northern wall of the North Pit to allow fresh water to enter the North Pit. In lieu of a circumferential bund, in area of steep terrain a fence is to be installed, as the topography will not allow for the access of construction machinery.

Additionally, the proposed abandonment bund was modified at the southwest corner of the North Pit to incorporate the existing levee. This will require a raise of an additional 2.5 m to at least 322.5 m AHD. The originally proposed and alternate bund alignments are shown on **DIAGRAM 5**.

The alignment of the South Pit bund proposed by PSM **[5]** is largely retained. A portion of the proposed bund is to be replaced by a fence to allow surface waters flows to enter the South Pit as detailed in **Section 4.2.2 below**The extents of the proposed bunds and fencing is depicted on **DIAGRAM 5**.

A small portion of the bund that intersects the Haul Road will be replaced by a fence to allow the landowner access to the North Pit. The alignments of the abandonment bunds are located outside the identified zones of instability identified by PSM **[5]**.

Where bunds are to be constructed. the geometry is to be in accordance with Western Australian Department of Industry and Resources **[6]**. This typical geometry is summarised in **Table 4**.

TABLE 4: ABANDONMENT BUND – TYPICAL GEOMETRY

Feature	Value

4 POST CLOSURE WATER BALANCE MODEL

4.1 Closure Water Balance Model Development

To assess the impact of surface water runoff, (both mine impacted and non-impacted), evaporation and groundwater inflows to the North Pit, South Pit and WRD Sediment Dam, a water balance model was developed using Goldsim Pro (Goldsim V12.1).

Goldsim is a dynamic probabilistic simulation program, which uses a range of parameters to represent the catchment surface water system, being routed through a time series of daily rainfall data for an estimated daily runoff. The water balance model reflects the effects of stormwater runoff, evaporation, and groundwater inflows/outflows at the site.

4.2 Model Structure and Inputs

The process flow chart for the Barbara site is depicted in **Diagram 6**. Primary water balance inputs applying to each of the elements in the model development are described the following sub-sections.

DIAGRAM 6: WATER BALANCE MODEL AT CLOSURE

4.2.1 Climatic Data

Climate data was obtained from SILO Data-drill specific to the site **[7]**, and brief details about the data parameters are provided in **Table 5**.

TAILINGS.WATER.WASTE.

TABLE 5: SITE WATER BALANCE – RAINFALL AND EVAPORATION INPUT DATA

Climate Data	Data Source	Comments
Daily Rainfall Rate (mm/day)	Rainfall data obtained from the SILO Data Drill Program for the Site Location (1889 - 2023)	Applied over dam surface areas, and as an input parameter for the estimation of surface runoff (AWBM).
Daily Evaporation Rate (mm/day)	Continuous record from SILO Data Drill formed by conjoining: CLIMARC estimates (1889 – 1957) and Class A Evaporation Data from proximate weather stations within the region (1889 – 2023).	Evaporation Data is scaled by evaporation factors for each site storage to reflect water storage conditions and expected water quality.
Daily Evapo-Transpiration Rate (mm/day)	As calculated by the FAO short crop reference methodology, assuming a wind speed of 2 m/s.	PET is calculated based on temperature, vapour pressure and solar global exposure parameters derived from climatic data and is adopted as a reasonable estimate of potential evapotranspiration losses from ground surfaces within the model.

4.2.2 Closure Catchment Delineation

Catchment delineation and estimation for the closure conditions was performed using survey and aerial photography. The catchments are depicted in **Diagram 7**. **Table 6** summaries the catchment delineation which was used to inform the AWBM Surface Runoff Volumes reporting. Two (2) scenarios were run for the South Pit to determine the best configuration of the bund/fence arrangement surrounding the South Pit. The impacts upon water quality are discussed in **[1]**.

TABLE 6: PIT AND WRD SEDIMENT DAM CATCHMENT DETAILS

Surface Runoff Type	Catchments (ha)		
	North Pit	South Pit	WRD Sediment Dam
Natural (Undisturbed)	10.1	-	7.8
Rehabilitated	-	-	20.3
Hardstand	0.5	3.2	4.6
Open Cut	3.1	8.2	-
Total Catchment Area	**10.2**	**Scenario 1 – 14.1** **Scenario 2 – 21.7**	**35.7**
Surface Water Area (at full supply)	1.5	8.2	3.0

TAILINGS.WATER.WASTE.

DIAGRAM 7: CATCHMENT EXTENTS

4.2.3 Groundwater Inflows

Groundwater interaction is likely to occur between the voids (from the North Pit to the South Pit due to base elevation differences). Additionally, both the North Pit and South Pit will receive groundwater flows from the surrounding area. Therefore, it is considered that inflows (and potential outflows) from the voids to the surrounding groundwater systems occur, with the direction of flow determined by the pit water level compared to the aquifer phreatic head. Reduced elevation of surface water levels within the pit are likely to cause inflows from the surrounding aquifer systems. Based on details of the groundwater monitoring bores outlined in Rob Lait & Associates **[8]**, groundwater inflow rates have been calculated using the Dupuit-Forchheimer approximation and outflows to the pit voids have been estimated through '*Darcy's Law for Flow in Confined Aquifers*'.

TAILINGS.WATER.WASTE.

DIAGRAM 8: GROUNDWATER INFLOW CONCEPTUAL MODEL*

*Reproduced from Figure 9 **[8]**

The groundwater inflow rates for each pit as calculated by Rob Lait **[8]** are reproduced in **Table 7**.

TABLE 7: GROUNDWATER INFLOW ESTIMATES

Pit	Groundwater Inflow (L/s)
North	0.05
South	0.54

As noted by Rob Lait **[8],** these estimates of groundwater represent the groundwater that resided in the orebody prior to mining, with long term natural recharge expected to be much slower. As such, the inflows estimates are considered to be conservative and are summarised in **Section 4.4**.

Groundwater outflows from the North Pit to the South Pit have been estimates to be approximately 0.0028 L/s based upon the guidance of Woessner and Poeter **[13]**.

4.2.4 Storage Curve Data and Initial Conditions

Storage curves were derived for both site pits from the provided survey file. The resulting storage curve is depicted in **Diagram 9** and **Diagram 10**. The site survey was used for the water balance assessment and to derive storage curves in the pit void. Initial water storages were provided by Aeris from values surveyed on 7 June 2022 Error! Reference source not found. and are illustrated in **Table 8**.

TABLE 8: INITIAL STORAGE INPUTS

Parameter	North Pit	South Pit	WRD Sediment Dam
Initial Volume* (ML)	39.8 (RL 304.53 m)	44.4 (RL 232.30 m)	23.5 (RL 332.24)
Total Capacity (ML)	112.7	3,296.4	131.9
Overflow Level (m)	RL 313.0 m	RL 334.3 m	RL 337.0 m

DIAGRAM 10: SOUTH PIT STORAGE CURVE

TAILINGS.WATER.WASTE.

DIAGRAM 11: WRD SEDIMENT DAM STORAGE CURVE

4.3 Model Development

The Australian Water Balance Model (AWBM) was incorporated to simulate daily runoff from rainfall generated within the various sub-catchment types that are present on the project site. **Diagram 12** represents a schematic of the AWBM model, reproduced from Boughton (2004) **[10]**.

The catchment types and AWBM model parameters used to simulate these different catchment types and the average yields from these catchment areas are summarised in **Table 9**. Model parameters have been selected based on experience with similar water balance model studies and are considered to be conservative in the context of an uncalibrated model.

TAILINGS.WATER.WASTE.

DIAGRAM 12: AWBM FOR RUNOFF CALCULATIONS

Where:
C1 - C3 = Surface Storage Capacities
A1 - A3 = Partial Areas Represented by Surface Storages
BFI = Baseflow Index
K_b = Daily Baseflow Recession Constant
BS = Current Volume in Baseflow Store
K_s = Daily Surface Flow Recession Constant
S = Current Volume in Surface Store Routing

TABLE 9: AWBM MODEL PARAMETERS

AWBM Parameters	Split Areas (sum=1.0)			Storage Capacities (mm)			Ks (day^{-1})	BFI	Kb (day^{-1})

4.4 Results

4.4.1 North Pit

The following conclusions can be drawn from **Diagram 13**:

- The North Pit rapidly accumulates water to 2033/2035, whereupon it reaches a state of 'dynamic equilibrium'. The 'dynamic equilibrium' has small variations throughout the year to account for periods of rainfall and evaporation.
- The mean (average) water level in the North Pit reaches a level of approximately RL 308.5 m to RL 309.5 m, with variations through the calendar year during periods of rainfall and evaporation.

TAILINGS.WATER.WASTE.

- The water level in the North Pit reaches the spill level of RL 313 m in years where the rainfall exceeds the 85th percentile.
- In any given year, the spill risk from the North Pit is approximately 9%.

The maximum modelled water level is approximately RL 313 m. The minimum modelled water level is approximately RL 303 m. These values represent the historically 'wettest' and 'driest' years occurring consecutively through the simulation.

DIAGRAM 13: NORTH PIT WATER SURFACE ELEVATION

Diagram 14 illustrates the mean accumulated groundwater inflows into the North Pit over a period of sixty-five (65) years is approximately 100 ML, or approximately 1.5 ML/year throughout the simulation period from 2022-2087.

TAILINGS.WATER.WASTE.

DIAGRAM 14: NORTH PIT ACCUMULATED GROUNDWATER INFLOWS

Diagram 15 illustrates the mean accumulated groundwater outflows from the North Pit towards the South Pit over a period of fifty-eight (58) years is approximately 0.26 ML, or approximately 0.0044 ML/year (4.4 kl/year) throughout the simulation period from 2023-2081. Based on the mean groundwater inflow rate of approximately 1.5 ML/year, the North Pit is a net groundwater sink.

DIAGRAM 15: NORTH PIT ACCUMULATED GROUNDWATER OUTFLOWS (INCLUDING TO THE SOUTH PIT

TAILINGS.WATER.WASTE.

4.4.2 South Pit – Scenario 1

The following conclusions can be drawn from **Diagram 16**:

- The South Pit rapidly accumulates water to the year 2040, with the rate of accumulation reducing by 2060. Whereupon the pit reaches a state of 'dynamic equilibrium'. The 'dynamic equilibrium' has small variations throughout the year to account for periods of rainfall and evaporation.
- The mean (average) water level in the South Pit reaches a level of approximately RL 286.5 m to RL 287.5 m.
- The water level in the South Pit never reaches the rim level of RL 334 m. As such, there are no modelled spills or overtopping events. This indicates the South Pit achieves long term containment.
- The maximum modelled water level is approximately RL 295 m. The minimum modelled water level is approximately RL 280 m. These values represent the historically 'wettest' and 'driest' years occurring consecutively through the simulation.

DIAGRAM 16: SOUTH PIT WATER SURFACE ELEVATION – SCENARIO 1

Diagram 17 illustrates the mean accumulated groundwater inflows into the South Pit over a period of fifty-eight (58) years is approximately 775 ML, or approximately 13.4 ML/year throughout the simulation period from 2023-2081.

TAILINGS.WATER.WASTE.

DIAGRAM 17: SOUTH PIT ACCUMULATED GROUNDWATER INFLOWS – SCENARIO 1

There were no modelled groundwater outflows from the South Pit, i.e., groundwater sink.

4.4.3 South Pit – Scenario 2

The following conclusions can be drawn from **Diagram 18**:

- The South Pit rapidly accumulates water to the year 2040, with the rate of accumulation reducing to 2065. Whereupon the pit reaches a state of 'dynamic equilibrium'. The 'dynamic equilibrium' has small variations throughout the year to account for periods of rainfall and evaporation.
- The mean (average) water level in the South Pit reaches a level of approximately RL 290 m to RL 291 m.
- The water level in the South Pit never reaches the rim level of RL 334 m. As such, there are no modelled spills or overtopping events. This indicates the South Pit achieves long term containment.
- The maximum modelled water level is approximately RL 300 m. The minimum modelled water level is approximately RL 282 m. These values represent the historically 'wettest' and 'driest' years occurring consecutively through the simulation.

TAILINGS.WATER.WASTE.

DIAGRAM 18: SOUTH PIT WATER SURFACE ELEVATION – SCENARIO 2

Diagram 19 illustrates the mean accumulated groundwater inflows into the South Pit over a period of fifty-eight (58) years is approximately 775 ML, or approximately 13.4 ML/year throughout the simulation period from 2023-2081.

DIAGRAM 19: SOUTH PIT ACCUMULATED GROUNDWATER INFLOWS – SCENARIO 2

There were no modelled groundwater outflows from the South Pit, i.e., groundwater sink.

4.4.4 WRD Sediment Dam

The following conclusions can be drawn from **Diagram 20**:

- The WRD Sediment Dam rapidly accumulates water to the year 2027, whereupon it reaches a state of 'dynamic equilibrium'. The 'dynamic equilibrium' has small variations throughout the year to account for periods of rainfall and evaporation.
- The mean (average) water level in the WRD Sediment Dam reaches a level of approximately RL 333 m to RL 334 m.
- The water level in the WRD Sediment Dam reaches the spillway level of RL 337 m each year, which is equivalent to the rainfall exceeding the 95th percentile.

Due to the presence of the HDPE liner on the WRD Sediment Dam, no groundwater inflows or outflows were included or modelled.

DIAGRAM 20: WRD SEDIMENT DAM WATER SURFACE ELEVATION

TAILINGS.WATER.WASTE.

5 SUMMARY

At closure, the North Pit residual void has a long term lake level of between RL 308.5 m and RL 309.5 m. The mean groundwater inflow in any year is approximately 1.5 ML/year. The mean groundwater outflow in any given year is approximately 0.0038 ML/year. As such, the North Pit is a net groundwater sink. The North Pit overtops in events greater than the 85th percentile rainfall conditions. An estimated 0.1 ML/yr of groundwater outflows from the North Pit enters the South Pit.

At closure, the South Pit (under Scenario 1) has a long term lake level of between RL 286.5 m and RL 287.5 m. The maximum lake level reaches approximately RL 295 m, which equates to an impounded volume of 1,033 ML. The mean groundwater inflows in any given year is approximately 13.4 ML/year. There were no modelled groundwater outflows. As such, the South Pit is a groundwater sink. The South Pit never overtops, with maximum water level of RL 293 m being lower that the pit crest elevation of RL 334 m.

At closure, the South Pit (under Scenario 2) has a long term mean lake level of between RL 290 m and RL 291 m. The maximum lake level reaches approximately RL 300 m, which equates to an impounded volume of 1,203 ML. The mean groundwater inflows in any given year is approximately 13.4 ML/year. There were no modelled groundwater outflows. As such, the South Pit is a groundwater sink. The South Pit never overtops, with maximum water level of RL 293 m being lower that the pit crest elevation of RL 334 m.

It is recommended that the Scenario 2 fencing arrangement be adopted to provide a higher potential yield in the South Pit. Refer to ATCW **[1]** for further discussion regarding water quality impacts.

The North Pit and South Pit will fill via rainfall over their respective extents, as well as groundwater inflows. Both the North Pit and South Pit reach a level of long term equilibrium just below the surrounding groundwater level.

The WRD Sediment Dam has a long term water level of between RL 333 m and RL 334 m. The WRD Sediment overtops via the spillway in events exceeding the 95th percentile. The WRD Sediment is HDPE lined and is therefore not subject to groundwater inflows or outflows.

1 OVERVIEW

1.1 PURPOSE

Round Oak understands that effective consultation with the communities within which it operates is central to its social licence to operate. The purpose of this Community Consultation Plan (the Plan) is to set out how Round Oak identifies and engages with the community stakeholders relevant to site specific Post Mine Land Uses (PMLU), as part of the Progressive Rehabilitation and Closure Plan (PRC Plan). It is also designed to ensure that Round Oak achieves compliance with the intent of its Social Responsibility Policy.

The Plan is site specific for the Barbara Copper Project, which is authorised under Environmental Authority (EA) EPML02840015.

1.2 SCOPE

This Plan applies to all Round Oak operations, projects, and exploration activities. Furthermore, this Plan applies to all Round Oak employees, as well as all persons who work for, with, act on behalf of, or represent Round Oak, including subsidiary employees, contractors, visitors, volunteers and anyone working on a Round Oak site, office or other location requested by the company.

1.3 OBJECTIVES FOR COMMUNITY CONSULTATION

Round Oak sets the following objective for its community consultation plan:

- Comply with all legal obligations and company commitments in effect for the Barbara Copper Project, as outlined in the Department of Environment and Science (DES) *Guideline Progressive Rehabilitation and Closure Plans*, ESR2019/4964, dated March 2021. This includes, but is not limited to:
    - Objectives for community consultation;
    - Community engagement tools;
    - Proposed consultation frequency;
    - Information provided as part of community consultation; and
    - How feedback will be considered.

1.4 PRINCIPLES OF COMMUNITY ENGAGEMENT

Round Oak agrees with the standards set by the Minerals Council of Australia through their Enduring Value Framework (MCA, 2015), as they relate to community engagement, specifically Principles Nine and Ten.

Principle Nine

Contribute to the social, economic and institutional development of the communities in which we operate.

Principle Ten

Implement effective and transparent engagement, communications and independently verified reporting arrangements with stakeholders.

These Principles were designed to be consistent with the International Council on Mining and Metals' (ICMM) Mining Principles, including Principles Nine and Ten.

Principle 9 – Social performance

Pursue continual improvement in social performance and contribute to the social, economic and institutional development of host countries and communities.

Principle 10 – Stakeholder Engagement

Proactively engage key stakeholders on sustainable development challenges and opportunities in an open and transparent manner, effectively report and independently verify progress and performance.

To achieve the intent of the Principles, Round Oak is committed undertake its community engagement in accordance with the Foundation Principles for effective community and stakeholder engagement as set out by the South Australian Chamber of Mines and Energy (SACOME, 2012). These are set out in Figure 1.

Inclusive

The engagement process identifies, reaches out to and includes participants who clearly represent all stakeholder groups from community (including Aboriginal and Torres Strait Islanders), government and industry.

Transparent and accountable

The engagement process is transparent and it is clear who is responsible and accountable for its implementation and management of any outcomes.

Clear and informed

The engagement process provides timely, balanced and objective information and promotes shared understanding between and within stakeholder groups. Issues on which stakeholder groups are to be engaged are clearly scoped and the factors that may or may not be influenced by their input are clear. In addition to outlining the key economic and social impacts that a proposal may bring to community and stakeholder groups, a framework for ensuring that the benefits of such a proposal are realised should be clearly articulated.

Accessible and timely

The engagement process is accessible to stakeholder groups. Time to deliberate is provided and an appropriate tone is created to encourage deliberation and the development of informed opinion.

Meaningful

The engagement process and outcomes are considered by regulatory and industry decision-makers and can influence decisions made. The engagement process provides feedback to stakeholder groups on how their input influenced the decision(s) and outcomes.

Figure 1: Foundation principles of effective community engagement (SACOME, 2012)

2 BARBARA COPPER PROJECT COMMUNITY STAKEHOLDERS

A successful community consultation program relies upon the identification of all community stakeholders, understanding the issues of interest or concern for each stakeholder, determining the appropriate level of engagement for each stakeholders, and utilising appropriate communication tools to engage with each stakeholder. These considerations (both opportunities and threats) should be captured through Round Oak's risk assessment process.

2.1 KEY COMMUNITY GROUPS

There is the potential for only a few or many community stakeholders to have an interest in the activities associated with a project or operation. These can include, but are not limited to:

- Affected landowners;
- Landowners necessary to access of land to which the PRC Plan relates;
- Traditional Owner groups (and associated Trustees);
- Local Government; and
- Local community groups.

Table 1: Key community stakeholders for the Barbara Copper Project

Stakeholder	Contact details
Adjoining landholder	Ron and Joan Croft – West Leichardt Station (07) 4743 8947 Lot 1 on AA29 West Leichardt Holdings Mt Isa, QLD 4825
Shire Council	Mount Isa City Council (all enquiries) (07) 4747 3200
Native Title claimant group	Kalkadoon Native Title Aboriginal Corporation 109 Barkly Highway (07) 4749 2766

3 COMMUNITY ENGAGEMENT TOOLS AND INFORMATION PROVIDED

There is a wide range of community engagement tools that can be, and are, employed by Round Oak to engage with the communities within which it operates. Selecting the right engagement tool that reflects the nature of the engagement is an important aspect of ensuring the engagement process is successful.

The types of community engagement tools utilised as part of the PRC Plan process are as follows:

1. Tools to inform;
2. Tools to consult; and
3. Tools to collaborate.

3.1 TOOLS TO INFORM

The first tier of community members is those who should be 'informed'. These community members are typically local individuals / landowners with general interest in the future of the Project. These community members only want to know 'what is going on', with direct communication to each landowner being undertaken. If available, newsletters and updates are also suitable communications media. Round Oak will provide objective and balanced information to inform community members on what is planned, and the progress being made with these plans.

3.2 TOOLS TO CONSULT

The second tier of community members is those who should be 'consulted'. They will have a direct interest and will want to both be informed and to provide feedback. This tier includes selected neighbouring operators and most government agencies (including DES and Mount Isa City Council). Meetings or forums will be held with these community members so that concerns and issues can be identified, and practical solutions or actions imposed. Targeted supplementary email updates may also be used.

3.3 TOOLS TO COLLABORATE

The third tier is community members who need to be 'engaged' and who have the potential to be directly impacted. This tier is those who have a direct and influential role in Local government, key State government agencies, cultural heritage groups, landholders and landholders on the land necessary for access to the land to which the proposed PRC Plan relates to. The best method of consultation for this tier is regular, face to face meetings enabling candid discussions to occur. Some of the things that can contribute to the success of these groups include:

- A clear terms of reference for the group;
- Continuity of representatives from both the company and stakeholders;
- Advanced scheduling of regular meetings;
- Notification of an agenda for each meeting prior to the meeting;
- Documented and distributed minutes that include the tracking of actions raised; and,
- Provision of supporting materials for items covered in meetings, where appropriate.

4 PROPOSED CONSULTATION FREQUENCY

Consultation should occur prior to any PRC plan schedule amendments that are likely to impact the community and the register should be updated when this consultation is finished.

Ongoing community consultation will continue throughout completion of proposed milestones so that progressive rehabilitation and the socio-economic and environmental impacts related to mine closure can be discussed with the community.

5 FEEDBACK

5.1 COMMUNICATION CHANNELS

Round Oak will maintain a range of channels by which stakeholders associated with the Project can communicate with the business to make inquiries, raise complaints, or to express grievances. These channels will include sufficient options so that community members are not restricted in their ability to provide feedback due to technological or other limitations.

As a minimum, Round Oak will make available contact details that allow communication by post, email, and telephone.

5.2 RECORD KEEPING

All complaints and grievances will be recorded as HSEC events in the InControl® event management system. If requested, a complaint or grievance can be made anonymously. General inquiries may be recorded as an InControl® event where it is felt that a record of the inquiry might be appropriate, or where any follow up actions will take some time to complete, and their progress needs to be tracked.

A community consultation register has been formulated to electronically track the following:

- Consultation date;

- Identification of each community member;
- Description of consultation type;
- Information provided;
- Issued raised;
- How issues have been considered;
- Decisions and outcomes of the engagement; and
- Any commitments made by Round Oak.

5.3 REPORTING ESCALATION

Any feedback received in relation to potential criminal activity will be managed in accordance with relevant local laws and regulations, as well as applicable Round Oak procedures.

Any report of potentially inappropriate behaviour by a Round Oak employee, contractor, visitor, or volunteer will be directed to the Round Oak Human Resources team for investigation and management.

Escalation of feedback from the community within the Round Oak organisation will occur in accordance with the timeframes set out in **Table 2**. Escalation is to be based upon a risk assessment of the issue that has been raised. (Risk assessment occurs as part of the standard process for entering a HSEC event into InControl®.)

Table 2 Internal escalation of community feedback based upon risk

Risk level	E&C Coordinator	HSEC Manager	General Manager	COO and CEO
Low	Within 2 days			
Medium	By the end of shift	Within 2 days	Within 2 days	
High	Within 2hrs	By the end of shift	By the end of shift	Within 2 days
Critical	Immediately	Within 2hrs	Within 2hrs	By the end of shift
