1 INTRODUCTION

Tick Hill Gold Mine (THGM or 'Site') is located approximately 40 km south of Duchess, 140 km southeast of Mount Isa and covers an area approximately 390 ha. THGM is managed under environmental authority EPML00863713 which permits mining and exploration activities across mining leases ML7094, 7096 and 7097. The site is currently non-operational, however in 1990 to 1994 was mined for gold, and 2020 to 2022 the tailings were extracted from the decommissioned TSF for reprocessing.

Version 1.0 of this transitional progressive rehabilitation and closure plan (PRCP) was submitted on 1 September 2023. A Queensland Government Department of Environment and Science[1] (DES) 'Information Request' Notice was received on 31 October 2023 requesting further information.

This PRCP (Version 2.0) has been submitted in response to the 19 February 2024 'Decision on request to extend the information response period' Notice (DES, 2024).

This PRCP has been prepared in accordance with the requirements of the 'Progressive rehabilitation and closure plans (PRCPs) Guideline (ESR/2019/4964, Version 3.01) published by DES (DETSI, 2024), and referred to as the 'PRCP Guidelines'.

The PRCP is comprised of two components:

- PRCP rehabilitation planning – provides a basis for the PRCP schedule
- PRCP schedule – presents the rehabilitation milestones (RM), milestone criteria, and associated timing. A standalone excel spreadsheet is provided separately.

This document fulfils the requirements for the rehabilitation planning part for Tick Hill Gold Mine. The purpose of the rehabilitation planning is to support and justify the development of the PRCP schedule, which has been submitted electronically (as a native excel file, as well as provided herein as Appendix A), and detail how progressive rehabilitation and closure will be carried out over the entire site, and on a rehabilitation and improvement basis (DETSI, 2024).

1.1 LAND OUTCOME DOCUMENTS

The Project is considered a transitional PRCP, as mining activities are in process or have already occurred. Land outcome documents were used to inform and guide this PRCP where relevant. Due, in part, to the rehabilitated nature of the site, and inactivity for the majority of years since gold mining ceased in 1995, the only land outcome documents currently applicable to THGM is the environmental authority (EA) EPML00820613 (dated 1 April 2022).

1.2 REHABILITATION OBJECTIVES

The overarching closure goal for THGM is to achieve a site that is safe, stable and non-polluting that can sustain the agreed post-mining land use/s (PMLU). This plan provides the strategies and controls to mitigate closure risks that will be implemented to achieve this goal.

Regarding rehabilitation and closure, Condition A16 of the current EA states that:

'*Land disturbance must be rehabilitated in accordance with the most recent edition of the administering authority's guideline* Rehabilitation requirements for mining projects.'

[1] It is noted that DES has been renamed as the Department of Environment, Science and Innovation (DESI). References will retain author name at time of document production.

However, the Rehabilitation requirements for mining projects (ESR/2016/1875) has been superseded by the PRCP Guidelines, therefore rehabilitation objectives have been based on the PRCP Guidelines (DETSI, 2024).

The intention of THGM is that the tailings material will be removed and relocated off-site to a third-party user. Therefore, the rehabilitation will include an engineered cover for the tailings storage facility (TSF) footprint. Additional disturbance areas will either undergo minor reshaping and revegetation; or directly revegetated to achieve the proposed PMLU.

The mining pit/void is proposed as a non-use management area (NUMA) and management milestones have been proposed to eliminate or reduce impact to sensitive receptors.

2 PROJECT PLANNING

2.1 SITE LOCATION AND TENEMENTS

THGM is in north-central Queensland, approximately 40km south of the township of Duchess, and approximately 140km southeast of Mt Isa. The site is accessible via the Duchess to Phosphate Hill Road which runs north-south 5 km to the east of the site. The partially unsealed Mount Isa Duchess Road is the main access to Mount Isa, and the sealed Cloncurry Duchess Road provides direct access to Cloncurry.

2.1.1 MINING TENEMENTS

The mining leases (ML) relevant to THGM are ML7097, ML7094, and ML7096. A summary of each is provided in Table 2-1 (noting that tenements are all the same size).

Table 2-1: Mining Tenements

Mining Lease	Granted	Expires	Area (ha)
ML7094	20/06/1991	30/06/2031	130
ML7096	20/06/1991	30/06/2031	130
ML7097	20/06/1991	30/06/2031	130
Total			390

2.2 SITE OWNERSHIP

2.2.1 MINE OWNERSHIP

The Site has had multiple owners since it was discovered in 1989. The current owners and Site information is provided in Table 2-2.

Table 2-2: Site Identification

Item	Details
Site owner	Tick Hill Mining Pty Ltd
Address	Tick Hill Gold Mine, Dajarra, QLD
Mine Leases	ML7094, ML7096, ML7097
Lot and plan number	Lot 13 on SP309109 (part), Lot 16 on SP309110 (part)
Area (mining lease)	390 ha lease area + 8.5 km road access
Zoning	Rural – Extractive and Mineral Resource
Local Government Authority	Cloncurry Shire
Coordinates (site centre)	-21.64645 Lat, 139.92561 Long
Current land use	Non-operational gold mine
Proposed future land use	Rehabilitated mining land

2.2.2 LANDHOLDERS

THGM is remotely located. The landholders are MDH Pty Ltd (MDH) being Stanbroke Station to the west and Chatsworth Station to the east. MDH is the lessee of the pastoral development. Carnaby Resources Pty Ltd (Carnaby) as the previous owners of THGM have an agreement for retention of infrastructure, and it is anticipated that this agreement will be transferred to THGM . Until this agreement has been confirmed, and for the purposes of this PRCP, it is assumed that all infrastructure at THGM will be rehabilitated.

2.3 BASELINE INFORMATION

This section provides the baseline knowledge of the Project prior to the commencement of mining activities. The technical reports which support this PRCP are provided as appendices where relevant.

2.3.1 TOPOGRAPHY

Terrain in proximity to the THGM is generally described as rolling to hilly with flat-top mesas. A ridge running north to south is located east of the THGM forming a notable geological feature, as evident in Figure 2-1.

The area of mine workings consists of generally flat plains with moderate hills and a gentle slope toward the northwest.

The site's elevation within the ML area ranges from 320 to 450 m Australian Height Datum (mAHD) although the former operational areas of the site are all between 320 and 360 mAHD.

2.3.2 CLIMATE

THGM is situated approximately 1,000 km west of the Coral Sea and approximately 370km south of the Gulf of Carpentaria, therefore the climate is considered 'Tropical Continental', defined as warm and mostly dry throughout the year; BSH - hot semi-arid climate on the Koppen climate classification. There are defined wet (summer) and dry (winter) seasons, although humidity varies throughout the year (BOM, 2023):

- Mild temperatures with low humidity (May to August).
- Hot temperatures with low humidity (September to December).
- Hot temperatures with high humidity (January to April).

The average daily temperatures range from 7°C to 24°C in the 'dry season' (April – September), and 17°C to 40°C in the 'wet season' (October to March) as confirmed by data obtained from the 'The Monument Airport'. During the wet season, the average rainfall is 47 mm per month whilst the average rainfall during the dry season is 8.8 mm per month (BOM, 2023).

2.3.3 GEOLOGICAL SETTING

The Tick Hill gold deposit is a high grade (22.5g/t) gold deposit located in the in the Mesoproterozoic (1900–1500 Ma) Mt Isa Inlier, northwest Queensland. The Mt Isa Inlier is one of Australia's foremost mineral provinces and is famous for its world-class Cu-Pb-Zn-Ag deposits (Mt Isa), SEDEX (Dugald River; Cannington), IOCG deposits (Ernest Henry; Starra), Mo deposits (Merlin), Co deposits (Walford Creek); and REE/U (Mary Kathleen) deposits.

During the Paleoproterozoic Era (2.5 to 1.6 billion years ago), the Mt Isa region experienced intense volcanic activity, resulting in the formation of large amounts of basalt and rhyolite. These volcanic rocks are important as they host significant mineral deposits, including copper, zinc, lead, silver, and gold (Laurie et al, 2012). The mineral deposits in the Mt Isa region were formed through a combination of volcanic activity, hydrothermal processes, and sedimentation. Historic volcanic activity released mineral rich fluids into the surrounding rocks which precipitated into mineral ore bodies located within underground fractures and faults.

Mineralization at Tick Hill is characterized by coarse grained gold associated with Bi-selenides, minor sulfides, and a general paucity of other metals except for a slight enrichment of Cu in the footwall to the ore zone. Alteration is characterized by early silicification and magnetite alteration that formed during the initial D_{1-2} events and may have coincided with the first stage of gold enrichment. During syn-D_3 (re-) mobilization of gold, alteration involved the destruction of magnetite, the emplacement of abundant laminar quartz veins, and the deposition of proximal albite, hematite, chlorite, amphibole, epidote overprinted by later K-feldspar, sericite, clay minerals and minor calcite. The ore zone is bounded by a strongly silicified zone and surrounded by a chlorite-epidote shell. The low pressure D_3 gold (re-} mobilization event involved an oxidized, S-under-saturated, acidic, saline aqueous fluid. In terms of alteration characteristics, the Tick Hill deposit shares similarities with IOCG deposits in the area. However, its high-grade gold-only nature, lack of Cu, and the presence of Bi-selenides makes it a unique deposit in the Mt Isa Inlier.

The high-grade gold-only Tick Hill deposit presents a unique mineralisation style in the Mt Isa Inlier. Gold is dominantly hosted within intensely silicified units affected by D_3 fracturing and associated alteration.

The Tick Hill ore body is hosted in fractured and silica-hematite-altered gneiss. The principle host rock to mineralization is a metasomatized quartz-feldspar mylonite that was labelled "galah stone" to denote its laminated pink and grey appearance. It was derived from sheared quartz-feldspar porphyry, pegmatite and/or calc-silicate metasediments (Laing, 1992; Tedman-Jones, 2001). To emphasise the metasomatic overprint of the mylonite and the presence of thin quartz-feldspar alteration selvedges along the mylonitic fabric, Laing (1992) proposed the term "quartz-feldspar laminite". In a later review of drill core, Tedman-Jones (2001) described the pervasive occurrence of dilation fractures and thin sheeted partings along S_1 mylonite planes and linked it to the introduction of K-Na feldspar metasomatism and gold.

2.3.4 HYDROGEOLOGY

A hydrogeological desktop review was undertaken in 2023 as part of the development of an Environmental Site Assessment (ESA) for THGM (EES, 2023). The review found groundwater located in fractured and weathered zones within hard-rock Proterozoic metasediments and igneous rocks. The regional aquifer was semi-confined to confined and of low yield (EES, 2023). Recharge was thought to occur from ephemeral surface watercourses and the limestone capped hills to the southeast of the mine (Cromer, 2020); (EES, 2023).

2.3.4.1 GROUNDWATER MONITORING NETWORK

A total of nine groundwater monitoring bores have been installed at THGM in 2012 (two), 2020 (four) and most recently in June 2023 (three). Data from groundwater sampling is available from 2012 through to the most recent sampling events in 2024 (EES, 2023; 2024).

2.3.4.2 GROUNDWATER LEVELS

The groundwater level fluctuates in response to changes in recharge rates, in turn due to seasonal and annual rainfall variability, and the open pit controls the local groundwater system in its immediate vicinity (Scott, 2020). Groundwater depths at THGM typically range between 15 and 30 meters below ground level (mbgl) (Cromer, 2020). Groundwater in the vicinity of THGM generally flows towards the open pit, which acts as a groundwater sink (Cromer, 2020).

It is estimated that the open pit loses groundwater through evaporation at an average rate of 1 L/s, which is replaced by groundwater flows towards the open pit (Cromer, 2020). The only area where groundwater flows did not appear to flow towards the pit was to the north of the WRD, at the western perimeter of the site (EES, 2023).

2.3.4.3 GROUNDWATER QUALITY PROPERTIES

Groundwater was found to be neutral to slightly alkaline, naturally elevated in salts and metals, with the pit water also being highly saline (EES, 2023). Drinking water quality criteria are typically exceeded for pH, salinity (TDS), chloride, sodium, fluoride, ammonia and nitrate. Fluoride is the only parameter that generally exceeds the stock watering criteria (EES, 2023). Assessment for the concentrations of metals in groundwater found that, while in exceedance of drinking water guidelines, there were no exceedances against stock watering criteria (EES, 2023). Nitrate and ammonia attributable to explosives residue was observed in several locations, downgradient from the WRD.

Concentrations of total cyanide were assessed due to presence in tailings. Cyanide concentrations in groundwater varied across groundwater bores at THGM. Low concentrations <0.004mg/L were generally found in all bores, with the exception of bores THGW001, THGW003 and THGW008, where concentrations exceeded screening criteria (>0.004 mg/L Total CN). The variation in concentration of cyanide in these bores (Bores 1, 3 and 8) was found to be consistent with the vertical gradation of cyanide concentration in groundwater sourced from infiltration from the tailing storage facility (TSF) to the south. It is highly likely that cyanide concentrations will steadily decrease over time and that cyanide expressing in pit water would be degraded by sunlight, as has already been occurring (EES, 2023).

2.3.5 HYDROLOGY AND FLUVIAL NETWORKS

There are several small and localised ephemeral drainage pathways surrounding THGM with flows being generally to the north and northwest. Following rainfall events, surface water generally flows into these drainage lines which ultimately discharge to Petticoat Creek, a larger ephemeral watercourse located approximately 1.5 km downstream of the site.

Petticoat Creek generally drains the area surrounding the mine and flows east into the Burke River, which then flows south into the Georgina River and ultimately terminates into Lake Eyre. Only small and localised ephemeral drainage pathways occur in proximity to THGM (as shown in Figure 2-2), with potential flows naturally to the north and northwest.

Historically disturbed areas of the THGM site are already rehabilitated, therefore any alteration of catchment flows would have occurred more than 30 years ago. Observations of the downstream receiving surface drainage lines show no evidence of negative impact or deterioration of condition resulting from any alterations undertaken. The residual void pit rim has an abandonment bund in place that is 10 m high and

20 m wide, that is significantly higher than the surrounds and will only capture the surface catchment within the bunded area.

The Queensland state mapping for flood risk areas also indicates that the THGM site is well outside of any mapped areas of concern as shown in Figure 2-3. This mapping has been sourced from the Interim Floodplain Assessment Overlay for the Georgina River Sub-Basin v1.0 (QRA, 2012), and is intended to show a spatial extent of where flooding has previously occurred; or has potential to occur in future but is not based on any flood model and do not represent a particular flood event. As such, the mapping is considered more conservative than the 0.1% AEP that is being taken as a 'floodplain' for PRCP purposes.

Further to this, previous risk assessments (Envirofin, 2020; EES, 2023) identified THGM as having no flood risk. As such, the 'flooding' requirements outlined by the PRCP guidelines (DES, 2023) have not been considered further in this PRCP.

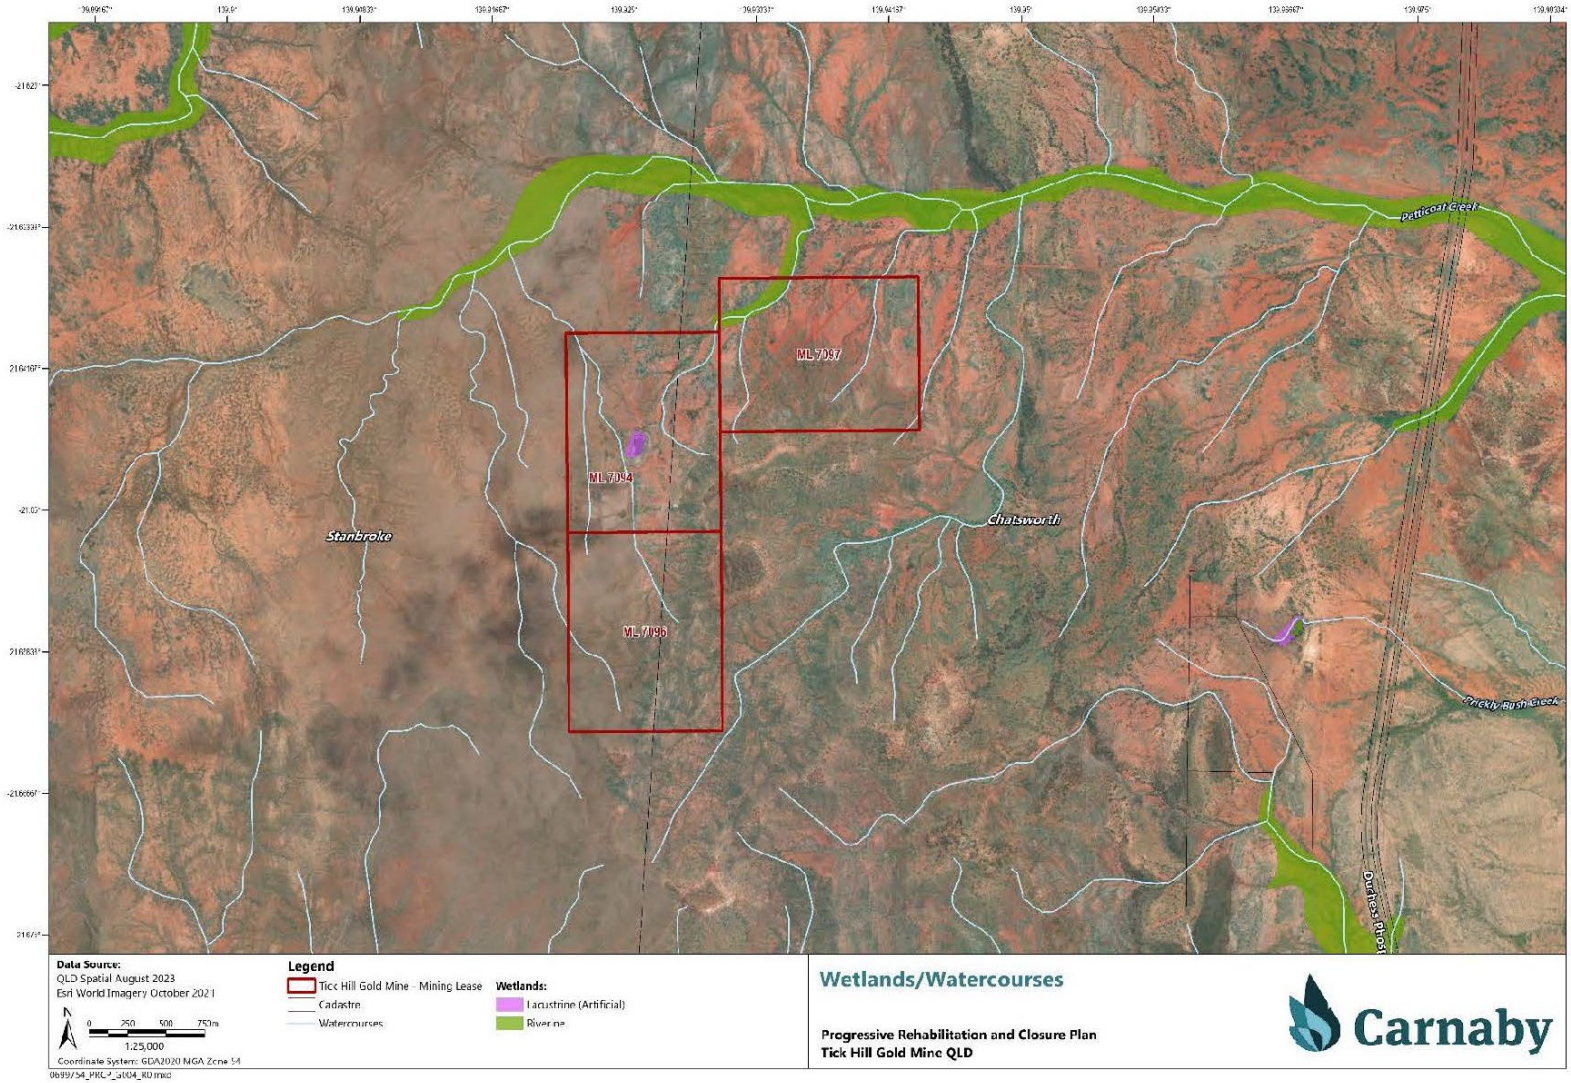

Figure 2-2: Watercourses and Wetlands (Carnaby, 2023)

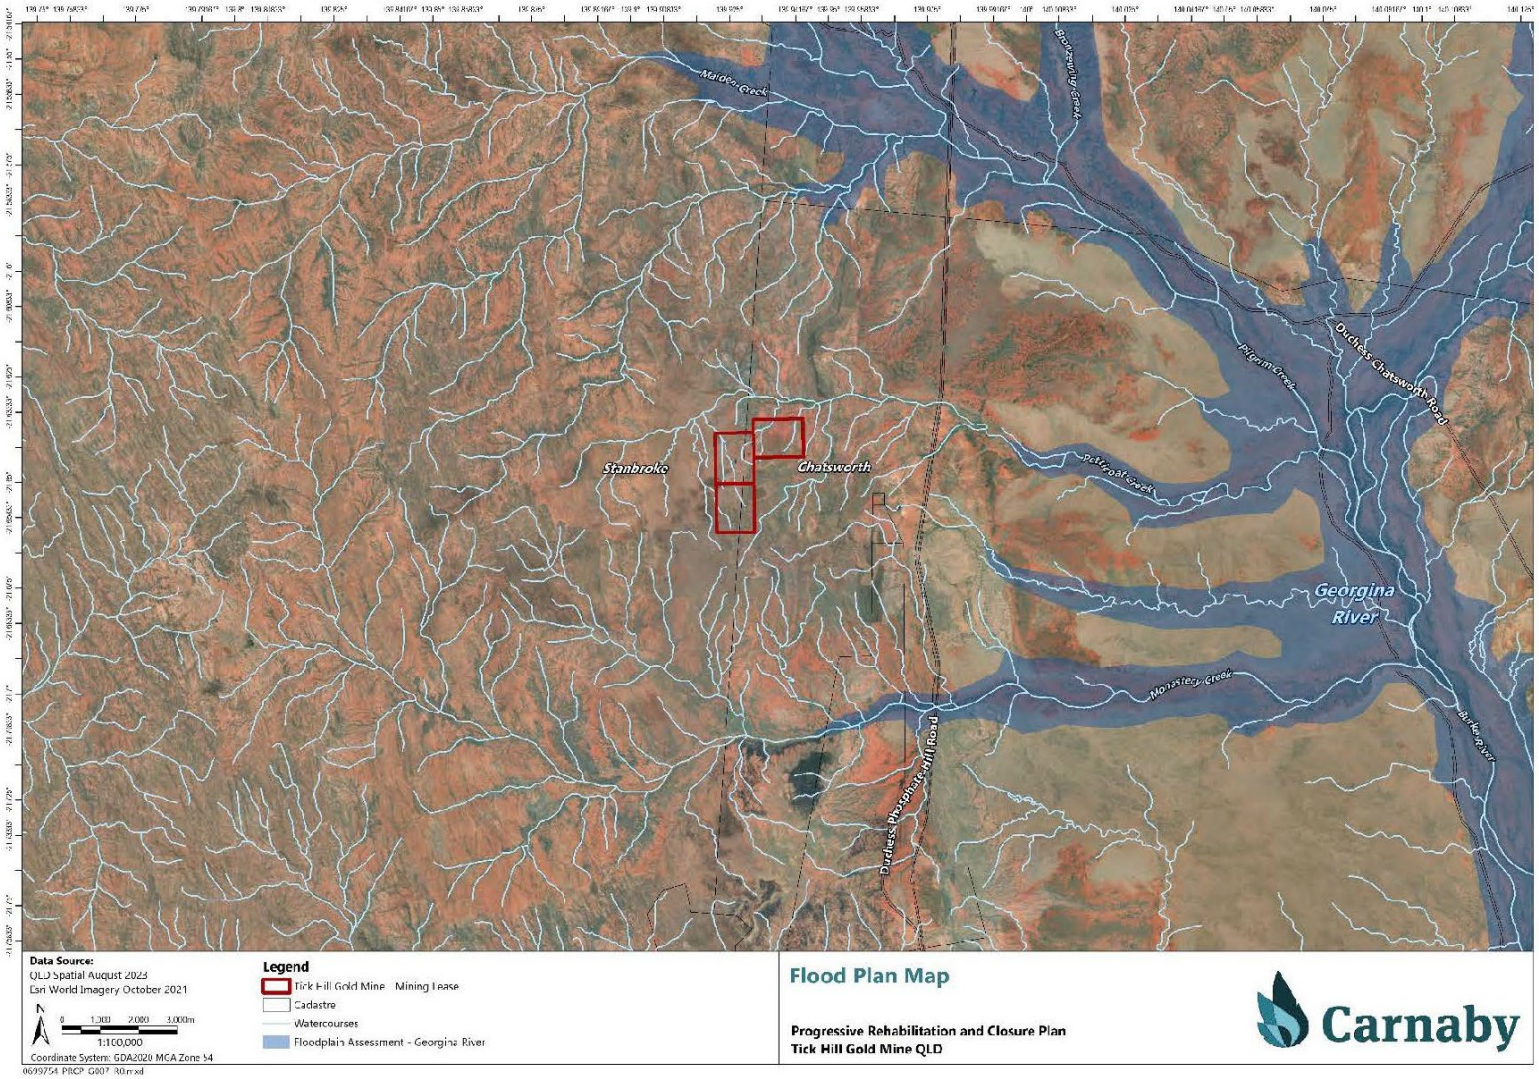

Figure 2-3: Flood Risk Assessment (Carnaby, 2023)

2.3.6 SOIL TYPES, PROPERTIES AND PRODUCTIVITY

Soil mapping for the site includes the 1:2M Atlas of Australian Soils (Northcote et. al. 1960- 1968) and the 1:1M Land Systems Survey of the Leichhardt-Gilbert Area (1964). The flatter sections in the north and west of the site are mapped as the Quamby land system which comprises sparsely timbered undulating plains. Soils associated with this land system are described as red smooth-ped earths. These soils are gradational red earths with no A2 horizon and alkaline smooth-ped whole columnar B horizon. The mesa hills in the southeast are the Merlin land system, which consists of stony spinifex country, gently undulating to undulating lands with occasional low mesas. Soils are earthy loams with uniform medium, porous coherent solum, and profile depth less than 0.6 m (EES, 2023). Soil mapping for the THGM site is provided as Figure 2-4.

Broadly undulating lands with granite outcrop occur on some ridge crests. The dominant soils are quartz-gravel-strewn moderately deep loamy red friable earths (Gn3.13), with the shallower type (Gn3.12) associated with some slopes consisting of gravel-strewn loamy red duplex soils (Dr2.12, Dr2.13) and gravel-strewn red clays (Uf6.31). On lower areas are deep brown or red-brown cracking clays (Ug5.32, Ug5.37). Shallow to moderately deep loamy red earths (Gn2.11, Gn2.12) and shallow gravelly loams (Um5.51) occur near rocky outcrops.

Surface soils, as identified by a 2024 field sampling and analysis program (provided in Appendix B), identified ‘Sandplains’, ‘Sand dunes’ and ‘Low rocky rises’ soil-landform associations (SLAs), based on collection of 16 samples, plus land system mapping, imagery and surface feature morphology. The Sand dunes SLA was not able to be sampled as the sand dunes currently form part of a habitat exclusion zone. The Sandplains and Low rocky rise SLAs are summarised as follows:

- Sandplains
  - Flat / low relief aeolian plains between longitudinal sand dunes
  - Thin aeolian sand surface layer over thin, weak crust
  - Deep sandy profiles, with increasing clay content with depth
  - Typically, no coarse fragments through top 0-20 cm of soil profile, with minor amounts of coarse fragments at varying depths within some profiles
  - Friable highly weathered lateritic layer consisting of ironstone pisoliths in a sandy matrix within some profiles at varying depths
  - Indurated calcrete layer at depth within some profiles
  - Soils characterised as Red deep sands (WA Soil Group 445) and Red sandy earths (WA Soil Group 463)
  - Soils are non-saline to moderately saline, non-sodic, potentially dispersive upon severe disturbance, have a low propensity to hard-set, have a very rapid hydraulic conductivity and are typically low in organic carbon and plant-available nutrients.
  - Concentrations of As and Se consistently measured above the average crustal abundance.
- Low rocky rises
  - Low relief rocky rises
  - Surface mantle of quartz and ironstone
  - Shallow surface soils over fractured/weathered and competent rock
  - High percentage of competent rock fragments through the surface soil profile

- Areas of outcropping competent rock present in some areas
- Soils characterised as Red shallow loams (WA Soil Group 522), Calcareous shallow loams (WA Soil Group 521) and Calcareous loamy earths (WA Soil Group 542)
- Soils ranged from non-saline to extremely saline, were typically non-sodic, potentially dispersive upon severe disturbance, have a low propensity to hard-set, have a moderately rapid hydraulic conductivity and are typically low in organic carbon and plant-available nutrients.
- Concentrations of As and Se consistently tested above the average crustal abundance (Mine Earth, 2025a).

The topsoil (0 to 20 cm) from all disturbance areas within the Sandplain, Sand dune and Low rocky rises SLAs is considered suitable as a surface rehabilitation material. If topsoil is sourced from these areas, Sandplain and Sand dune SLA material should be stockpiled separately to the topsoil collected from the Low rocky rises disturbance areas.

The 2024 sampling and analysis investigation (Mine Earth, 2025a), assessed 15 analogue (undisturbed) soil samples from five locations and found the soils to have the following attributes:

- Weakly to moderately structured 'clayey sand' to 'medium heavy clay' soils with variable coarse rock content (>2mm), up to 20%
- Low concentrations of plant-available nutrients and organic carbon
- Typically classified as non-sodic, with a low potential for clay dispersion
- Classified as non-saline. Soil pH range from pH 7.1 to pH 9.0, classified as neutral to strongly alkaline
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance.

The erodibility of all the topsoils is likely to be relatively low, unless subject to concentrated surface water flow (Mine Earth, 2025a).

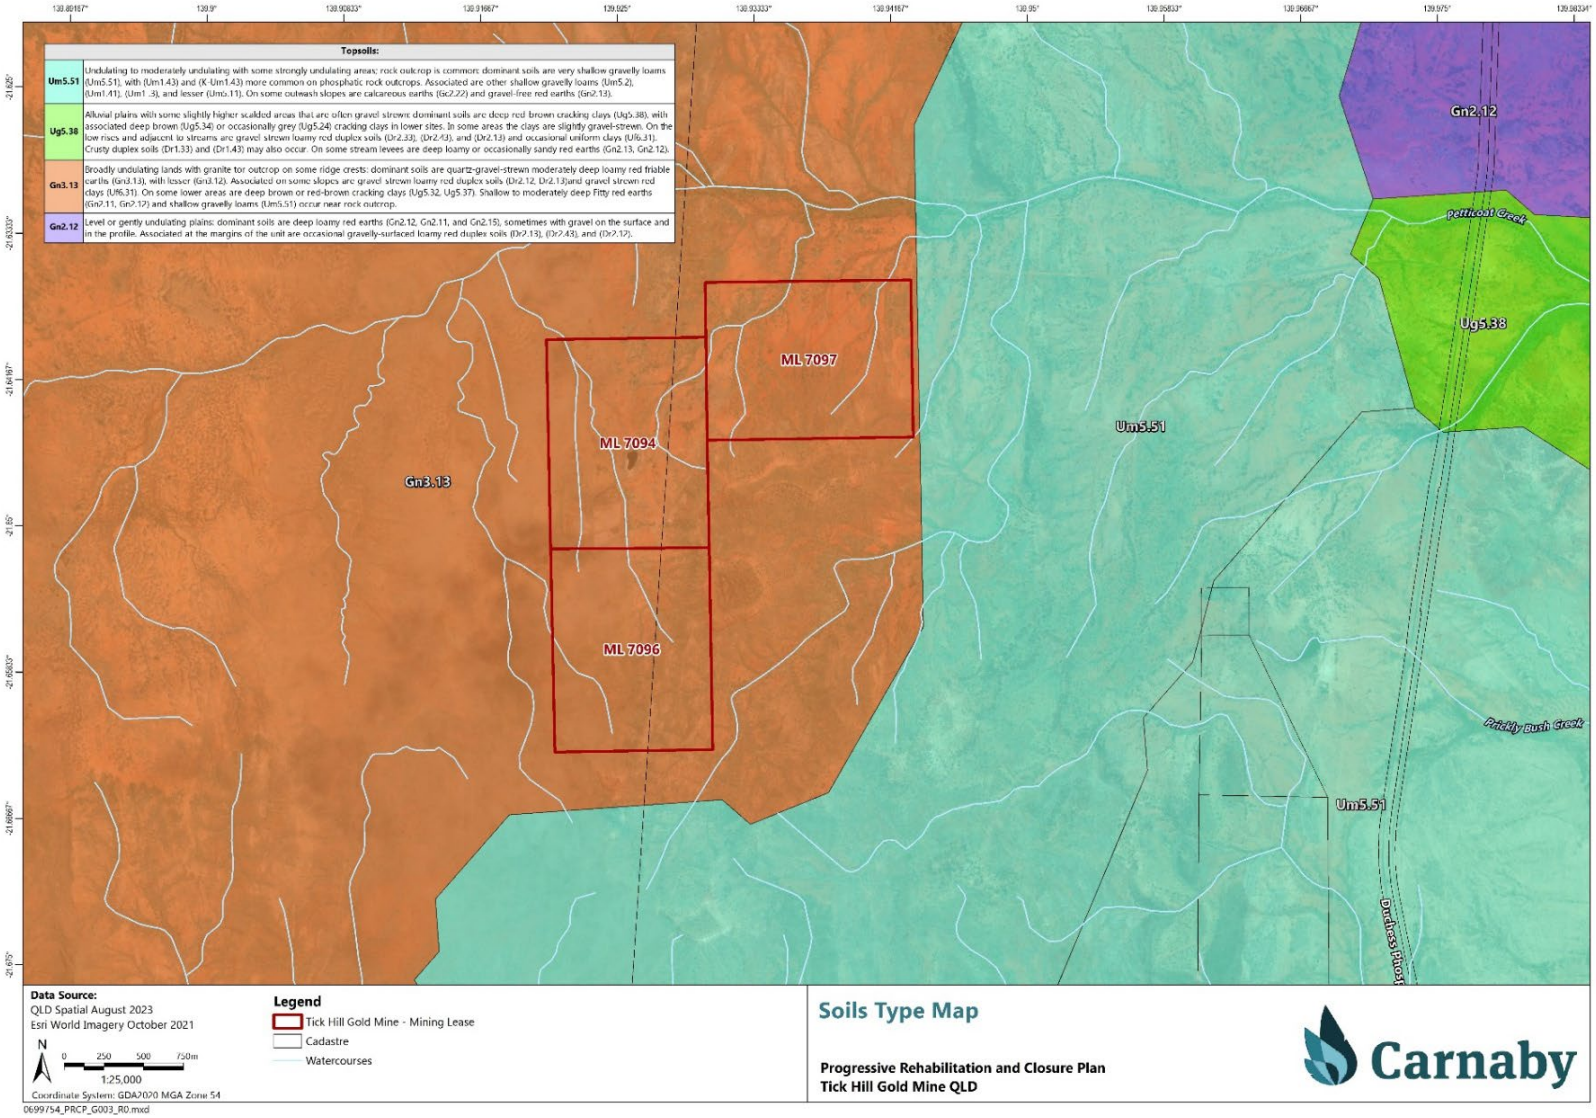

Figure 2-4: Soils in the Tick Hill area (Carnaby, 2023)

2.3.7 LAND STABILITY, SUITABILITY AND CAPABILITY

The surrounding land, and previous land use at THGM, has consistently been for low-intensity cattle grazing. The land has numerous drainage lines in the landscape, with cattle grazing resulting in minor disturbance to the land and the erosion of drainage banks. Red earths are known to be susceptible to water erosion, especially during high intensity rainfall events. The runoff from these soils can create surface flow, leading to the detachment and transportation of soil particles. This erosion process can result in gullies, rills, and sheet erosion, which can further contribute to land instability.

The erodibility tends to be worsened by cattle grazing. However, as the land will continue to be used for low-intensity cattle grazing, erosion is expected to remain as a minor issue, with only minor impact on the land stability. Since mining ceased in the 1990s, the land has been capable of maintaining its structural integrity and maintain sufficient vegetation growth to remain established overall. Surrounding lands are stable and considered moderately disturbed as the regional land use is grazing.

Five land suitability classes are defined as per the Guidelines for agricultural land evaluation in Queensland (DSITI & DNRM, 2015). Based on the 2013 THGM rehabilitation assessment, all soil units (either undisturbed or reused as a growth medium during rehabilitation) were unlikely to have significant agricultural value (either prior to or post-mining) and are likely classified as either:

- Class 3 – suitable land with moderate limitations – land which is moderately suited to a proposed use, but which requires significant inputs to ensure sustainable use; or
- Class 4 – marginal land with severe limitations on land use requiring major inputs to ensure sustainability. Such inputs may outweigh the returns from the land.

This assessment was based on the assumption that plant available water capacity (PAWC) was the highest-ranking limiting factor (SKM, 2013).

2.3.8 VEGETATION

2.3.8.1 NATIVE SPECIES

The vegetation reflects the region's climate and landscape. The site and surrounds are predominantly low open woodland consisting of scattered native trees and shrubs, and dominated by annual and perennial grasslands – including the naturalised Cloncurry buffel grass (*Cenchrus pennisetiformis*).

Dominant tree and shrub species throughout the area include Cloncurry box (*Eucalyptus leucophylla*), desert bloodwood (*Corymbia terminalis*), Whitewood (*Atalaya hemiglauca*), Chisholm's Wattle (*Acacia chisholmii*), Conkerberry (*Carissa lanceolata*), Native Cotton (*Gossypium australe*), and the naturalised Sweet Acacia (*Vachellia farnesiana* syn. *Acacia farnesiana*).

Dominant grass species include Spinifex (*Triodia pungens*), Long-head Spinifex (*Triodia longiceps*), Purple Three-awn Grass (*Aristida pruinosa*), Nine-leafed Grass (*Enneapogon polyphyllus*), and the naturalised Fountain Grass (*Cenchrus pennisetiformis*).

The colluvial slopes and central area of THGM consists predominantly of *Eucalyptus leucophylla* (Cloncurry box), desert bloodwood *(Corymbia terminalis*), and Whitewood (*Atalaya hemiglauca*). Open plains to the west are characterised by Tussock grasslands dominated by Mitchell grass (*Astrebla* spp.) and Feathertop Wiregrass (Aristida latifolia) (Queensland Government, 2024).

The remnant regional ecosystems (RE) around the THGM area are shown in Figure 2-5 and summarised in Appendix C. The species listed have guided the revegetation requirements remaining at site.

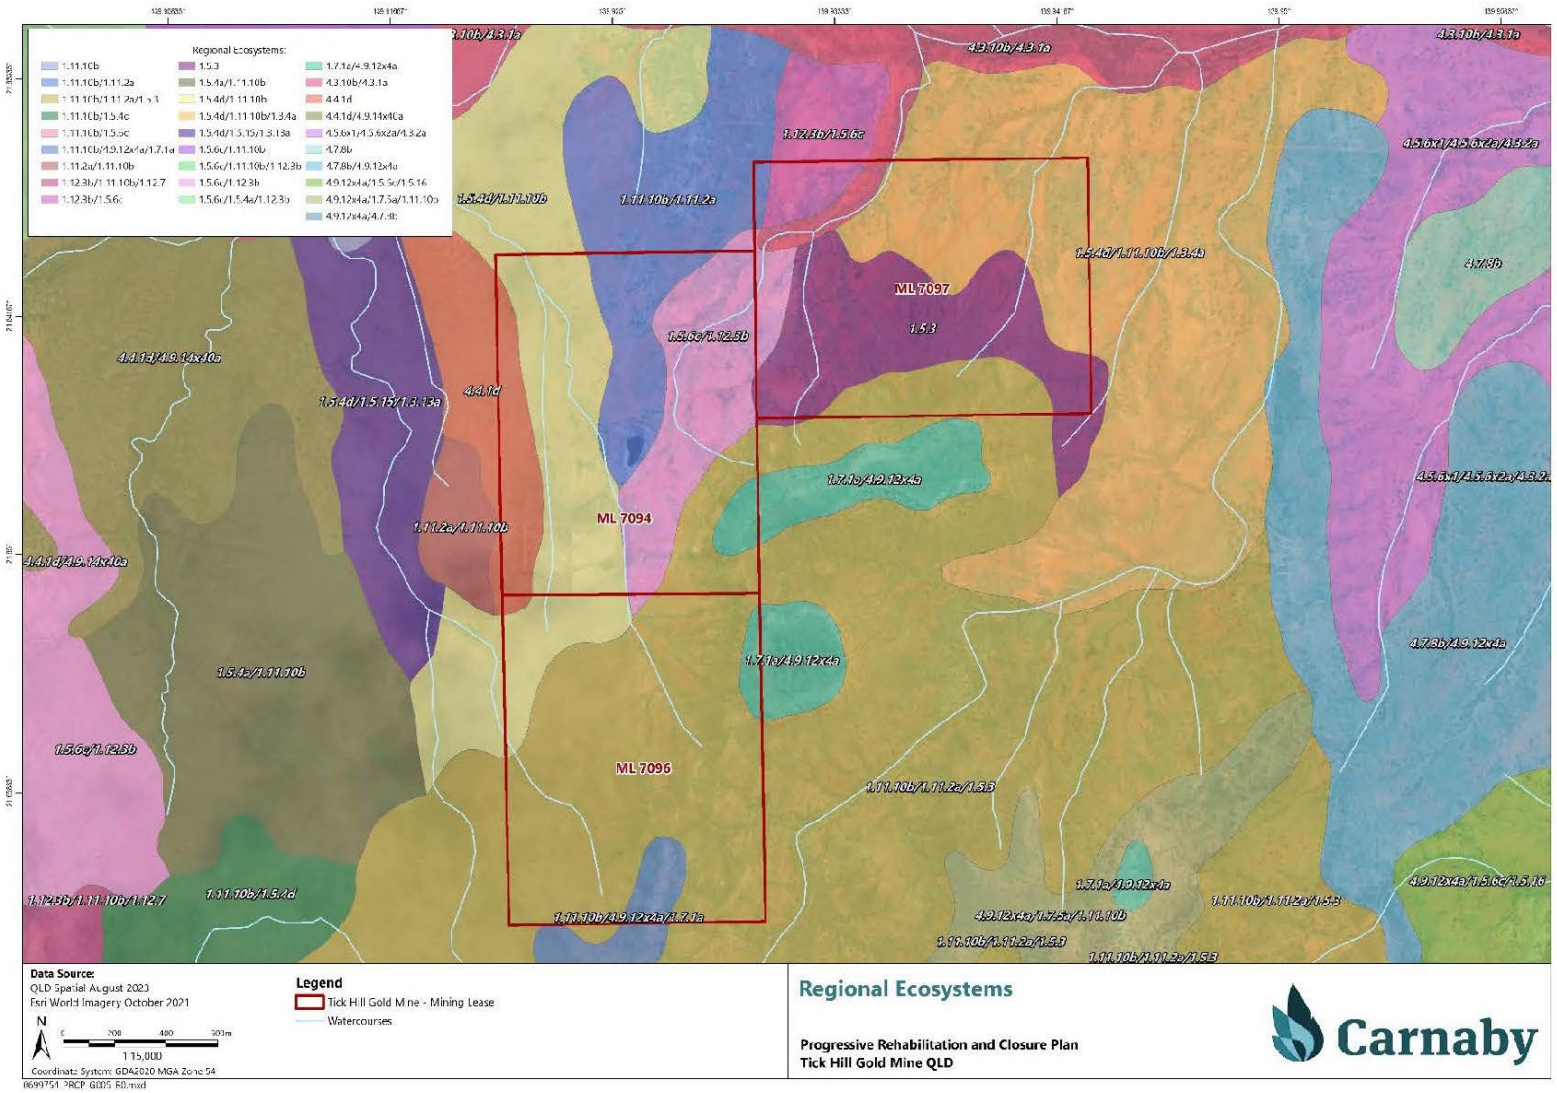

Figure 2-5: Regional Ecosystems of the Tick Hill Gold Mine area (Carnaby, 2023)

2.3.8.2 WEEDS

Kapok bush (*Aerva javanica*) and Buffel Grass (*Cenchrus ciliaris*) were the only introduced species identified in the 1999 flora survey (SKM, 1999). Recent site observations (2024) have also confirmed an abundance of Buffel Grass, however it appears to be at levels consistent with the surrounding area, as shown in Figure 2-6.

Figure 2-6: Buffel Grass at Tick Hill Gold Mine and surrounding area

Table 2-3 provides a list of weed species previously recorded at THGM. Note that buffel grass (*Cenchrus ciliaris*) is considered naturalised and not a weed species (DES, 2019).

Table 2-3: Weed species identified at Tick Hill Gold Mine

Pest plants	Common Name	Status under the Biosecurity Act
Acacia nilotica	Prickly Acacia	Category 3 restricted invasive plant
Parthenium hysterophorus	Parthenium	Category 3 restricted invasive plant
Parkinsonia aculeata	Parkinsonia	Category 3 restricted invasive plant
Ziziphus mauritiana	Chinee Apple	Category 3 restricted invasive plant
Cryptostegia grandiflora	Rubber Vine	Category 3 restricted invasive plant
Ricinus communis	Castor Oil Plant	Not a prohibited or restricted invasive plant under the *Biosecurity Act 2014*. However, by law, everyone has a general biosecurity obligation (GBO) to take reasonable and practical steps to minimise the risks associated with invasive plants under their control.
Cylindropuntia fulgida var. mamillata	Coral Cactus	Category 3 restricted invasive plant
Bryophyllum delagoense	Mother of Millions	Category 3 restricted invasive plant
Calotropis procera	Calotrope	Not a prohibited or restricted invasive plant under the *Biosecurity Act 2014*. However, by law, everyone has a general biosecurity obligation (GBO) to take reasonable and practical steps to minimise the risks associated with invasive plants under their control.
Prosopis spp.	Mesquite	Prohibited invasive plant

2.3.9 FAUNA

2.3.9.1 PEST SPECIES

Pest species within the Cloncurry Shire pose challenges to both the local population and the environment. The primary species of concern is the Feral Pig, known for its destructive foraging habits.

Table 2-4 outlines the known and most common pest species in the Cloncurry Shire and their status under the *Biosecurity Act 2014* (CSBP, 2018).

Table 2-4: Animal pest species at Tick Hill Gold Mine

Pest animals	Common Name	Status under the *Biosecurity Act 2014*
Canis lupus familiaris	Dog (other than a domestic dog)	Restricted invasive animal
Sus scrofa	Feral Pig	Category 3, 4 and 6 restricted invasive animal.
Felis catus and *Prionailurus bengalensis x Felis catus*	Cat (other than a domestic cat)	Category 3, 4 and 6 restricted invasive animal
Locusts including: *Chortoicetes terminifera* *Locusta migratoria* *Austracris guttulosa* *Gastrimargus musicus*	Locusts including: Australian plague locust Migratory locust Spur-throated locust Yellow-winged locust	All landholders are responsible for locust management as part of their general biosecurity obligation under the *Biosecurity Act 2014*.

2.4 SITE CONTEXT

This section provides information that has been collected and/or modelled since the site became operational. This information directly informs the approach to the rehabilitation and management methodology provided in Section 6.

2.4.1 SITE HISTORY

The site is currently non-operational, however from 1990 to 1994 it was mined for gold by Carpentaria Gold Ltd (A subsidiary of MIM Holdings Ltd). From 1995 to 2020, there were multiple exploration programs from numerous companies, however no active mining occurred. Minor operations have been undertaken between 2020 and 2022 to extract and reprocess tailings material from within the TSF with selected materials further transported offsite for processing. Most recently tailings reprocessing onsite has occurred with Blue Cap Mining as the operational contractor and Carnaby Resources maintaining the tenements and EA approval.

The THGM timeline of development is shown in Table 2-5.

Table 2-5: Timeline of Site Operations

Year	Event
1989	The Tick Hill gold deposit was discovered in September
1990	A Mining Lease Application was made in March
1991	The lease was granted in June

Year	Event
	Mining and construction of the plant and infrastructure began in early August Commissioning of the plant began in early December with the first gold poured by end of year
1992	Development of the underground mining operation in January First ore produced from underground in August
1995	Mine closure by Carpentaria Gold Ltd (subsidiary of MIM Holdings Ltd)
1995 to 2004	Further exploration by MIM Holdings Ltd
2004 to 2019	THGM divested to Diatreme Resources Limited (Diatreme), further exploration activities occurred
2019	THGM divested to Carnaby Resources Pty Ltd, further explorations activities occurred
2020 to 2021	Carnaby Resources obtained approval for reprocessing of tailings (with operations undertaken by BIMS Metals), including transport of tailings to Lorena Gold Mine offsite processing facility for extraction
2021 to 2022	Reprocessing of tailings onsite (with operations undertaken by Blue Cap mining) on behalf of Carnaby Resources Pty Ltd

A summary of the THGM features and approved disturbance areas as per the THGM EA (DESI, 2022), is provided in Table 2-6.

Table 2-6: Approved disturbance areas

Feature	Approved disturbance area (ha)
Waste rock dump	6.9
Tailings dam (including decant ponds)	10.89
Tailings dam reclamation area (part of the 17.4 ha of Tailings Dam)	6.51
Open Pit	3
Infrastructure (including processing plant area)	6.66
Borrow pit (part of infrastructure)	0.24
Access tracks	2.0
Borrow pits	13.9
Exploration	<1.0
Total	**51.0**

The main features of THGM are outlined below and locations shown in Figure 2-7:

- Open cut pit (70 m deep with approximately 25 m depth of water).
- Underground mining area under the open cut pit and extending to the west.
- WRD north-east of the open cut mine pit.
- Core yard.
- Water tank (landholder use).
- Administration and processing area.
- Decant pond.
- TSF south of the open cut mine pit.
- Groundwater monitoring bores.

The open cut mine pit is currently a pit lake (due to groundwater recovery) and the tailings within the TSF and decant ponds are dry. Most permanent infrastructure from the original mining operation has been removed. There are the remains of the underground working vent and cables, disconnected piping, shipping containers used for storage of maintenance equipment, water tank and the reprocessing plant stationed at the TSF.

2.4.2 CURRENT OPERATION

Following the previous tailings reprocessing operation, the current proposed operation under existing approvals involves the removal of all remaining in situ tailings from the TSF to a facility located offsite in Mount Isa. The operation will be undertaken with a truck and shovel method loading onto a road-train and then transported to Mount Isa along the Mount Isa – Cloncurry Highway via Cloncurry, (as the majority of this route is sealed). It is expected that all tailings material from the TSF will be removed and relocated from site. The duration of this operation is not yet known; however, it is anticipated to take less than two years to complete.

The WRD, decant pond, pit, and old processing infrastructure area are not required for this operation, therefore there are no plans to disturb these areas during removal of the tailings material.

2.4.3 PIT

2.4.3.1 PHYSICAL

The pit is an internally draining mining pit with a footprint of approximately 3 ha and depth of 70 m with water level approximately 25 m from the base of the void as shown in Figure 2-8. The pit straddles a low ridge near the base of the Tick Hill mesa (i.e. the open pit occurs on a local drainage divide).

The pit area is 5.8 ha in total and consists of the pit lake, pit walls (angles range from 56-65°), and the offset area from the crest of the pit to the outer batter toe of the abandonment bund. The catchment area is restricted to the area within the pit crest (3 ha) and the area outside the crest (2.8 ha). A perimeter bund, barbed wire fence and signage have been erected in a location aligning to the maximum extent of the NUMA, to restrict public and livestock access to the area.

The pit appears to be in good condition given the duration of exposure, with little erosional or weathering effects which is a good indication of a reasonably high quality rock mass. A section of the west wall ramp has failed into the pit and the west wall has slipped however this was most likely due to the crown pillar extraction following cessation of operations (WKG, 2020). This previous slippage is all contained within the abandonment bund.

2.4.3.2 HYDROGEOLOGICAL

Several investigations into the groundwater conditions at THGM have been completed (EES, 2023; 2024), to improve the conceptual understanding of the groundwater and TSF interaction, as well as refine the groundwater inputs to the void model. The reports from this investigation are provided in Appendix D and Appendix E. These investigations found the following:

- Baseline conditions reflect the current state in terms of groundwater flow characteristics and level. In summary:
  - Local/ regional geology is highly fractured, resulting in hard rock aquifers with unconfined conditions. Typically only a single aquifer is present
  - Depth to the groundwater table ranges from 15 - 21mbgl, with low bore yields (<0.5 - 1.3l/s).
- The hydrogeological model indicates that the pit acts as a groundwater sink and will continue to do so under a wide range of climatic conditions (EES, 2024).
- No plausible rainfall scenario was identified which raised the pit water level to either the level of the surrounding water-table, or to the top of the pit. Long term pit water level modelled under various rainfall scenarios is shown in Figure 2-9.

- The pit water level is controlled by the limited rainfall runoff due to the small catchment area around the pit.
- No sensitive receptors were identified that might be impacted by either groundwater quality (EES, 2023), or mine pit water quality (EES, 2024).

Groundwater contours developed from monitoring information to illustrate the drawdown occurring are shown in Figure 2-10, with corresponding conceptual hydrogeological cross-sections provided in Figure 2-11 and Figure 2-12.

Figure 2-8: Tick Hill Gold Mine pit (WKG, 2020)

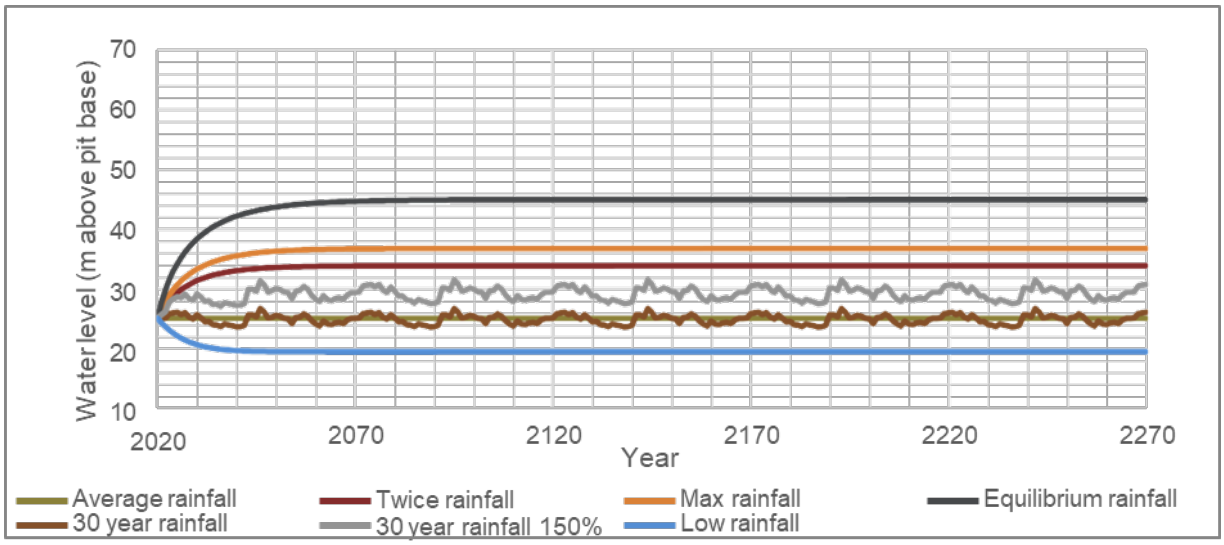

Figure 2-9: Long term pit water level under various rainfall scenarios (EES, 2024)

The groundwater and pit water chemistry are summarised as:

- Groundwater at THGM is naturally elevated in salts and metals which make it unsuitable for potable use without treatment:
  - Low concentrations of total cyanide are found across the site. The cyanide impact to groundwater between the TSF and open pit is stable, with concentrations likely to steadily decrease over time. It is not expected that cyanide impacted groundwater will adversely impact pit water quality to any significant extent and cyanide in pit water will be degraded by sunlight. Further, removal of tailings from the TSF and rehabilitation of the TSF will eliminate the main source of cyanide (tailings) and it is anticipated to therefore reduce the release of cyanide to the shallow groundwater and limit cyanide discharge to the pit
  - Nitrate and ammonia attributed to explosive residue was observed in several locations, including bore THGW004, down gradient of the WRD.
- Comparison of groundwater composition between monitoring bores and the pit indicates the following:
  - Salinity of groundwater bores is generally correlated with depth, indicating that the deeper aquifer is less saline
  - The pit is more saline than all bores except one - THGW008 which is located between the TSF and the Pit
  - The pit has higher concentrations of sodium, magnesium, potassium, chloride and sulfate than most bores
  - The pit has lower or mid-range concentrations of calcium, ammonia, bicarbonate, nitrate, phosphate and fluoride compared to most bores.

To understand the pit salt water balance, the current pit water quality provides the best available indication of how the various water sources combine to influence pit water composition. In order to determine how this would change into the future, a mass balance was developed using the pit water inflow (20.6 m^3/day) and estimate for groundwater inflow salinity.

This was modelled from the initial filling using modelled salt accumulation results, along with actual measurements of pit salinity between 2012 and 2023. Individual ion and metal concentrations were modelled with a direct concentration/ dilution from the 2021 to 2023 pit water quality results. The pit water quality model was then extended for 250 years using in the PHREEQC V3 software (EES, 2024). Modelled concentrations of gypsum, calcium sulfate, calcite, dolomite, calcium carbonate, magnesium carbonate, carbonate, Goethite, Iron (III) hydroxide, ferric iron compounds, and ferrous iron compounds, are provided in Appendix E.

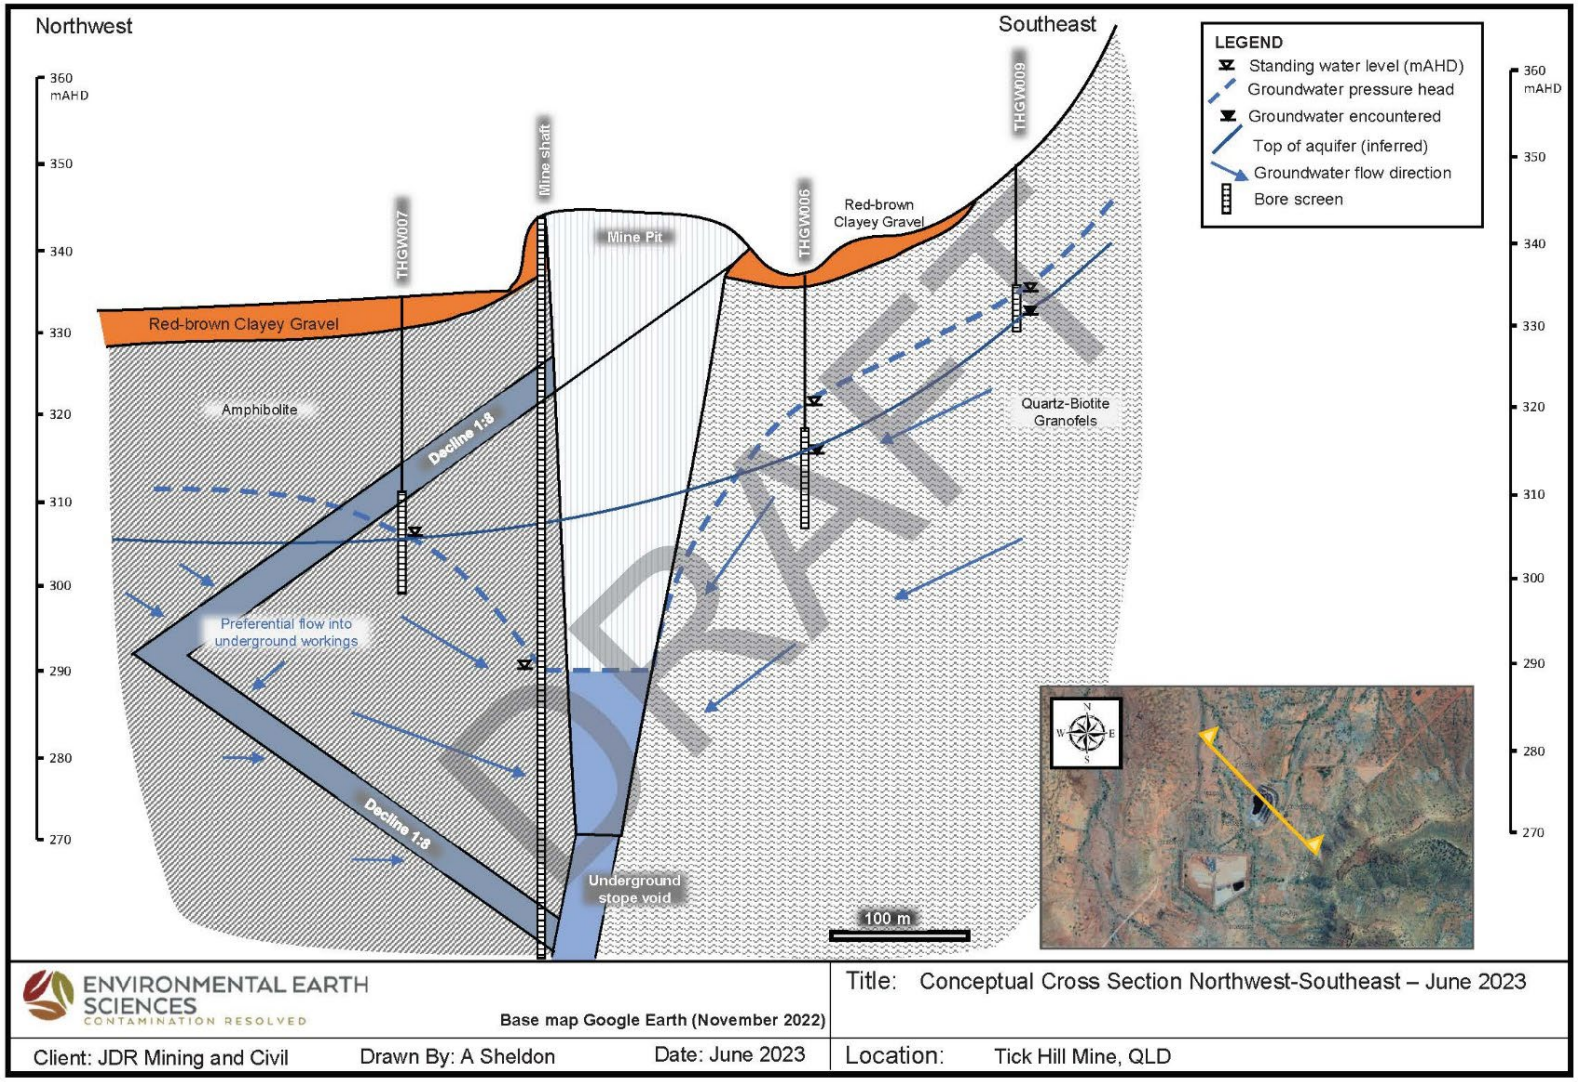

Figure 2-12: Conceptual Cross Section Northwest-Southeast (EES, 2024)

2.4.4 TAILINGS STORAGE FACILITY

The TSF was constructed as a 'turkey nest' structure with waste rock overlaying a clay lined floor (approximately 0.5 m thick) and clay cut off cores in the walls (except upstream/southern wall) in compliance with regulatory guidelines at the time construction occurred. The TSF comprises two separate cells which drained to the north into a (now capped) decant pond that enabled the re-use of water during operations. Table 2-7 provides a design and operational summary of the TSF. Images of the TSF during operations and in 2024 are provided in Figure 2-13 and Figure 2-14 respectively.

Table 2-7: TSF summary

Feature	Summary
Structure type and details	• Above ground turkey nest structure. Referable dam with no external catchment • Maximum landform elevation of 352 m RL, TSF embankment height 10.5 m • Surface area in eastern cell is 4.4 ha, and western cell is 4.5 ha
Capacity	600,000 m^3
Embankment and base details	• Outer embankment walls and an inner cell wall • Installed with a 500 mm clay liner in the base, and walls with clay core • Clay materials used for lining sourced from borrow pits/scrapes on site • Outer embankment walls at a batter angle of 1:3 and are higher than the cell surface; likely constructed in single stages
Cellular details	• Two cells, ranging from 6-10 m depth, flat topped, with cell surface lower than perimeter embankment • Tailings material recently (2020-2022) removed from Eastern cell • Western cell tailings remain; topsoil removed and stockpiled in the TSF precinct
Cover system	• Consisted of a waste rock mulch, covered with topsoil. • Validated depth between 700mm-1000mm; less distinct topsoil cover of 100mm • Not designed to prevent/ restrict water infiltration; designed as a non-enhanced store and release cover • Both cells were originally capped/seeded as per initial rehabilitation • Clay/topsoil cover materials sourced from on-site borrow pits/scrapes
Design Storage Allowance	For the previously proposed tailings reprocessing operation, total DSA volume of 29.5 ML required for each cell (noting area disturbed is being staged), as per CCA (ATC Williams, 2022)
Water Management	• Decant pond constructed to same specification as the TSF • Currently rehabilitated • Total capacity (historically) of 93,000 m^3
Spillway location	• Constructed drain located on the northern end of the eastern cell • Runoff for all of structure directed to this location • Full supply level (at spillway location) at 346.7 m RL
Leak detection systems	Nothing installed
Seepage collection systems	Nothing installed
Tailings material	• Tailings have low sulfide-sulfur composition and excess acid neutralisation capacity resulting in negative NAPP values through the profile • Material considered NAF or PAF-LC at worst, and do not contain high risk PAF material. Risk of generating AMD or NMD was low • Potential for seepage from the TSF was understood to be very low, and directed to the open cut/ residual void (PSM, 2020)
Rehabilitation performance	• Previously capped and seeded; low scrubby vegetation is well established on areas not yet cleared • TSF batter slopes all well vegetated and in good condition
Current disturbance	• 2 ha has been disturbed for reprocessing of residue • Disturbed capping material stockpiled on undisturbed part of TSF

Rehabilitation of the TSF involved placement of a waste rock cover (as a rocky mulch layer) up to 1.0 m thick, followed by application of stockpiled topsoil. The surface and batters of the TSF and the stormwater drainage structures were assessed in 2013 and were considered to be well stabilised and did not present an erosion and stream sedimentation hazard (Envirofin, 2020).

The 2013 rehabilitation assessment provided the following summary of the TSF rehabilitation (SKM, 2013):

- Vegetation has covered the surface of the tailings dam and the batters relatively evenly.
- At the time of inspection, there were no visible signs of scouring, slumping or bulging of any of the batters or the toe of the embankments.
- There were also no signs of sink holes or slumping on the top surface.
- The spillway showed no signs of erosion, and the wire rock protection was intact and in good condition.
- It has a very low residual risk associated with instability and scouring. Based on the performance in the last 17 years, it is reasonable to expect that stability will be maintained in the future and scour will not become an issue.

The 2024 soil sampling campaign (to improve baseline and rehabilitation material knowledge) also observed that all TSF batters and the spillway were well vegetated with no visible erosion rills or gullies.

Topsoil and growth media (topsoil plus subsoil) removed as part of the previous tailings extraction and reprocessing has been stockpiled on the surface of the TSF western cell.

Following removal and relocation of the tailings material, capping material will be placed over the compacted clay floor and seeded with shallow-rooted species as agreed with the landowner.

Figure 2-13: TSF during operations looking east (Carnaby, 2023)

Figure 2-14: TSF in 2024 looking west

2.4.4.1 GEOCHEMICAL CHARACTERISATION

The expected geochemistry of tailings (and potential for AMD, salinity, and other contaminants) influences how they need to be contained and subsequently rehabilitated. A summary of the tailings material characterisation is provided in Section 2.4.5.

In general, the processing waste (and tailings materials in particular) can be regarded as having very low acid generation potential, and low total metals – meaning low risk of neutral metalliferous drainage (NMD). It has been highlighted that a few analytes have been elevated (such as copper and cyanide), resulting in extensive further investigations to understand the geochemical risk posed by these components. Further detail of these investigations is provided in Section 2.4.6, and as Appendix B.

It is also noted that available pit, surface water and groundwater quality analysis do not reflect AMD or NMD conditions, which would be expected to be apparent by now given the long time since operations have ceased (almost 30 years).

2.4.4.2 GEOTECHNICAL AND RHEOLOGICAL CHARACTERISATION

The TSF has been in place, and non-operational for tailings storage, for almost 30 years. During this time, the batters have remained stable and have revegetated well. As an entirely rehabilitated structure, the likelihood of failure was assessed as being low with respect to harm to humans, general environmental harm and general economic loss or property damage (Envirofin, 2020). This consequence category assessment was completed in accordance with the 'Manual for Assessing Consequence Categories and Hydraulic Performance of Structures' (DES, 2016).

Considering physical properties, both the embankment and cover layers are dry and compacted. As part of planning for the reclamation/reprocessing of the TSF, heavy machinery (drill rigs) operated on the TSF, effectively testing the material's resistance to deformation and stability under loading conditions. No stability issues were noted, even though sampling completed in 2022 reported that the tailings were saturated at a depth between 4 and 5 m (EES, 2023). Reclamation of tailings residue material has also shown materials to be dry and compact.

It was considered that the geotechnical and rheological requirements associated with the PRCP guideline are not relevant to the THGM situation and have not been considered further.

2.4.4.3 LEAK DETECTION AND SEEPAGE MANAGEMENT

Leak detection and seepage management measures were not previously installed at THGM, however it is well understood that seepage reports to the residual void (which is a NUMA) and is currently contained within the mine tenement.

2.4.5 WASTE ROCK DUMP

The WRD was decommissioned following cessation of mining in 1998. Kinhill (1991a) undertook waste rock analysis, including kinetic column leaching, and determined that the structure would not present an acid rock drainage (ARD) risk, therefore the decommissioning design did not include capping. However, recent investigative drilling found that there was at least a 0.5 m cover of non-waste material. A summary of the WRD is provided in Table 2-8.

The WRD drains through a small sediment trap to a drainage line which reports to Petticoat Creek, and Envirofin (2020) suggests that drainage from the WRD is not resulting in any downstream environmental harm.

The 2013 assessment (SKM, 2013) found that the structure was stable and summarised the rehabilitation of the WRD as:

- Vegetation has covered the surface of the waste rock dump and the batters.
- At the time of inspection, there were no visible signs of slumping or bulging of any of the batters or the toe of the embankment. There were also no signs of sink holes or slumping on the top surface.
- The surface of the WRD is showing evidence of termite activity.
- The flat-top surface is not graded towards the spillway and a number of erosion sites are evident on slopes, however most sites of erosion appear to be stable and exhibit hard-panning and concreting of particles long the edges of eroded gullies.
- Some scouring had occurred in the drainage path 10 m west of the western WRD batter; however it was considered unlikely that possible further scouring of the drainage path will negatively impact the stability of the toe of the waste rock dump since the scouring depth would need to be approximately a further 3 m in order to do so.

The assessment in 2013 (SKM, 2013) observed a number of erosion sites evident on the slopes. The 2024 soil sampling campaign (to improve baseline and rehabilitation material knowledge) also observed that there were some visible minor erosion rills and gullies on the northern batter, however they appeared stable and well vegetated.

Table 2-8: WRD summary

Feature	Summary
Structure type and details	• Constructed in 5 m lifts • Capped with rock mulch and topsoil • Waste rock material was confirmed as inert prior to placement • At times, there is minor water ponding on the southern side where a drainage line meets the WRD • No evidence of acid scalding or seepage around the perimeter of the WRD • Soil sampling indicated material was non-saline, slightly alkaline, with elevated phosphorus, very low nitrogen and organic carbon, and no evidence of metal concentration. Results support the use of the area for grazing
Rehabilitation	• Batters are well vegetated and stable, only with minor scour observed on the northern side • WRD is stable and becoming integrated into the surrounding landscape

2.4.6 MINE WASTE MANAGEMENT

The only areas where mine waste has been placed on the THGM site are the WRD area and the TSF. Given that both areas were rehabilitated almost 30 years ago, it is expected that any mineral waste risks or concerns would have been apparent by now. As such, review of the receiving environment surface and groundwater quality provides the strongest indication of any underlying mine waste issues. Extensive

investigations have also been completed into potential cyanide migration from the TSF to the surrounding groundwater system, of which the latest assessment and understanding is provided in Appendix D. This has also been the focus of more recent geochemical investigations and sampling efforts.

The remainder of this section is a compilation of the information available as to mine waste characterisation, as a compilation of relevant historical information, noting that the tailings material will be relocated offsite and the remaining structure capped. Enhancements to the cover system on the TSF are planned, as per Section 6.2.

2.4.6.1 CHARACTERISATION AND POTENTIAL HAZARDS

The Tick Hill gold deposit was hosted in the middle Proterozoic Corella formation, locally made up of banded calcsilicates, quartzites and amphibolites. Originally these were sediments of evaporitic, detrital and possibly igneous origin, that had been metamorphosed to mid-amphibolite facies. An estimated 90% of the original gold occurred in highly strained pink quartz-feldspar laminates, with the remainder occurring in the surrounding quartzitic schists and amphibolites. The quartz-feldspar laminates varied in width from 1 to 150 cm and often carried visible grains of gold of up to 2 mm in size.

The orebody contained virtually no accessory or pathfinder minerals, with only very minor pyrite and chalcopyrite. The ore and host geology therefore comprise a low sulfidation mineralising system with native gold, accessory silver and minor copper and cobalt. This reflected in the groundwater and pit water chemistry which has detectable copper, cobalt, arsenic, and selenium.

Available geochemical characterisation data have been sourced from previous reports and other sources from 1993 to more recent sampling completed (in 2020). The results presented herein also correlate with available pit water and groundwater analysis, which after almost 30 years do not reflect AMD or NMD conditions.

Acid generation potential overall has been consistently very low with occasional elevated samples (less than 7%). The majority of post oxidation pH from test samples were alkaline to strongly alkaline reflecting high neutralisation capacity from the predominant carbonate and bicarbonate rich host rock. Of all samples taken, the highest oxidisable sulfur level recorded has been 0.1%. Under relevant guidelines (AMIRA, 2002), most samples were classified as non-acid forming materials (NAF), with the exception of one sample which was classifies as uncertain (UC). The tailings indicated negative NAPP values through the profile and based on sulfide sulfur, were classified as NAF.

A conservative NAPP calculation using Total Sulfur results in very weak acidity, <1kg H2SO4/t (0.91mg/kg TS), in one sample. The NAG testing showed weak acidity at pH 7 and a NAG pH of 4.2 which would be neutralised by the excess ANC in the bulk of the tailings mass.

Total metal concentrations have been low to very low at all sampling depths, consistent with early geology descriptions of the orebody. Test work indicates that the TSF wall material (as representative of overburden) was very low in sulfur, macronutrients (N,P,K), oxidisable sulfur (inferred sulfides) and strongly alkaline. The tailings materials were also low in macronutrients, strongly alkaline, and contains moderate levels of oxidisable sulfur (inferred sulfides) with low peroxide pH. With exception of slightly elevated copper levels (which were still within normal background levels), the material contained low levels of other metals.

Scott (2020) noted that metals concentrations for the Decant pond were slightly elevated compared to concentrations for tailings material for copper, lead, and zinc, but not enriched compared to average crustal abundance. As such, the potential for metalliferous drainage was considered to be low overall.

The tailings cation composition was strongly dominated by magnesium over calcium, and overall cation concentrations are moderate, so the potential for calcium and magnesium carbonate and bicarbonate dissolution by AMD generated acid was very low. As a result, the potential for saline mine drainage was also considered to be low. In summary, acid base accounting analysis for THGM shows that tailings and waste rock samples predominantly exhibit the following negligible geochemical risk characteristics:

- Alkaline to strongly alkaline pH and oxidised pH.
- Low total sulfur, sulfide levels < 0.1%.
- Low NAG fizz ratings.
- High Acid Neutralising Capacity (ANC).
- Negative to strongly negative NAPP values.
- ANC: MPA ratios are low (5th percentile of 2.4).
- Below detection limits NAG values.

Slightly elevated concentrations of copper have been noted in the tailings, as has moderately high free cyanide levels (and total nitrogen- cyanide proxy), increasing with sampling depth. Free and weak acid dissociable (WAD) cyanide concentrations have been shown to have decayed significantly over the time since decommissioning; and are now below relevant limits of reporting.

However, reclamation of tailings materials will further reduce the potential risk of seepage of cyanide and cyanide compounds from un-reclaimed tailings to groundwater. Improvement of the cover system on the TSF will also reduce the risk of infiltration through to the underlying tailings waste material.

2.4.6.2 SAMPLING AND ANALYSIS REGIME

Geochemical investigation at THGM has been completed in several campaigns over time, dating from 1993 during the operational period of the site to more recent sampling completed in 2020. Details of each sampling campaign completed is provided in Table 2-9. Further to this, as a mineral mine, characterisation of the orebody itself is considered to be complementary to direct sampling to understand the potential geochemical hazards from placed tailings.

It is noted that each campaign has reinforced previous findings, to provide a deeper understanding of the mine waste. On the basis of the sampling and analysis trends discussed above, the tailings and waste rock at THGM were considered very low risk and kinetic leaching has not been considered necessary (Scott, 2020).

Table 2-9: Tick Hill Gold Mine geochemical sampling campaigns

Campaign/Report Name and Date	Material Type	Number of Samples Taken	Suite of Analysis
Carpentaria Gold (1993)	• TSF wall material • Tailings	• 2 samples	• Acid-base accounting • pH and EC, Sulfur • Major cations and anions
Dames and Moore (circa 1994)	• Tailings • Decant Pond	• 58 samples over 17 sites, at 3 depths	• Acid-base accounting • pH, EC pHox • Oxidisable sulfur/sulfate • Major cations and anions • Total metals
Diatreme Resources Metallurgical Testwork (2015)	• Tailings • Waste Rock	• 2 composited samples, plus 14 discrete samples at 12 locations • 8 samples	• Acid-base accounting • pH and EC • oxidisable sulfur/sulfate • Major cations and anions • Total metals

Campaign/Report Name and Date	Material Type	Number of Samples Taken	Suite of Analysis
Carnaby Resources (May 2020)	• Tailings • Waste Rock	• 7 samples, followed by an additional 13 depth samples • 8 samples, at a range of depths	• Acid-base accounting • pH and EC • Sulfur • Major cations and anions • Total metals • Cyanide speciation

A total of 112 samples have been taken, and it is estimated that approximately 700,000m^3 of material (such as tailings and waste) has been moved for the THGM operation. This equates to one sample for every ~6 tonnes of material moved, which is considered a very high sampling resolution meets contemporary standards in terms of coverage, as well as testing methods employed. Long-term surface and groundwater water monitoring is also available to supplement the waste characterisation. As such, there is a very comprehensive understanding of the mine waste and associated geochemical concerns for THGM, with low uncertainty.

2.4.6.3 CLASSIFICATION OF MINE WASTE STREAMS

All mined material for THGM has been classified based on acid-forming potential. This is based on Australian and international leading practice guidance (AMIRA, 2002; INAP, 2018), which sorts waste into three classes. These classes are:

- Non-Acid Forming (NAF)
- Potentially Acid Forming (PAF)
- Neutral Metalliferous Drainage generating (NMD) metal leaching under near neutral leaching conditions.

Classes are defined by reference to total sulfur concentration, NAG pH and NAPP, and metal leaching capacity (for release of metal contaminants of concern).

2.4.6.4 CONTAMINANTS OF CONCERN

A detailed Environmental Site Assessment (ESA) (Appendix D) completed a thorough investigation of contamination relevant to THGM. This involved a review of historical aerial photographs and reports, investigation of site ownership and mining activities, consideration of relevant government registers, analysis of past monitoring results and supplementary sampling. This allowed for an understanding of contaminant sources for THGM and activities with potential to result in land, air or water contamination. The following chemicals or contaminants were identified as of potential concern, and subject to investigation within the ESA (EES, 2023):

- Cyanide (CN) – cyanide leach process and residual cyanide in tailings
- Heavy metals – metals from within processed ore and tailings, from workshops, batteries, and degraded site infrastructure
- Petroleum hydrocarbons (TRH) – with fuel and oil storage
- Benzene, toluene, ethyl benzene, xylenes and naphthalene (BTEXN) – fuel storage
- Per- and Poly-fluoroalkyl substances (PFAS) – fire suppression
- Polychlorinated biphenyls (PCBs) – transformer oil
- Organochlorine pesticides (OCPs)– pest control
- Acids, alkalis & other reagents – gold ore processing
- Nitrogen compounds – explosive residue

- Nutrients in effluent and soil.

2.4.6.5 SOURCE – PATHWAY – RECEPTOR CONCEPTUAL SITE MODEL

A conceptual site model (CSM) of the site can be formed by considering the geophysical characteristics at play, the contaminant source, potential receptors, and the pathways to the receptors. Potential for environmental harm can occur due to soil, airborne, surface water bound or groundwater contamination This is an iterative process which may be updated as more information becomes available.

As part of the ESA provided in Appendix D, a preliminary CSM was developed, then investigation undertaken to improve the understanding of the source-pathway-receptor interactions, as well as further the understanding of potential contaminants of concern. A summary for this iterative investigation for each aspects of the relevant source – pathway – receptor concerns for THGM is summarised in Table 2-10.

The source-pathway-receptor model determined that there is no risk to receptors due to the groundwater contamination identified on site. However, it was considered that the exposed tailings material does not meet conditions for long term site management and required containment (EES, 2023). Long-term containment requirements for the TSF were previously considered in Section 2.4.4. Section 6.2 provides the rehabilitation and closure requirements to address the long-term management and containment of the TSF.

Figure 2-15 and Figure 2-16 provide schematic cross-sectional views of the site identifying the potential sources, pathways and receptor connections regarding waste material and the void/underground areas respectively.

Table 2-10: Conceptual site model (EES, 2023)

	Preliminary CSM Concern	Investigation result
Source	Release of fuel or chemicals associated with historical mine operations and ore processing	No evidence to suggest concern
	Release of fuel or chemicals associated with recent tailings reprocessing	No evidence to suggest concern
	Release of tailings from the TSF	Tailings metals and cyanide are within relevant criteria for these materials Current nature of exposed tailings does not meet long term site management requirements
	Leaching of cyanide, metals or other contaminants from the TSF or WRD	With the exception of cyanide and nitrogen compounds, exceedances are considered to be naturally occurring and related to the natural lithology of the aquifer
Pathway	Dermal/ inhalation/ ingestion exposure to contaminants or groundwater by site workers and visitors	Confirmed that seepage and groundwater migration occurs from WRD and TSF to aquifer
	Direct contact or uptake by flora or terrestrial fauna	No evidence to suggest concern
	Overland flow resulting in runoff to local soil and waterways	No evidence to suggest of concern
	Impacted groundwater migrating towards local waterways	Not of concern, as ESA confirmed that groundwater inflows to pit
	Use of impacted groundwater for stock watering	Not of concern, given highly localised nature of groundwater migration and distance to known stock watering bores

	Preliminary CSM Concern	Investigation result
Receptor	Impact to neighbouring grazing property and surrounding areas Site workers and visitors	Dilution and degradation of cyanide (in the open pit) reduces concentration to below criteria Groundwater is accessed via direct pumping only Groundwater impacts are restricted to within the mine tenure boundary, due to the pit being a sink
	Impact to watercourses north and west of the site draining to Petticoat Creek	No evidence to suggest concern, as no GDEs or groundwater discharge zones identified
	Impact to off-site receptors	Not of concern, as pit water is not intended to be used for stock watering Noted that wildlife may consume water directly from the mine pit, and also that pit water may be used as dust suppression during tailings relocation activities.

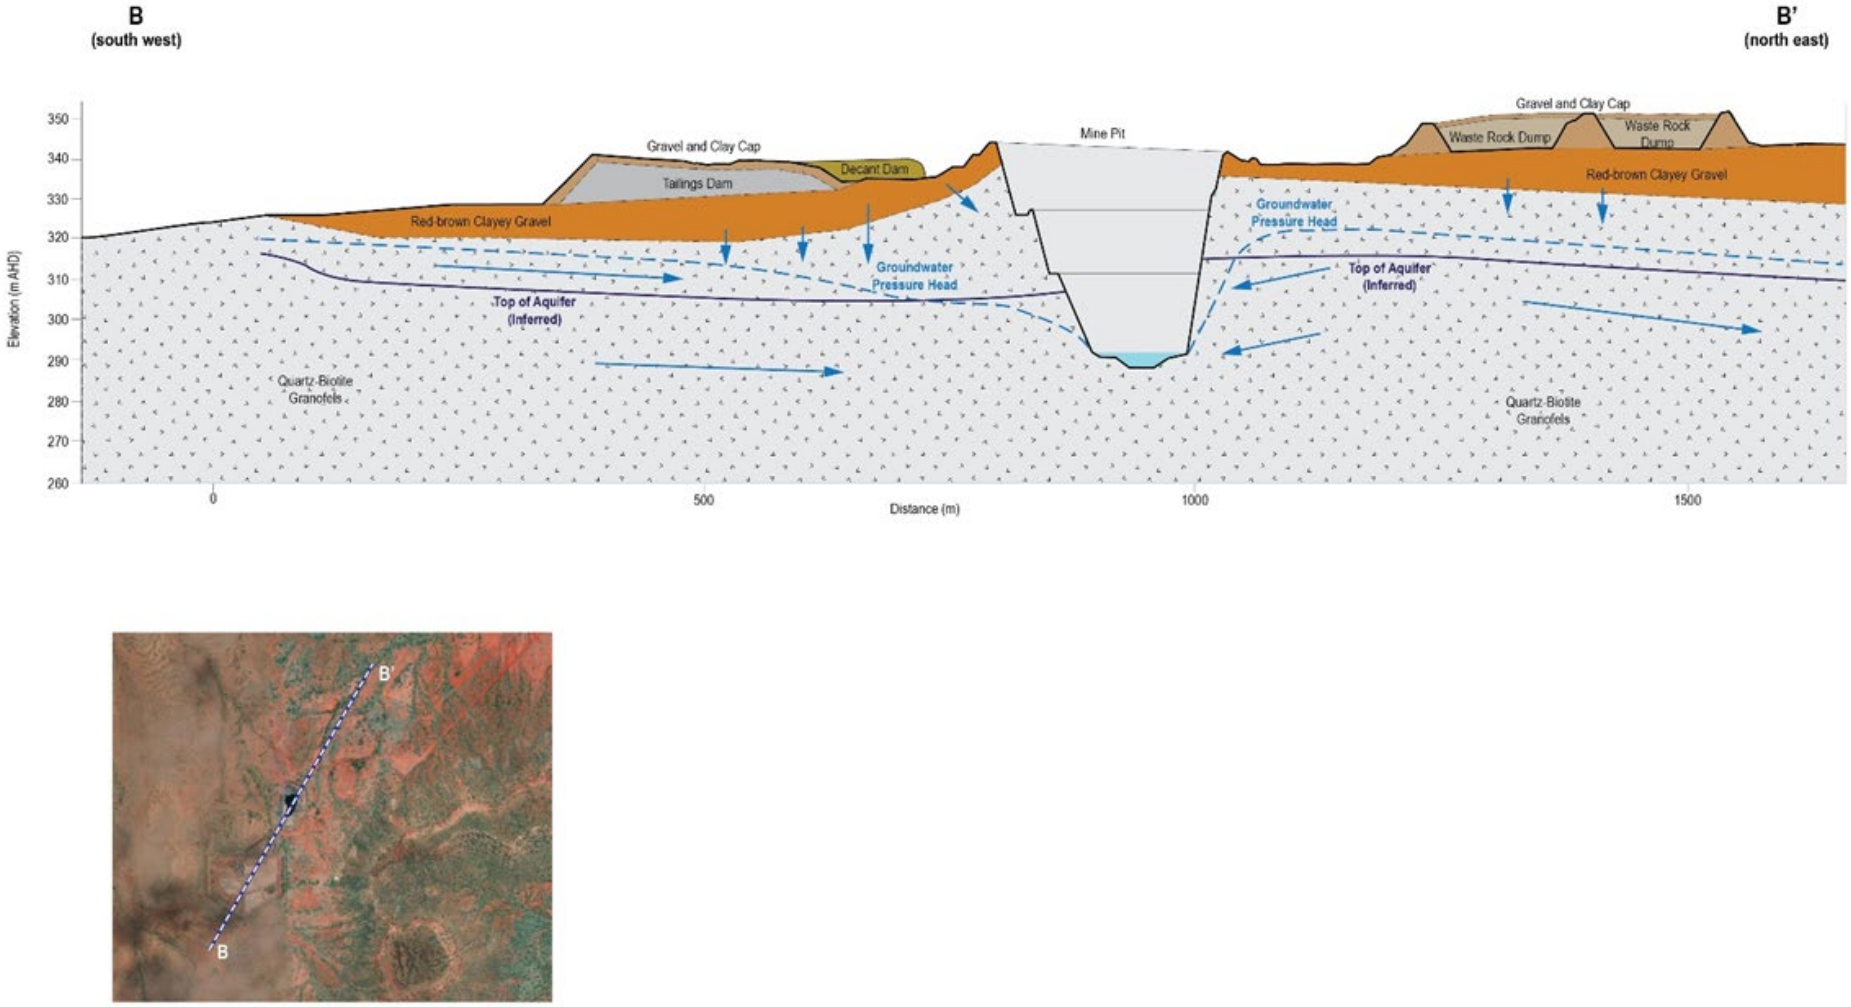

Figure 2-15: Conceptual site model – waste material (Carnaby, 2023)

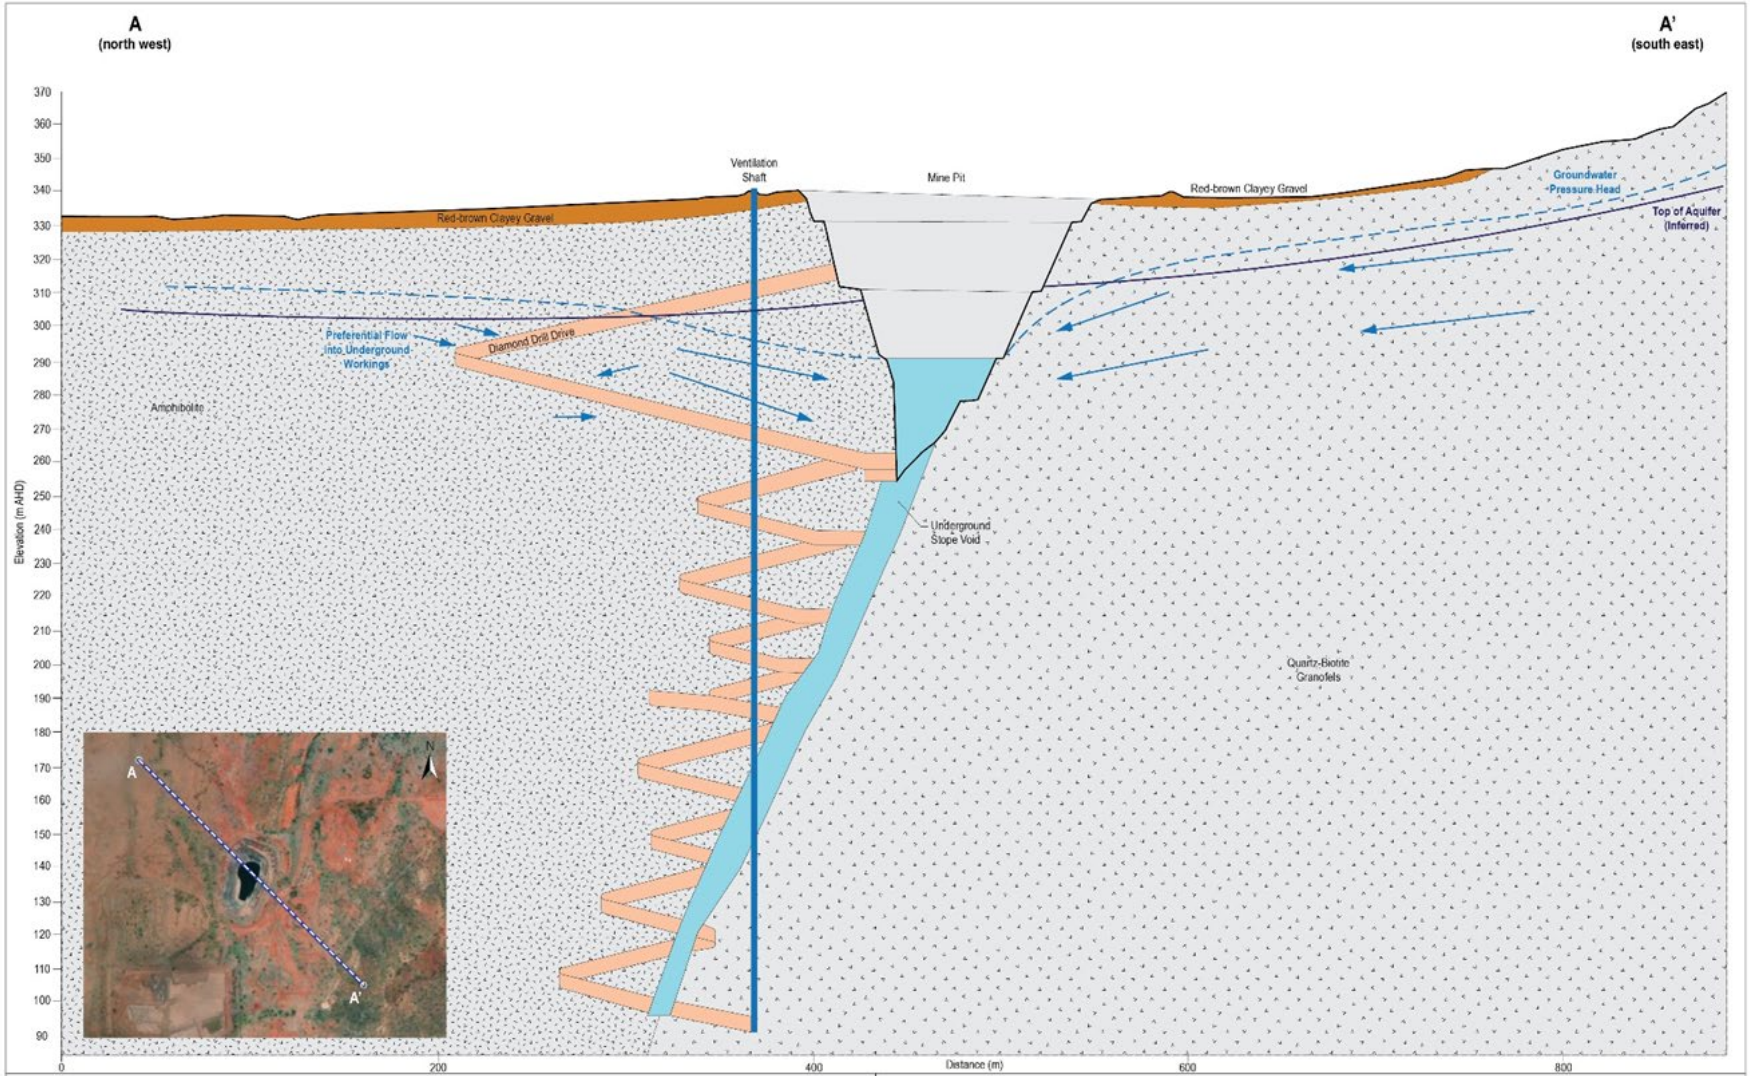

Figure 2-16: Conceptual site model – void and underground (Carnaby, 2023)

2.4.7 BORROW PITS

The THGM EA describes borrow pits in the vicinity of the TSF (typically of 300 mm depth), with an approved disturbance of 13.9 ha. However, the 2018-2020 Plan of Operations, stated that borrow pits could not be identified within the areas, and "... reports also indicated that to the extent that the borrow pits were located within the mining lease areas, they have been rehabilitated".

Diatreme stated that no information to delineate the area of the borrow pits was identified in the information library provided by MIM (at the time) and Diatreme suspect that the original location of the borrow pits is outside the area of the mining leases. (Diatreme, 2017a).

The location of the borrow pits could not be readily identified during the 2013 site inspection (SKM, 2013) as the profile and vegetation type and density in these areas was observed to be similar to the surrounding undisturbed areas, suggesting successful rehabilitation of these areas.

Therefore, for the purposes of the PRCP, two borrow pit locations have been proposed; one to the northeast of the decant pond, and one directly to the south. These two borrow pits have a footprint of approximately 7.8 ha in total and will be used as required for TSF capping and site rehabilitation.

2.4.8 WATER MANAGEMENT

As detailed in Section 2.3.5, THGM is drained by several ephemeral watercourses which flow to the north and northwest. The open pit lake retained as part of the residual void NUMA is the only permanent water holding body on site. There is an abandonment bund in place around the NUMA extent, so that all external catchment is separated from the void catchment and remains in the receiving environment. Further information on the void is provided in Section 2.4.3.

During operations, the Decant pond would have held water, however as part of closure activities conducted from 1995, the surface was reshaped and capped with rocky mulch and is now free-draining. Capping of the TSF was also completed as part of the initial 1995 site closure, however the eastern cell capping has recently been removed to access tailings for reprocessing. Today, the TSF and Decant Pond remain dry, except for short periods of time after a rain event.

A water tank remains in use and supplies stock water for the surrounding area (under an agreement with the landholder). Water is sourced from a borefield 15 km east of site. The only current water infrastructure on site is the pipeline that supplies the water tank. The pipeline runs north-east from the tank around the hill to the north-east. The pipeline is subject to the same landowner agreement as the supply tank.

During its time in operations, THGM was a zero-discharge site, with all infrastructure sized for full containment and no authorisation for mine water releases.

2.4.8.1 REGULATED STRUCTURES

A Consequence Category Assessment (CCA) was undertaken for the previously proposed tailings reprocessing operation. During operations, the TSF was assessed as a regulated structure due an overall consequence category of 'Significant'. The rating was a result of a 'Significant' rating for Failure to Contain – Overtopping, and Failure to Contain – Dam Break (ATC Williams, 2022). The CCA report is provided in Appendix F.

This rating requires for additional Design Storage Allowance volume to be made available during the reprocessing operations. However, as all the tailings material is planned to be relocated offsite during

operations, and the TSF rehabilitated with a cover system, it is anticipated that the consequence category for the TSF after closure to be low based on the Consequence Category guidelines (DES, 2016).

2.4.9 DESIGN FOR CLOSURE

Transitional PRCPs are not required to demonstrate how aspects of the mine site have been designed for closure for existing or approved disturbance, however, any expansion to an existing site must demonstrate how it has been designed for closure.

THGM is under a transitional PRCP and has no current expansions to the existing site, therefore this section is not applicable to this transitional PRCP.

2.5 EXISTING SITE REHABILITATION STATUS

The THGM features were rehabilitated following cessation of operations in 1995, with minor rehabilitation undertaken following exploration works between approximately 2014 to 2024. Recent tailings reprocessing activities have re-disturbed the TSF and access roads, resulting in 28 ha of the site still rehabilitated from the original 51 ha of disturbance approved.

Whilst rehabilitation of the previous mining disturbance was considered successful, there has always been recognition that additional resources exist at THGM and as such, no effort to certify existing rehabilitation, or to relinquish the current MLs has occurred.

Rehabilitation activities previously undertaken at THGM include:

- Surface infrastructure removed other than water line and storage reservoir
- Roads deep ripped and seeded
- Processing area reshaped and seeded
- Roads other than major access track seeded
- Tailings dam capped and seeded
- Decant pond capped and seeded
- Borrow pits backfilled and seeded
- Waste rock dump walls battered and seeded
- Waste rock dump capped and seeded
- Final void bunded and fenced (Envirofin, 2020).

The following sections provide a summary of the rehabilitation monitoring that has been undertaken at THGM since 1999 and was based on the following two primary sources:

- Sinclair Knight and Merz (SKM) report titled 'Tick Hill Rehabilitation Survey. Flora and Fauna Survey' (SKM, 1999).
- An Interim Rehabilitation Report (SKM, 2013) was commissioned by then owners Xstrata, to produce a Final Rehabilitation Report to relinquish the THGM MLs. This is provided in Appendix F.

The following sections provide a summary of these document findings (plus observational commentary from more recent site visits where applicable), regarding site stability, ecology, exploration, and progressive rehabilitation. Soils and rehabilitation material characterisation and balance information is provided in 6.5.

2.5.1 GENERAL SITE STABILITY

The 2013 SKM report (SKM, 2013) summarised the general rehabilitation status as physically stable and that preliminary limit equilibrium stability analyses of the tailings dams, decant pond and waste rock dumps indicated that the design and construction was adequate to maintain long term stability.

Stability analyses for the tailings dam, decant pond and waste rock dump resulted in a factor of safety (FoS) of 1.0 for earthquakes and greater than 1.5 for all other scenarios as shown in Table 2-11.

Table 2-11: Stability analyses results for landform features

Feature	Factor of Safety			
	Long term	Long term cutoff	Earthquake	Earthquake cutoff^
TSF	1.8	1.5	1.57	1.0
Decant Pond	1.77	1.5	1.53	1.0
WRD	2.4	1.5	2.09	1.0

^Note: Cutoff from USACE (1970)

The report also stated that the tailings dam, decant pond and waste rock dump are expected to be stable over the long term and comply with the decommissioning/rehabilitation criteria of the (at the time) DEHP's Code of environmental compliance for Mining Lease Projects January 2001 - Version 0.' (Diatreme, 2017b).

More recent site observations during exploratory works 2020-2022 plus the 2024 soil and rehabilitation material characterisation sampling campaign (Mine Earth, 2025a) have identified stable landforms and there is no mention in recent documentation of any batter, bank, or containment failures or erosion features that warrant further investigation.

2.5.2 ECOLOGY

Two surveys focused on rehabilitation have been undertaken since the former gold mine ceased operations in 1995:

- 1999 SKM flora and fauna survey (SKM, 1999)
- 2013 SKM Interim Rehabilitation Report that included:
  - flora and fauna survey with the same methodology as the 1999 survey
  - baseline BioCondition survey to assess the condition, health, or ecological integrity of the habitats on site (SKM, 2013).

The following sections provide a summary of these survey's findings.

2.5.2.1 1999 SKM SURVEY

The rehabilitation flora and fauna survey was undertaken in 1999 by SKM assessing a reference (analogue) colluvial slope site, the rehabilitated WRD, and the TSF plateaux. Abundance and richness of plant, invertebrate and vertebrate taxa were used as ecological indicators to assess the similarity of rehabilitated and reference sites on the Tick Hill mine lease.

The survey was undertaken in January and August 1999. Survey locations were established at five reference sites and two rehabilitated sites (WRD and TSF plateau). Overall, the survey concluded that:

- The results of this survey were promising (e.g. the seasonal consistency in vertebrate assemblages) although further seasonal surveys over time would confirm the relationship between the sites. The high seasonal changes in plant species richness and ground cover on the tailings dam and the

invertebrate assemblages on the tailings dam and rock dump suggests that the development of a greater proportion of perennial vegetation and some change to substrate characteristics (probably related) may be required to provide ongoing rehabilitation success.

- While different in composition to reference sites, rehabilitation sites generally showed an acceptably high diversity and abundance of various organisms. (SKM, 1999)

The results tended to focus upon seasonal variation, however, were found to be 'promising' and are summarised below:

- Plant species and invertebrate order composition and abundance showed that the rehabilitation sites were different to the reference sites in both winter and summer
- Invertebrate order richness was as high or higher on the rehabilitated sites as the reference sites
- Seasonal changes in plant and invertebrate richness and abundance were greater at the rehabilitation sites than the colluvial slope reference site
- There were generally more reptile, bird and mammal species at reference sites than at rehabilitation sites, and there was a similar change in community composition between summer and winter
- Plant species richness declined between summer to winter on the rehabilitated sites; however multidimensional scaling showed that, while there were differences between the reference and rehabilitated sites, the overall trend in seasonal variation was similar between summer and winter
- Vertebrate species composition showed that the TSF fauna resembled the colluvial slope reference site although less rich in species. Furthermore, both these sites showed a similar seasonal change in vertebrate faunal community structure. In contrast, the vertebrate fauna at the WRD site did not show a marked seasonal change (SKM, 1999).
- The TSF fauna monitoring results indicated similar seasonal variation to the background site and WRD and was similar in winter to the background site. This suggests that while there is a large degree in variation between the sites, particularly in vegetative composition, the rehabilitated areas are performing as an integral part of faunal habitat (Envirofin, 2020).

2.5.2.2 2012-2013 SKM SURVEY

The 2013 flora and fauna rehabilitation survey replicated the 1999 survey methodology and also included an initial baseline BioCondition survey that was undertaken concurrently and included assessing vegetation condition using the Queensland Government's BioCondition Assessment Manual available at the time (DERM, 2012).

Terrestrial flora results indicate the rehabilitation in terms of establishing a self-sustaining vegetation cover suitable for soil stabilisation and grazing has been successful.

There was a reduction in ground cover between 1999 and 2012 at a reference site, however no significant changes between survey years were detected at the other reference or rehabilitated survey locations. The percentage of bare ground appears to have no significant change between the 1999 and 2012 surveys, indicating the amount of plant material (live plus dead) has remained reasonably constant.

The following 2013 BioCondition survey results were summarised as:

- Native grass and other ground cover species richness was consistently lower than the benchmark at all survey locations, including the reference sites. This may have been factor of the very dry conditions resulting in a general paucity of fertile material making differentiation and detection of species difficult.
- Tree canopy cover was below the benchmark at the rock dump, and surprisingly also on the colluvial slope, as this site appeared to have been subject to very little disturbance.
- Organic litter cover was higher than the benchmark at all sites, presumably due to the abundance of dead Buffel grass adding to the litter layer.

Importantly, all other indicators measured using the BioCondition methodology were within the ranges specified in the BioCondition benchmark document (DERM, 2012).

Visual observation of the previously disturbed mine areas indicates that the current ground cover is self-sustaining, and cover densities are sufficient to prevent soil erosion (SKM, 2013).

The rehabilitation in 2013 (SKM, 2013) was assessed against the completion criteria of the environmental permitting at the time, and was found to have achieved all criteria against the relevant rehabilitation objectives:

- Vegetation cover to minimise erosion.
- Establish specified self-sustaining natural vegetation and/or grazing land.

2.5.2.3 REVEGETATION OVER TIME

Further to the results from 1999 and 2013 (plus observations during 2020-2024), Figure 2-17 provides a comparison of TSF vegetation cover between 2005 and 2024 (Google Earth, 2024). Note the 2024 image where vegetation (dark areas) can clearly be seen establishing directly on tailings material within the eastern cell.

2.5.3 SOILS

In July 2024, a material sampling and analysis program was undertaken to improve knowledge of the THGM soil and growth media (Mine Earth, 2025a). The materials sampled were considered a valuable source of potential rehabilitation / cover materials for use in mine closure. The samples included were from the WRD, tailings and tailings cover material, stockpiled topsoil, potential borrow material locations, decant pond cover and embankment material, plus analogue soils from five locations. The findings of this assessment are summarised below:

- Chemical characteristics of the materials, while variable, were generally within the range exhibited by the analogue soils within the Project area
- Potential sources of rehabilitation / cover material sampled were generally non-saline, low in plant-available nutrients (similar to analogue soils) and, as evidenced by field observations, were capable of supporting the growth of local vegetation species
- Physical characteristics of the materials were variable, reflecting the range of particle sized distributions present. Hydraulic conductivity of the materials (at 95% of MDD) was highly variable, with drainage classifications ranging from 'Extremely slow' to 'Very rapid'
- Water retention characteristics of the potential sources of rehabilitation / cover material (<2mm fraction) were also variable, with the water content at field capacity (i.e. the amount of water held in the materials after gravity induced drainage has ceased) and the plant-available water content (PAW) ranged from 'low' to 'moderate'
- Results for the WRD samples were variable, with PAW contents ranging from 9.7 to 20.4% (i.e., low to moderate), again reflective of the variable particle size distribution of the WRD samples
- Root growth was classified as either 'many' or 'abundant' in the topsoil layer of all analogue sites as well as all of the rehabilitated sites, except where material had been removed and stockpiled on the TSF (Mine Earth, 2025a). This is a good indicator that the rehabilitated areas are able to support revegetation and are on a trajectory to sustain the required PMLU vegetation types in the long term.

Based on the above summary, the material sampled would not require ameliorants to support and sustain revegetation. The use of fertiliser may assist with plant growth; however it would also likely encourage weed growth which may become problematic.

Appendix B provides detailed characterisation of all the analogue and rehabilitated area samples tested.

During the environmental assessment site visit in 2023, no evidence of soil or sediment contamination was observed on site (EES, 2023).

June 2024

Figure 2-17: Imagery of the Tick Hill TSF vegetation cover over time (Google Earth, 2024)

2.5.4 EXPLORATION

Various exploration campaigns have occurred at Tick Hill since 1995, however there is only minor evidence of historical exploration disturbance on site. This includes rehabilitated drill holes, costeans, and access tracks. Rehabilitation of exploration drilling involved the following:

- Upon completion of drilling, a plastic hole plug was pushed approximately 1.0 m down the hole (typically using the drill rod)
- Back filling the drill holes with drill chips and drill material (Envirofin, 2020).

Any future exploration works will be rehabilitated using the same approach.

2.5.5 PROGRESSIVE REHABILITATION

Progressive rehabilitation will be considered wherever possible, including potential progressive rehabilitation of the TSF. At this point in time however, it is expected that minimal opportunities will arise for progressive rehabilitation prior to closure execution. Therefore it is currently planned that the majority of rehabilitation works will be conducted following final transport of tailings material from site.

Table 2-12 provides a summary of the site features, operational status and progressive rehabilitation balance.

Table 2-12: Progressive rehabilitation

Mine Feature Name*	Approved disturbance area (ha)	Revised Features	Operational Status	Areas rehabilitated (ha)	Areas not yet rehabilitated (ha)
Waste rock dump	6.9	Waste rock dump	Decommissioned and rehabilitated	6.9	0.0
Tailings dam (including decant ponds)	10.89	Decant pond	Decommissioned and rehabilitated	5.0	6.2
Tailings dam reclamation area (part of the 17.4 ha of Tailings Dam)	6.51	Tailings dam	Operational^	0.0	6.2
Open Pit#	3.0	Open Pit	Decommissioned	0.0	0#
Infrastructure (including processing plant area)	6.7	Infrastructure (including processing plant area)	Decommissioned and rehabilitated	7.0	1.1
Borrow pit (part of infrastructure)	0.2	Borrow pit (part of infrastructure)	Decommissioned and rehabilitated	0.2	0.0
Access tracks	2.0	Access tracks	Operational	0.0	3.1
Borrow pits	13.9	Borrow pits	Decommissioned and rehabilitated	7.9	0.0
Exploration	<1	Exploration	Decommissioned and rehabilitated	1.7	0.0
				28.6	16.6
Total PMLU area	48.0			45.2	
Total NUMA area	5.8			5.8	
Total area (PMLU + NUMA)	**51.0**			**51.0**	

Notes:

*As listed in EA EPML00820613

^Assumes area within TSF embankment only will be disturbed

#Area is a NUMA so will not be rehabilitated

3 COMMUNITY CONSULTATION

3.1 STAKEHOLDERS

The key focus of community engagement for the PRCP is the directly affected landowners in the vicinity of the mine and other affected groups include traditional owners, local government, and local businesses. It is the intention of Tick Hill Mining to continue stakeholder engagement in the same manner as previous owners Carnaby Resources.

For the purpose of consultation frequency, key stakeholder groups for THGM have been categorised into tiers according to their level of impact and engagement. Figure 3-1 and Table 3-1 provide the identification and level of impact and engagement of relevant THGM stakeholders.

It is noted that none of the stakeholders are considered sensitive receptors, as they are not in proximity to the THGM site (i.e. they are greater than 500 m away), and as such, are not likely to be directly affected by any operational, rehabilitation or closure activities at the site.

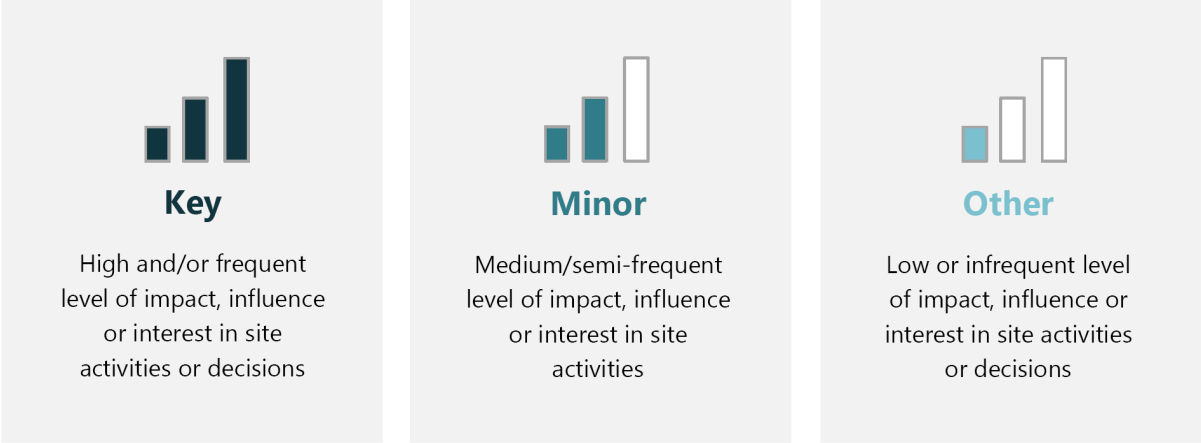

Figure 3-1: Stakeholder classification

Table 3-1: Stakeholder Identification and Categorisation

Category	Identification	Level of impact and engagement
Landholders M.D.H Pty Ltd	Stanbroke Station	Key
	Chatsworth Station	Key
Community	Duchess	Other
	Dajarra	Other
	The Monument	Other
	Cloncurry	Other
	Mt Isa	Other

Category	Identification	Level of impact and engagement
Business operators and employees in the locality	Duchess Hotel	Minor
	Camps/caravan parks	Other
	Schools/daycare	Other
	Hospitality (restaurants, pubs, bars)	Other
	General stores and markets.	Other
Traditional Owners	Yulluna People	Minor
	Kalkadoon Tribal Council	Other
	Kalkadunga Association in Mt Isa	Other
Government	Local: Cloncurry Mayor	Other
	State Department of: • Environment, Tourism, Science, and Innovation • Natural Resources and Mines, Manufacturing and Regional and Rural Development • State Development, Infrastructure and Planning • Transport and Main Roads • Women, Aboriginal and Torres Strait Islander Partnerships and Multiculturalism • Local Government, Water and Volunteers	Other

3.2 HISTORY OF STAKEHOLDER CONSULTATION

A register of previous stakeholder and community consultation has been provided as Appendix H.

Given the small number of stakeholders, the remote nature of the region and the limited site activities, THGM adopt a bespoke approach to stakeholder consultation. This means that the methods, frequency and format of engagement is tailored to the stakeholder, but generally an informal and 'neighbourly' approach, whereby THGM personnel engage freely in a direct manner as required.

For example, a key stakeholder is the landholder - MDH Pty Ltd (MDH), being the operator of Stanbroke Station and Chatsworth Station. The owners of THGM have a formal agreement in place with MDH, the latest being from 13th of October 2021. This agreement spells out responsibilities and rights for operating pastoral activities within the THGM mining leases now, and outlines obligations for both parties now and into the future. There are commitments around ensuring current access and land management activities continue post relinquishment. There are also statements regarding environmental harm and having controls in place, division and access of water and the maintenance of the water pipeline. Communication between both parties has been face to face in a cooperative manner.

In contrast, consultation with parties such as the wider community, business operators, traditional owners and the government have been primarily transactional and targeted towards achieving a specific purpose.

Information has been shared during these transactions, according to the interests and queries of the stakeholders. This may have been because of support for exploration programs, approvals and compliance requirements or other specific purposes.

3.3 COMMUNITY CONSULTATION PROCESSES

Through the community consultation process, THGM will achieve the following objectives:

- Identify, notify and engage the community regarding rehabilitation and closure of THGM, ensuring that the communities wishes in regard to PMLUs are being considered;
- Provide ongoing community consultation throughout the life of the operation to ensure impacts related to mine rehabilitation and closure are communicated and understood;
- Collaborate with the community to identify rehabilitation and closure opportunities and constraints that could influence effectiveness of final land outcomes; and
- Provide a platform for comments and feedback mechanism to ensure closure and rehabilitation goals and expectations are effectively communicated and addressed.

Further detail of ongoing consultation processes and methods is as detailed in Appendix H.

4 POST-MINING LAND USE

The current and adjacent land uses at THGM include low-intensity cattle grazing and some mineral exploration activities. Historically, mining activities and cattle grazing have been the predominant land use. There are two proposed PMLU:

- **Low-intensity grazing** that consists predominantly of native species across the majority of the site
- **Tussock grassland** on the TSF footprint to prevent negatively impacting the proposed TSF capping and cover system.

It is intended that some assets (tracks, water tank, etc.) are to be retained by the landowner following lease relinquishment, however until there is a formal asset transition agreement in place, these assets will require rehabilitation.

The following sections provide the regulatory context, justification, and description of the proposed PMLUs.

4.1 PMLU DEVELOPMENT

A PMLU is defined under Section 112 of the *Environmental Protection Act 1986* (EP Act) as "the purpose for which the land will be used after all relevant activities for the PRCP carried out on the land have ended". Determining the appropriate PMLUs is a critical first step in mine rehabilitation planning. It supports and informs the remainder of the proposed PRCP, including rehabilitation and management strategies, and the PRCP schedule.

Mining is considered as a temporary land use and therefore, it is important to consider a future land use that aligns with social, economic, environmental expectations for the site, as per Section 126C(1)(d) of the EP Act.

The justification for the identified PMLUs is provided in Section 4.1.1.

Criteria for all PMLUs to be adopted for THGM will align to the requirements of the EP Act as described. The EP Act and Regulations contain several additional sections that need to be complied with, as outlined in Sections 4.1.2 and 0.

4.1.1 POST-MINING LAND USE CONTEXT

THGM is remotely located in north-central Queensland. THGM is located approximately 40 km south of the township of Duchess and approximately 140 km southeast of Mt Isa. THGM is currently operated by a non-resident workforce which also service other small operations in the area.

The nearest township is Duchess, a historic location that currently has a population of less than 30 people. This includes the Duchess Hotel, where THGM personnel stay when on site. The town is surrounded by several large grazing properties including Mayfield Station and Stradbroke Station.

Mount Isa and Cloncurry are the nearest regional centres, with both towns over 100 km away by road. The remoteness of the site and the low stocking rates achievable in the region (given the marginal grazing value of the land) suggest that an alternative to the pre-mining PMLU is likely to be sustainable.

The pre-mining land use was low density cattle grazing which is consistent with the general area surrounding THGM. The land has previously been, and is still, leased by Stanbroke Pty Ltd, on a rolling term lease, on a pastoral holding tenure.

There are no obvious tourism or sport opportunities or attractions, the site is not located near a major power network that may support renewable energy production, and there is a lack of local infrastructure required to support a future industrial precinct or opportunity. Additionally, almost all the permanent infrastructure from the original mining operation has been removed. A summary of the PMLU options and selection is provided in Table 4-1.

The proposed PMLU are consistent with the community consultation outcomes (section 4.1.4), relevant planning schemes and strategies (section 4.1.5), plus local and regional cultural heritage aspects (section 4.1.6).

Table 4-1: PMLU selection summary (preferred options shaded green)

PMLU	Description	Selection	Justification
Low-intensity grazing	Revegetation using predominantly native species (trees, shrubs, and grasses)	Yes	Directly aligns with adjacent land uses
Tussock grassland	As above without using deep-rooted species (to maintain TSF cover integrity). Barriers in place to exclude livestock.	Yes	Aligns with vegetation and appearance of adjacent land uses
Cropping / agriculture	Cropping, higher-intensity agriculture, or horticulture	No	Land not suitable. Also limited infrastructure including proximity to general utilities
Tourism	Nature-based tourism	No	Limited infrastructure, population, or alignment with planning schemes
Alternative Energy	Solar, wind or similar alternative energy production	No	Lack of infrastructure including proximity to major power grid/network
Sport	Mountain biking, golf course, etc.	No	Limited infrastructure, population, or alignment with planning schemes

4.1.2 SECTION 111A OF THE EP ACT

In order for a proposed PMLU to be accepted, the PRCP schedule must demonstrate that the land can be rehabilitated to a stable condition in accordance with the following definition from Section 111A of the EP Act:

Land is in a stable condition if:

a) The land is safe and structurally stable; and

b) There is no environmental harm being caused by anything on or in the land; and

c) The land can sustain a PMLU.

This PRCP provides detail of how the above requirements can be achieved for the nominated PMLUs. The background context explains how historically rehabilitated areas inform the transitional, and previously approved, PMLU to be adopted for THGM. Clarity is provided as to how this historic information informs the acceptable land outcomes for the site.

4.1.3 EP REGULATION

The EP Regulations require that each PMLU:

a) Is viable, having regard to the use of land in the surrounding region, and

b) Satisfies at least one of the following:

   i. The use is consistent with how the land was used before a mining activity was carried out on the land;

   ii. The use is consistent with a development approval relating to the land;

   iii. The use is consistent with a use of the land, other than a use that is mining, permitted under a State or Commonwealth Act, including, for example, a planning instrument under the Planning Act; and

   iv. The use will deliver, or is aimed at delivering, a beneficial environmental outcome.

4.1.3.1 TRANSITIONAL PRCP CONTEXT

As previously noted, THGM has an existing EA for mining activities, and has received a transition notice to submit a proposed PRCP that meets the requirements in Sections 126C and 126D of the *Environmental Protection Act 1994* (EP Act).

The PRCP Guideline (DETSI, 2024) highlights that the rehabilitation reforms will not be retrospective, and outcomes agreed in existing approvals will be maintained and preserved. To clarify what has previously been agreed for THGM, approved land outcomes have been explored. These pre-approved land outcomes may be either PMLU or Non-Use Management Areas (NUMA) and will be taken as pre-approved if contained in a 'land outcome document'.

Land outcome documents are defined in Section 750 of the EP Act and are limited to:

a) an EA;

b) a document made under a condition of an EA that:

   i. relates to the management or rehabilitation of land (e.g. rehabilitation and closure plan or residual void management plan); and

   ii. was provided to the administering authority, and had not been superseded, before 30 November 2018; and

   iii. before 15 January 2019, the administering authority had not notified the EA holder that the document was insufficient.

c) a document made under a condition of an EA that:

   iv. relates to the management or rehabilitation of land (e.g. rehabilitation and closure plan or residual void management plan); and

   v. was provided to the administering authority between 20 November 2019 and 30 November 2021; and

   vi. within 20 business days after receiving the document, the administering authority had not notified the EA holder that the document was insufficient.

d) a report evaluating an EIS under section 34D of the *State Development and Public Works Organisation Act 1971*;

e) an EIS assessment report; or

f) a written agreement between the EA holder and the State that is in force on 30 November 2018.

Of the list of potential land outcome documents, only an EA exists for THGM (as per item (a)).

However it is important to note, the EA is partial in nature to only the restricted areas and activities that are currently authorised for the site with limited information as to suitable rehabilitation outcomes for the site.

As such, in developing this PRCP, an approach has been taken to view the previously completed rehabilitation as an intrinsic part of the landscape given the works have nearly 30 years of demonstrated performance. Future rehabilitation efforts for the THGM site will be targeted to ensure consistency with the previously completed rehabilitation.

This approach is further supported by considering the Estimated Rehabilitation Cost (ERC) for the site. Both the spatial information to reflect the historical Rehabilitation Areas (RA) and land outcomes have consistently been provided to DETSI as part of ERC calculations to enable lodgement of Financial Assurance (FA) for the site. As such, the administering authority can be said to be aware of the existence of the rehabilitated areas associated with THGM (including a residual void, as well as rehabilitated WRD area and TSF) and have not previously raised concern about these land outcomes being unsuitable or not authorised. Furthermore, it is understood that DES Compliance Officers have historically inspected the site and the historic rehabilitation.

Further to this, this PRCP illustrates how these historic areas meet a stable condition in line with the contemporary definition and meaning as per Section 111A of the EP Act. The proposed land outcomes are considered to be appropriate within the context of the surrounding environmental, social, and economic context. Further, all land outcomes, including both PMLU and NUMA, will be managed so that achievement of completion criteria can be demonstrated to ultimately relinquish the MLs.

The proposed PMLUs are described in the following parts of this section.

4.1.4 COMMUNITY CONSULTATION FOR PMLU

As outlined in Section 3, the planned PMLU's for THGM have previously been discussed with interested and affected parties, as well as sensitive receptors. It is again noted that the site effectively completed rehabilitation and closure activities almost 30 years ago, and as such, the current arrangement represents an overall post-mining scenario. It is currently the case that the few nearby neighbours utilise the retained infrastructure for their own operations, and agreements have already been entered into to formalise this arrangement.

Current agreements will be amended to reflect any further rehabilitation and closure activities to be completed for the site. It is understood that the key PMLU outcomes will be as already adopted for the rehabilitated mining landforms associated with the site. Consultation has also indicated that neighbouring pastoral operations are likely to agree to a transfer of ownership for existing infrastructure such as access to water and pipeline/pumping facilities.

It has been communicated and is accepted by the community that the residual void will remain with the existing barriers (fence/bunds/rock) in place.

4.1.5 ALIGNMENT WITH RELEVANT STRATEGIES AND PLANS

4.1.5.1 CLONCURRY SHIRE PLANNING SCHEME 2016

Under the Cloncurry Shire Planning Scheme 2016, State Planning Policy and the North-West Regional Plan, the project area has been zoned as 'Rural Land'. The Cloncurry Shire Planning Scheme 2016 states that the purpose of the rural zone is to:

- Provide for rural uses and activities
- Provide for other uses and activities that are compatible with existing and future rural uses and activities, as well as in line with the character and environmental features of the zone
- Maintain the capacity of land for rural uses and activities by protecting and managing significant natural resources and processes.

Furthermore, the Cloncurry Shire Planning Scheme 2016 actively promotes the interplay between mining and low-intensity cattle grazing within the Strategic Frameworks which underpins the regulatory framework within the Scheme. The pursuit of economic opportunities associated with the mining sector are actively encouraged by Cloncurry Shire Council.

The proposed PMLUs are considered appropriate given the surrounding land use are predominately grazing and native vegetation. Given the existing rehabilitated areas have been in place since before the development of these planning schemes, the uses are already part of the character and features of the zone. The return of most of the site to native vegetation and low-intensity grazing will provide beneficial environmental, social and economic outcomes for the region.

4.1.5.2 NORTH-WEST REGIONAL PLAN 2010-2031

The vision for the northwest region is that the '...North West region has a robust, diverse and sustainable economy and well-planned and coordinated infrastructure and services, built through the economic benefits of mining and agricultural industries. It is a place where people choose to live and visit due to its liveability, well-managed natural resources and the community's strong sense of cultural identity' (Queensland Government, 2010).

The North-West Regional Plan presents a set of strategic directions for 2010-2031, and these were reviewed and considered when developing the PMLU for THGM. The PMLUs are consistent with the strategic directions as listed:

- Creating a more sustainable future.
- Protecting regional landscapes and supporting regional production values.
- Creating liveable communities.
- Promoting a dynamic, robust, and diversified economy.
- Providing infrastructure and services.
- Integrating land use, economic activity, and transport infrastructure.
- Adapting to climate change.
- Managing mining growth (Queensland Government, 2010).

4.1.5.3 A STRATEGIC BLUEPRINT FOR QUEENSLAND'S NORTH WEST MINERALS PROVINCE

A Strategic Blueprint for Queensland's North West Minerals Province: supporting strong and prosperous regional communities ('the Blueprint') was produced by the Queensland Government (2017) and is the pre-cursor to the 2019 North West Queensland Economic Diversification Strategy. The proposed PMLU aligns with the following strategic priorities for the Blueprint:

- Facilitating continued resources sector development
- Diversifying the regional economy and creating employment opportunities
- Working with businesses and communities to deliver integrated and appropriate services.

4.1.5.4 NORTH WEST QUEENSLAND ECONOMIC DIVERSIFICATION STRATEGY

The 2019 North West Queensland Economic Diversification Strategy provides a 'plan of action' across four key sectors: resources, agriculture, tourism, and business and industry (DSDMIP, 2019).

A key opportunity in the resource sector is the 'retreatment of mine waste (tailings)' which is currently the primary operation of the site. Additionally, 'innovative technologies' is listed as another opportunity and there are potential alternative industrial uses for the tailings material that are currently being investigated (no further information currently available). The PMLU is consistent with the future economic strategy of the region and directly aligned to several opportunities identified in the report.

4.1.6 LOCAL AND REGIONAL CULTURAL HERITAGE

There were no statutory constraints from Indigenous Land Use Agreements, potential site management plans (contaminated land) or registered heritage places.

4.1.7 CONTAMINATED LAND MANAGEMENT

The Environmental Site Assessment report produced for this PRCP and as an Environmental Evaluation of the site (EES, 2023) (Appendix C) provided the following summary of contaminated land (separate from mine waste contamination):

- No evidence of soil or sediment contamination was observed on site.
- No hydrocarbons or benzene, toluene, ethyl benzene, xylenes and naphthalene (BTEXN) compounds were detected in groundwater at the site.
- Per- and poly-fluoroalkyl substances (PFAS) was detected in most groundwater monitoring bores, and PFAS detections were consistent with the requirement for fire suppression at the mining operation. However, as PFAS with screening criteria were only detected in the mine shaft bore, the potential for off-site impact is considered negligible.
- Perfluorooctanesulfonic acid (PFOS) exceeded the 99% ecological protection criteria at the mine shaft bore but was not detected at any other location. No other exceedances were observed.

It is noted that Lot 13 on SP309109 is on the Environmental Management Register (EMR), as a result of the following notifiable activities occurring, likely associated with the mining operation:

- Engine reconditioning works
- Landfill
- Petroleum product or oil storage
- Mine wastes.

When land is listed on the EMR for a notifiable activity (as is the case for THGM), it is an indication that the land may be contaminated but it does not mean it needs to be remediated or is not suitable for its current land use. This will depend on the nature, extent, and risks of any contamination on the land, which can be determined by engaging a suitably qualified person to carry out a site investigation. This has been considered when proposing the PMLU's.

Lot 16 on SP309110 is not listed on either the EMR or the Contaminated Land Register (CLR).

A review of the monitoring data at closure will determine whether further investigation and/or a Site Management Plan will be required when relinquishment of the MLs is being considered.

4.2 DESCRIPTION OF EACH PMLU

The low-intensity grazing and tussock grassland PMLUs are described in Sections 4.2.1 and 4.2.2 with their locations shown in Figure 4-1.

4.2.1 LOW-INTENSITY GRAZING

This PMLU applies to all site areas except the TSF and the pit footprint. This PMLU aligns directly with adjacent land uses and will target:

- Open woodland grazing environment that achieves the level of Land Class Suitability 3 as per Guidelines for agricultural land evaluation in Queensland (DSITI & DNRM, 2015).
- Native tree, shrub, grass and forb species. The species list will align with the relevant RE in the area (dependent upon seed availability).
- Preferential revegetation of native pasture species to promote low-intensity grazing (e.g. Mitchell grass, bluegrass, and ribbon grass); however naturalised species, such as Cloncurry Buffel grass will be used as necessary to establish ground cover and provide erosional stability.
- The return of the site to grazing land will also provide beneficial environmental outcomes as it will provide both habitat and ecosystem services to native fauna in the area.

4.2.2 TUSSOCK GRASSLAND

This PMLU applies to the TSF footprint and is designed to maintain the long-term integrity of the TSF cover system. The PMLU will consist of the following:

- Native grass, forb, and shrub seed species as the low-intensity grazing PMLU to reduce the opportunity for deeper-rooted species to recolonise the area.
- Additionally, this PMLU will have barriers erected in place (bunds, rocks, fences) to prevent cattle/grazing access but allow safe passage of native fauna.

4.3 REHABILITATION AREAS

The site disturbance areas have been grouped into areas that require a similar rehabilitation treatment that are targeting the same PMLU. The Rehabilitation Areas proposed are summarised in Table 4-2 and shown in Figure 4-2. The rehabilitation and management methodologies for these areas are provided in Section 6.

Table 4-2: Rehabilitation Area summary

No.	Rehabilitation Area	PMLU	Disturbance	Rehabilitated (ha)	Yet to be rehabilitated (ha)	Area (ha)
RA1	TSF	Tussock grassland	TSF footprint (eastern + western cells)	0^	12.4	12.4
RA2	WRD and TSF Decant Pond	Low-intensity grazing	WRD and TSF Decant Pond	11.8	0	11.8
RA3	Infrastructure	Low-intensity grazing	Infrastructure area, ROM, laydown, waste disposal trench, borrow	15.1	1.1	16.1*

No.	Rehabilitation Area	PMLU	Disturbance	Rehabilitated (ha)	Yet to be rehabilitated (ha)	Area (ha)
			pits, water tank, miscellaneous areas			
RA4	Roads and tracks	Low-intensity grazing	Access tracks	0	3.0	3.0
RA5	Exploration, decline and underground workings	Low-intensity grazing	Exploration pads	1.7	0	1.7
Total				**28.6**	**16.6**	**45.1**

Notes:

^ Not all TSF has been recently disturbed, however, it is expected that the majority of TSF will be disturbed during tailings relocation activities

* 16.1 due to rounding up of input values

4.4 REHABILITATION MILESTONES AND CRITERIA

Rehabilitation milestones have been developed for THGM with due consideration for the advanced state of its rehabilitation.

Greater than 50% of disturbed areas on site have been rehabilitated, however the rehabilitation milestones developed for THGM still include the relevant steps necessary to achieve rehabilitation outcomes, i.e. from infrastructure removal through to achievement of a stable condition.

Criteria to measure the achievement of these milestones were developed using the following inputs:

- Risk assessment (acknowledging that all residual risks were assessed as 'low', so the 'moderate' current risks were used to assist milestone development)
- Monitoring data (e.g. groundwater, ecological)
- Recent site investigations (e.g. soils, rehabilitation material)
- Recent modelling studies (e.g. TSF cover design, long-term pit water behaviour).

Wherever possible, monitoring or investigation data from site locations were used to inform the criteria.

Table 4-3 summarises the relationship between rehabilitation milestones, rehabilitation areas, and the PMLU at THGM.

Table 4-4 provides the rehabilitation milestones and criteria as presented in the PRCP Schedule (Appendix A).

Table 4-3: Rehabilitation Milestones, rehabilitation areas and post-mining land uses

Post-Mining Land Use	Rehabilitation Areas	Milestone #	Milestone Activities
Tussock grassland	RA1: TSF	RM1	Infrastructure decommissioning and removal, remediation of contaminated land
		RM2	Minor earthworks and general reshaping
		RM3	Installation of cap / cover on tailings dam
		RM4	Placement of growth medium
		RM6	Revegetation (Tussock grassland)
		RM7	Achievement of surface requirements
		RM8	Achievement of a stable condition
Low-intensity grazing	RA2: WRD and TSF Decant Pond	RM7	Achievement of surface requirements
		RM8	Achievement of a stable condition
	RA3: Infrastructure	RM1	Infrastructure decommissioning and removal, remediation of contaminated land
		RM2	Minor earthworks and general reshaping
		RM4	Placement of growth medium
		RM5	Revegetation (Low-intensity grazing)
		RM7	Achievement of surface requirements
		RM8	Achievement of a stable condition
	RA4: Roads, tracks	RM1	Infrastructure decommissioning and removal, remediation of contaminated land

Post-Mining Land Use	Rehabilitation Areas	Milestone #	Milestone Activities
		RM2	Minor earthworks and general reshaping
		RM4	Placement of growth medium
		RM5	Revegetation (Low-intensity grazing)
		RM7	Achievement of surface requirements
		RM8	Achievement of a stable condition
	RA5: Exploration	RM1	Infrastructure decommissioning and removal, remediation of contaminated land
		RM2	Minor earthworks and general reshaping
		RM4	Placement of growth medium
		RM5	Revegetation (Low-intensity grazing)
		RM7	Achievement of surface requirements
		RM8	Achievement of a stable condition

Table 4-4: Rehabilitation Milestones and criteria

#	Rehabilitation Milestone	Milestone criteria
RM1	Infrastructure decommissioning and removal, Remediation of contaminated land	(a) With the exception of any infrastructure to remain as part of the PMLU or where infrastructure is agreed to be retained by the landholder as evidenced by a signed landholder agreement, the following are complete: i) All buildings demolished and removed ii) All roads decommissioned and removed iii) All boreholes decommissioned (cut and cap method) (b) All rubbish and demolition waste has been removed from the mining lease (c) Contaminated land assessment undertaken by an appropriately qualified person and indicates that contamination has been remediated or is acceptable for the proposed post-mining land use
RM2	Minor earthworks and general reshaping	(a) All major earthworks completed with slopes no greater than 20° and a surface which is free draining with the exception of minor ponding (b) Minor earthworks undertaken to reshape, reduce compaction and scarify areas for revegetation (c) Erosion and sediment control systems placed where needed
RM3	Installation of cap / cover on tailings dam	(a) Certification from an appropriately qualified person that the TSF cover system functions as it was designed including: (b) Review of cover system design, to achieve a net percolation of less than 10% (c) Cover to include 0.3 m compacted clay material plus either ≥1 m of WRD material or ≥1 m of borrow material (or other design as produced by a suitably qualified engineer)
RM4	Placement of growth medium	(a) Growth medium placed at a depth of ≥100 mm where material is available (b) Following growth medium placement, shallow ripping completed at a depth of greater than 100mm (except TSF to be ripped at no more than 100 mm)
RM5	Revegetation (Low-intensity grazing)	(a) Native seed mix applied at a rate ≥5 kilograms per hectare (kg/ha) (b) Key native species are recorded (e.g. *Corymbia terminalis, Eucalyptus leucophylla, E. leucophloia, Acacia* spp. and *Triodia* spp.) (c) Mean native plant frequency > 25 per 10 m^2 (d) Ground cover (live and dead material) is >25%
RM6	Revegetation (Tussock grassland)	(a) Native seed mix contains only shallow-rooted species (e.g. grasses and forbs) (b) Native seed mix applied at a rate ≥5 kilograms per hectare (kg/ha) (c) Mean native plant frequency >50 per 10m^2. (d) Ground cover (live and dead material) is >25%
RM7	Achievement of surface requirements	(a) Weed cover % (not including naturalised species) is within 20% of analogue site weed cover % (b) Mean native plant frequency >50 per 10m^2 (c) Ground cover (live and dead material) is >50% (d) Key native species are recorded in 'Low-intensity grazing'; grass and forb species only are recorded in 'Tussock grassland' (e) No active areas of rill or gully erosion and drainage follows appropriate drainage paths (f) Evidence of native fauna within revegetated areas
RM8	Achievement of a stable condition	(a) A rehabilitation performance review with at least three monitoring events has been completed using the methodology outlined in Section 3.7 of the PRCP

#	Rehabilitation Milestone	Milestone criteria
		(b) No evidence of seepage from any landforms beyond the boundary of the Mining Lease (c) Proportion of Category 3 restricted invasive plant species, as defined by the *Biosecurity Act 2014*, and Weeds of National Significance (WONS), as defined by the "Australian Weeds Strategy 2017 to 2027", are not >10% of total vegetative groundcover (d) Vegetation cover and composition (averaged over monitoring events) are comparable to analogue monitoring locations (i.e. ≥70% of analogue values) (e) Surface water quality results from the pit and the reclaimed TSF footprint (or as the EA requires) comply with: i) pH 6.5-9.0 ii) <10,000 µS/cm EC iii) Suspended solids <4,000 mg/L iv) total cyanide <0.004 mg/L (f) Groundwater quality results from monitoring locations THGW001 to THGW009, plus Mine Shaft bores comply with: i) pH 6.5-9.0 ii) <10,000 µS/cm EC iii) Total dissolved solids <4,000 mg/L iv) <0.004 mg/L total cyanide (g) Overall erosion risk is classified as 'Low' or 'Moderate' as defined by NCST (2009) Australian Soil and Land Survey Field Handbook (4th edition) (NCST, 2024) (h) Geotechnical stability of the pit walls and area behind western pit wall have been assessed by a suitably qualified geotechnical engineer as stable in the long term (i) Hazard and Safety Assessment completed by an appropriately qualified person demonstrates hazards in the rehabilitation area are similar to hazards in neighbouring unmined landscapes subject to a similar PMLU.

5 NON-USE MANAGEMENT AREA

The only proposed NUMA onsite is the pit void area. The pit void area is 3.0 ha and pit surrounds is approximately 2.8 ha, totalling 5.8 ha that is included as the NUMA. The NUMA area is shown in Figure 4-1.

The following sections provide further information on the pit NUMA.

5.1 REGULATORY

The EA EPML00820613 is the only land outcome document for this PRCP, and this EA allows a maximum pit disturbance area of 3.0 ha. The location of the pit is also evident in Figures 1a, 1b, and 2 of the EA.

The administering authority (DETSI) has authorised the existence of a residual void at THGM for almost 30 years and has not requested additional rehabilitation activities to ensure the area is safe, stable, and non-polluting. This is deemed as acknowledgement that the land outcomes are pre-approved for transitional PRCP purposes.

5.2 CONTEXT TO LAND

The closure of the THGM has been previously discussed, as needed, with interested and affected parties over time. Overall, there are few stakeholders who are aware of the residual void, given that it is confined to the area of the resource tenure, in a remote location.

The intent for the pit has always been that it would be retained as a permanent residual void. There is continued exploration interest in the site such that removing the void through backfilling would potentially sterilise the existing resource (or at least make cost prohibitive) to access in the future.

Current compensation and land access agreements reflect that the void will be retained and fenced. These agreements will be amended to reflect any further rehabilitation and closure activities to be completed for the site and to explicitly address future requirements for access to the residual void if a safe arrangement can be made. However, the primary objective for the residual void NUMA is to ensure the current management measures such as fencing and bunding continue to remain in place, so the area remains safe.

The strategies and plans outlined in Section 4.1.5 for PMLUs are just as relevant to the residual void NUMA. The Cloncurry Shire Planning Scheme 2016, State Planning Policy and the North-West Regional Plan all support land uses and outcomes that are compatible with existing and future rural uses and activities, as is the case for the residual void NUMA.

There are no local and regional cultural heritage aspects of relevance to the residual void NUMA. Further, there are no statutory constraints related to potentially contaminated land particularly relevant to the Residual Void NUMA.

The presence of the void has a strong influence on the local groundwater behaviour, as the evaporative demand from the open pit lake results in groundwater being continually drawn toward the pit lake, creating an evaporative sink. This is having a positive impact on the local environmental values and is eliminating a potentially greater risk if the residual void was not in place (had been backfilled) and the area became a source of potential contamination.

The residual void also mitigates the risk of environmental harm associated with elevated concentrations of cyanide seeping from the adjacent TSF (EES, 2023). The groundwater sink establishes a passive groundwater reticulation 'remediation system' that draws the cyanide to the surface of the void lake where it is degraded in sunlight. If the residual void lake was not in place, it is possible that the cyanide would continue to be present in the localised groundwater aquifer and potentially migrate beyond the immediate area and the ML boundaries.

5.3 MANAGEMENT MILESTONES AND CRITERIA

Since cessation of operations in 1995, management of the void has included monitoring and maintenance on the abandonment bund, fencing and access points, plus monitoring of surrounding groundwater. These activities will be continued until ML relinquishment.

The proposed management milestones, milestone references, and milestone criteria for the void improvement area are provided in Table 5-1. Table 5-2 provides the rehabilitation milestones and criteria as presented in the PRCP Schedule (Appendix A).

Table 5-1: Milestones for the non-use management area

Non-Use Management Area (NUMA)	Improvement Areas (IA)	Milestone #	Milestone Activities Required
Residual Void	IA1: Residual Open Pit Void	MM1	Maximum extent
		MM2	Achievement of surface requirements
		MM3	Achievement of sufficient improvement
		MM4	Management of crest zone

Table 5-2: Management milestones and criteria

#	Management milestone	Milestone criteria
MM1	Maximum extent	(a) Maximum NUMA extent no greater than 6ha in size and 70 m in depth.
MM2	Achievement of surface requirements	(a) Confirmation that fencing and abandonment bunds are erected around the perimeter and intact. (b) Warning signage posted at no less than 500 m intervals around perimeter. (c) Adequacy of sealed underground entry at top of pit verified by an appropriately qualified person.
MM3	Achievement of sufficient improvement	(a) At the time of relinquishment of the Mining Lease, certification by an appropriately qualified person body that: i) Residual void water quality and quantity will not cause environmental harm outside relevant tenure boundary ii) Residual void acts as a groundwater sink to the surrounding aquifer system iii) Residual void is safe for humans and livestock iv) The long-term stability of the underground mine layout, and the suitability of all life of mine seals. (b) Water levels within the residual void do not reach the maximum operational WSL (water surface level) of 305 m AHD.
MM4	Management of crest zone	(a) Certification that the area of crest cracking remains within abandonment bund. (b) Geotechnical review completed to verify that pit void is safe, stable and non-polluting.

6 REHABILITATION AND MANAGEMENT METHODOLOGY

6.1 VOID CLOSURE

This section provides the approach to managing the void area to minimise environmental harm in the long term. The residual void has been in a non-operational state for almost 30 years, and it has attained an equilibrium state in this time. There are limited options to design for alternate closure outcomes, or minimise final void area and volume without creating greater disturbance or undesirable environmental impact.

6.1.1 FINAL VOID CONFIGURATION AND DESIGN

The initial pit design was to minimise the residual void extent as much as practical within the constraints of the mining operation (Lewins, 1993). The steep nature of the pit walls and water quality have guided the NUMA designation.

The configuration of the THGM residual void is outlined in Table 6-1. The 3D pit design plan is in Figure 6-1, and a photo showing the void with abandonment bund within the landscape is provided in Figure 6-2.

Table 6-1: THGM Final Void Configuration

Feature	Detail
Land Outcome	NUMA (Residual Void)
Extent of area (to outer edge of abandonment bund)	5.8 ha
Details of pit walls	5 m wide benches at ~20 m intervals. Wall slopes at angle of repose in hard rock
Vertical depth from base to crest, and top elevation	70 m, 340 mAHD
Width across crest	230 m L x 160 m W
Average height and base width of abandonment bund	10 m H and 20 m W
Depth of water body (at equilibrium) and elevation at base	~25 m @265 m AHD
Pit lake surface area and elevation at water surface	0.8 ha @290 m AHD
Exposed pit catchment area (between pit crest and bund)	2.8 ha
Area within pit crest	3.0 ha

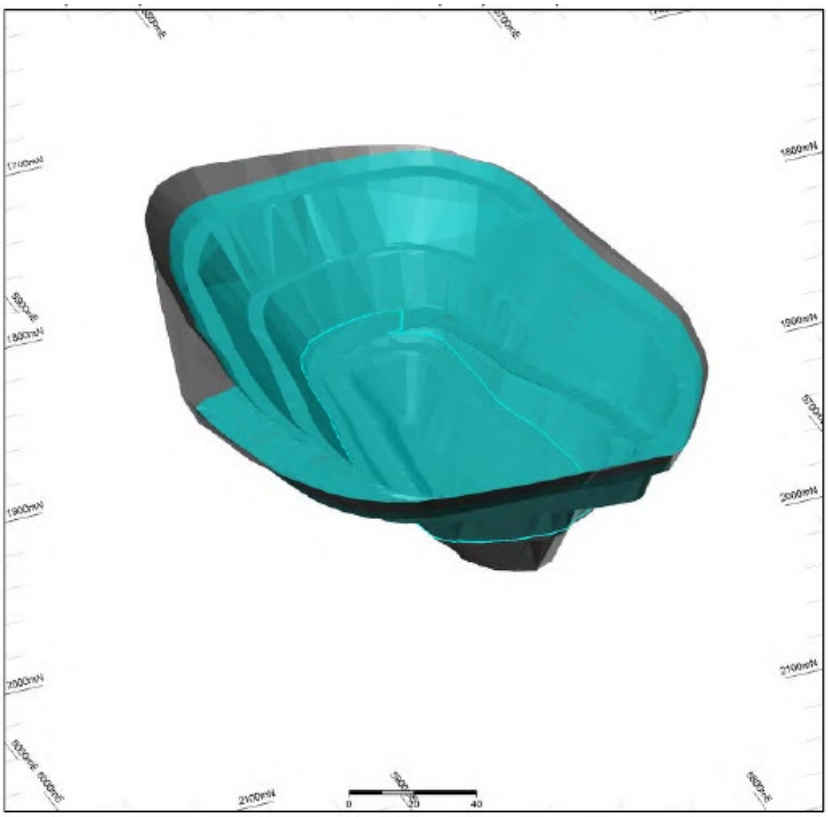

Figure 6-1: 3D model of pit void area

Figure 6-2: Pit area context within the landscape

6.1.2 GEOTECHNICAL STABILITY

The mine pit void has been monitored by an appropriately qualified geotechnical specialist over the years of non-mining. In 2020 a detailed geotechnical study of THGM was undertaken for a potential commercial-in-confidence expansion project (WKG, 2020). This report provided some information on the existing pit, however focused primarily on an altered pit shape and therefore only relevant pages from this report have been provided in Appendix J to maintain confidentiality.

The WKG report (WKG, 2020) did include a pit wall inspection (including the potential failure zone on the north-west wall), inspection of available cores previously drilled, plus review of historical information and records. This study found the following:

- Discontinuity shape/roughness and alteration/infill have not been recorded previously and are thus not expected. Rock quality designation generally agrees with comments regarding shear zones or core loss. This suggests that the initial understanding of the geotechnical characteristics of the TGHM void remain valid.
- Site inspection indicated that the pit was in good condition given the duration of exposure, with little erosional or weathering effects. This was deemed to be indicative of a reasonably high-quality rock mass.
- The observed slippage on the western wall ramp was deemed to be due to crown pillar extraction, above the old underground workings. This failure was likely to have occurred in weathered material and considered to be related to tensile stress forming in the remaining ground bridging above the stopes. Monitoring was established behind the west wall crest, with movement of 1cm recorded over time.
- The current western, northern and southern pit wall are at a batter face angle of 65°, with berm widths of 4m, and an overall slope angle of 52.5°. The current eastern pit wall is at a batter face angle of 56°, with berm widths of 5 m, and an overall slope angle of 44°.
- The geotechnical model calculated rock quality ranging from poor to good, which agreed with direct observations of the pit.

It is noted that entire open pit/residual void area (including the area of slippage on the western wall), is fully contained within the NUMA extent and within the existing abandonment bund. Fencing and signage is also installed to prevent vehicular access and deter livestock access.

6.1.3 VOID WATER QUALITY AND BALANCE

The THGM void is currently at an equilibrium level, with the water level in the pit at approximately 25 m from the pit base of the 70 m pit. Water levels have not fluctuated substantially for many years and have remained within the range of several metres. Water levels in the pit are primarily influenced by rainfall and runoff inputs, evaporative losses and groundwater inflow.

There has been sampling of the void water over time, since operations ceased at THGM. Samples were collected in 2012, 2017, 2020, 2022, 2023, and 2024. The most relevant environmental value for void waters is for stock water, and it is noted that there have been instances of exceedances of ANZECC (2000) stock water guidelines include pH (marginal), aluminium, fluoride, selenium and lead.

Pit water is also strongly alkaline and low/moderate in sulfate as would be expected with a primarily oxide resource with minimal pyritic elements. Increasing levels of cations, sulfate and chloride have also been noted over time, potentially resulting from the extended drought conditions in the region, or perhaps indicative of void water salinity increases over time.

The water chemistry of a mine pit after closure is influenced by a variety of physical, chemical, and environmental factors. Understanding these factors is required for predicting and managing water quality in closed mine pits and ensuring long-term environmental safety. Key factors that were considered to understand the long-term pit water behaviour included:

- Geochemistry of the surrounding rocks including acid metalliferous drainage (AMD) and acid neutralising minerals (e.g. carbonate minerals)
- Groundwater and surface water interactions including influx of groundwater and surface water runoff

- Pit lake hydrodynamics including stratification and mixing
- Climate and precipitation including rainfall and evaporation
- Presence of biological activity including microbial processes and algal growth
- Mining waste and tailings including residual tailings and waste rock piles
- Remediation efforts such as water treatment and material capping (EES, 2024).

Recent modelling demonstrates that the pit water acts as a groundwater sink, is not going to cause harm to environmentally sensitive receptors and will not overtop under extreme rainfall events. Therefore, the management requirements for the pit area include:

- Ongoing monitoring and maintenance of the abandonment bund
- Ongoing monitoring and maintenance of the fence and signage around the pit area
- Ongoing monitoring confirming integrity of the sealed underground entry at the top of pit
- Ongoing monitoring of the geotechnical stability of the area within the abandonment bund
- Ongoing monitoring confirming water levels do not exceed 305 m AHD.

Management milestones and milestone criteria relevant to these management requirements are provided in Section 5.3.

6.2 TAILINGS STORAGE FACILITY

Once the TSF material removal and relocation operation has ceased, the TSF area will undergo the following treatment:

- Identify and demarcate any remaining tailings material areas
- Refine the final landform shape based on remaining tailings material
- Ensure tailings material has been covered by inert waste material
- Reprofile embankment batters into the disturbed TSF area in alignment with proposed cover design
- Cover the disturbed area with an engineered capping system to reduce net percolation
- Apply growth media
- Rip and seed with shallow-rooted species
- Fence area
- Monitor vegetation establishment and development

The following sections provide further information on the capping system and revegetation of the area.

6.2.1 TSF COVER DESIGN SYSTEM

Following the 2024 rehabilitation materials characterisation investigation (Mine Earth, 2025a), a TSF cover design was developed based on the chemical and physical properties of potential rehabilitation materials available on site. The cover modelling was undertaken to indicate the types and potential quantities of on-site material required to reduce net percolation to less than 10%. Review and refinement of the cover design and material sources will be undertaken to understand optimal cost and constructability efficiencies. The modelling report is provided in Appendix I.

The design basis for the engineered cover included:

- Improving current cover performance
- Reducing net percolation to 10% or less
- Final surface able to sustain tussock grassland PMLU

- Target a store-and-release design due to the hot arid climate
- Use material available on site (rather than synthetic barriers such as HDPE)
- Prioritising use of site material over import of material from off-site sources

Water balance and solute transfer/salt dynamic models were developed to support the vadose modelling required to determine the net percolation of various cover material combinations. 1D SEEP/W transient flow analysis was used to model the six different cover scenarios shown in Table 6-2.

The model was run assuming no vegetation which is a conservative approach as vegetation will increase evapotranspiration and subsequently reduce infiltration. The model was set up for 3650 days (10 years) and four hours increments (21,900 steps) were used to run the model (Mine Earth, 2025b).

The base material refers to the existing material below the clay lined base of the TSF. The compacted clay layer parameters (soil characteristics, compaction equipment employed, strength of underlying materials, etc.) were estimated and these will require verification prior to construction.

Compacted clay at a thickness of 0.3 m was deemed a sufficient thickness for a cover. When the thickness was modelled at 0.5 m, there was only a minor net percolation reduction achieved as shown in Table 6-2. The thickness of the material layer in the cover system is not as significant in reducing net percolation as the properties and constructability of the materials (Mine Earth, 2025b).

Table 6-2: TSF cover model scenarios

Scenario name	Base material (m)	Compacted clay (m)	Borrow pit material (m)	Waste rock material (m)	Existing tailings over material (m)	Growth media[1] (m)
0.5CCL+1.5BM+0.2GM	5	0.5	1.5			0.2
0.3CCL+1.5BM+0.2GM	5	0.3	1.5			0.2
0.3CCL+1BM+0.2GM	5	0.3	1			0.2
0.3CCL+1WR+0.2GM	5	0.3		1		0.2
0.3CCL+1TC+0.2GM[2]	5	0.3			1	0.2

Notes: 1. The growth media thickness may reduce once final construction materials have been identified and further assessed.
2. Existing cover system used as baseline in model

The results from the modelling found that all scenarios except the existing cover system achieve a net percolation less than the targeted 10%, as shown in Table 6-3.

Table 6-3: Average annual water balance component of all modelled scenarios

Scenario name	Rainfall[1] (mm)	Infiltration (mm)	Evaporation[1] (mm)	Runoff / Ponding (mm)	Net percolation (%)
0.5CCL+1.5BM+0.2GM	411	36.4	252.6	121.9	4.60%
0.3CCL+1.5BM+0.2GM	411	39.6	250.2	212.1	5.57%
0.3CCL+1BM+0.2GM	411	41	249	121	6.36%
0.3CCL+1WR+0.2GM	411	13	264.8	133.2	1.56%
0.3CCL+1TC+0.2GM[2]	411	79	266.7	65.3	15.49%

Notes: 1. Average rainfall data for analyses period (1981, 1984, 2004-2006, 2008-2010, 2012 and 2013); refer Mine Earth (2025b) for further information.
2. Existing cover system used as baseline in model

The material from the WRD outperforms all other cover scenario analyses with net percolation as low as 1.56%. By replacing the cover, there is at least a 50% reduction in the seepage as indicated by the analysed cover scenarios.

Salinities in cover material including tailings were very low and are not likely to affect vegetation growth. This is evidenced by the existing vegetation on the exposed eastern cell, visible during field sampling, in aerial imagery, and also the soil profile description recording 'abundant root growth' (Mine Earth, 2025a).

The embankments will be shaped to accommodate the required cover design once this has been refined and confirmed.

Information on TSF revegetation is provided in Section 6.6.

6.3 LANDFORM AND COVER DESIGN

Two main landforms have been constructed at THGM: the TSF (including decant pond) and the WRD. It is not confirmed whether the current WRD configuration will remain or whether material will be required for TSF capping. If WRD material is utilised, the remaining WRD landform will be reprofiled to match or improve existing slope angles and geometries, include a 2m cover over exposed sections, tie into the existing topography, and maintain existing drainage paths wherever possible.

The following section considers the landform design and cover system for the TSF.

Landform design was undertaken for both structures when the initial rehabilitation activities occurred (~1995), and the rehabilitated structures have persisted in a safe and structurally stable state since this time. Both areas are well-vegetated in a manner which is consistent with, and becoming integrated into, the surrounding vegetated landscape.

The 'landform design' requirements outlined by the PRCP guidelines (DES, 2023) are intended to explore and predict future landform stability to ensure long-term acceptable performance of landform features.

These requirements are not relevant to the THGM context, given there are no new landforms to be designed, placed or rehabilitated. As such, the requirements of the PRCP guideline as they relate to landform design are not considered to be applicable and have not been considered further.

Cover design specific to the TSF is provided in Section 6.2.1.

6.4 MINE WASTE

Section 2.4.5 provides the background to THGM waste material sampling, characterisation, and storage. The bulk of the waste materials have already been placed when the site was active, almost 30 years ago. The remaining active areas are limited to part of the TSF. The residue tailings material within the TSF is being relocated offsite, therefore there are no specific handling or placement requirements for the management and mitigation of waste streams at Tick Hill.

Capping requirements for the TSF have been outlined in Section 6.2.

6.5 SOIL AND CAPPING MATERIAL ASSESSMENT

An understanding of media suitability (quantity and quality of materials) is required to plan for closure activities and rehabilitation material characterisation was undertaken in 2024 (Mine Earth, 2025a). This report is also provided in Appendix B.

As the site approaches closure, the rehabilitation material inventory and balance will be reviewed to refine and confirm alignment with proposed rehabilitation activities occurring. Additional sampling may be completed to confirm or improve understanding of the quality of materials. This will ensure selection of the best source of growth media and capping materials for rehabilitation, while optimising the location of material. This will also confirm the quality and quantity of materials to provide additional assurance of rehabilitation success.

The areas requiring rehabilitation include the TSF (capping and revegetation), minor infrastructure and access tracks (revegetation) subject to infrastructure retention agreement with MDH and THM.

6.5.1 REHABILITATION MATERIAL CHARACTERISTICS

This section provides the findings from several material characterisation investigations, with the topsoil stockpile and potential borrow locations shown in Figure 6-3.

Information on the rehabilitation material balance is provided in Section 6.5.2.

6.5.1.1 GROWTH MEDIA

Growth media stockpiled on the TSF western cell consists of approximately 14,400 m^3. The material was sampled and analysed in 2023 and 2024 and was summarised as:

- pH indicates that soils are moderately alkaline, with values above pH 8 for all sites
- Predominantly single grained soil with up to 40% coarse rock material, clay content up to 29%
- Non-sodic (ESP was low for all samples) indicating the soils are not dispersive
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Classified as non-saline
- Cation exchange capacity at the high end of the desirable range
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Less than 5 mg/kg cyanide for all samples
- Field observations indicate the stockpiled topsoil material supports the growth of local vegetation.

Further rehabilitation material balance information is provided in Section 6.5.2.

6.5.1.2 SUBSOIL (STORE AND RELEASE) MATERIAL

It is proposed to install a store and release-type TSF cover including a 1-1.5 m layer of material over a compacted clay layer as described in Section 6.2.1. The source for this material includes the WRD, Decant Pond cover and embankment material, plus borrow material from either the northern or southern borrow pits. Information on these various potential rehabilitation material sources is provided below.

Waste rock material

- Single grained to weakly aggregated oxide waste rock with variable coarse competent rock content

- Substantial variability in the texture of the soil sized fraction, with clay content ranging from 2% to 24%
- Samples classified as non-sodic or sodic, with potential for partial clay dispersion in some samples
- Variable hydraulic conductivity (at the measured 95% MDD), with drainage classifications of 'extremely slow' to 'very rapid'
- Variable soil water retention characteristics, field capacity and plant-available water content of the soil sized fraction (>2mm) ranging from low to moderate
- Classified as non-saline. Soil pH classified as strongly alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils.
- Field observations indicate the waste rock supports the growth of local vegetation.

Decant cover material

- Weakly structured to single grained oxide waste rock material with a loose consistence and up to 70% coarse fragment content
- Variable sodicity, ranging from non-sodic to highly sodic. High propensity for clay dispersion
- Drainage classifications (at 95% MDD) of 'very slow' to 'extremely slow'
- Moderate field capacity and plant-available water content
- Classified as slightly saline. Soil pH classified as strongly alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the decant cover material supports the growth of local vegetation.

Decant embankment material

- Weakly structured soil with a loose consistence, approximately 20% clay and 40% coarse fragments
- Minor propensity for clay dispersion upon severe disturbance
- Drainage classification (at 95% MDD) of 'extremely slow'
- Moderate field capacity and plant-available water content
- Field observations indicate the decant embankment material supports the growth of local vegetation.

Borrow area material

- Single grained to massively structured sandy clay material (up to 22% clay) with variable coarse fragment content, up to 31%
- Non-sodic, with a low propensity for clay dispersion
- Drainage classification (at 95% MDD) of 'extremely slow'
- Moderate field capacity and plant-available water content
- Classified as non-saline. Soil pH classified as neutral
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the potential borrow material supports the growth of local vegetation

The characterisation assessments above demonstrate the findings that materials sampled as part of 2024 investigation were considered a valuable source of potential rehabilitation / cover materials for use in mine closure (Mine Earth, 2025a).

6.5.1.3 LOW PERMEABILITY LAYER FOR CAPPING

A low permeability layer is proposed in the TSF cover design (Section 6.2.1). This layer is based on material with a higher clay percentage – such as that found in the borrow pit areas (up to 22% clay). Once placed, it is intended that the clay layer be compacted by the operating machinery at the time. Further refinement of compaction requirements will be required with the TSF cover final design to be completed prior to construction.

In order of preference, the following potential material locations have been identified:

- Northern borrow area – previously opportunistically stripped for clay materials used to construct the Decant and TSF. Recent testing suggests material still contains up to 29% clay increasing with depth
- Southern borrow area – also understood to have been utilised as a suitable source of natural clay materials in the past. Recent testing suggests material still contains up to 29% clay increasing with depth
- Decant pond – previously constructed clay core dam wall structure as a potential source of clay material. An estimated total of 15,000 m^3 is available however cross-contamination with decant pond material may have occurred to a level that is deemed unusable. Further investigation will be undertaken once a final cover design is confirmed.

6.5.1.4 SUITABILITY OF SOILS TO SUPPORT PMLU OUTCOMES

The suitability of growth media materials to support the establishment of native plant or grazing species has been assessed. This has considered a range of common plant nutrition indicators, with sufficiency criteria developed from a range of reference texts against which the growth media quality was investigated. It is also noted that in the arid surrounds of THGM, it is common to have undisturbed environments with skeletal or minimal topsoil (<100 mm).

As such, it is considered that topsoil is not essential to ensuring rehabilitation success for the proposed PMLUs. Review of the suitability of capping materials will occur immediately prior to rehabilitation works, by an appropriately qualified person, and may require additional sampling to confirm suitability for the intended use.

6.5.1.5 NEED FOR AMELIORANTS AND FERTILISERS

Growth media materials stockpiled for use do have some quality limitations but are generally acceptable for use as is. Given that the cation exchange capacity (and saturation rates for Ca and Mg) are at the higher end of the range, fertiliser application are not likely to improve plant response. It is considered that the current nutrient status is approaching potential fertility for the bioregion.

The addition of organic material (e.g., hay mulch) may be worthwhile, however it is noted that the presence of a grassy cover crop, and high biomass annual and perennial grass species in the seed mixture, would likely bolster organic carbon anyhow. Use of top surface/growth media materials from borrow areas (which incorporate the ground vegetation also stripped) are also likely to improve additional organic material.

Review of the required ameliorants and fertilisers for each rehabilitation area, and borrow source, will occur immediately prior to rehabilitation works, by an appropriately qualified person. This may require some additional sampling to confirm the suitability of material for their intended use as a growth media or capping material.

6.5.2 REHABILITATION MATERIAL BALANCE

A preliminary soil resource inventory has been developed to provide an indicative volume of topsoil and subsoil (store and release) materials likely to be available for salvage from the previously disturbed areas. The volumes have been calculated based on the information derived from the soil survey conducted, aerial and landscape photography, site topography and the conceptual project disturbance layout, and include a 10% soil loss factor during salvage / stockpiling operations.

The disturbance area requiring a growth media layer across the site is 12.5 ha. Placing topsoil at 100 mm depth will require a volume of approximately 25,000 m^3. Utilising material won from other areas such as the borrow material location will provide sufficient material to adequately provide a topsoil/growth media layer on all areas to be rehabilitated.

It should be noted that this is a conservative calculation as access tracks and laydown areas only require ripping and seeding as it is likely there is some residual *in-situ* topsoil or subsoil material remaining on surface. This approach has been used successfully for previous infrastructure areas rehabilitated on the site.

A nominal stripping depth of 0.2 m was utilised for topsoil calculations and a nominal salvage depth from 0.2 to 1.0 m for subsoil (store and release). Clay material from the borrow areas is assumed to be salvaged from a depth of 1.0 to 1.5 m. At this time it is not planned to disturb previously undisturbed areas to access rehabilitation material.

Competent rock material is not required in closure current rehabilitation activities, however there is a considerable volume within the WRD if this material was required.

The inventory has considered use of borrow material for the TSF capping material as all materials (growth media, store and release material, and clay material) are all available in these two locations. Additionally, the borrow areas are preferred as it is estimated that they contain a greater volume of clay material than other areas.

This rehabilitation material balance will be updated as the Project footprints are finalised and the actual volume of topsoil salvaged from each disturbance area is identified. This should then be updated within the inventory and balanced against the volume of soil required for rehabilitation works, to facilitate optimal application of soil resources to rehabilitation areas. Table 6-4 provides a summary of the rehabilitation material balance and Table 6-5 presents the material requirements. Further information on the material characterisation is provided in Appendix B. Information on rehabilitation material requirements regarding the TSF cover are provided in Section 6.2.1 and Appendix I.

Table 6-4: Rehabilitation material available

Feature	Approximate area available (ha)	Topsoil volume (m^3) [1]	Subsoil material (m^3)[2]	Clay material (m^3)[3]	Potential growth media (m^3)[4]
Borrow Pits (northern and southern)	7.8	14,040	56,160[5]	35,100	42,120
Decant Pond	5	9,000	9,000	13,500	27,000
Tailings cover[6]	8	14,400	0	0	43,200
Waste Rock	6.9	12,420	55,200	0	37,260
Total	**27.9**	**49,860**	**127,600**	**48,600**	**149,580**

1. Assumes average topsoil salvage depth of 0.2m and 10% soil loss factor during salvage / stockpiling operations.
2. Additional subsoil material available if required, assumes average subsoil salvage depth of 0.2 to 1.0 m and 10% soil loss factor during salvage / stockpiling operations
3. Assumes salvage depth of 1.0-1.5 m and 10% soil loss factor during salvage / stockpiling operations.
4. Based on 1:2 ratio of topsoil:subsoil material
5. Additional material is available laterally and/or at depth
6. Includes blend of topsoil and upper-layer tailings cover material

Table 6-5: Rehabilitation material required

Feature requiring rehabilitation	Area (ha)	Growth media (m^3)	Store and release cover material (m^3)	Clay material (m^3)
TSF	8	16,000	120,000	24,000
Roads and tracks	3.5	7,000	0	0
Infrastructure	1	2,000	0	0
TOTAL	**12.5**	**25,000**	**120,000**	**24,000**

6.6 REVEGETATION

A plan for revegetation is summarised in this section and is focused on the remaining disturbed areas at THGM, where rehabilitation (and revegetation) activities are required.

6.6.1.1 REVEGETATION OBJECTIVES

The revegetation objective at THGM is to establish self-sustaining ecosystems that achieve their respective PMLUs. The goals for revegetation at THGM are:

- Rehabilitated areas support revegetation of plant species known to occur on similar landforms and on similar soils
- Local native species are preferred for revegetation
- Vegetation is sustained after rehabilitation and closure activities are completed
- Grazing capacity of the post-mining land area is the same or better than the surrounding grazing areas.

6.6.1.2 PLANT SPECIES SELECTION

For the areas to be revegetated at THGM, both pasture plant species and native understory species that are considered appropriate for use. It is noted that all infrastructure areas are to be returned to a Grazing Native Vegetation PMLU, and as such, pasture species are preferrable. In addition, the areas requiring revegetation to a Native Vegetation PMLU at THGM is limited to the TSF, and for this location, seeding of tree and shrub species is not desirable due to potential negative impact on the cover system. For this area, a mixture of pasture and native understorey species are preferred.

The selection of suitable flora species has considered regulatory constraints relevant to the site, the surrounding land use, and the capacity of the available growth media resources at the time of revegetation to support the selected species. It will allow for a resilient vegetation adapted to the conditions, while providing habitat and grazing values.

Table 6-6 presents a list of preferred plant species used in revegetation. It is intended that THGM will consider this list as options to be selected from, to make up an intended seeding rate of ≥ 5 kg/ha.

Table 6-6: Seed Mix for THGM

Post-mining Land-Use	Rehabilitation Areas	Scientific Name	Common Name	Vegetation Type
Low-intensity grazing	RA2, RA3, RA4, RA5	*Acacia cambagei*	Gidgee	Tree

Post-mining Land-Use	Rehabilitation Areas	Scientific Name	Common Name	Vegetation Type
		Malvastrum americanum	Malvastrum	Forb
		Medicago spp.	Burr Medic	Forb
		Psoralea tenax	Emu Foot	Forb
		Solanum esuriale	Potato Bush	Forb

6.6.1.3 REVEGETATION ACTIVITIES

The steps to revegetating all disturbed areas, except the TSF surface, are as follows:

- Complete general earthworks and erosion structures in the area to be revegetated
- Place growth media at a depth of ≥100mm where material is available
- Shallow ripping completed at a depth of greater than 100 mm on all areas requiring revegetation except TSF. The TSF is to be ripped at no more than 100 mm to reduce potential damage to the cover system
- Seeding using the seed mixes outlined in Section 6.6.1.2 and presented in Table 6-6

The additional considerations necessary for revegetating the TSF surface are provided in Section 6.6.1.4.

6.6.1.4 TSF REVEGETATION

Revegetation of the TSF is as per Section 6.6.1.3, however growth media depth would preferentially be 100 – 200 mm depth. Additionally, and importantly to maintain the integrity of the engineered cover system, it is proposed that the TSF area is revegetated with only shallow-rooted species – predominantly grasses and forbs, with no tree and shrub species included in the seed mix.

There is a potential for deep-rooted species such as shrubs and trees to reduce integrity of the TSF cover that subsequently promotes infiltration. Grasses are already known to colonise the TSF at THGM, and the further selection of native grass species will support natural colonisation.

Additionally, and to maintain integrity of the engineered cover, shallow ripping at no more than 100 mm depth, will be undertaken following placement of the capping material. Seeding will take place after this.

6.7 UNDERGROUND

Infrastructure and activities to support underground mining at THGM occurred in a region to the north-west of the residual void and commenced in 1992 with the installation of a ventilation shaft. This shaft was blind drilled from surface to 250 m depth, with a finished diameter of 2.6m. Once drilling and lining was completed, the shaft was equipped with a ladderway and air, water, and drainage lines from the surface to the base depth of the shaft.

Return air circuits were established and supported subsequent development of the underground decline. The surface portal was established 25 m below the surface, off the open cut haul road at the top of the pit. The decline is designed at 4.5 m wide and 4.8m high, with an overall slope of 1.8. The underground stope void is continuous with the base of the open cut pit/ residual void.

As part of closure activities that occurred in 1995, the portal to the underground has been sealed off. Potential access via the base of the pit is also restricted due to the recovery of a 25 m deep pit lake.

Detail of the underground workings is shown in a conceptual site model for THGM provided in Section 2.4.6.5 as Figure 2-16.

6.7.1 REMOVAL AND DECOMMISSIONING OF INFRASTRUCTURE

Given that sealing has already occurred, the portal will be retained as part of the sealing structure. It is also proposed for the vent shaft to be retained, as it is the key mechanism by which the water level in the final void can be managed. These have both been in place 'as is' since 1995 and are located within the NUMA extent.

6.7.2 SURFACE IMPACTS

No ground subsidence has been evident over the area mined, which consists of both the open void and the decline to the north-west. Given that underground mining ceased, and the mine closed in 1995, it is expected that any surface subsidence would be apparent by now. No further ground subsidence is expected at THGM. No water ponding above the underground workings is evident, and there is no apparent impact on stream flows due to THGM.

However, the surface area associated with underground mining has been allocated to a unique rehabilitation area and will be subject to monitoring to verify that no surface impacts (such as subsidence) are occurring prior to relinquishment.

6.7.3 SURFACE CRACKING

It is noted that historical slippages have occurred on the north-western face of the residual void, including a section of the pit crest, due to removal of the crown pillar as part of the underground workings. This has resulted in minor cracking, which is wholly contained within the abandonment bund.

THGM have sought advice from an appropriately qualified geotechnical specialist, with the conclusion that, given that the area is wholly within the current abandonment bund, it poses little risk to the safety of people or animals, and did not warrant intervention (WKG, 2020). This area will be subject to ongoing monitoring to verify that the surface cracking area is following current predictions, prior to relinquishment.

6.7.4 VEGETATION IMPACTS

Subsidence above the underground mining areas has either not occurred, or has not resulted in any direct visual indicators, such as impacts on vegetation. Vegetation cover and composition is observed to be generally similar to outside of the surface areas above the underground workings. Grazing practices are considered more likely to have had a greater impact on vegetation than the underground workings.

6.8 BUILT INFRASTRUCTURE

All remaining infrastructure utilised by THGM will either be decommissioned, demolished, salvaged and/or disposed, except where formally retained by an appropriate stakeholder (e.g., tracks, tanks and pipelines), where it is consistent with the PMLU after the completion of rehabilitation and closure for the site. Demolition planning and execution will be undertaken in accordance with relevant standards, policies and legislation requirements, and will include investigation of the site and surrounding aspects.

All infrastructure is to be decommissioned, removed from the site, and the associated disturbance rehabilitated at closure, unless written approval by landowner/new landowner is obtained. There is an expectation that infrastructure such as pumps, pipelines, bores, tanks, tracks and fences will remain at closure and be handed over to the relevant landholder. However, until the agreement is confirmed and for the purposes of this PRCP, all infrastructure will be rehabilitated. Once infrastructure has been removed, any areas of contamination will be remediated, and the areas will then be revegetated as per the requirements of the PMLU.

7 RISK ASSESSMENT

The objective of the PRCP risk assessment is to identify and assess potential failures or risks that could lead to rehabilitation and closure activities not achieving a stable condition. Consideration has also been given to the risk of management measures proposed for the NUMAs not being effective, resulting in environmental harm. The assessment also provides a framework for mitigating those risks before they become an issue.

7.1 RISK FRAMEWORK

7.1.1 RISK IDENTIFICATION

Risk identification refers to the process of detecting, recognising, and describing sources of risks. Therefore, characterising potential hazards, threats or uncertainties that could negatively impact the completion of milestones and affect the success of the post closure and rehabilitation outcomes. Risks identified have also included those that are out of THGM's control such as weather. Once the risks have been identified, potential consequences, flow-on and cumulative effects have been examined.

As the PRCP Guideline states, 'the objective of this step is to create a comprehensive list of risks based on events, which may impede, enhance, delay or accelerate the rehabilitation of land to a stable condition or the potential for environmental harm and inability of a NUMA being safe and structurally stable'.

7.1.2 RISK ANALYSIS

Risk analysis involves the systematic assessment and evaluation of the identified risks to determine their potential impact. The analysis identifies a cause and/or source of risk and a magnitude of consequence. The analysis then helps to prioritize risks based on their significance and provides a basis for decision making and risk mitigation strategies. The analysis finally elaborates on assumptions made to gain a high level of confidence for the risk outcome.

7.1.3 RISK EVALUATION

Once an analysis has been completed for the identified risks, they have been prioritised and managed accordingly. This step involves comparing the level of risk found during the analysis process and using this to determine the need of risk treatment.

7.1.4 RISK TREATMENT

Risk treatment refers to the process of selecting and implementing measures to address and mitigate identified risks. The treatment option has been selected after consideration of multiple factors including cost benefit, regulatory obligations, social responsibility, and protection of the surrounding environment. The PRCP Guideline states, 'the risk treatment step in the risk assessment must detail:

- The reasons for selecting the treatment option;
- Those responsible for the approval and implementation of the plan;
- Proposed actions;
- Resource requirements;
- Performance measures and constraints;
- Reporting and monitoring requirements; and
- Timing and scheduling'.

7.2 RISK ASSESSMENT

The risk assessment refers to the specific rehabilitation and management milestones as proposed within the PRCP schedule. This process has considered how potential risks, controls and events could affect the ability of land being rehabilitated to a stable condition; or being managed as a NUMA.

This has influenced the milestones and milestone criteria, as well as informed the timing and scheduling of activities for the PRCP schedule. The results of the risk assessment are as provided in Table 7-1.

7.3 REHABILITATION TRIALS

THGM rehabilitated the site almost 30 years ago, and hence the successful performance of the rehabilitated areas has been shown through observation and monitoring. Rehabilitation and revegetation processes were actively trialled through on-ground application.

Further dynamic adjustments will be made for the remaining rehabilitation areas, with the benefit of this further experience as to positive practice both from the site, but also from leading practice experience and knowledge of those specialists involved. In addition, the findings from monitoring of completed rehabilitation areas at THGM will inform ongoing rehabilitation practices for the site.

Table 7-1: THGM closure risk assessment

Item No.	Milestone Reference	Identification	Potential risk event/ incident	Cause	Consequence	Likelihood	Current Level of Risk	Treatment Plan (new or improved controls)	Reasons for Selecting Treatment Option	Responsibility	Proposed Actions	Consequence	Likelihood	Level of Residual Risk	Resource Requirements	Performance Measures and Constraints	Reporting and Monitoring	Timing and Scheduling
1	MM1	Maximum extent	Maximum NUMA extent becomes greater than 6ha in size and 70 m in depth exceeding criteria.	Ongoing erosion, extreme flooding event, highwall collapse.	2 - Minor / Short Term Impact	E - Rare	3 Low	Continue to undertake geotechnical review and assessment as needed to inform void stability and capability, triggered in response to changes in pit conditions. Maintain geotechnical observation / monitoring until tenure relinquishment.	Assessment will confirm void stability from a specialist.	THGM	Existing geotechnical assessment confirms that failure/slippage areas are wholly contained within abandonment bund. No anticipated concerns with void stability and capability.	1 - No Impact	E - Rare	1 Low	Appropriately Qualified Person - geotechnical Void and underground designs and details	Geotechnical assessment report	Initial report and ongoing monitoring.	Report before relinquishment and as required monitoring.
2	MM2	Achievement of surface requirements	Sealed underground entry at top of pit subsides, creating an opening to the underground.	Original seal may not meet contemporary standards. Erosion or pit wall failures may cause opening to subside.	2 - Minor / Short Term Impact	C - Possible	8 Moderate	Verification of formerly sealed underground entry at top of pit to confirm suitability of seals, by an appropriately qualified person. Confirmed that sealed underground entry is wholly within NUMA extent, and as such area is restricted.	Verification by an AQP will confirm suitability of seals.	THGM	Arrange specialist to inspect and report on the sealed underground entry for stability, and develop additional control measures if required.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person - geotechnical Void and underground designs and details	Geotechnical assessment report	Initial report and ongoing monitoring.	Report before relinquishment and as required monitoring.
3	MM2	Achievement of surface requirements	Fencing, signage and gates are damaged, or non-existent, causing injury to human, cattle and/or wildlife via falling into pit void.	Fencing is damaged during nearby rehabilitation efforts or access attempts by vehicle or personnel. Gates are left open, other factor e.g, vegetation, animals or weather events damage fencing, signage and gates allowing humans, cattle and wildlife to freely walk into restricted pit void area.	1 - No Impact	D - Unlikely	2 Low	Maintain existing fence, gates and signage around the void. Warning signage posted adjacent to access tracks.	Existing treatment is effective and should be maintained.	THGM	Undertake inspections of fencing, gates and signage, and report and maintain	1 - No Impact	E - Rare	1 Low	Appropriately Qualified Person	Inspection Checklist	Ongoing monitoring on an ad hoc basis, and/or during annual rehabilitation monitoring.	Prior to relinquishment.
4	MM3	Achievement of sufficient improvement	Mine pit water has potential to cause impact to groundwater. Consequently impacting nearby human or ecological receptors.	Seepage or inflow from pit into surrounding groundwater system.	2 - Minor / Short Term Impact	E - Rare	3 Low	ESA completed in 2023 confirms that Pit Void currently acts as a groundwater sink, based on current pit water chemistry and water balance. Also confirmed that pit will continue to act as a groundwater sink under all feasible climate change scenarios. Location of potential impact (base of weathering) also well known and used as a pit level control trigger. No current known nearby receptors.	No further actions required.	THGM	Alert if water is increasing to the base of weathering.	1 - No Impact	E - Rare	1 Low	Qualified surveyor. Database for reporting results.	Report results to Carnaby Resources.	Maintain records.	Annual
5	MM4	Management of crest zone	Geotechnical failure/ slippage. Major structural slope failure causing impacts outside of predicted zone of influence (exclusion / safety fence) and impacting land use or intercepting overland flow from an adjoining watercourse/ floodplain.	Obtain causes of failure modes from geotechnical engineer, e.g. insufficient buttressing, failure along fault plane, etc.	3 - Moderate / Medium Term Impact	D - Unlikely	9 Moderate	Geotechnical review confirmed that pit crest cracking due to removal of the crown pillar from underground workings, and unlikely to result in further failure. Confirm signoff from AQP that design and rehabilitation treatment, including applied safety zone (fenced area), meets design intent and is considered to be geotechnically safe and stable Maintain geotechnical observation / monitoring until tenure relinquishment	Sign-off provides pathway for design intent (including consideration of slope failure) to be met	THGM	Continue geotechnical reviews as needed to inform void stability and capability, triggered by change in pit conditions.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person - geotechnical	Inspection report	Maintain records	As required
6	RM1	Infrastructure decommissioning and removal, Remediation of contaminated land	Temporary infrastructure decommissioning is left behind with potential residual contamination.	Inappropriate handling/disposal of hazardous materials Lack of clarity regarding asset decommissioning prescription Lost opportunities for recycling and reuse	2 - Minor / Short Term Impact	D - Unlikely	5 Low	Identify any infrastructure items requiring special treatment, e.g. process chemicals, hazardous substances, energised assets Waste to be disposed using a legally acceptable option	Plan selected to facilitate comprehensive removal of infrastructure and appropriate waste disposal pathway	THGM	Arrange inspection of areas once removal has taken place to confirm treatment plan has been met	1 - No Impact	D - Unlikely	2 Low	Appropriately Qualified Person	Sign-off by Inspection Agent	Maintain records	As required
7	RM1	Infrastructure decommissioning and removal, Remediation of contaminated land	Unknown contaminated land area not meeting target remediation outcome	Contamination not identified, and/or inadequate contamination clean up.	2 - Minor / Short Term Impact	D - Unlikely	5 Low	No evidence of soil or sediment contamination was observed on site. Ensure capping is sufficient at tailings and the waste facility to stop potential contamination.	Aim to prevent potential contamination liabilities are avoided	THGM	Arrange contaminated land assessment undertaken by an appropriately qualified person, and indicates that contamination unsuitable for the post-mining land use is occurring.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person	Sign-off by Inspection Agent	Maintain records, monitor annually with rehabilitation monitoring.	Prior to relinquishment.
8	RM1	Infrastructure decommissioning and removal, Remediation of contaminated land	Boreholes are not decommissioned/rehabilitated leading to groundwater contamination with fertilisers, pesticides or other pollutants. Abandoned boreholes can also cause a physical hazard to humans and wildlife, and may cause sinkholes in the environment.	Existing boreholes are left unmaintained and/or abandoned.	2 - Minor / Short Term Impact	D - Unlikely	5 Low	All boreholes decommissioned (cut and cap method).	The decommissioning process remove the hazard.	THGM	Arrange to have all boreholes decommissioned (cut and cap method), prior to relinquishment.	2 - Minor / Short Term Impact	E - Rare	3 Low	Drill rig, specialist equipment and people to undertake borehole decommissioning works.	Sign-off and inspection post works.	Completion report	Prior to relinquishment.
9	RM2	Infrastructure retention for handover	Infrastructure is retained without clear no transfer of ownership. There has been no upkeep of infrastructure. Upon relinquishment ensure the agreements are valid.	Lack of agreements.	2 - Minor / Short Term Impact	E - Rare	3 Low	Permanent infrastructure has been removed (except roads and water infrastructure) unless useful and desirable to landowner.	Currently already a process in place.	THGM	Ensure any infrastructure not retained is removed prior to transfer of ownership, except where an agreement is in place. Undertake inspection, any infrastructure that has not been removed must have an agreement in place.	1 - No Impact	E - Rare	1 Low	Appropriately Qualified Person	Sign-off by responsible manager.	Maintain records	Prior to relinquishment.
10	RM4	Installation of cap / cover on tailings dam	Contamination to surrounding environment from insufficient capping of tailings.	Tailings landform design inadequate.	2 - Minor / Short Term Impact	C - Possible	8 Moderate	Modify tailings cover design to prevent infiltration.	Design will be modified to prevent infiltration, thus reducing migration of contaminants to surrounds.	THGM	Modify tailings design to prevent infiltration. Incorporate an LPL into cover for area disturbed.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person - with experience in geochemistry and cover design Quality assurance processes (Surveyor)	Sign-off by an appropriately qualified person	Quality assurance processes (Surveyor) Signoff on completed Tailings Dam rehabilitation.	Once capping of Tailings Dam is complete.
11	RM5	Placement of growth medium	Growth medium quality not suitable for vegetation establishment, revegetation failure or reduced growth Decline in soil structure, nutrient bank and soil biota	Limited pre-existing biological resource Insufficient salvage of topsoil resource Decline in condition of stockpiled resource Incorrect amelioration applied	2 - Minor / Short Term Impact	C - Possible	8 Moderate	Amelioration (fertiliser, pH adjustment) in accordance with laboratory testing results.	Laboratory testing determines amelioration required	THGM	Scope and arrange testing of growth medium at time of rehabilitation . Growth medium placed at a depth of ≥150mm. Soil ameliorants and fertilisers applied as required to address soil limitations identified. Shallow ripping completed at a depth of greater than 100mm after growth medium placement.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person Soil Scientist	Sampling and analysis.	Action any areas that indicate unsuitable amelioration has taken place	As per rehabilitation schedule
12	RM8	Achievement of a stable condition	Downstream water quality is effected by surface runoff quality causing downstream impacts.	Sediment or contaminant migration from mine affected areas, resulting in impact to receiving environment.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriate capping of tailings dam and rehabilitation waste rock dump. Revegetation of all surface disturbance areas as per PMLU outcomes. Review of regional and downstream surface and groundwater quality does not indicate any impact or migration of contaminants off site.	Capping and rehabilitation will appropriately manage surface run-off.	THGM	Confirm suitability of tailings capping for reducing infiltration. Have AQP inspect rehabilitation once complete.	1 - No Impact	E - Rare	1 Low	Appropriately Qualified Person As-constructed plan for Tailings Dam.	Sign-off by an appropriately qualified person	Maintain rehabilitation records	Once capping and rehabilitation is complete.
13	RM8	Achievement of a stable condition	Extreme rainfall event, causing rehabilitation failures. Extending relinquishment timing.	Climate change or natural variability	2 - Minor / Short Term Impact	D - Unlikely	5 Low	Maintain rehabilitation monitoring and maintenance program to achieve rehabilitation success criteria. Follow standard design criteria.	Monitoring and maintenance allows for timely correction if required.	THGM	Scope and arrange annual rehabilitation monitoring Action all areas that require maintenance	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person	Rehabilitation Monitoring Report	Rehabilitation Monitoring	As required
14	RM8	Achievement of a stable condition	Extended drought, causing revegetation failure, accelerated erosion, and /or wild fire. Extending relinquishment timing.	Climate change or natural variability	2 - Minor / Short Term Impact	D - Unlikely	5 Low	Maintain bushfire management measures, use appropriate species mix, maintain fire breaks around establishing rehabilitation areas. Select drought tolerant native species (preferably sourced locally) within the seed mix.	Plan provides for resilience of site rehabilitation in face of bushfire risk or drought	THGM	Establish vegetation communities that are resilient to drought and fire. Maintain firebreaks.	2 - Minor / Short Term Impact	E - Rare	3 Low	Appropriately Qualified Person	Composition of species within rehabilitated areas Exclusion of fire until the vegetation community is mature	Rehabilitation Monitoring Monitor firebreaks	As required
15	RM8	Achievement of a stable condition	Rehabilitation that is not comparable to analogue monitoring locations (so as to meet criteria).	Impact from stock, pests, weeds, erosion, contaminants or natural disaster.	2 - Minor / Short Term Impact	E - Rare	3 Low	Maintain annual maintenance and monitoring program and implement maintenance or remedial activities as required. Exclude stock from areas where native vegetation is proposed as the PMLU. Manage stocking rates for areas proposed to have a PMLU of grazing.	Ongoing monitoring will identify poorly performing rehabilitation early.	THGM	Implement rehabilitation monitoring	1 - No Impact	E - Rare	1 Low	Appropriately Qualified Person	Sign-off suitably qualified person	Rehabilitation Monitoring	As required

8 MONITORING AND MAINTENANCE

Rehabilitation monitoring for THGM has been previously undertaken irregularly but at intervals that demonstrate progression towards the desired closure outcomes for the site.

No baseline assessments are available to illustrate the initial conditions of the site as mining commenced in the early 90's. The baseline assessment would normally include information on vegetation, soil quality, water quality, and wildlife populations. These data serve as a pre-mining reference point for measuring the success of rehabilitation efforts in future. As an alternative, areas of rehabilitation will be compared to analogue sites.

The primary objective of the rehabilitation monitoring program is to produce concise and targeted rehabilitation datasets using scientifically robust and repeatable methods which demonstrate compliance to the PMLUs and provide evidence that the milestone criteria have been met. Rehabilitation monitoring allows for adaptive management, meaning that the collected data are used to adjust and refine the rehabilitation strategies and techniques. If any issues or challenges are identified through monitoring, appropriate corrective measures can be implemented promptly to ensure the desired outcomes are achieved. The program will demonstrate that the rehabilitation at THGM complies with regulatory requirements and is satisfactory for relinquishment.

8.1 MONITORING METHODOLOGIES

Monitoring will be conducted at various frequencies (depending upon the aspect), and then reducing in frequency as monitoring data demonstrates that the site is on a trajectory towards achieving rehabilitation milestones.

A combination of field-based, desktop and spatial, and post-processing GIS-based rehabilitation monitoring will be used to gain a thorough understanding of the rehabilitation performance in a whole-of-site context. The outcomes of the monitoring will be used to determine the performance of the rehabilitation, in terms of meeting of being on trajectory to achieve milestone criteria.

Rehabilitation areas will be assessed against the milestone criteria and regularly reviewed to determine progress towards achieving relevant criteria and progressing towards the subsequent milestone.

The monitoring will include, but is not limited to, identification and/or assessment of:

- Adequacy and appropriateness of infrastructure decommissioning including mine rubbish and other waste (tyres, bulk containers, etc.)
- Adequacy of constructed TSF cover
- Ecological aspects including weed presence
- Erosion (rill, gully and tunnel) on rehabilitated areas
- Stability and functioning of erosion and sediment control and water management structures
- Groundwater and surface water quality
- Geotechnical stability of pit walls
- Safety hazards

The monitoring events are to be completed by appropriately qualified persons to provide independent appraisal of performance, and to inform aftercare and maintenance activities required for rehabilitated areas.

The timing for all monitoring disciplines is provided in the monitoring schedule provided in Section 8.2.

8.1.1 ECOLOGICAL MONITORING

8.1.1.1 ANALOGUE SITES

Previously used 'Colluvial slope' and 'Plains' reference sites utilised in the 2012/13 rehabilitation BioCondition assessment (SKM, 2013), and shown in Figure 8-1, will be used as a point of comparison to assess ecological performance of the rehabilitated areas with regard to groundcover, productivity, weed proportion, and species mix and composition. BioCondition assessment will continue to be utilised.

8.1.1.2 VEGETATION SURVEY

The discrete point sampling method used in SKM's 1999 and 2013 flora surveys (SKM, 1999; 2013) is proposed as it is quantitative, time-efficient and relatively objective, ensuring repeatability between different operators. Additionally, it will maintain data consistency and improve confidence when analysing and comparing data over time.

Transects previously monitored at the WRD, TSF, mine infrastructure area (plus the two reference locations) will continue to be utilised. At each location three 100 m transects will be set up, and along each transect the following assessment will be undertaken:

- Recorded every 1 m: ground cover percentage (live or dead plant material, or bare ground)
- Recorded every 10 m in a 1 m x 1 m quadrat:
  - Native species frequency and identification recorded
  - Weed species cover percentage plus presence of declared weed species
- Opportunistic sightings of fauna or evidence of fauna presence (scats, tracks, burrows, nests, etc.)

8.1.1.3 BIOCONDITION ASSESSMENT

The Queensland Government BioCondition assessment framework is a simple, rapid assessment approach that evaluates ecosystem health by measuring vegetation structure, species composition, and ecological function against reference sites (Eyre, 2015). The monitoring data is then compared to Queensland Government benchmark data for regional ecosystem in the area; for THGM, this is the Northwest Highlands Regional Ecosystem Technical Descriptions document.

Monitored data is then assessed against this benchmark data and used to inform rehabilitation progression towards achievement of rehabilitation milestones. The rehabilitated areas data will be compared with the reference site data using the benchmarking attributes. It is not expected that all the BioCondition benchmark attributes will be achieved, as the PMLUs for THGM are not a return to native ecosystems; however the rehabilitated areas will be targeting data within an acceptable range of the reference sites.

Ecological monitoring will be undertaken following the end of the wet season when the presence of diagnostic parts (flowers, seeds, etc.) for many grasses, annuals, and other species are optimal for identification.

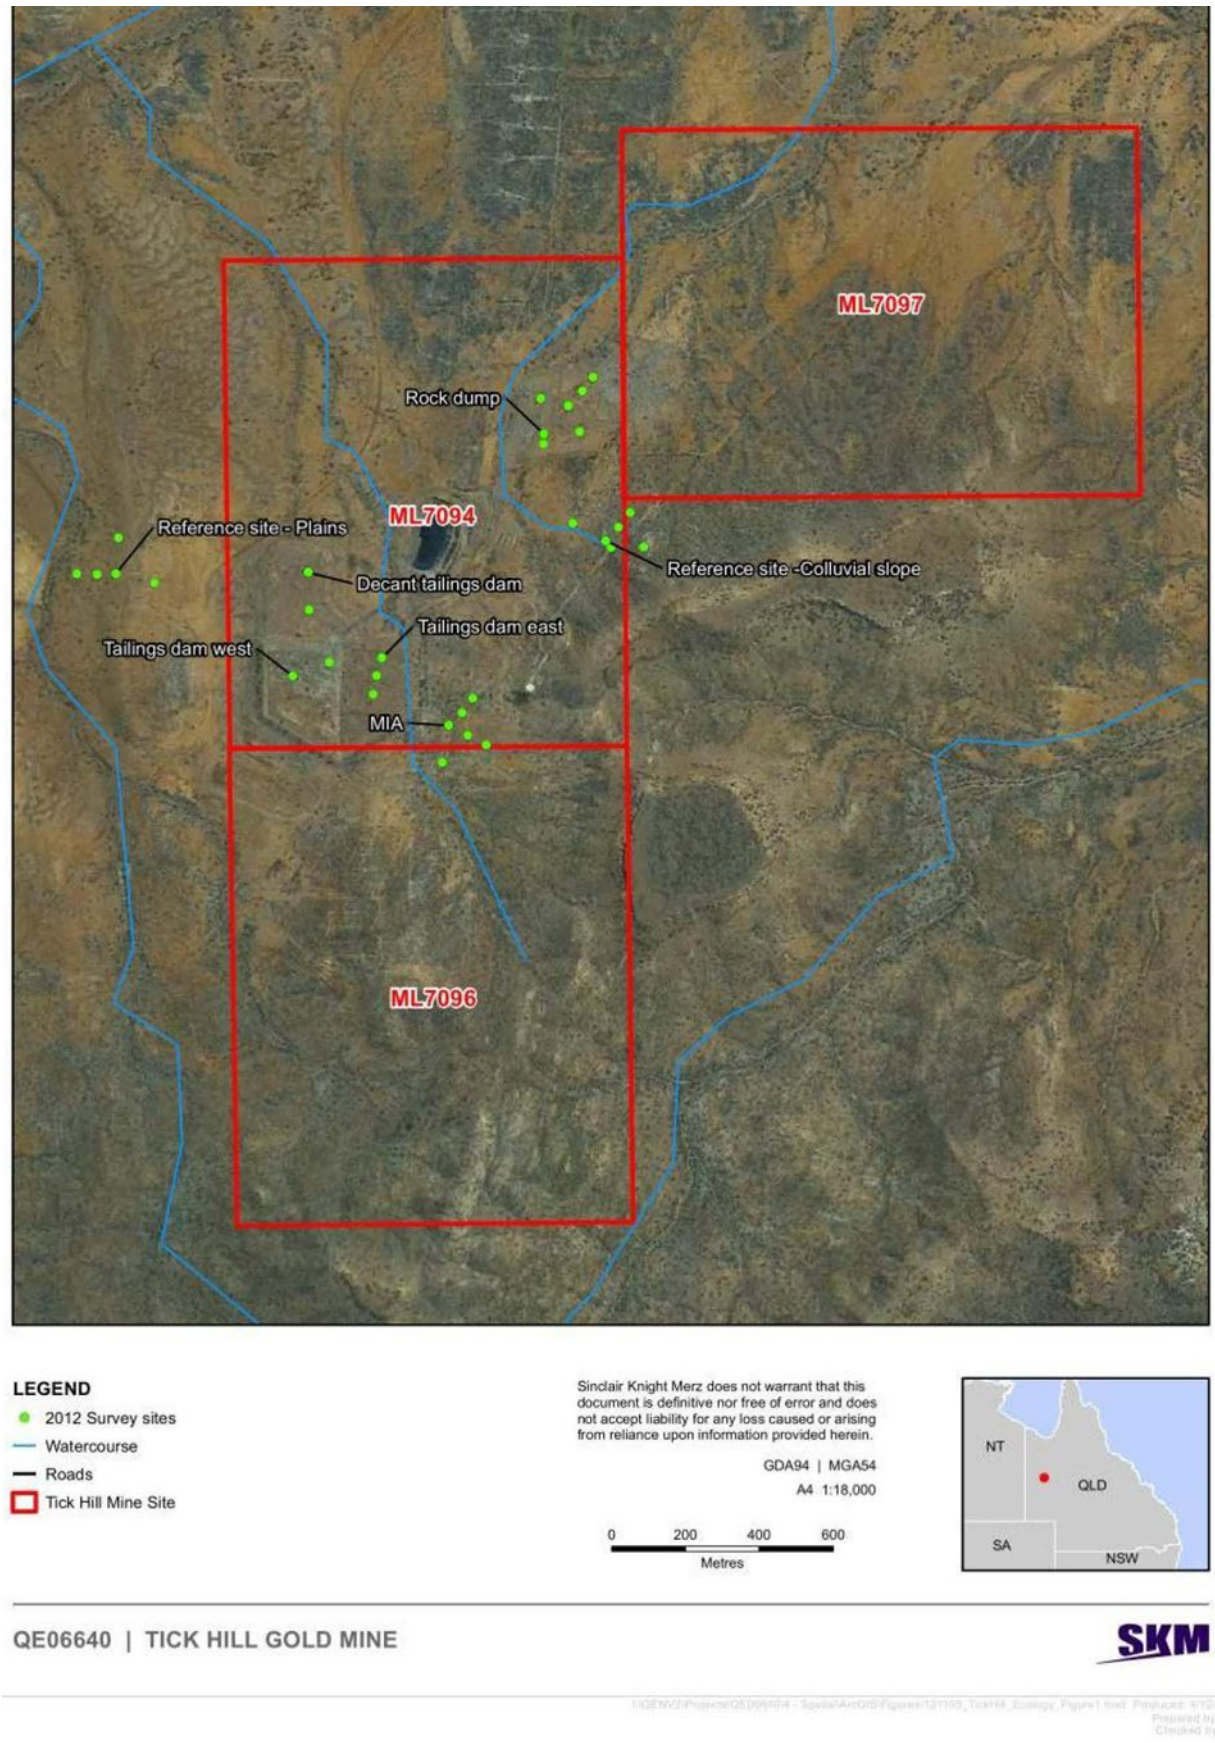

Figure 8-1: Ecological monitoring points (SKM, 2013)

8.1.2 GROUNDWATER MONITORING

Groundwater monitoring will be conducted as per the EA, and will include monitoring of the following 11 bores : THGW001, THGW002, THGW003, THGW004, THGW005, THGW006, THGW007, THGW008, THGW009, Pit Water, and Mine Shaft bore. Location of these bores is shown in Figure 2-10.

Parameters and contaminant limits to be assessed are provided in the EA. In accordance with the EA, all monitoring will be undertaken with the requirements of the latest version of the following documents unless otherwise approved by the administering authority:

- for waters and aquatic environments, the Queensland Government's Monitoring and Sampling Manual 2009 – Environmental Protection (Water) Policy 2009
- for groundwater, Groundwater Sampling and Analysis – A Field Guide (2009:27 GeoCat#6890.1) and Australian Standard AS/NZS 5667.11:1998 Water Quality – Sampling – Guidance on sampling of groundwaters
- for subterranean aquatic fauna, the Guideline for the Environmental Assessment of Subterranean Aquatic Fauna.

Where contaminant limits are not yet determined, data shall be assessed against revised tables provided in the 2023 ESA Groundwater addendum (supporting this PRCP).

8.1.3 SURFACE WATER MONITORING

Surface water monitoring will be undertaken annually following wet season rainfall due to the ephemeral nature of the waterways on site. The monitoring sites consist of the open cut pit and reclaimed TSF footprint for the parameters listed in the EA (as per Condition A24 of the EA).

8.1.4 EROSION MONITORING

Erosion monitoring will be conducted with the ecological monitoring and will be conducted in the following way:

- For newly constructed landforms, monitoring along the 100 m transect used for ecological monitoring will involve recording the presence, state, type, and severity of erosion based on the Australian Soil and Land Survey Field Handbook (NCST, 2024)
- For landforms constructed circa 1994 (WRD, Decant Pond, TSF outer embankments), observational monitoring is proposed during the ecological monitoring.

Rehabilitation monitoring is to be undertaken following the end of the wet season to allow for an accurate assessment of erosion features and an understanding of the movement of water across the rehabilitated landscape following the previous wet season.

8.1.5 GEOTECHNICAL AND SAFETY MONITORING

A geotechnical engineer (or similar appropriately qualified person) will assess the pit wall and constructed landforms following closure and prior to relinquishment for signs of movement that may negatively impact the stability of the features and safety of humans and animals in the areas.

A combination of photographs, satellite imagery, plus existing monitoring equipment (i.e. tell-tale measure) will be used to assess movement as determined at the time.

Safety aspects to be monitored include visual observations of abandonment bund condition, exclusion fence and signage around the pit area.

8.2 MONITORING SCHEDULE

The monitoring program and schedule for THGM is provided in Table 8-1.

It should be noted that the monitoring program may not run its full course if the site achieves the relevant criteria within 15 years, and rehabilitation certification is attained.

Table 8-1: Tick Hill Gold Mine monitoring program and schedule

RM #	Rehabilitation Milestone	Aspect	Monitoring Methodology	Frequency	Contingency / Maintenance	Reporting	Review
RM1	Infrastructure decommissioning and removal, remediation of contaminated land	Infrastructure	Document review of legal agreements for retention of any infrastructure. On site inspection to review: • Confirm removal of agreed infrastructure. • Review and confirm contaminated land status aligns to PMLU and/or landowner agreement • Geotechnical stability of pit walls and constructed landforms • Safety hazards	Annual	• Arrange decommissioning. • Arrange landowner agreement. • Arrange contaminated land assessment. • Investigate non-compliant results as required • Update documentation and mapping as required	Internal	Upon completion of inspection. At formalisation of landowner agreement
		Geotechnical Safety	• Geotechnical stability of pit walls and constructed landforms • Safety hazards	Annual	• Identify and mitigate geotechnical and safety hazards.		
RM2	Minor earthworks and general reshaping	Earthworks	On site inspection to review: • Constructed landform slopes angles • Surfaces are observed to be free-draining (with allowance for minor ponding) • Erosion structures constructed and functioning appropriately	Annual	• Reshape landform to design prior to topsoiling	Internal	Annual
RM3	Installation of cap / cover on tailings dam	Earthworks	• Document / design review • Visual inspection and ground survey following construction	Following TSF cover construction	• Arrange appropriately qualified person to undertake a review of cover system design report and construction report	Internal	Following TSF cover construction
RM4	Placement of growth medium	Revegetation	Visual inspection during or following construction for: • Growth media application • Evidence of ripping	Following construction	• Arrange appropriately qualified person to undertake a review of rehabilitation design including growth media source and mix (if blended with subsoil). • Reapply growth media if deficient	Internal	Following construction
RM5	Revegetation (Low-intensity grazing)	Revegetation	Inspection of revegetated areas for: • Key species germination success • Mean plant frequency • Ground cover (live and dead material) • Presence of declared weeds	Years 1, 3, 6, 10, 15	• Identify cause and reseed if necessary. • Implement weed management.	Internal	Annual
RM6	Revegetation (Tussock grassland)	Revegetation	Inspection of revegetated areas for: • Germination success and presence of shallow-rooted species only • Mean plant frequency • Ground cover (live and dead material) • Presence of declared weeds	Years 1, 3, 6, 10, 15	• Identify cause and reseed and/or remove deep-rooted species as necessary. • Implement weed management. •	Internal	Annual
RM7	Achievement of surface requirements	Revegetation	Inspection of revegetated areas for: • Presence of key native species and shallow-rooted species in relevant target PMLUs • Mean plant frequency • Ground cover (live and dead material) • Presence of declared weeds • Weed cover % • Native fauna evidence/presence	Years 1, 3, 6, 10, 15	• Arrange appropriately qualified person(s) to undertake inspection of rehabilitated areas • Identify cause and reseed and/or remove deep-rooted species as necessary. • Implement weed management.	Internal	Annual
		Water	Review: • Surface water quality at the open cut pit and on the reclaimed TSF footprint comply with nominated criteria. Parameters to be monitored are pH, electrical conductivity, suspended solids, and total cyanide • Groundwater quality at 'THGW001' – 'THGW009' bores plus 'Mine Shaft' (10 locations) comply with nominated criteria. Parameters to be monitored are pH, electrical conductivity, suspended solids, and total cyanide	Years 1, 3, 6, 10, 15	• Arrange appropriately qualified person(s) to review results and/or identify and mitigate potential causes		
		Erosion	• Erosion risk as defined by Australian Soil and Land Survey Field Handbook (NCST, 2024)	Years 1, 3, 6, 10, 15	• Identify erosion cause and remediate impacted area and/or erosion control structures		
		Geotechnical Safety	• Geotechnical stability of pit walls and constructed landforms • Safety hazards	Years 1, 5, 10, 15	• Identify and mitigate geotechnical and safety hazards.		

RM #	Rehabilitation Milestone	Aspect	Monitoring Methodology	Frequency	Contingency / Maintenance	Reporting	Review
RM8	Achievement of a stable condition	Revegetation	Inspection to assess: • Rehabilitated landforms can sustain agreed PMLU Inspection of revegetated areas for: • Presence of key native species and shallow-rooted species in relevant target PMLUs • Mean plant frequency • Ground cover (live and dead material) • Presence of declared weeds • Weed cover % • Native fauna evidence/presence	Years 7, 10, 15	• Arrange appropriately qualified person(s) to undertake inspection of rehabilitated areas. • Identify cause and reseed and/or remove deep-rooted species as necessary. • Implement weed management. • Identify erosion cause and mitigate impacted area and/or erosion control structures. • Identify and mitigate geotechnical and safety hazards.	Internal, administrating authority	Annual
		Water	• Seepage from mining activities is not present beyond ML boundary • Surface water quality at the open cut pit and on the reclaimed TSF footprint comply with nominated criteria. Parameters to be monitored are pH, electrical conductivity, suspended solids, and total cyanide • Groundwater quality at 'THGW001' – 'THGW009' bores plus 'Mine Shaft' (10 locations) comply with nominated criteria. Parameters to be monitored are pH, electrical conductivity, suspended solids, and total cyanide	Years 1, 3, 6, 10, 15	• Arrange appropriately qualified person(s) to review results and/or identify and mitigate potential causes		
		Erosion	• Erosion risk as defined by Australian Soil and Land Survey Field Handbook (NCST, 2024)	Years 1, 3, 6, 10, 15	• Identify erosion cause and remediate impacted area and/or erosion control structures		
		Geotechnical Safety	• Geotechnical stability of pit walls and constructed landforms • Safety hazards	Years 1, 5, 10, 15	• Identify and mitigate geotechnical and safety hazards.		

8.3 REPORTING AND REVIEW

8.3.1 QUALITY ASSURANCE AND DATA MANAGEMENT

All monitoring will be undertaken by appropriately qualified personnel.

Data will be collected for storage in a database and will be reviewed by appropriately qualified personnel and evaluated for the purpose of trending, reporting, and future reference.

8.3.2 REPORTING

Annual rehabilitation monitoring summary reports for internal purposes will be prepared to capture and collate and enable ongoing comparison of the data. These reports will present analyses of monitoring results and assess the rehabilitation progress over time as well as against success criteria.

8.3.3 MONITORING PROGRAM REVIEW

The THGM monitoring program will be reviewed every five years or sooner in response to changes in the PRCP or schedule, the data demonstrate that the milestone criteria are not practical, or changes to the EA.

Milestone r	Rehabilitation milestone	Milestone criteria
RM1	Infrastructure decommissioning and removal, remediation of contaminated land	(a) With the exception of any infrastructure to remain as part of the post-mining land use (PMLU) or where infrastructure is agreed to be retained by the landholder as evidenced by a signed landholder agreement, the following are complete: (i) All buildings demolished and removed (ii) All roads decommissioned and removed (iii) All boreholes decommissioned (cut and cap method) (b) All rubbish and demolition waste has been removed from the mining lease (c) Contaminated land assessment undertaken by an appropriately qualified person and indicates that contamination has been remediated or is acceptable for the proposed post-mining land use
RM2	Minor earthworks and general reshaping	(a) All major earthworks completed with slopes no greater than 20° and a surface which is free draining with the exception of minor ponding (b) Topsoil stripped and stockpiled where relevant (c) Minor earthworks undertaken to reshape, decompact and scarify areas for revegetation (d) Erosion and sediment control systems placed where needed
RM3	Installation of cap / cover on tailings dam	(a) Certification from an appropriately qualified person (AQP) that the TSF cover system functions as it was designed including: (i) Review of cover system design, to achieve a net percolation of less than 10% (ii) Cover to include 0.3m compacted clay material plus either ≥1m of WRD material or ≥1m of borrow material (or other design as produced by a suitably qualified engineer)
RM4	Placement of growth medium	(a) If topsoil not used, growth medium used will support land suitability Class 3 or Class 4 (b) Growth medium placed at a depth of ≥100mm where material is available (c) Following placement of growth medium, shallow ripping completed at a depth of greater than 100mm (except TSF to be ripped at no more than 100mm)
RM5	Revegetation (Low intensity grazing)	(a) Seed mix applied at a rate ≥5 kilograms per hectare (kg/ha) (b) Key native species are recorded (e.g. *Corymbia terminalis, Eucalyptus leucophylla, E. leucophloia, Acacia spp.* and *Triodia* spp.) (c) Mean native plant frequency >25/10m^2 (d) Ground cover (live and dead material) is >25%
RM6	Revegetation (Tussock grassland)	(a) Only shallow-rooted species (e.g. grasses and forbs) are used in the seed mix (b) Native seed mix applied at a rate ≥5 kilograms per hectare (kg/ha) (c) Mean native plant frequency >50/10m^2. (d) Ground cover (live and dead material) is >25%
RM7	Achievement of surface requirements	(a) Weed cover % (not including naturalised species) is within 20% of analogue site weed cover % (b) Mean plant frequency >50/10m^2 (c) Ground cover (live and dead material) is >50% (d) Key native species are recorded in 'Low intensity grazing'; grass and forb species only are recorded in 'Tussock grassland' (e) No active areas of rill or gully erosion and drainage follows appropriate drainage paths (f) Evidence of native fauna within revegetated areas
RM8	Achievement of a stable condition	(a) A rehabilitation performance review with at least three monitoring events has been completed using the methodology outlined in Section 3.7 of the PRCP (b) No evidence of seepage from any landforms beyond the boundary of the Mining Lease (c) Proportion of Category 3 restricted invasive plant species, as defined by the Biosecurity Act 2014, and Weeds of National Significance (WONS), as defined by the "Australian Weeds Strategy 2017 to 2027", are not >10% of total vegetative groundcover (d) Vegetation cover and compositon (averaged over monitoring events) are comparable to analog monitoring locations (i.e. ≥70% of analog values) (e) Surface water quality results from monitoring locations THSWR01 ref, THSW01, THSW02, and THSWPC01 DS comply with: (i) pH 7.0-8.0 (ii) EC <500 µS/cm (iii) Suspended solids <4,000 mg/L (iv) total cyanide <0.004 mg/L (f) Groundwater quality results from monitoring locations THGW001 to THGW009, plus Pit Water and Mine Shaft bores comply with: (i) pH 6.5-9 (ii) <10,000 µS/cm EC (iii) Total dissolved solids <4,000 mg/L (iv) <0.004 mg/L total cyanide (g) Overall erosion risk is classified as 'Low' or 'Moderate' as defined by NCST (2009) Australian Soil and Land Survey Field Handbook (3rd edition) (h) Geotechnical stability of the pit walls and area behind western pit wall have been assessed by a suitably qualified geotechnical engineer as stable in the long term (i) Hazard and Safety Assessment completed by an appropriately qualified person demonstrates hazards in the rehabilitation area are similar to hazards in neighbouring unmined landscapes subject to a similar PMLU.

Milestone reference	Management milestone	Milestone criteria
MM1	Maximum extent	(a) Maximum NUMA extent no greater than 6ha in size and 70m in depth.
MM2	Achievement of surface requirements	(a) Confirmation that fencing and abandonment bunds are erected around the perimeter and in tact. (b) Warning signage posted at no less than 500 m intervals around perimeter. (c) Adequacy of sealed underground entry at top of pit verified by an appropriately qualified person.
MM3	Achievement of sufficient improvement	(a) At the time of relinquishment of the Mining Lease, certification by an appropriately qualified person body that: (i) Residual void water quality and quantity will not cause harm not cause environmental harm outside of the relevant tenure boundary (ii) Residual void acts as a groundwater sink to the surrounding aquifer system; (iii) Residual void is safe for humans and livestock; and (iv) The long-term stability of the underground mine layout, and the suitability of all life of mine seals. (b) Water levels within the residual void do not reach the maximum operational WSL (water surface level) of 305m AHD
MM4	Management of crest zone	(a) Certification that the area of crest cracking remains within abandonment bund. (b) Geotechnical review completed to verify that pit void is safe, stable and non-polluting.

Executive Summary

Mine Earth was commissioned by Tick Hill Mining Pty Ltd to conduct an assessment of soil, waste rock and tailings materials for the Tick Hill Gold Mine (THGM), located approximately 110km southeast of Mt Isa in western Queensland.

The assessment of the physical and chemical characteristics of soil resources, waste rock and tailings materials was conducted to address the identified knowledge gaps, to identify potential use of available materials for rehabilitation / mine closure, and to provide data to facilitate relevant landform modelling and closure design parameters.

The objectives of the assessment were to:

- Characterise the physical and chemical characteristics of soil, waste rock and tailings materials within the THGM Project area
- Interpret the field-based information and analytical results, and develop recommendations for potential use of soil and waste rock resources as a source of rehabilitation / cover material for mine closure.

Material Types

The following materials from the Project area were sampled and analysed as part of this assessment:

- In situ, analogue soils
- Waste rock
- Tailings material
- Tailings cover material
- Stockpiled topsoil
- Potential soil borrow material
- Decant cover material
- Decant embankment material

The collected samples were analysed for a range of physical and chemical parameters which influence their suitability as a growth medium / surface rehabilitation material. Additional physical analyses were conducted on selected materials to provide data for modelling and preparation of rehabilitation / closure designs.

Material Characteristics

A summary of the characteristics of each material type, based on the field observations and laboratory analysis program is presented as follows:

Analogue soils

- Weakly to moderately structured ‘clayey sand’ to ‘medium heavy clay’ soils with variable coarse rock content (>2mm), up to 20%
- Non-saline, with a neutral to moderately alkaline pH
- Low concentrations of plant-available nutrients and organic carbon
- Typically classified as non-sodic, with a low potential for clay dispersion
- Classified as non-saline. Soil pH range from pH 7.1 to pH 9.0, classified as neutral to strongly alkaline

- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance

Waste rock

- Single grained to weakly aggregated oxide waste rock with variable coarse competent rock content
- Substantial variability in the texture of the soil sized fraction, with clay content ranging from 2% to 24%
- Samples classified as non-sodic or sodic, with potential for partial clay dispersion in some samples
- Variable hydraulic conductivity (at the measured 95% MDD), with drainage classifications of 'extremely slow' to 'very rapid'
- Variable soil water retention characteristics, field capacity and plant-available water content of the soil sized fraction (>2mm) ranging from low to moderate
- Classified as non-saline. Soil pH classified as strongly alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the waste rock supports the growth of local vegetation

Tailings

- Moderately structured material 'near surface', massive structure from approximately 0.5m depth, with a firm consistence
- Soil texture classified as a Sandy Loam, with approximately 12% clay
- Classified as sodic, however Emerson Test indicates a low propensity for clay dispersion
- Drainage classification (at the measured 95% MDD) of 'moderately slow'
- High water holding capacity (field capacity) and plant-available water content
- Classified as non-saline. Soil pH classified as moderately alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the tailings material supports the growth of local vegetation

Tailings cover material

- Compacted oxide waste rock with variable coarse rock % (up to approx. 80%). Clay content of the soil sized fraction ranging from 9 to 12%
- Non-sodic, with a low propensity for clay dispersion
- Drainage classifications (at 95% MDD) of 'moderate' to 'moderately rapid'
- Low water holding capacity (field capacity) and plant-available water content
- Classified as non-saline. Soil pH classified as moderately alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Classified as non-saline. Soil pH classified as strongly alkaline

- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the tailings cover material supports the growth of local vegetation

Stockpiled topsoil

- Predominantly single grained soil with up to 40% coarse rock material, clay content up to 29%
- Non-sodic, with a low propensity for clay dispersion
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Classified as non-saline. Soil pH classified as moderately alkaline
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the stockpiled topsoil material supports the growth of local vegetation

Potential borrow material

- Single grained to massively structured sandy clay material (up to 22% clay) with variable coarse fragment content, up to 31%
- Non-sodic, with a low propensity for clay dispersion
- Drainage classification (at 95% MDD) of 'extremely slow'
- Moderate water holding capacity (field capacity) and plant-available water content
- Classified as non-saline. Soil pH classified as neutral
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the potential borrow material supports the growth of local vegetation

Decant cover material

- Weakly structured to single grained oxide waste rock material with a loose consistence and up to 70% coarse fragment content
- Variable sodicity, ranging from non-sodic to highly sodic. High propensity for clay dispersion
- Drainage classifications (at 95% MDD) of 'very slow' to 'extremely slow'
- Moderate water holding capacity (field capacity) and plant-available water content
- Classified as slightly saline. Soil pH classified as strongly alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the decant cover material supports the growth of local vegetation

Decant embankment material

- Weakly structured soil with a loose consistence, approximately 20% clay and 40% coarse fragments

- Minor propensity for clay dispersion upon severe disturbance
- Drainage classification (at 95% MDD) of ‘extremely slow’
- Moderate water holding capacity (field capacity) and plant-available water content
- Field observations indicate the decant embankment material supports the growth of local vegetation

Suitability of materials for use as a rehabilitation / cover material

The materials sampled as part of this investigation are considered a valuable source of potential rehabilitation / cover materials for used in mine closure. The chemical characteristics of the materials, while variable, were generally within the range exhibited by the analogue soils within the Project area. The potential sources of rehabilitation / cover material sampled are generally non-saline, low in plant-available nutrients (similar to analogue soils) and, as evidenced by field observations, are capable of supporting the growth of local vegetation species.

The physical characteristics of the materials were variable, reflecting the range of particle sized distributions present. Hydraulic conductivity of the materials (at 95% of MDD) was highly variable, with drainage classifications ranging from ‘Extremely slow’ to ‘Very rapid’. The water retention characteristics of the potential sources of rehabilitation / cover material (<2mm fraction) were also variable, with the water content at field capacity (i.e. the amount of water held in the materials after gravity induced drainage has ceased) and the plant-available water content (PAW) ranging from ‘low’ to ‘moderate’. The results for the waste rock samples were variable, with PAW contents ranging from 9.7 to 20.4% (i.e., low to moderate), again reflective of the variable particle size distribution of the waste rock samples.

The relevant material characteristics presented in this report are being utilised in a concurrent investigation, modelling the potential performance of the materials as a cover for the TSF (Mine Earth 2025).

Introduction

1. Introduction

The Tick Hill gold mine (THGM) is located approximately 110km south-southeast of Mount Isa (Figure 1). Operations ceased in 1994. The site was held in care and maintenance under various owners until recent investigations and attempts to re-commercialise the Project through tailings reprocessing.

Site features include an open cut pit, tailings storage facility (TSF) that is partially capped, waste rock dump (WRD), run of mine (ROM) pad, topsoil stockpiles, processing area plus hardstand areas for workshops and administrative buildings (Figure 2).

Following cessation of operations, the site was decommissioned, infrastructure demolished and removed, and ground disturbance was rehabilitated. Rehabilitation at the site has not been certified and therefore requires a Progressive Rehabilitation and Closure Plan (PRCP) to present the rehabilitation, monitoring and maintenance requirements to achieve rehabilitation milestones and criteria.

The assessment of the physical and chemical characteristics of soil resources, waste rock and tailings materials was conducted to address identified knowledge gaps pertaining to material characteristics, to identify potential use and / or limitations of available materials for rehabilitation / mine closure, and to provide data to facilitate relevant landform modelling and closure design parameters.

This report includes:

- A description of the materials and methods used during the sampling and analysis stages.
- A summary of the field-based observations of the materials sampled and photographs of each sampling location.
- Analysis and discussion of the physical and chemical characteristics of the sampled materials.
- Recommendations for suitability / potential use of the soil and waste rock materials as a potential rehabilitation / closure resource.

Materials and methods

2. Methods and Materials

2.1 Sampling regime

Samples of in situ, analogue soils, stockpiled soil resources, potential borrow materials, existing decant and tailings cover materials, and waste rock from the waste rock dump were collected by Mine Earth and Tick Hill Mining Pty Ltd representatives from 19 locations within the Project area in July 2024 (Figure 5), comprising a total of 24 samples.

The sampling locations and sample details for each material type are summarised as follows:

- In situ analogue soils (5 sampling locations) collected from 2 to 3 depth intervals through the soil profile
- Waste rock (3 sampling locations) composited from depths up to 1.0m on the WRD
- Tailings material (2 sampling locations) composited from depths up to 0.6m on the TSF where tailings are exposed
- Tailings cover material (2 sampling locations) composited from depths up to 0.6m in the existing TSF cover material
- Stockpiled topsoil (2 sampling locations) composited from depths up to 0.7m in existing topsoil stockpiles on the TSF
- Potential borrow material (2 sampling locations) composited from depths up to 1.0m within areas previously identified as a potential source of borrow material
- Decant cover material (2 sampling locations) composited from depths up to 0.5m in the existing decant cover material
- Decant embankment material (1 sampling location) composited from depths up to 0.5m on the existing decant embankment

Details of sample locations, soil profile descriptions, photographs of the materials and surrounding landscape / vegetation at each location are included in Appendix A.

2.2 Test work and procedures

Laboratory test work on the sampled materials was conducted at the Trilab laboratory (soil physical parameters) and the ALS Laboratory (soil chemical parameters) in Brisbane.

The collected samples were analysed for a range of physical and chemical parameters which influence their suitability as a growth medium / surface rehabilitation material. Additional physical analyses were conducted on selected materials to provide data for modelling and preparation of rehabilitation / closure designs. The analysis suite included:

- Physical characteristics:
    - Soil texture and particle size distribution (Including coarse rock fraction >2 mm)
    - Emerson Aggregate test to indicate soil structural stability and potential for clay dispersion upon saturation
    - Hydraulic conductivity
    - Soil water retention characteristics and plant-available water
    - Atterberg limits
    - Maximum dry density and optimum moisture content

- Chemical characteristics:
    - Soil pH and electrical conductivity.
    - Plant-available nutrients (N, P, K, S).
    - Total organic carbon (to indicate organic matter content).
    - Exchangeable cations, effective cation exchange capacity (eCEC) and exchangeable sodium percentage (ESP).
    - Total metal concentrations.

All physical soil test work was conducted in accordance with standard analytical procedures to assess potential soil erodibility and soil properties related to the support of plant growth (Rayment & Lyons, 2010). Descriptions of relevant soil classification categories are detailed in Appendix B. All external laboratory results for the soils sampled are provided in Appendix C.

Results

3. Results

The results from the laboratory analysis program are presented in the following sections. A summary of the field-based observations and photographs from each sampling location is provided in Appendix A.

3.1 Soil physical characteristics

The physical characteristics of the soils, waste rock and tailings materials, as identified by the field sampling and laboratory analysis program are discussed in the following sections.

3.1.1 Soil texture

Soil texture describes the proportions of sand, silt and clay (the particle size distribution) within the <2 mm fraction of a soil. The particle size distribution and resulting textural class of a soil is an important factor influencing most physical, and many chemical and biological, properties. Soil structure, water holding capacity, hydraulic conductivity, soil strength, fertility, erodibility, and susceptibility to compaction are some of the factors closely linked to the texture of a soil material.

There was a wide range of soil textures recorded for the sampled materials, ranging from 'coarse sand' (approximately 2% clay), for the soil sized fraction of the one of the waste rock samples (WR3) to 'medium clay' (49% clay) for one of the analogue soil samples (A3, 10-20cm depth) (Table 1).

The highest clay contents were consistently recorded for the analogue soil samples. The tailings materials recorded clay contents of 11% and 12%, with the texture of the tailings classified as 'sandy loam'. There was substantial variability in the texture of the waste rock materials, with the clay content ranging from 2% to 24% (Table 1).

3.1.2 Soil structure

Soil structure describes the arrangement of solid particles and void space in a soil. It is an important factor influencing the ability of soil to support plant growth, store and transmit water and resist erosional processes. A well-structured soil is one with a range of different sized aggregates; with component particles bound together to give a range of pore sizes facilitating root growth and the transfer of air and water.

Soil structure can be influenced by the particle size distribution, chemical composition, and organic matter content of a soil. Soil structure is often influenced by root growth, vehicle compaction and, with respect to reconstructed soil profiles, the methods of soil handling and deposition. When a soil material is disturbed, the breakdown of aggregates into primary particles can lead to structural decline (Moore, 1998). This can result in hard-setting and crusting at the soil surface and a 'massive' soil structure at depth, potentially reducing the ability of seeds to germinate, roots to penetrate the soil matrix and water to infiltrate to the root zone.

There were a range of soil structures exhibited for the sampled materials, ranging from loose, single grained material, to moderately structured, aggregated soils, to massive, dense material with no aggregation. (Appendix A).

3.1.3 Structural stability

The structural stability of a soil and its susceptibility to structural decline is complex and depends on the net effect of several properties, including the amount and type of clay present, organic matter content, soil chemistry and the nature of disturbance. Soil aggregates that slake and, particularly those that disperse, indicate a weak soil structure that is easily degraded. These soils should be seen as potentially problematic when used as a rehabilitation medium, particularly if left exposed at the surface.

The Emerson Aggregate Test identifies the potential slaking and dispersive properties of soil aggregates. The dispersion test identifies the properties of the soil materials under a worst-case scenario, where severe stress is applied to the soil material. Generally, samples allocated into Emerson Classes 1 and 2 are those most likely to exhibit dispersion of the clay sized fraction and therefore be the most problematic. A description of the Emerson test classifications is provided in Appendix B.

The Emerson test results for the materials identified as potential sources of rehabilitation material are detailed in Table 1. Emerson test classifications and the associated potential for dispersion of the clay fraction for the materials were variable. Emerson Class 2 was recorded for samples of the decant cover (DC2) and waste rock (WR2), indicating that those materials are susceptible to partial dispersion of the clay fraction. The variability of the waste rock materials was again indicated by the variable propensity for dispersion, with the individual samples classified as Emerson Class 2, 5 and 6 (Table 1).

Table 1 Soil texture, clay content, % coarse rock (>2mm) and Emerson Test Class

WR3	Waste rock	10-100	Coarse Sand	2	60	5

[1] Class 2 – partial dispersion of natural aggregate
Class 3 - aggregate slakes but does not disperse, complete or partial dispersion of remoulded soil
Class 4 - Dry aggregate slakes but does not disperse; remoulded soil does not disperse; carbonates and gypsum are present
Class 5 - aggregate slakes but does not disperse, no dispersion of remoulded soil, soil:water suspension remains dispersed
Class 6 - Dry aggregate slakes but does not disperse; remoulded soil does not disperse; carbonates and gypsum are absent; 1:5 suspension remains flocculated

3.1.4 Hydraulic conductivity

Hydraulic conductivity (K_{sat}) refers to the saturated permeability of soil, or the ability of water to infiltrate and drain through the soil matrix and is dependent on soil properties such as texture and structure (Moore, 2004). Freely draining soils with high K_{sat} values will generally be less susceptible to surface runoff and erosion. Slow draining soils with low K_{sat} values, are more likely to experience waterlogging, increased surface runoff and erosion.

It should be noted that the laboratory assessment of K_{sat} was conducted on samples packed to 95% of their maximum dry density (Section 3.1.7). The K_{sat} of these materials in the field may be substantially higher if the materials are placed at a lower bulk density.

The hydraulic conductivity of the tested samples was highly variable, reflecting the wide range of soil textures / clay content (Table 2). Drainage classes were determined according to their K_{sat} (Hunt, N and Gilkes, R, 1992). The majority of samples recorded drainage classifications of 'Extremely slow' to 'Moderately slow'. The highest K_{sat} values were recoded for individual samples of the tailings cover (TC2) and waste rock (WR3), which recorded drainage classifications of 'Moderately rapid' and 'Very rapid' (Table 2).

Table 2 Saturated hydraulic conductivity (K_{sat})

Sample ID	Sample description	Sample depth interval (cm)	K_{sat} (m/s)	Drainage Class[1]
B1	Potential borrow material	0-70	2.4×10^{-8}	Extremely slow
B2	Potential borrow material	0-100	9.3×10^{-9}	Extremely slow
DC1	Decant cover	20-50	2.3×10^{-7}	Very slow
DC2	Decant cover	20-50	3.6×10^{-10}	Extremely slow

Sample ID	Sample description	Sample depth interval (cm)	K_{sat} (m/s)	Drainage Class[1]
DE1	Decant embankment	20-50	1.4×10^{-9}	Extremely slow
T1	Tailings	0-60	3.3×10^{-6}	Moderately slow
T2	Tailings	0-60	1.5×10^{-6}	Moderately slow
TC1	Tailings cover	5-50	1.0×10^{-5}	Moderate
TC2	Tailings cover	20-60	3.1×10^{-5}	Moderately rapid
WR1	Waste rock	20-150	7.2×10^{-9}	Extremely slow
WR2	Waste rock	20-100	1.8×10^{-8}	Extremely slow
WR3	Waste rock	10-100	6.8×10^{-5}	Very rapid

[1] (Hunt, N and Gilkes, R, 1992)

3.1.5 Soil water retention

The water holding capacity at saturation (0kPa) field capacity (approx. 30kPa) and wilting point (approx. 1500kPa) of the tested samples was assessed to provide an indication of the amount of water held in the materials after gravity induced drainage has ceased (i.e. field capacity) and the % volume likely to be available to vegetation (field capacity minus wilting point), known as the plant-available water content (PAW) (Table 3). The soil water characteristic curves for each material tested are provided in Appendix C.

It should be noted that, as the water retention test work is conducted on the <2 mm size fraction, it does not take into account the percentage of coarse rock material present.

The water retention characteristics of the materials tested was again variable, reflecting the wide range of soil textures / clay contents (Table 3). The tailings cover samples recorded the lowest PAW content, with the tailings material having the largest PAW capacity. The waste rock results were variable, with PAW contents ranging from 9.7 to 20.4%, again reflective of the variable particle size distribution of the waste rock samples.

Table 3 Soil water retention characteristics

Sample ID	Sample description	Gravimetric soil water (%) at measured tension points						
		0 kPa	10 kPa	33 kPa	100 kPa	500 kPa	1500 kPa	PAW % [1.]
T1	Tailings	44.3	33.3	30.9	6.2	3.8	2.3	31.0
T2	Tailings	39.7	32.4	29.9	5.6	3.5	1.6	30.8
TC1	Tailings cover	13.5	10.6	9.4	4.8	3.4	2.4	8.2
TC2	Tailings cover	11.8	9.2	8.1	3.0	2.2	1.5	7.6
WR1	Waste rock	37.5	30.4	28.7	19.4	12.8	10.0	20.4
WR2	Waste rock	35.5	24.8	23.4	18.2	9.0	6.7	18.1
WR3	Waste rock	13.4	10.4	9.2	1.8	1.1	0.7	9.7
B1	Potential borrow material	35.0	30.1	28.0	15.5	13.2	10.2	19.9

Sample ID	Sample description	Gravimetric soil water (%) at measured tension points						
		0 kPa	10 kPa	33 kPa	100 kPa	500 kPa	1500 kPa	PAW % [1.]
B2	Potential borrow material	36.1	32.2	30.0	20.7	12.7	10.0	22.2
DC1	Decant cover	27.3	25.2	22.7	7.6	3.9	2.5	22.7
DC2	Decant cover	32.2	26	23.2	22.3	13.1	10.3	15.8
DE1	Decant embankment	36.6	30.8	26.0	24.9	15.4	12.3	18.5

1. Plant available water (PAW) is the water content of the soil at Saturation (0 kPa) minus wilting point (1500 kPa).

3.1.6 Atterberg Limits

The Atterberg Limits identify the soil water content at which the soil fraction transitions between solid, semi-solid, plastic and liquid states (Table 4). The percentage linear shrinkage of the ROM material identifies the potential for shrink / swell of the material upon wetting / drying. The range of linear shrinkage values recorded for the materials tested ranged from 4% for one of the tailings cover samples to 18% for one of the potential borrow material samples. This range is considered a low to moderate shrink / swell capacity, with the potential borrow material likely to exhibit shrinkage and cracking upon wetting / drying cycles.

Table 4 Atterberg Limits for selected samples

Sample ID	Sample description	Atterberg Limits			
		Liquid Limit (%)	Plastic Limit (%)	Plasticity Index (%)	Linear Shrinkage (%)
TC1	Tailings cover	26	17	9	7.0
TC2	Tailings cover	23	17	6	4.0
WR2	Waste rock	34	20	14	7.5
WR3	Waste rock	Non-attainable	Non-attainable	Non-plastic	Non-attainable
B1	Potential borrow material	36	19	17	10.0
B2	Potential borrow material	44	21	23	18.0
DC1	Decant cover	Non-attainable	Non-attainable	Non-plastic	Non-attainable
DC2	Decant cover	41	21	20	11.5
DE1	Decant embankment	45	20	25	14.5

3.1.7 Maximum Dry Density

The maximum dry density (MDD) and moisture content at the MDD (Optimum moisture %), for the sampled materials are detailed in Table 5. The highest MDD values were consistently recorded for the waste rock and tailings cover materials, with the lowest MDD recorded for the tailings sample.

Table 5 Maximum dry density (MDD) and optimum moisture content of selected samples

Sample ID	Sample description	Maximum dry density (t/m^3)	Optimum moisture (%)
T2	Tailings	1.57	15.1
TC1	Tailings cover	2.21	8.0
TC2	Tailings cover	2.19	8.4
WR1	Waste rock	1.98	10.7
WR2	Waste rock	2.06	10.8
WR3	Waste rock	2.04	7.4
B1	Potential borrow material	1.88	12.5
B2	Potential borrow material	1.84	13.8
DC1	Decant cover	1.88	9.7
DC2	Decant cover	1.88	13.5
DE1	Decant embankment	1.86	14.1

3.2 Soil chemical characteristics

3.2.1 Soil pH and Electrical Conductivity

Soil pH (H_2O) measures the acidity or alkalinity of the soil in relation to suitability for plant growth. Ratings for soil pH, based on the Land Evaluation Standards for Land Resource Mapping categories (van Gool, 2005) are provided in Appendix B.

Individual soil pH (H_2O) values for each sample are presented in Table 6, with the average for each material type presented in Figure 6. Soil pH values were variable across the sample materials, with individual soil pH (H_2O) values ranging from pH 7.1 (classified as 'neutral') to pH 9.6 ('strongly alkaline'). The pH of the analogue soils ranged from pH 7.1 to pH 9.0, indicating that the majority of the potential cover / rehabilitation materials have pH values within the range exhibited by the analogue soils. Exceptions were the samples of the tailings cover material, which recorded the most alkaline soil pH values (Table 6 and Figure 6).

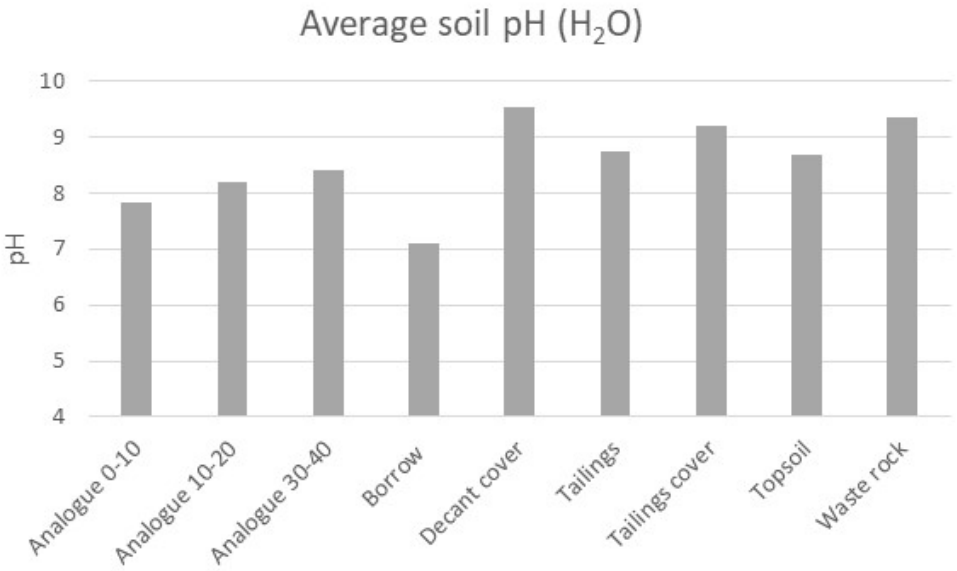

Figure 4 Average soil pH (H_2O) values for sampled materials

Electrical conductivity (EC) is a measurement of the soluble salts in soils or water. Soil salinity results from natural processes of landscape evolution, hydrological processes, and rainfall (Hunt, N and Gilkes, R, 1992). Soil electrical conductivity classes, based on the standard USDA and CSIRO electrical conductivity categories are provided in Appendix B

Individual EC values for each sample are presented in Table 6, with the average EC for each material type presented in Figure 7. The individual soil EC values of the materials sampled ranged from 0.008 dS/m (classed as non-saline) to 0.374 dS/m (slightly saline). On average, all materials apart from the decant cover samples were classified as non-saline (Figure 7). Salinity is considered unlikely to be a limiting factor to the use of the sampled materials as a rehabilitation / cover material.

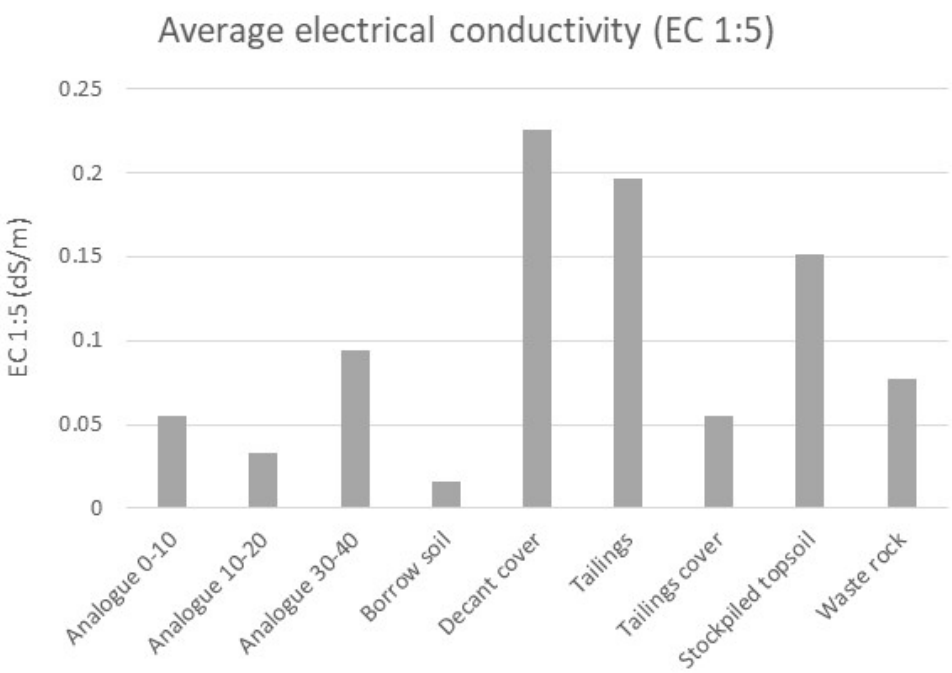

Figure 5 Avergae electrical conductivity (dS/m) for sampled materials

3.2.2 Soil Nutrients

The most important macro-nutrients for plant growth are nitrogen (N), Phosphorus (P), potassium (K) and sulphur (S). These nutrients are largely derived from the soil mineral component and organic matter. Native plant species have a number of physiological adaptations that enable them to be productive in areas where the supply of macronutrients is limited. Therefore, the use of analogue sites is an effective way to baseline the soil nutritional requirements of native plant species within the Project area.

3.2.2.1 Nitrogen

Most (>98%) N in soils is organic (Moore, 1998). Plant-available forms of inorganic N (nitrate and ammonium) are produced via mineralisation of soil organic matter. The plant-available N concentrations of the materials sampled were all very low, with all concentrations of ammonium (NH_4^+) below the limit of reporting (Table 6). The concentrations of N in the form of nitrate (NO_3^-) ranged from below detection (<1 mg/kg) to 4.1 mg/kg, with no apparent correlation with material type.

3.2.2.2 Phosphorus

Phosphorus is essential for the growth of vegetation as it plays a key role in the formulation of energy producing organic compounds. Adequate P nutrition enhances many aspects of plant physiology, including the fundamental processes of photosynthesis, nitrogen fixation, flowering, fruiting (including seed production), and maturation (Brady, N. and Weil, R., 2002).

The plant-available P concentrations of the material sampled were all low, ranging from below the limit of reporting (<5 mg/kg) to 10 mg/kg (Table 6).

3.2.2.3 Potassium

Potassium (K) plays a critical role in a number of plant physiological processes. Adequate amounts of K have been linked to improved drought tolerance, better resistance to certain fungal diseases and greater tolerance to insect pests (Brady, N. and Weil, R., 2002).

The plant-available K concentrations of the materials sampled were variable, ranging from below the limit of reporting (<5 mg/kg) to 927 mg/kg (Table 6). These values range between a low and high rating (low rating: <90 mg/kg, high rating: >200 mg/kg (Moore, 2004)). The plant-available K concentrations of the majority of the potential rehabilitation / cover materials were within the range of values recorded for the analogue soils.

3.2.3 Soil Organic Matter

The organic matter content of soil is an important factor influencing many physical, chemical, and biological soil characteristics. Directly derived from plants and animals, its functions in soil include supporting the micro and macro fauna and flora populations, increasing the water retention capacity, buffering pH and improving soil structure.

The organic matter content of the materials sampled was determined as a measure of the soil organic carbon percentage (SOC%). The SOC% of all materials sampled was low, as is typical of most highly weathered soils, ranging from below the limit of reporting (<0.5%) to 1.1% (Table 6).

Table 6 Electrical conductivity, soil pH, plant-available macronutrient and organic C % of sampled materials

3.2.4 Exchangeable Cations and Exchangeable Sodium Percentage

Exchangeable cations, held on clay surfaces and within organic matter, are an important source of soil fertility and can influence the physical properties of soil. Generally, if cations such as Ca2+, Mg2+ and K+ are dominant on the clay exchange surfaces, the soil will typically display increased physical structure and stability, leading to increased aeration, drainage and root growth (Moore, 2004). If Na cations (Na+) are dominant on exchange surfaces and the exchangeable sodium percentage (ESP) exceeds more than 6% of the total exchangeable cations, then the soil is considered to be 'sodic', which can lead to poor physical properties (i.e. dispersion, hard setting and erosion in clay-rich soils). ESP values over 15% are classified as 'highly sodic'.

Exchangeable cation concentration, effective cation exchange capacity (eCEC) and ESP results for the sampled materials are detailed in Table 7. The exchangeable cation results were variable, with the concentration of Mg and Na below the limit of reporting for many of the analogue soils and potential rehabilitation / cover materials. The eCEC values ranged from approximately 1.2 to 18.6, considered to be 'low' to 'moderate'. The majority of the materials were classified as non-sodic, indicating a low propensity for dispersion of the clay fraction, with the exception of one of the decant cover samples (DC2), classified as highly sodic (Table 7). This correlates with the Emerson Test Class 2 recorded for sample DC3 (Section 3.1.3), indicating a propensity for partial dispersion upon saturation.

Table 7 Exchangeable cations, effective cation exchange capacity (eCEC) and exchangeable sodium percentage (ESP) of selected samples. Shading of ESP values denotes non-sodic, sodic and highly sodic classifications

3.2.5 Total metal / metalloid concentrations

The total concentration of selected metals / metalloids was measured for selected samples, with the results presented in Table 8. The soils samples were digested using a hydrochloric and nitric acid mixture and read using inductively couple plasma mass spectroscopy (ICP-MS). As a point of comparison, the average crustal abundance (ACA) (Reimann, C. and de Caritat, P, 1998) for each metal is also provide in Table 6.

Of note are the high baseline concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance. The metals / metalloid concentrations were consistent across the analogue and potential rehabilitation / cover materials sampled and are unlikely to have any implications for material management or rehabilitation.

Table 8 Total metal / metalloid concentrations for selected samples. Concentrations above the ACA are denoted in bold font

Conclusions and recommendations

4. Conclusions and recommendations

4.1 Material characteristics

A summary of the characteristics of each material type, based on the field observations and laboratory analysis program is presented as follows:

Analogue soils

- Weakly to moderately structured 'clayey sand' to 'medium heavy clay' soils with variable coarse rock content (>2mm), up to 20%
- Low concentrations of plant-available nutrients and organic carbon
- Typically classified as non-sodic, with a low potential for clay dispersion
- Classified as non-saline. Soil pH range from pH 7.1 to pH 9.0, classified as neutral to strongly alkaline
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance

Waste rock

- Single grained to weakly aggregated oxide waste rock with variable coarse competent rock content
- Substantial variability in the texture of the soil sized fraction, with clay content ranging from 2% to 24%
- Samples classified as non-sodic or sodic, with potential for partial clay dispersion in some samples
- Variable hydraulic conductivity (at the measured 95% MDD), with drainage classifications of 'extremely slow' to 'very rapid'
- Variable soil water retention characteristics, field capacity and plant-available water content of the soil sized fraction (>2mm) ranging from low to moderate
- Classified as non-saline. Soil pH classified as strongly alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils.
- Field observations indicate the waste rock supports the growth of local vegetation

Tailings

- Moderately structured material 'near surface', massive structure from approximately 0.5m depth, with a firm consistence
- Soil texture classified as a Sandy Loam, with approximately 12% clay
- Classified as sodic, however Emerson Test indicates a low propensity for clay dispersion
- Drainage classification (at the measured 95% MDD) of 'moderately slow'
- High field capacity and plant-available water content
- Classified as non-saline. Soil pH classified as moderately alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils.

- Field observations indicate the tailings material supports the growth of local vegetation

Tailings cover material

- Compacted oxide waste rock with variable coarse rock % (up to approx. 80%). Clay content of the soil sized fraction ranging from 9 to 12%
- Non-sodic, with a low propensity for clay dispersion
- Drainage classifications (at 95% MDD) of 'moderate' to 'moderately rapid'
- Low field capacity and plant-available water content
- Classified as non-saline. Soil pH classified as moderately alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils.
- Classified as non-saline. Soil pH classified as strongly alkaline
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils.
- Field observations indicate the tailings cover material supports the growth of local vegetation

Stockpiled topsoil

- Predominantly single grained soil with up to 40% coarse rock material, clay content up to 29%
- Non-sodic, with a low propensity for clay dispersion
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Classified as non-saline. Soil pH classified as moderately alkaline
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the stockpiled topsoil material supports the growth of local vegetation

Potential borrow material

- Single grained to massively structured sandy clay material (up to 22% clay) with variable coarse fragment content, up to 31%
- Non-sodic, with a low propensity for clay dispersion
- Drainage classification (at 95% MDD) of 'extremely slow'
- Moderate field capacity and plant-available water content
- Classified as non-saline. Soil pH classified as neutral
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the potential borrow material supports the growth of local vegetation

Decant cover material

- Weakly structured to single grained oxide waste rock material with a loose consistence and up to 70% coarse fragment content
- Variable sodicity, ranging from non-sodic to highly sodic. High propensity for clay dispersion

- Drainage classifications (at 95% MDD) of ‘very slow’ to ‘extremely slow’
- Moderate field capacity and plant-available water content
- Classified as slightly saline. Soil pH classified as strongly alkaline
- Low concentrations of plant-available nutrients and organic carbon, similar to analogue soils
- Generally low concentrations of total metals, with elevated concentrations of cadmium (Cd), selenium (Se), beryllium (Be) and copper (Cu), relative to the average crustal abundance, within the range measured for the analogue soils
- Field observations indicate the decant cover material supports the growth of local vegetation

Decant embankment material

- Weakly structured soil with a loose consistence, approximately 20% clay and 40% coarse fragments
- Minor propensity for clay dispersion upon severe disturbance
- Drainage classification (at 95% MDD) of ‘extremely slow’
- Moderate field capacity and plant-available water content
- Field observations indicate the decant embankment material supports the growth of local vegetation

4.2 Suitability of materials for use as a rehabilitation / cover material

The materials sampled as part of this investigation are considered a valuable source of potential rehabilitation / cover materials for used in mine closure. The chemical characteristics of the materials, while variable, were generally within the range exhibited by the analogue soils within the Project area. The potential sources of rehabilitation / cover material sampled are generally non-saline, low in plant-available nutrients (similar to analogue soils) and, as evidenced by field observations, are capable of supporting the growth of local vegetation species.

The physical characteristics of the materials were variable, reflecting the range of particle sized distributions present. Hydraulic conductivity of the materials (at 95% of MDD) was highly variable, with drainage classifications ranging from ‘Extremely slow’ to ‘Very rapid’. The water retention characteristics of the potential sources of rehabilitation / cover material (<2mm fraction) were also variable, with the water content at field capacity (i.e. the amount of water held in the materials after gravity induced drainage has ceased) and the plant-available water content (PAW) ranging from ‘low’ to ‘moderate’. The results for the waste rock samples were variable, with PAW contents ranging from 9.7 to 20.4% (i.e., low to moderate), again reflective of the variable particle size distribution of the waste rock samples.

Sample site descriptions

MINE EARTH

Site Ref:	Analogue 1	**Datum:**	GDA94 z54
Site Description:	Analogue soil site – hill foot slope, adjacent to road cutting	**Easting:**	389082.2
		Northing:	7605553.6

Plate A1: Soil profile at Site A1

Soil profile description:

0-10cm: Weakly structured red to brown soil with a loose consistence and approximately 30% coarse fragments, 2 to 80mm in size. Root growth classified as 'many'.

10 to 20cm: Single grained, loose grey soil within fractured, partly weathered rock. Rock fraction approx. 50%. Root growth classified as 'few'. Excavator refusal at 20cm.

Soil surface:
Weak soil crust with scattered coarse fragments. No visual signs of surface erosion present.

Vegetation:
Buffel Grass, sparse shrubs and small trees.

Plate A2: Vegetation at Site A1

Site Ref:	Analogue 2 (A2)	**Datum:**	GDA94 z54
Site Description:	Analogue soil site – flat	**Easting:**	389218.0
		Northing:	7606042.2

Plate A3: Soil profile at Site A2

Soil profile description:

0-10cm: Weakly structured brown to red soil with a loose consistence and approximately 60% coarse fragments, 2 to 50mm in size. Root growth classified as 'many'.

10-30cm: Weakly structured brown to red soil with a firm consistence and approximately 20% coarse fragments, 2 to 50mm in size. Root growth classified as 'many'.

30-60cm (base of excavation): Massive sandy clay horizon with approx. 20% coarse fragments, 2 to 50mm in size. Root growth classified as 'few'.

Soil surface:
Weak soil crust with coarse fragment lag. No visual signs of surface erosion present.

Vegetation:
Buffel Grass, sparse shrubs and small trees.

Plate A4: Vegetation at Site A2

Site Ref:	Analogue 3 (A3)	**Datum:**	GDA94 z54
Site Description:	Analogue soil site - flat	**Easting:**	388627.7
		Northing:	7606427.0

Plate A5: Soil profile at Site A3

Soil profile description:

0-20cm: Moderately structured red to brown soil with a loose consistence and approximately 50% coarse fragments, 2 to 50mm in size. Root growth classified as 'many'.

20-70cm (base of excavation): Weakly structured brown to red soil with a firm consistence and approx. 20% coarse fragments, 2 to 50mm in size. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
Weak soil crust with coarse fragment lag. Minor evidence of surface erosion present.

Vegetation:
Buffel Grass, sparse shrubs and small trees.

Plate A6: Vegetation at Site A3

Site Ref:	Analogue 4 (A4)	**Datum:**	GDA94 z54
Site Description:	Analogue soil site - flat	**Easting:**	389123.1
		Northing:	7606432.8

Plate A7: Soil profile at Site A4

Soil profile description:

0-20cm: Moderately structured red to brown soil with a loose consistence and approximately 50% coarse fragments, 2 to 30mm in size. Root growth classified as 'abundant'.

20-70cm (base of excavation): Weakly structured to massive brown to red soil with a firm consistence and approximately 30% coarse fragments, 2 to 50mm in size. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
Weak soil crust with coarse fragment lag. Minor evidence of surface erosion present.

Soil surface:
Buffel Grass, shrubs and small trees.

Site Ref:	Analogue 5 (A5)	**Datum:**	GDA94 z54
Site Description:	Analogue soil site - flat	**Easting:**	388407.1
		Northing:	7606235.1

Plate A9: Soil profile at Site A5

Soil profile description:

0-40cm: Moderately structured red to brown soil with a loose consistence and approximately 40% coarse fragments, 2 to 30mm in size. Root growth classified as 'abundant'.

40-70cm (base of excavation): Moderately structured red to brown soil with a loose to firm consistence and approximately 30% coarse fragments, 2 to 50mm in size. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
Weak soil crust with coarse fragment lag.

Vegetation:
Buffel Grass, shrubs and small trees.

Plate A10: Vegetation at Site A5

Site Ref:	Borrow 1 (B1)	**Datum:**	GDA94 z54
Site Description:	Potential borrow area	**Easting:**	388576.2
		Northing:	7605197.4

Plate A11: Soil profile at Site B1

Soil profile description:

0-20cm: Single grained red to brown soil with a loose consistence and approximately 60% coarse fragments, 2 to 30mm in size. Root growth classified as 'many'.

20-70cm (base of excavation): Massive red to brown soil with a moderate consistence and approximately 30% coarse fragments, 2 to 30mm in size. Increase in clay content with depth. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
No surface crust, coarse fragment lag.

Vegetation:
Buffel Grass, native grasses, scattered shrubs and small trees.

Plate A12: Vegetation at Site B1

Site Ref:	Borrow 2 (B2)	**Datum:**	GDA94 z54
Site Description:	Potential borrow area	**Easting:**	388637.3
		Northing:	7605832.9

Plate A13: Soil profile at Site B2

Soil profile description:

0-10cm: Weakly structured red to brown soil with a loose consistence and approximately 40% coarse fragments, 2 to 20mm in size. Root growth classified as 'many'.

10-100cm: Moderately structured to massive sandy clay with a firm consistence and approx. 25% coarse fragments

>100cm: Massive sandy clay. Rock fragments increasing in size and abundance.

Soil surface:
No surface crust, coarse fragment lag.

Vegetation:
Native grasses, Buffel grass, scattered shrubs and small trees.

Plate A14: Vegetation at Site B2

Site Ref:	Decant cover 1 (DC1)	**Datum:**	GDA94 z54
Site Description:	In situ decant cover material	**Easting:**	388469.0
		Northing:	7605686.9

Plate A15: Soil profile at Site DC1

Soil profile description:

0-20cm: Brown, weakly structured to single grained with a loose consistence and approximately 60% coarse fragments, 2 to 40mm in size. Root growth classified as 'abundant'.

20-50cm: Mottled, brown, weakly structured to single grained oxide material with a loose consistence and approximately 70% coarse fragments, 2 to 50mm in size. Root growth classified as 'many', decreasing with depth.

>50cm: Tailings.

Soil surface:
Weak surface crust

Vegetation:
Buffel grass, scattered shrubs and small trees.

Plate A16: Vegetation at Site DC1

Site Ref:	Decant cover 2 (DC2)	**Datum:**	GDA94 z54
Site Description:	In situ decant cover material	**Easting:**	388506.0
		Northing:	7605825.6

Plate A17: Soil profile at Site DC2

Soil profile description:

0-20cm: Red to brown, moderately structured soil with a loose consistence and approximately 60% coarse fragments, 2 to 40mm in size. Root growth classified as 'abundant'.

20-50cm: Mottled, brown, weakly structured to single grained oxide material with a loose consistence and approximately 70% coarse fragments, 2 to 50mm in size. Root growth classified as 'many', decreasing with depth.

>50cm: Tailings.

Soil surface:
Weak soil crust

Vegetation:
Buffel grass, scattered shrubs and small trees.

Plate A18: Vegetation at Site DC2

Site Ref:	Decant embankment 1 (DE1)	**Datum:**	GDA94 z54
Site Description:	In situ decant embankment material	**Easting:**	388506.0
		Northing:	7605825.6

Plate A19: Soil profile at Site DE1

Soil profile description:

0-20cm: Red to brown, weakly structured soil with a loose consistence and approximately 30% coarse fragments, 2 to 40mm in size. Root growth classified as 'abundant'.

20-50cm: Brown, weakly structured soil with a loose consistence and approximately 30% coarse fragments, 2 to 50mm in size. Root growth classified as 'many', decreasing with depth.

Soil surface:
No surface crust.

Vegetation:
Buffel grass, scattered shrubs.

Plate A20: Vegetation at Site DE1

Site Ref:	Tailings 1 (T1)	**Datum:**	GDA94 z54
Site Description:	In situ tailings	**Easting:**	388637.9
		Northing:	7605581.9

Plate A21: Soil profile at Site T1

Soil profile description:

0-20cm: Silty, light brown to grey tailings, moderate structure with a firm consistence. Abundant root growth.

20-60cm (base of excavation): Silty, light brown to grey tailings, moderate structure decreasing to massive structure with depth. Firm consistence. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
Loose surface, minor signs of erosion.

Vegetation:
Sparse grasses and shrubs.

Plate A22: Vegetation at Site T1

Site Ref:	Tailings 2 (T2)	**Datum:**	GDA94 z54
Site Description:	In situ tailings	**Easting:**	388627.7
		Northing:	7605487.8

Plate A23: Soil profile at Site T2

Soil profile description:

0-30cm: Silty, light brown to grey tailings, moderate structure with a firm consistence. Abundant root growth.

30-60cm (base of excavation): Silty, light brown to grey tailings, moderate structure decreasing to massive structure with depth. Firm consistence. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
Predominantly loose, friable surface, minor signs of erosion.

Vegetation:
Scattered small shrubs

Plate A24: Vegetation at Site T2

Site Ref:	Tailings cover 1 (TC1)	**Datum:**	GDA94 z54
Site Description:	In situ tailings cover material – cleared area of TSF surface	**Easting:**	388439.3
		Northing:	7605515.8

Plate A25: Soil profile at Site TC1

Soil profile description:

0-50cm: Thin topsoil layer extending to approximately 5cm depth, overlying compacted soil / oxide material with approximately 80% rock fragments.

Soil surface:
Disturbed from vegetation / topsoil clearing.

Vegetation:
None.

Plate A26: Vegetation at Site TC1

Site Ref:	Tailings cover 2 (TC2)	**Datum:**	GDA94 z54
Site Description:	In situ tailings cover material – vegetated area of TSF surface	**Easting:**	388547.2
		Northing:	7605410.4

Plate A27: Soil profile at Site TC2

Soil profile description:

0-20cm: Well structured, reddish brown topsoil layer with approximately 25% rock fragments. Abundant root growth.

20-60cm: Predominantly single grained soil / oxide waste material with approximately 80% rock fragments. Root growth classified as 'many', decreasing to 'few' with depth.

Soil surface:
Predominantly loose, friable surface. Approximately 25% rock fragment cover.

Vegetation:
Buffel grass and scattered small shrubs

Plate A28: Vegetation at Site TC2

Site Ref:	Topsoil 1 (TS1)	**Datum:**	GDA94 z54
Site Description:	Stockpiled topsoil – salvaged from TSF surface	**Easting:**	388511.1
		Northing:	7605591.7

Plate A29: Soil profile at Site TS1

Soil stockpile description:

0-70cm: Reddish brown, predominantly single grained soil with approximately 20% rock fragments. Root growth classified as 'few'.

Soil surface:
Weak surface crust, minor surface erosion

Vegetation:
Scattered shrubs and grasses

Plate A30: Vegetation at Site TS1

Site Ref:	Topsoil 2 (TS2)	**Datum:**	GDA94 z54
Site Description:	Stockpiled topsoil – salvaged from TSF surface	**Easting:**	388539.6
		Northing:	7605576.5

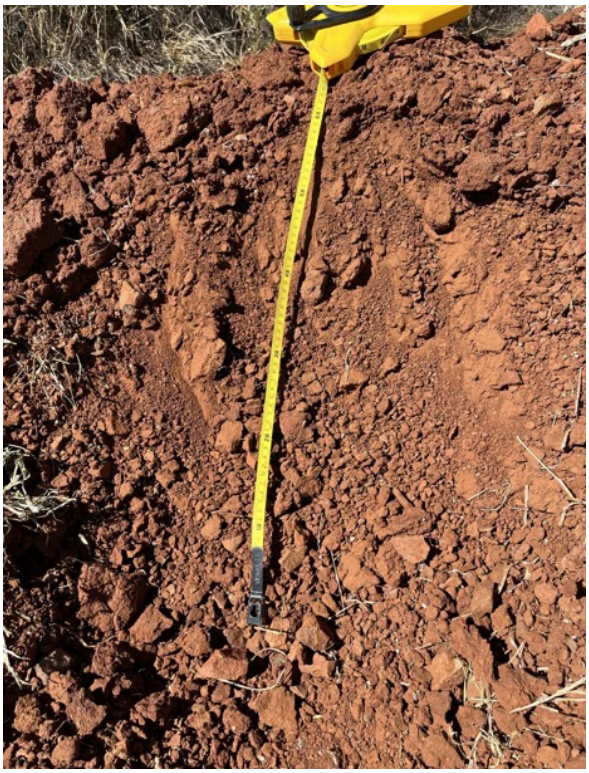

Plate A31: Soil profile at Site TS2

Soil stockpile description:

0-70cm: Reddish brown, predominantly single grained soil with some weak to moderate aggregates. Approximately 40% rock fragments. Root growth classified as 'few'.

Soil surface:
Weak surface crust, minor surface erosion

Vegetation:
Scattered shrubs and grasses

Plate A32: Vegetation at Site TS2

Site Ref:	Waste rock 1 (WR1)	**Datum:**	GDA94 z54
Site Description:	WRD batter – upper lift	**Easting:**	389032.1
		Northing:	7606177.9

Plate A33: Soil profile at Site WR1

Soil profile description:

0-20cm: Reddish brown, predominantly single grained topsoil with some weak aggregates. Approximately 30% rock fragments. Root growth classified as 'many'.

20-150cm: Brown to grey oxide waste rock, single grained matrix with weak to moderate aggregates and approximately 40% gravel sized coarse fragment. Root growth classified as 'few', decreasing with depth.

Soil surface:
Predominantly loose, friable surface. Approximately 30% rock fragment cover.

Vegetation:
Scattered shrubs, small tress and grasses

Plate A34: Vegetation at Site WR1

Site Ref:	Waste rock 2 (WR2)	**Datum:**	GDA94 z54
Site Description:	WRD - upper surface	**Easting:**	389075.0
		Northing:	7606319.0

Plate A35: Soil profile at Site WR2

Soil profile description:

0-20cm: Brown, aggregated topsoil material with weak to moderate aggregates. Approximately 25% rock fragments. Root growth classified as 'abundant'.

20-100cm: Brown to grey oxide waste rock, single grained matrix with some weak to moderate aggregates and approximately 40% coarse fragments. Root growth classified as 'many', decreasing with depth.

Soil surface:
Predominantly loose, friable surface. Approximately 20% rock fragment cover.

Vegetation:
Scattered shrubs and grasses

Plate A36: Vegetation at Site WR2

Site Ref:	Waste rock 3 (WR3)	**Datum:**	GDA94 z54
Site Description:	WRD - upper surface	**Easting:**	389097.5
		Northing:	7606173.7

Plate A37: Soil profile at Site WR3

Soil profile description:

0-10cm: Reddish brown, predominantly single grained topsoil with some weak aggregates. Approximately 10% rock fragments. Root growth classified as 'many'.

10-100cm: Brown to grey oxide waste rock with fresh competent waste rock throughout (approximately 60% coarse material, but variable). Root growth classified as 'few', decreasing with depth.

Soil surface:
Predominantly loose, friable surface. Approximately 20% rock fragment cover.

Vegetation:
Sparse grasses.

Plate A38: Vegetation at Site WR3

Appendix B

Soil Classifications

MINE EARTH

Emerson Dispersion Test Classes (Moore 1998)

Class	Description
Class 1	Dry aggregate slakes and completely disperses
Class 2	Dry aggregate slakes and partly disperses
Class 3a	Dry aggregate slakes but does not disperse; remoulded soil disperses completely
Class 3b	Dry aggregate slakes but does not disperse; remoulded soil partly disperses
Class 4	Dry aggregate slakes but does not disperse; remoulded soil does not disperse; carbonates and gypsum are present
Class 5	Dry aggregate slakes but does not disperse; remoulded soil does not disperse; carbonates and gypsum are absent; 1: suspension remains dispersed
Class 6	Dry aggregate slakes but does not disperse; remoulded soil does not disperse; carbonates and gypsum are absent; 1:5 suspension remains flocculated
Class 7	Dry aggregate does not slake; aggregate swells
Class 8	Dry aggregate does not slake; aggregate does not swell

Soil Electrical conductivity classes (based on standard USDA and CSIRO categories)

EC (1:5) (dS/m)						
Salinity class	**Sand**	**Sandy loam**	**Loam**	**Clay loam**	**Light / medium clay**	**Heavy clay**
Non-saline	<0.13	<0.17	<0.20	<0.22	<0.25	<0.33
Slightly saline	0.13 – 0.26	0.17 – 0.33	0.20 – 0.40	0.22 – 0.44	0.25 – 0.50	0.33 – 0.67
Moderately saline	0.26 – 0.52	0.33 – 0.67	0.40 – 0.80	0.44 – 0.89	0.50 – 1.00	0.67 – 1.33
Very saline	0.52 – 1.06	0.67 – 1.33	0.80 – 1.60	0.89 – 1.78	1.00 – 2.00	1.33 – 2.67
Extremely saline	>1.06	>1.33	>1.60	>1.78	>2.00	>2.67

Soil pH classes

	Soil pH rating						
	Very strongly acid (Vsac)	**Strongly acid (Sac)**	**Moderately acid (Mac)**	**Slightly acid (Slac)**	**Neutral (N)**	**Moderately alkaline (Malk)**	**Strongly alkaline (Salk)**
pH_w	<5.3	5.3 – 5.6	5.6 – 6.0	6.0 – 6.5	6.5 – 8.0	8.0 – 9.0	>9.0
pH_{Ca}	<4.2	4.2 – 4.5	4.5 – 5.0	5.0 – 5.5	5.5 – 7.0	7.0 – 8.0	>8.0

PERMEABILITY BY CONSTANT HEAD TEST REPORT

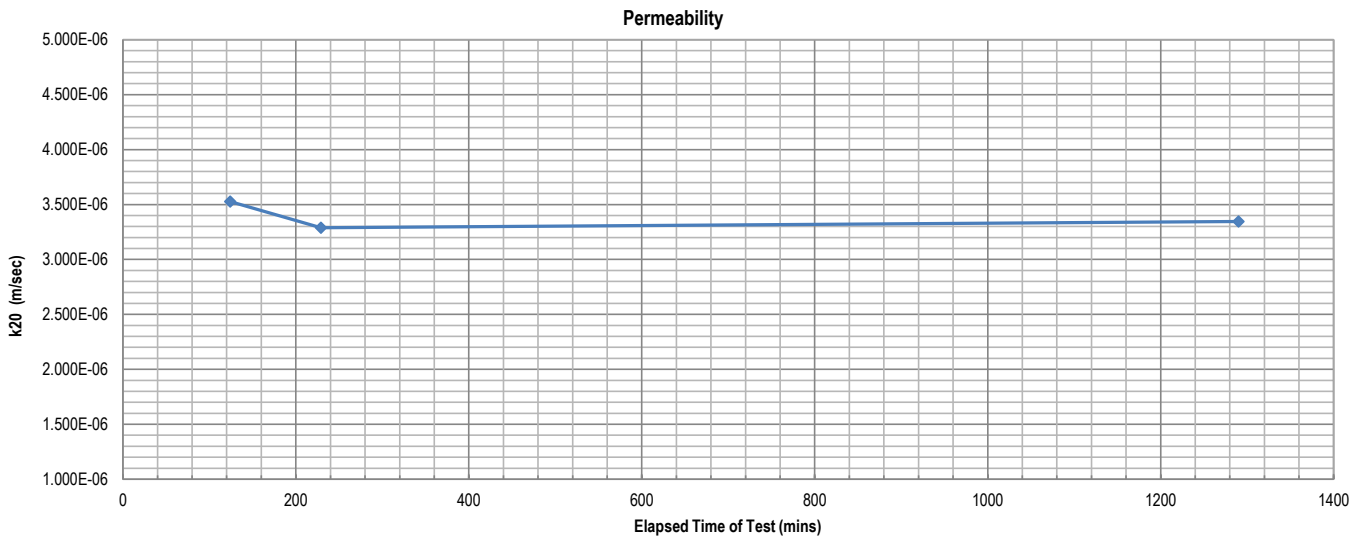
Test Method AS 1289 6.7.1, 5.1.1

Client	Mine Earth	**Report No.**	24090390-CPER
		Workorder No.	9919/T/654
Address	Unit 1, 94 Forsyth Street O'Connor WA 6163	**Test Date**	8/10/2024
		Report Date	25/10/2024
Project	TCK-2405		
Client ID	T1	**Depth (m)**	Not Supplied
Description	Not Supplied	**Sample Type**	Remoulded Soil Specimen

RESULTS OF TESTING

Compaction Method	**AS1289.5.1.1 - Standard Compaction**		
Maximum Dry Density (t/m^3)	**1.58**	Hydraulic Gradient	**2.3**
Optimum Moisture Content (%)	**5.8**	Surcharge (kPa)	**2.9**
Placement Moisture Content (%)	**6.2**	Head Pressure Applied (kPa)	**2.65**
Moisture Ratio (%)	**107.0**	Water Type	**Deaerated**
Placement Wet Density (t/m^3)	**1.59**	Percentage Material Retained/Sieve Size (mm)	**0 % / 19 mm**
Density Ratio (%)	**94.6**	Sample Height and Diameter (mm)	**116.52 / 101.51 mm**

PERMEABILITY $k_{(20)}$ = **3.3×10^{-06} (m/sec)**



Remarks: The above specimen was remoulded to a target of 95% of Standard Maximum Dry Density and at Optimum Moisture Content.

Sample/s supplied by client

Accredited for compliance with ISO/IEC 17025 - Testing

Method:
- Moisture Content calculated using Moisture Tension Plate
- Available Water (%Grav.) = Field Capacity (%Grav.) - Wilting Point (%Grav.)

Note: particles ≥ 10mm diameter have been removed prior to measurement. Results for samples with particles ≥ 10mm diameter have been rescaled assuming particles ≥ 10mm are functionally impervious.

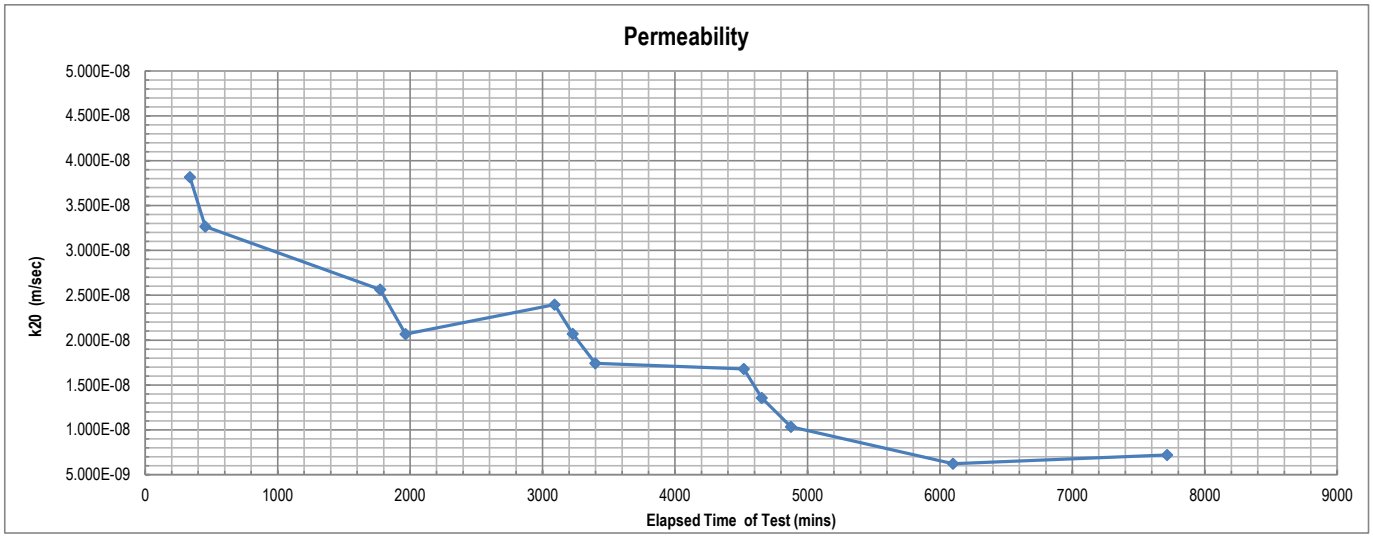
Address	Unit 1, 94 Forsyth Street O'Connor WA 6163	**Test Date**	17/10/2024
		Report Date	20/11/2024
Project	TCK-2405		
Client ID	WR1	**Depth (m)**	Not Supplied
Description	Not Supplied	**Sample Type**	Remoulded Soil Specimen

RESULTS OF TESTING

Compaction Method	**AS1289.5.1.1 - Standard Compaction**		
Maximum Dry Density (t/m^3)	**1.98**	Hydraulic Gradient	**11.2**
Optimum Moisture Content (%)	**10.7**	Surcharge (kPa)	**3.7**
Placement Moisture Content (%)	**10.8**	Head Pressure Applied (kPa)	**12.75**
Moisture Ratio (%)	**101.2**	Water Type	**Deaerated**
Placement Wet Density (t/m^3)	**2.08**	Percentage Material Retained/Sieve Size (mm)	**0 % /19 mm**
Density Ratio (%)	**94.9**	Sample Height and Diameter (mm)	**116.41 / 152.4 mm**

PERMEABILITY $k_{(20)} = 7.2 \times 10^{-09}$ **(m/sec)**



Remarks: The above specimen was remoulded to a target of 95% of Standard Maximum Dry Density and at Optimum Moisture Content.

Sample/s supplied by client The compaction data was supplied by the client. **Page: 1 of 1** REP06301

Accredited for compliance with ISO/IEC 17025 - Testing

Test Method AS 1289 6.7.1, 5.1.1

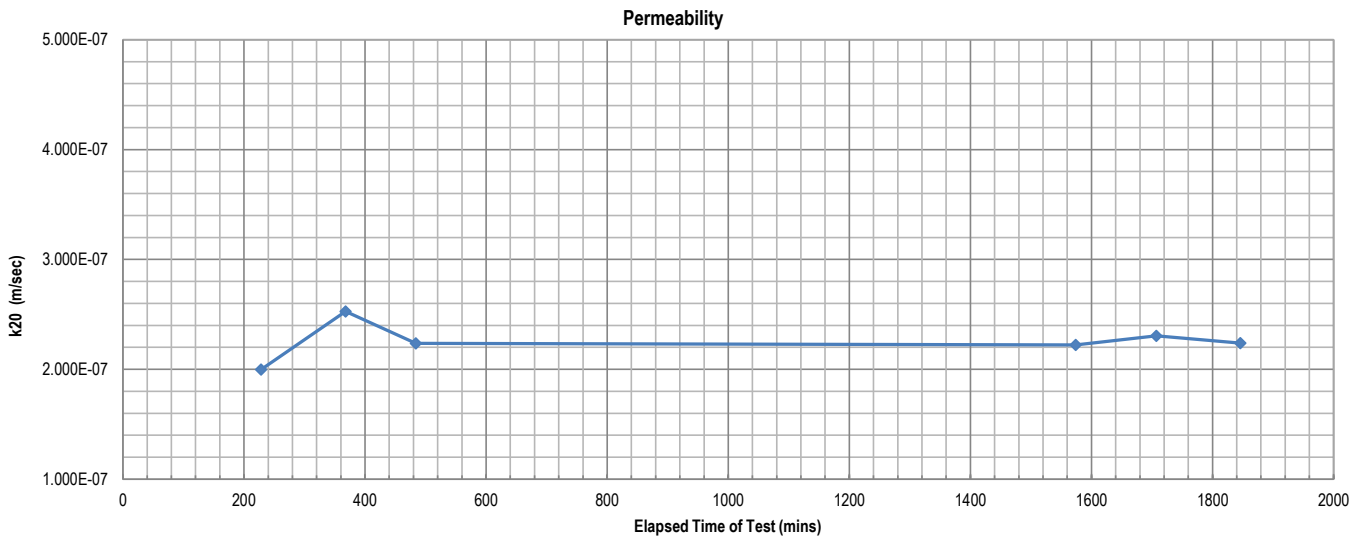
Client	Mine Earth	**Report No.**	24090399-CPER
		Workorder No.	9919/T/654
Address	Unit 1, 94 Forsyth Street O'Connor WA 6163	**Test Date**	30/10/2024
		Report Date	20/11/2024
Project	TCK-2405		
Client ID	DC1	**Depth (m)**	Not Supplied
Description	Not Supplied	**Sample Type**	Remoulded Soil Specimen

RESULTS OF TESTING

Compaction Method	**AS1289.5.1.1 - Standard Compaction**		
Maximum Dry Density (t/m^3)	**1.88**	Hydraulic Gradient	**3.6**
Optimum Moisture Content (%)	**9.7**	Surcharge (kPa)	**3.7**
Placement Moisture Content (%)	**10.0**	Head Pressure Applied (kPa)	**4.12**
Moisture Ratio (%)	**103.3**	Water Type	**Deaerated**
Placement Wet Density (t/m^3)	**1.96**	Percentage Material Retained/Sieve Size (mm)	**0 % / 19 mm**
Density Ratio (%)	**94.7**	Sample Height and Diameter (mm)	**116.57 / 152.36 mm**

PERMEABILITY $k_{(20)} =$ **2.3×10^{-07} (m/sec)**



Remarks: The above specimen was remoulded to a target of 95% of Standard Maximum Dry Density and at Optimum Moisture Content.

Sample/s supplied by client

Accredited for compliance with ISO/IEC 17025 - Testing

NOTES/REMARKS: -

Moisture Content 7.7% -2.36mm Soil Particle Density(t/m^3) 2.64

Sample/s supplied by the client

Accredited for compliance with ISO/IEC 17025 - Testing

*NATA is a signatory to the ILAC Mutual Recognition Arrangement for the mutual recognition of the equivalence of testing, medical testing, calibration, inspection, proficiency testing scheme providers and reference materials producers reports and certificates

Approved Signatory

Michael Hamilton

NATA WORLD RECOGNISED ACCREDITATION

Tested at Trilab Brisbane Laboratory

Laboratory No. 9926

The results of calibrations and tests performed apply only to the specific instrument or sample at the time of test unless otherwise clearly stated.
Reference should be made to Trilab's "Standard Terms and Conditions of Business" for further details.

Contact	: Matt Braimbridge	Contact	: Customer Services EB
Address	: 1 BREAKFAST CREEK ROAD NEWSTEAD 4006	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: ----	Telephone	: +61-7-3243 7222
Project	: TCK-2405	Date Samples Received	: 07-Aug-2024 09:50
Order number	: ----	Date Analysis Commenced	: 20-Aug-2024
C-O-C number	: ----	Issue Date	: 28-Aug-2024 22:10
Sampler	: JEREMY DURBIN		
Site	: ----		
Quote number	: EN/222		
No. of samples received	: 24		
No. of samples analysed	: 24		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Vincent Muller	Chemist - Inorganics	Brisbane Soil Preparation, Stafford, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- ED009-X (Standard Anions - Extended Method –by IC): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- EA150H: Soil particle density results fell outside the scope of AS1289.3.6.3. Results should be scrutinised accordingly.
- ALS is not NATA accredited for the analysis of Exchangeable Aluminium and Exchange Acidity in soils when performed under ALS Method ED005.
- ALS is not NATA accredited for the analysis of Exchangeable Cations on Alkaline Soils when performed under ALS Method ED006.
- As per QWI – EN55-3 Data Interpreting Procedures, Ionic balances are typically calculated using Major Anions - Chloride, Alkalinity and Sulfate; and Major Cations - Calcium, Magnesium, Potassium and Sodium. Where applicable and dependent upon sample matrix, the Ionic Balance may also include the additional contribution of Ammonia, Dissolved Metals by ICPMS and H+ to the Cations and Nitrate, SiO2 and Fluoride to the Anions.
- Ionic Balance out of acceptable limits due to analytes not quantified in this report.
- EG005T (Total Metals by ICP-AES): Sample EB2428324-003 shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.
- ED093C (Leachable Major Cations): Unable to report Sodium results due to it's inclusion in the extraction fluid.
- ED006 (Exchangeable Cations on Alkaline Soils): Unable to calculate Magnesium/Potassium Ratio result for some samples as required Exchangeable Magnesium and/or Potassium results are less than the limit of reporting.
- ED006 (Exchangeable Cations on Alkaline Soils): Unable to calculate Calcium/Magnesium Ratio result for some samples as required Exchangeable Calcium and/or Magnesium results are less than the limit of reporting.
- ED006 (Exchangeable Cations on Alkaline Soils): Sample DC-ALS (EB2428229-006) shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.
- It is recognised that EG005T (Total Metals by ICP-AES) is less than EG005C (Leachable Metals by ICP-AES) for some samples. However, the difference is within experimental variation of the methods.
- ED045G (Chloride)/ ED041G (Sulfate as SO4): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- EA058 Emerson: V. = Very, D. = Dark, L. = Light, VD. = Very Dark
- ED007 and ED008: When Exchangeable Al is reported from these methods, it should be noted that Rayment & Lyons (2011) suggests Exchange Acidity by 1M KCl - Method 15G1 (ED005) is a more suitable method for the determination of exchange acidity (H+ + Al3+).
- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.
- ED045G: The presence of Thiocyanate, Thiosulfate and Sulfite can positively contribute to the chloride result, thereby may bias results higher than expected. Results should be scrutinised accordingly.

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. All pages of this report have been checked and approved for release. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to Assist with Quality Review and Sample Receipt Notification.

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	Position (Accreditation Category)
Beatriz Llarinas	Senior Chemist - Inorganics (Brisbane Inorganics, Stafford, QLD)
	Senior Chemist - Inorganics (Brisbane Soil Preparation, Stafford, QLD)
Ben Felgendrejeris	Senior Acid Sulfate Soil Chemist (Brisbane Acid Sulphate Soils, Stafford, QLD)
	Senior Acid Sulfate Soil Chemist (Brisbane Soil Preparation, Stafford, QLD)
Dave Gitsham	Metals Instrument Chemist (Brisbane Inorganics, Stafford, QLD)
Layla Hafner	Acid Sulphate Soils - Chemist (Brisbane Acid Sulphate Soils, Stafford, QLD)
Vincent Muller	Chemist - Inorganics (Brisbane Inorganics, Stafford, QLD)
	Chemist - Inorganics (Brisbane Soil Preparation, Stafford, QLD)

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.
Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.
Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Where a result is required to meet compliance limits, the associated uncertainty **must be** considered. Refer to the ALS Contract Terms and Conditions for details, and EnviroMail 53 for a guide on how to interpret the measurement of uncertainty (MU).

Work Order Specific Comments

- ED009-X (Standard Anions - Extended Method –by IC): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- EA150H: Soil particle density results fell outside the scope of AS1289.3.6.3. Results should be scrutinised accordingly.
- ALS is not NATA accredited for the analysis of Exchangeable Aluminium and Exchange Acidity in soils when performed under ALS Method ED005.
- ALS is not NATA accredited for the analysis of Exchangeable Cations on Alkaline Soils when performed under ALS Method ED006.
- As per QWI – EN55-3 Data Interpreting Procedures, Ionic balances are typically calculated using Major Anions - Chloride, Alkalinity and Sulfate; and Major Cations - Calcium, Magnesium, Potassium and Sodium. Where applicable and dependent upon sample matrix, the Ionic Balance may also include the additional contribution of Ammonia, Dissolved Metals by ICPMS and H+ to the Cations and Nitrate, SiO2 and Fluoride to the Anions.
- Ionic Balance out of acceptable limits due to analytes not quantified in this report.
- EG005T (Total Metals by ICP-AES): Sample EB2428324-003 shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.
- ED093C (Leachable Major Cations): Unable to report Sodium results due to it's inclusion in the extraction fluid.
- ED006 (Exchangeable Cations on Alkaline Soils): Unable to calculate Magnesium/Potassium Ratio result for some samples as required Exchangeable Magnesium and/or Potassium results are less than the limit of reporting.
- ED006 (Exchangeable Cations on Alkaline Soils): Unable to calculate Calcium/Magnesium Ratio result for some samples as required Exchangeable Calcium and/or Magnesium results are less than the limit of reporting.
- ED006 (Exchangeable Cations on Alkaline Soils): Sample DC-ALS (EB2428229-006) shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.
- It is recognised that EG005T (Total Metals by ICP-AES) is less than EG005C (Leachable Metals by ICP-AES) for some samples. However, the difference is within experimental variation of the methods.
- ED045G (Chloride)/ ED041G (Sulfate as SO4): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- EA058 Emerson: V. = Very, D. = Dark, L. = Light, VD. = Very Dark
- ED007 and ED008: When Exchangeable Al is reported from these methods, it should be noted that Rayment & Lyons (2011) suggests Exchange Acidity by 1M KCl - Method 15G1 (ED005) is a more suitable method for the determination of exchange acidity (H+ + Al3+).
- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.
- ED045G: The presence of Thiocyanate, Thiosulfate and Sulfite can positively contribute to the chloride result, thereby may bias results higher than expected. Results should be scrutinised accordingly.

Address	: 1 BREAKFAST CREEK ROAD NEWSTEAD 4006	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: ----	Telephone	: +61-7-3243 7222
Project	: TCK-2405	Date Samples Received	: 07-Aug-2024
Order number	: ----	Date Analysis Commenced	: 20-Aug-2024
C-O-C number	: ----	Issue Date	: 28-Aug-2024
Sampler	: JEREMY DURBIN		
Site	: ----		
Quote number	: EN/222		
No. of samples received	: 24		
No. of samples analysed	: 24		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC
* = The final LOR has been raised due to dilution or other sample specific cause; adjusted LOR is shown in brackets. The duplicate ranges for Acceptable RPD% are applied to the final LOR where applicable.

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Sub-Matrix: **SOIL**

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

Sub-Matrix: **SOIL**

Site	: ----	Issue Date	: 28-Aug-2024
Sampler	: JEREMY DURBIN	No. of samples received	: 24
Order number	: ----	No. of samples analysed	: 24

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Laboratory Control outliers occur.**
- **Duplicate outliers exist - please see following pages for full details.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **For all regular sample matrices, where applicable to the methodology, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **Quality Control Sample Frequency Outliers exist - please see following pages for full details.**

Outliers : Quality Control Samples

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: ✗ = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001	SOIL	In house: Referenced to Rayment and Lyons 4B3 (mod.) or 4B4 (mod.) 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
pH (1:5)	EA002	SOIL	In house: Referenced to Rayment and Lyons 4A1 and APHA 4500H+. pH is determined on soil samples after a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
pH by Auto Titrator	EA005-P	SOIL	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM Schedule B(3)
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Total Dissolved Solids (High Level)	EA015H	SOIL	In house: Referenced to APHA 2540C. A gravimetric procedure that determines the amount of `filterable` residue in an aqueous sample. A well-mixed sample is filtered through a glass fibre filter (1.2um). The filtrate is evaporated to dryness and dried to constant weight at 180+/-5C. This method is compliant with NEPM Schedule B(3)
Moisture Content	EA055	SOIL	In house: A gravimetric procedure based on weight loss over a 12 hour drying period at 105-110 degrees C. This method is compliant with NEPM Schedule B(3).
Emerson Aggregate Test	EA058	SOIL	In house: Referenced to AS1289.3.8.1. Testing is performed only on soils with suitable aggregates; sands and gravels are usually unsuitable for this test. The test classifies the behaviour of soil aggregates, when immersed, on their coherence in water.
Particle Size Analysis by Hydrometer	EA150H	SOIL	Particle Size Analysis by Hydrometer according to AS1289.3.6.3
Soil Particle Density	EA152	SOIL	Soil Particle Density by AS 1289.3.5.1: Methods of testing soils for engineering purposes - Soil classification tests - Determination of the soil particle density of a soil - Standard method
Exchange Acidity by 1M Potassium Chloride	* ED005	SOIL	In house: referenced to Rayment and Lyons, method 15G1. This method is unsuitable for near neutral and alkaline soils. NATA accreditation does not cover performance of this service.
Exchangeable Cations on Alkaline Soils	* ED006	SOIL	In house: Referenced to Soil Survey Test Method C5. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with alcoholic ammonium chloride at pH 8.5. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil.
Exchangeable Cations	ED007	SOIL	In house: Referenced to Rayment & Lyons Method 15A1. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations with pre-treatment	ED008	SOIL	In house: Referenced to Rayment & Lyons Method 15A2. Soluble salts are removed from the sample prior to analysis. Cations are exchanged from the sample by contact with Ammonium Chloride. They are then quantitated in the final solution by ICPAES and reported as meq/100g of original soil. This method is compliant with NEPM Schedule B(3).
Standard Anions -by IC (Extended Method)	ED009-X	SOIL	In house: Referenced to APHA 4110B. This method is compliant with NEPM Schedule B(3)
Bicarbonate Extractable K (Colwell)	ED021	SOIL	In house: Referenced to Rayment & Lyons Method 18A1 Potassium is extracted from the soil using 0.5M NaHCO3 at a 1:100 soil:solution ratio and determined by ICP.

Analytical Methods	Method	Matrix	Method Descriptions
Alkalinity by Auto Titrator	ED037-P	SOIL	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) on a settled supernatant aliquot of the sample using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM Schedule B(3)
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	SOIL	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM Schedule B(3)
Chloride by Discrete Analyser	ED045G	SOIL	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride. In the presence of ferric ions the liberated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm.
DTPA Extractable Metals	* ED092	SOIL	In house: Referenced to Rayment and Lyons 12A1
Leachable Major Cations	ED093C	SOIL	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations in leachates are determined by either ICP-AES or ICP-MS techniques.
Leachable Metals by ICPAES	EG005C	SOIL	In house: referenced to APHA 3120; USEPA SW 846 - 6010: The ICPAES technique ionises leachate sample atoms emitting a characteristic spectrum. This spectrum is then compared against matrix matched standards for quantification. This method is compliant with NEPM Schedule B(3).
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3)
Leachable Mercury by FIMS	EG035C	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the TCLP solution. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Total Mercury by FIMS	EG035T	SOIL	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2) (Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. Mercury in solids are determined following an appropriate acid digestion. Ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3)
Fluoride by Auto Titrator	EK040P	SOIL	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM Schedule B(3)
Ammonia as N by Discrete analyser	EK055G	SOIL	In house: Referenced to APHA 4500-NH3 G Ammonia is determined by direct colorimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Ammonia Using Steam Distillation and Titrimetric Finish	EK055-P	SOIL	In house: Referenced to APHA 4500-NH3 B&G, H Samples are steam distilled prior to analysis and quantified using titration, FIA or Discrete Analyser.
Nitrite as N - Soluble by Discrete Analyser	EK057G	SOIL	In house: Referenced to APHA 4500-NO3- B. Nitrite in a water extract is determined by direct colourimetry by Discrete Analyser.

Analytical Methods	Method	Matrix	Method Descriptions
Nitrate as N - Soluble by Discrete Analyser	EK058G	SOIL	In house: Referenced to APHA 4500-NO3- F. Nitrate in the 1:5 soil:water extract is reduced to nitrite by way of a chemical reduction followed by quantification by Discrete Analyser. Nitrite is determined seperately by direct colourimetry and result for Nitrate calculated as the difference between the two results.
Nitrite and Nitrate as N (NOx)- Soluble by Discrete Analyser	EK059G	SOIL	In house: Thermo Scientific Method D08727 and NEMI (National Environmental Method Index) Method ID: 9171. This method covers the determination of total oxidised nitrogen (NOx-N) and nitrate (NO3-N) by calculation, Combined oxidised Nitrogen (NO2+NO3) in a water extract is determined by direct colourimetry by Discrete Analyser.
TKN as N By Discrete Analyser	EK061G	SOIL	In house: Referenced to APHA 4500-Norg-D Soil samples are digested using Kjeldahl digestion followed by determination by Discrete Analyser.
Total Nitrogen as N (TKN + NOx) By Discrete Analyser	EK062G	SOIL	In house: Referenced to APHA 4500 Norg/NO3- Total Nitrogen is determined as the sum of TKN and Oxidised Nitrrogen, each determined seperately as N.
Total Phosphorus By Discrete Analyser	EK067G	SOIL	In house: Referenced to APHA 4500 P-B&F This procedure involves sulfuric acid digestion and quantification using Discrete Analyser.
Reactive Phosphorus as P-By Discrete Analyser	EK071G	SOIL	In house: Referenced to APHA 4500-P F Ammonium molybdate and potassium antimonyl tartrate reacts in acid medium with othophosphate to form a heteropoly acid -phosphomolybdic acid - which is reduced to intensely coloured molybdenum blue by ascorbic acid. Quantification is by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Bicarbonate Extractable P (Colwell)	EK080	SOIL	In house: Referenced to Rayment & Lyons Method 9B1 Phosphorus is extracted from the soil using 0.5M NaHCO3 at a 1:100 soil:solution ratio and determined by FIA.
Organic Matter	EP004	SOIL	In house: Referenced to AS1289.4.1.1. Dichromate oxidation method after Walkley and Black. This method is compliant with NEPM Schedule B(3)

Preparation Methods	Method	Matrix	Method Descriptions
pH in soil using a 0.01M CaCl2 extract	EA001-PR	SOIL	In house: Referenced to Rayment and Lyons 4B1, 10 g of soil is mixed with 50 mL of 0.01M CaCl2 and tumbled end over end for 1 hour. pH is measured from the continuous suspension. This method is compliant with NEPM Schedule B(3).
Exchangeable Cations Preparation Method (Alkaline Soils)	* ED006PR	SOIL	In house: Referenced to Rayment and Lyons method 15C1.
Exchangeable Cations Preparation Method	ED007PR	SOIL	In house: Referenced to Rayment & Lyons method 15A1. A 1M NH4Cl extraction by end over end tumbling at a ratio of 1:20. There is no pretreatment for soluble salts. Extracts can be run by ICP for cations.
Bicarbonate Extractable K (Colwell)	ED021PR	SOIL	In house: Referenced to Rayment & Lyons Method 18A1 Potassium is extracted from the soil using 0.5M NaHCO3 at a 1:100 soil:solution ratio and determined by ICP.
DTPA Extraction for Cu, Zn, Mn, Fe (2 hour leach)	ED092PR	SOIL	In house: Referenced to Rayment & Lyons Method 12A1 2 hour end over end tumbler extraction with 0.005M DTPA at a ratio of 1:2. Extracts can be run by ICP for metals.
TKN/TP Digestion	EK061/EK067	SOIL	In house: Referenced to APHA 4500 Norg- D; APHA 4500 P - H. Macro Kjeldahl digestion.
Sample Preparation for Bicarbonate Extractable P (Colwell)	EK080-PR	SOIL	In house: Referenced to Rayment & Lyons Method 9B1 Phosphorus is extracted from the soil using 0.5M NaHCO3 at a 1:100 soil:solution ratio.
Digestion for Total Recoverable Metals in TCLP Leachate	EN25C	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)

Preparation Methods	*Method*	*Matrix*	*Method Descriptions*
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
ASLP for Non & Semivolatile Analytes - Glass Leaching Vessel	EN60a-G	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM Schedule B(3).
Organic Matter	EP004-PR	SOIL	In house: Referenced to AS1289.4.1.1. Dichromate oxidation method after Walkley and Black. This method is compliant with NEPM Schedule B(3).

APPENDIX C REGIONAL ECOSYSTEM SUMMARY

Local Regional Ecosystem summary

RE No.^	% composition	Vegetation management status	Biodiversity status	Description	Structure	Key species			Notes	Intersecting site features
						Trees	**Shrubs**	**Grasses and forbs**		
1.11.10b	85	Least concern	No concern at present	Mixed low open woodland on metamorphic plains	Low open woodland	*Eucalyptus leucophylla, Corymbia terminalis, C. aparrerinja, Atalaya hemiglauca, Grevillea striata, Hakea spp., Acacia excelsa subsp. angusta* and *A. cambagei*	*Senna* spp. and *Eremophila* spp.	Short annual grasses and forbs	Very open communities with very sparse ground cover	Pit
1.11.2a	15	Least concern	No concern at present	*E. leucophloia* low open woodland	Low open woodland	Eucalyptus leucophloia, Corymbia terminalis, C. capricornia, Terminalia aridicola and E. leucophylla	Acacia spp.	Triodia spp.	Occurs on steep hills and strike ridges	
1.5.6c	85	Least concern	No concern at present	Atalaya hemiglauca, Ventilago viminalis, Grevillea striata low open woodland on red earth plains	Low open woodland	Atalaya hemiglauca, Acacia excelsa, Acacia cambagei, Ventilago viminalis, Grevillea striata, Hakea lorea subsp. lorea, Ehretia saligna, Corymbia terminalis and C. aparrerinja	Acacia spp. and Carissa lanceolata	Aristida contorta	Mixed low open woodland. Prone to scalding	WRD
1.12.3b	15	Least concern	No concern at present	Eucalyptus leucophylla and/or Corymbia terminalis +/- C. aparrerinja low open woodland on igneous rocks	Low open woodland	Eucalyptus leucophylla, Atalaya hemiglauca, Corymbia terminalis, C. aparrerinja, Acacia cambagei, Grevillea striata, Hakea spp. and Acacia excelsa subsp. angusta	-	Short tussock grasses and *Triodia* spp	These are usually extremely open communities with very sparse ground layers	
1.5.4d	85	Least concern	No concern at present	Eucalyptus leucophylla and/or Corymbia terminalis low open woodland on red earths	Low open woodland	Eucalyptus leucophylla and Corymbia terminalis. Occasional Corymbia aparrerinja, Atalaya hemiglauca and Grevillea striata	-	Annual grasses with areas of *Triodia* spp	**Cenchrus pennisetiformis* (Cloncurry buffel grass) is present	TSF
1.11.10b	15	Least concern	No concern at present	Mixed low open woodland on metamorphic plains	Low open woodland	Eucalyptus leucophylla, Corymbia terminalis, Corymbia aparrerinja, Atalaya hemiglauca, Grevillea striata, Hakea spp., Acacia excelsa subsp. angusta and Acacia cambagei	-	Short annual grasses and forbs	-	
4.4.1d	100	Least concern	No concern at present	Astrebla pectinata +/- Aristida latifolia +/- Eulalia aurea grassland on Tertiary clays overlying limestone	Tussock Grassland	Atalaya hemiglauca, Acacia georginae, Acacia cambagei and Ventilago viminalis	-	Astrebla pectinate, Eulalia aurea, Astrebla spp., Aristida latifolia, Iseilema spp., annual grasses and forbs	-	TSF
1.5.3	100	Least concern	No concern at present	*Eucalyptus leucophloia* low open woodland to woodland on sandy and gravelly red soils	Low open woodland	Eucalyptus leucophloia and Corymbia terminalis	Acacia spp	Triodia spp		

^Note: only REs relevant to rehabilitation of THGM have been listed

Exploration Manager

Dear Paul

Environmental Site Assessment of Tick Hill Gold Mine, Dajarra QLD

Please find enclosed a copy of our report entitled as above. Thank you for the opportunity to undertake this work.

Should you have any queries, please do not hesitate to contact us on (07) 3852 6666.

EXECUTIVE SUMMARY

Introduction

Environmental Earth Sciences QLD was commissioned by Carnaby Resources Ltd to undertake an Environmental Site Assessment (ESA) of Tick Hill Gold Mine, Dajarra, Queensland (the site). The site occupies mining leases ML7094, 7096 and 7097 and is located approximately 40 km south of Duchess and 140 km southeast of Mount Isa. The site covers an area of approximately 390 ha.

The investigation was required to meet the requirements of the progressive rehabilitation and closure plan (PRCP) and Environmental Evaluation (EE) for the site. The site is currently non-operational, however was previously an operational gold mine between 1990 and 1994 and tailings have been extracted for reprocessing between 2020 and 2022. The site is managed under Environmental Authority EPML00820613.

Objectives

The objectives of the ESA include the following:

- Identify potential sources of contamination and associated chemicals of potential concern (CoPC) associated with historical and recent mining activities;
- Identify potential human and ecological receptors;
- Identify potentially impacted media (soil, tailings, groundwater, surface water);
- Further develop the hydrogeological conceptual site model for the pit and surrounds; and
- Provide recommendations regarding requirements for future remediation or monitoring.

Scope

To achieve the project objectives, the following scope was undertaken:

- Desktop assessment of the site and surrounding area's environmental and physical setting, and available historical information;
- Site inspection to complement the findings of the desktop assessment and to identify any additional relevant site information;
- Groundwater investigation program, including expansion of the existing monitoring network;
- Soil investigation program targeting historical site uses and mine wastes.

Summary of findings

The findings of the investigation into groundwater, soil and tailings at Tick Hill can be summarised as follows:

- Groundwater:
    - Groundwater is naturally elevated in salts and metals which make it unsuitable for potable use without treatment.
    - Low concentrations of total cyanide (CN) are found across the site, with the highest concentrations observed at bores THGW001 and THGW008. Free CN exceeding screening criteria was observed in these two bores.
    - Nitrate and ammonia attributed to explosive residue was observed in several locations, including bore THGW004, down gradient of the waste rock dump (WRD).
    - The groundwater model indicates that the open pit acts as a groundwater sink for the site, with the exception of the area north of the WRD and potentially the western site perimeter around bore THGW003. No sensitive receptors were identified that might be impacted by groundwater quality at these locations.
    - The cyanide impact to groundwater between the tailings storage facility (TSF) and open pit is assessed as being stable, with concentrations likely to steadily decrease over time. It is not expected that cyanide impacted groundwater will adversely impact pit water quality to any significant extent and cyanide in pit water will be degraded by sunlight.
- No evidence of soil or sediment contamination was observed on site.
- Tailings material retains some cyanide as total cyanide, which is likely present as iron cyanide. This form is non-toxic. No free cyanide remains. Some elevated concentrations of copper occur within the tailings due to natural elevations of copper in the ore material. Copper concentrations are acceptable if tailings materials are managed appropriately within the TSF. No observed acid generation potential exists within tailings material.
- The waste rock dump is stable and well vegetated. However, due to age and permeability, the WRD appears to have been releasing nitrogen compounds from explosive residues into the surrounding landscape.

Conclusions

Based on the above findings the following conclusion have been made:

- The mining void currently serves as a groundwater sink, influencing groundwater flow across the site, with the exception of the area around the WRD.
- The long term scenario is that the pit will act as a groundwater sink under all plausible site conditions.

- The water quality of the pit poses no current risk of contamination to the surrounding aquifer.
- Potential for pit stratification is not currently known.
- Cyanide (free and total) at bores THGW001 and THGW008 will remain at stable concentrations for some time before decreasing.
- Free cyanide at bores THGW001 and THGW008 does not have the potential to adversely impact pit water quality or discharge to watercourses.

Recommendations

Based on the above conclusions the following recommendations have been made:

- Rectification works should be undertaken to reinstate stockpiled tailings into the eastern TSF cell and recover the TSF.
- Regular groundwater monitoring should continue, with the analysis suite extended from the current parameters to include ammonia, nitrate and phosphate. Bi-annual monitoring is recommended until at least after the TSF rectification works are completed.

This executive summary is not a standalone document and should be read in conjunction with the rest of this report.

TABLE OF CONTENTS

1 INTRODUCTION 1

2 OBJECTIVES 1

3 SCOPE OF WORK 1

4 SITE SETTING 2

4.1 SITE IDENTIFICATION 2
4.2 SITE DESCRIPTION AND LAYOUT 5
4.3 SURROUNDING LAND USE 6
4.4 ENVIRONMENTALLY RELEVANT ACTIVITIES 7

5 SITE ENVIRONMENTAL SETTING 7

5.1 TOPOGRAPHY AND VEGETATION 7
5.2 SURFACE WATER DRAINAGE AND HYDROLOGY 8
5.2.1 Surface water environmental values 8
5.2.2 Flood risk 9
5.3 SOILS 9
5.4 REGIONAL SURFACE GEOLOGY 9
5.5 HYDROGEOLOGY 11
5.5.1 Registered bore search 11
5.5.2 Aquifers and aquitards 11
5.5.3 Groundwater dependent ecosystems 11
5.6 CLIMATE AND METEOROLOGY 14
5.7 SENSITIVE RECEPTORS 14
5.7.1 Sensitive human receptors 14
5.7.2 Environmentally sensitive areas 15

6 SITE HISTORY 15

6.1 HISTORICAL AERIAL PHOTOGRAPHS 15
6.2 SUMMARY OF SITE OWNERSHIP AND MINING ACTIVITIES 16
6.3 LOCAL AND STATE GOVERNMENT REGISTERS RELATING TO THE SITE 17
6.4 PREVIOUS REPORTS 17
6.4.1 Interviews with relevant site staff 17
6.4.2 Assessment of cyanide degradation and acid generation potential 1990 18
6.4.3 Summary of Mine Operations 1993 18
6.4.4 Tick Hill Tailings Reclamation Project. EA amendment application supporting information 2020 20
6.4.5 Tick Hill Mining Lease MLs 7094, 7096 & 7097. Initial Development Plan, for period 1 July 2021 to 30 June 2025 21

6.4.6 Tailings Reclamation Project – Consequence Category Assessment. Tick Hill Mine 2022 21
6.4.7 Tick Hill Environmental Evaluation Groundwater Geochemistry Report. ML7097, ML7094, ML7096. Environmental Authority EPML00820613 2022 21
6.5 PREVIOUS ENVIRONMENTAL MONITORING 22
6.5.1 Groundwater monitoring 22
6.5.2 Surface water monitoring 24

7 SITE CONDITIONS.....25

7.1 SIGNIFICANT SITE FEATURES 25
7.1.1 Open pit 26
7.1.2 Waste rock dump (WRD) 28
7.1.3 Tailings Storage Facility (TSF) 29
7.1.4 Decant dam 32
7.1.5 Former processing plant area and remaining infrastructure 32
7.2 SUMMARY OF SITE CONDITIONS 33
7.2.1 Site activities/ uses 33
7.2.2 Utility infrastructure 33
7.2.3 Building construction, basements and crawl spaces 34
7.2.4 Industrial processes carried out on site 34
7.2.5 Chemical storage and transfer areas 34
7.2.6 Raw materials used 34
7.2.7 Product spills, losses, incidents, accidents, fires 34
7.2.8 Discharges to land and water 35
7.2.9 Waste produced and waste storage areas, management practices and disposal areas 35
7.2.10 Power generation 35
7.2.11 Historical earthworks and areas of fill 35
7.2.12 Existing monitoring infrastructure 35

8 PRELIMINARY CONCEPTUAL SITE MODEL.....35

8.1 PRELIMINARY RECEPTOR PATHWAY EVALUATION 36
8.1.1 Sources 36

1 INTRODUCTION

Environmental Earth Sciences QLD was commissioned by Carnaby Resources Ltd to undertake an Environmental Site Assessment (ESA) of Tick Hill Gold Mine, Dajarra, Queensland (the site). A Site Locality Plan is provided in **Figure 1**. The site occupies mining leases ML7094, 7096 and 7097 and is located approximately 40 km south of Duchess and 140 km southeast of Mount Isa. The site covers an area of approximately 390 ha.

The investigation was required to meet the requirements of the progressive rehabilitation and closure plan (PRCP) and Environmental Evaluation (EE) for the site. The site is currently non-operational, however was previously an operational gold mine between 1990 and 1994 and tailings have been extracted for reprocessing between 2020 and 2022. The site is managed under Environmental Authority EPML00820613.

This report should be read in conjunction with the limitations detailed in **Section 17** of this report.

2 OBJECTIVES

The objectives of the ESA include the following:

- Identify potential sources of contamination and associated chemicals of potential concern (CoPC) associated with historical and recent mining activities;
- Identify potential human and ecological receptors;
- Identify potentially impacted media (soil, tailings, groundwater, surface water);
- Further develop the hydrogeological conceptual site model for the pit and surrounds; and
- Provide recommendations regarding requirements for future remediation or monitoring.

3 SCOPE OF WORK

To meet the stated objectives the following scope of work was undertaken:

- Desktop assessment of the site and surrounding area's environmental and physical setting;
- Desktop site history review to identify historical potentially containing land uses and activities;

- Site inspection to complement the findings of the desktop assessment and to identify any additional relevant site information;
- Groundwater investigation program, including expansion of the existing monitoring network;
- Soil investigation program targeting historical site uses and mine wastes;
- Analysis of samples by a laboratory accredited by the National Association of Testing Authorities (NATA) for the selected analytical suite;
- Quality assurance and quality control (QA/QC) sampling;
- Provision of a report detailing the findings of the ESA and recommendations for further assessment and/or remediation if required.

4 SITE SETTING

4.1 Site identification

Site identification details are provided in **Table 1**. A plan of the regional locality of the site, along with site lot configuration is provided in **Figure 1**. **Figure 2** presents the site layout, investigation area and surrounding land-use.

Table 1: Site Identification

Item	Details
Site Owner	Carnaby Resources Limited
Address	Tick Hill Gold Mine, Dajarra, QLD
Mine leases	ML7094, ML7096, ML7097
Lot & Plan number	Lot 13 on SP309109 (part), Lot 16 on SP309110 (part)
Area (Mining lease)	390 ha lease area + 8.5 km road access
Zoning	Rural – Extractive and Mineral Resource
Current land use	Non-operational gold mine
Proposed future land use	Rehabilitated mining land
Local Government Authority	Cloncurry Shire
Coordinates (site centre)	-21.64645 Lat, 139.92561 Long
Site Location and Layout	**Figure 1 and Figure 2**

Title: Site Layout
Inset – mine layout during operations

Client: Carnaby Resources | Drawn By: A Sheldon | Date: June 2023

Location: Tick Hill Mine, QLD

Figure 2

4.2 Site description and layout

The site is located approximately 40 km south of the locality of Duchess, and approximately 140 km southeast of Mount Isa. Tick Hill is accessed via the Duchess Phosphate Hill Road which runs north-south 5 km to the east of the site.

The site is currently comprised of the former mine features including the flooded open pit, the tailings and decant dams and the waste rock dump. Site features are shown on **Figure 2.** Also present are the water supply tank, located on the hill to the east of site and the core yard, located south of the waste rock dump. Adjacent to the core yard are shipping containers for storage of maintenance equipment. Almost all other mining infrastructure from the original operations has been removed.

The former site layout is shown in **Figure 3** below. This aerial photograph shows the open pit (centre), tailings and decant dam to the right (south) and waste rock dump on the left (north). Also evident is the processing plant and mine operations are to the east of the tailings dams.

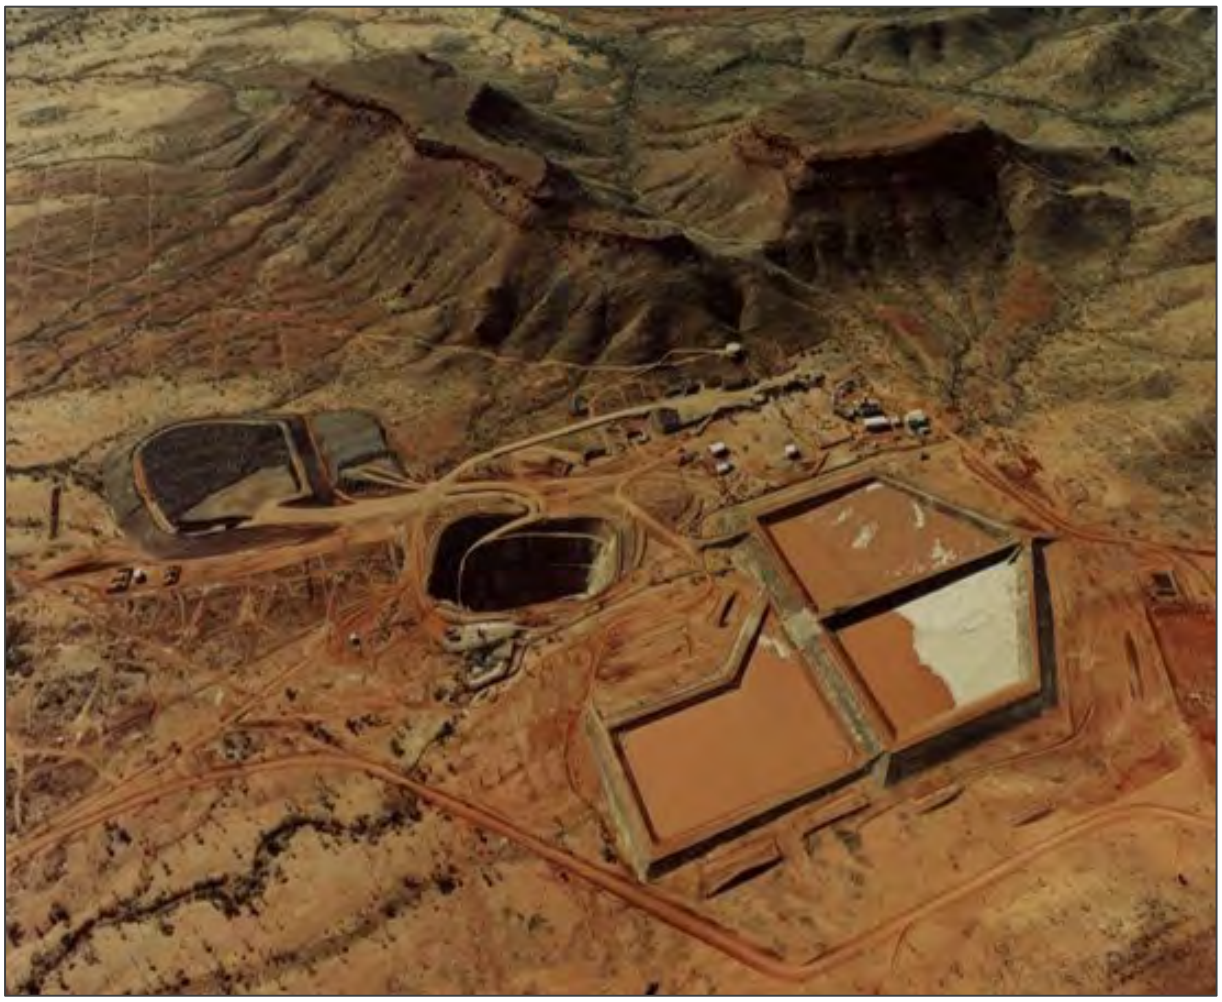

Figure 3: Aerial photograph of site during operations (from west to east)

Recent tailings re-working has included stripping and excavation of the eastern tailings cell. Cover material and some of the tailings are stockpiled on the western tailings cell. Some

tailings material has been removed from site. Equipment involved in the tailings re-working project is present on and about the tailings cells, including screening and processing plant, pumps and pipe.

For the purposes of clarity in further discussion regarding site setting or nearby activities, distances as shown on **Figure 4** are taken from the Tick Hill mine pit.

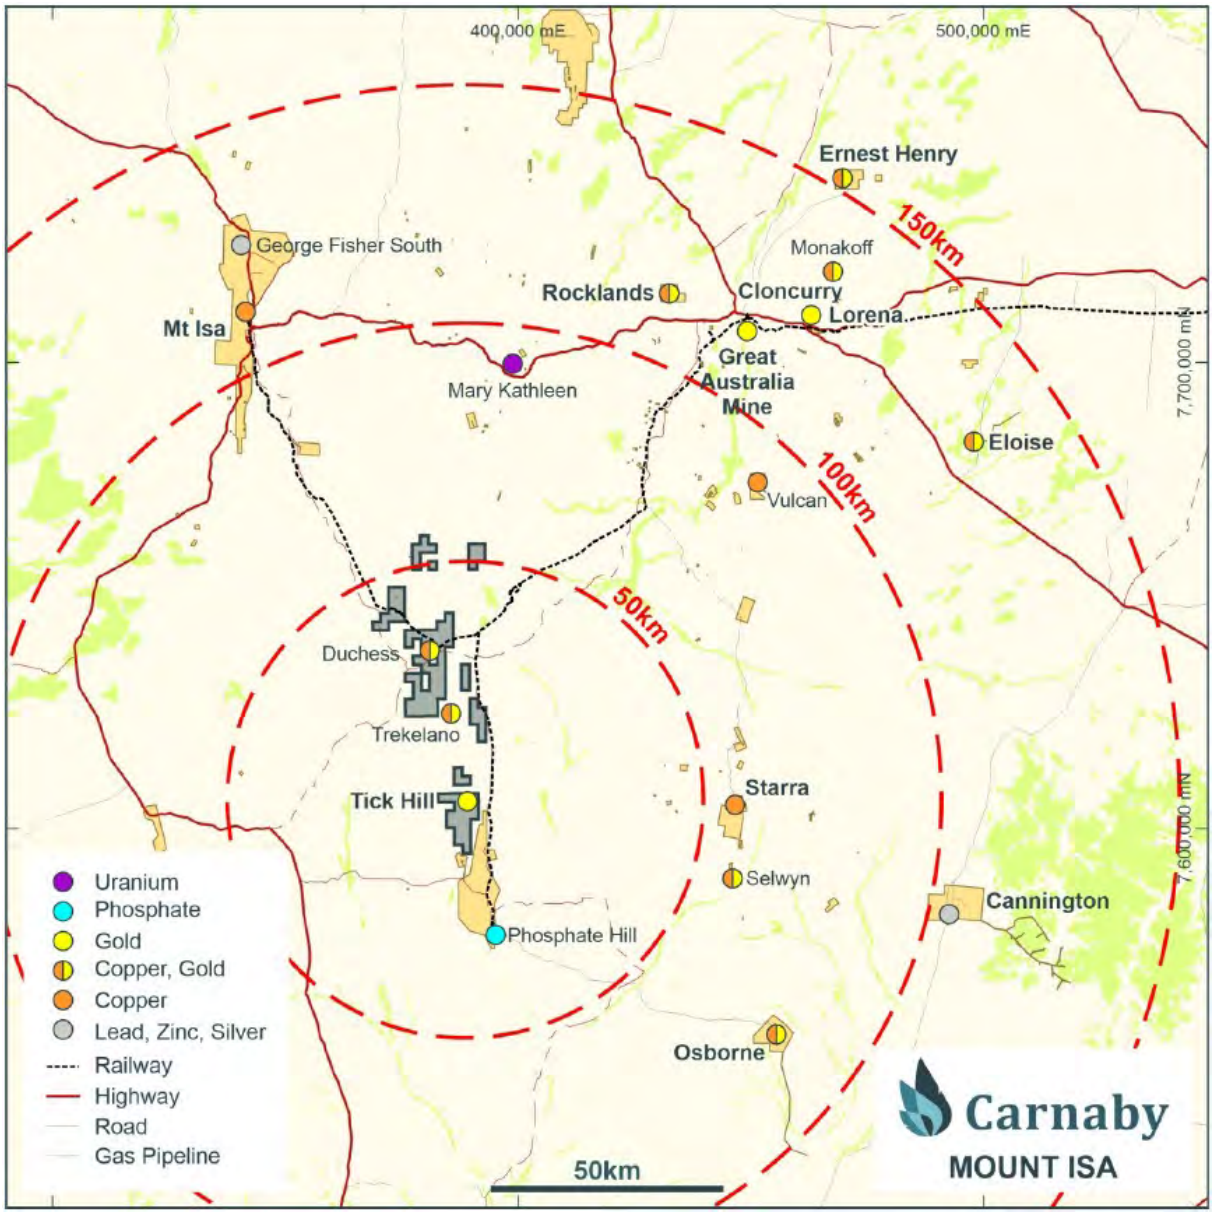

Figure 4: Mining and exploration leases within 150 km of the site

4.3 Surrounding land use

The following adjacent land uses were observed at the time of the site inspection and based on the desktop assessment:

- North: Low density grazing land. The former Trekelano Copper mine is located 19 km to the north;

- South: Low density grazing land. The Monument / Phosphate Hill mine, airstrip and village are located 12 – 26 km south of the site;
- East: Low density grazing land, Duchess Phosphate Hill Road and the Phosphate Hill branch line of the Mount Isa Railway; and
- West: Low density grazing land.

Surrounding land uses are shown on **Figure 2**. Nearby mining and exploration leases are shown on **Figure 4**.

4.4 Environmentally Relevant Activities

The site is managed under Environmental Authority (EA) EPML00820613 for the following Environmentally Relevant Activities (ERAs):

- Resource Activity, Schedule 3, 21: A mining activity that is an ineligible ERA, other than a mining activity mentioned in items 9 to 20 (ML7094, ML7096 and ML7097);
- Ancillary, Schedule 2, 31: Mineral processing 2(a) - Processing, in a year, the following quantities of mineral products, other than coke – 1,000t to 100,000t (ML7094); and
- Ancillary, Schedule 2, 60 – Waste Disposal 2: Operating a facility for disposing of, in a year, the following quantity of waste mentioned in subsection (1)(b)(a) less than 2,000 t (ML7094).

The EA is held by Carnaby Resources (holdings) Pty Ltd and is included as **Appendix A**.

5 SITE ENVIRONMENTAL SETTING

5.1 Topography and vegetation

The regional topography is described as gently rolling to hilly terrain with flat top mesas. The site's elevation within the lease areas ranges from 320 to 450 m Australian Height Datum (mAHD) although the former operational areas of the site were between 320 and 360 mAHD (**Figure 5**). The site slopes gently to the northwest and is bound by steep hills to the southeast.

Vegetation at the site consists of regrowth open woodlands, shrubs and grasses. Vegetation type are typically described as low open woodlands dominated by Eucalyptus leucophylla (Cloncurry box) or less extensively Corymbia terminalis (long-fruited bloodwood), low open woodlands and related associations, mainly lower slopes and valleys. Open plains to the west are described as Tussock grasslands dominated by Astrebla spp. (Mitchell grass) or Dichanthium spp. (bluegrass) often with Iseilema spp. on undulating downs or clay plains.

An aerial photograph from the time of site operations indicates that the site was extensively cleared, with topsoil scraped around the tailings dams. Recent site observations indicate

that site vegetation has recovered well, particularly along drainage lines and in sheltered areas, and that significant weed infestation has not occurred.

5.2 Surface water drainage and hydrology

The site is drained by several ephemeral watercourses which flow to the north and northwest. These join the larger ephemeral watercourse Petticoat Creek around 1.5 km downstream. Petticoat Creek drains the area surrounding the mine and flows east into the Burke River which flows south into the Georgina River and into Lake Eyre. Watercourses are shown on **Figure 5**.

On site water bodies include the open pit, which has partially refilled to form a permanent water body. Part of the eastern tailings cell which has been excavated for tailings reclamation also intermittently holds water.

Ephemeral watercourses at the site are potentially losing streams which contribute to groundwater recharge.

5.2.1 Surface water environmental values

Surface water quality is managed according to the Environmental Protection (Water and Wetland Biodiversity Protection) Policy 2019 (EPP[WWD] 2019). The site is located within the Lake Eyre Basin, for which water quality targets have not yet been nominated. When assessing the environmental values for the site and surrounds, site and regional conditions, observed land uses and proximity of human and environmental receptors is considered. Relevant environmental values are presented in **Table 2**. Relevant assessment guidelines have been adopted with consideration of these environmental values.

Where groundwaters interact with surface waters, groundwater quality should not compromise identified EVs and WQOs for those waters.

Table 2: Environmental Values for water

Environmental Value	Surface Water	Applicability
Aquatic Ecosystems	While all water courses at or near the site are ephemeral, surface water quality is important to maintaining these ecosystems. Due to the regional land use for grazing, ephemeral waterways would be considered slightly to moderately disturbed. No mapped riverine aquatic conservation areas occur within the vicinity of the site. The site is mapped as having low conservation significance.	Yes
Irrigation	No irrigated agriculture occurs in the vicinity of the site	No
Farm Supply use	Farm Supply within this area is primarily for stock watering. Occupied residential properties are located 17 km and 23 km from site (see drinking water below).	Yes
Stock Water	Stock will utilise available surface water.	Yes
Aquaculture	Surface water in the area is not used for aquaculture.	No
Human Consumer	Surface water in the area is not used for the production of food.	No

Environmental Value	Surface Water	Applicability
Primary Recreation	Surface water in the area is highly ephemeral; the area is very isolated from common human recreational pursuits and is not used for primary, secondary or visual recreational use.	No
Secondary Recreation		No
Visual Recreation		No
Drinking water	The nearest residences are located approximately 17 km to the SE and 23 km W, both adjoining significant waterways isolated from the Petticoat Creek system. Therefore, no drinking water is sourced in the vicinity of the site, nor would site activities impact local surface waters at these locations.	No
Industrial Use	There are numerous mining operations in the region, but none within 30 km of the site. It is therefore no considered possible that site activities would impact on surface water at other mines. Site water supply is sourced from a borefield 15 km E.	No
Cultural, Spiritual and Ceremonial Values	There are no known environmental values in relation to cultural and spiritual values of surface water in the vicinity of the site.	No

5.2.2 Flood risk

No flood risk has been identified at the site.

5.3 Soils

Soil mapping for the site includes the 1:2M Atlas of Australian Soils (Northcote et. al. 1960-1968) and the 1:1M Land Systems Survey of the Leichhardt-Gilbert Area (1964).

The flatter sections in the north and west of the site are mapped as the Quamby land system which is comprised of sparsely timbered undulating plains. Soils associated with this land system are described as red smooth-ped earths. These soils are gradational red earths with no A2 horizon and alkaline smooth-ped whole columnar B horizon.

The mesa hills in the southeast are the Merlin land system: stony spinifex country, gently undulating to undulating lands with occasional low mesas. Soils are earthy loams with uniform medium, porous coherent solum, and profile depth less than 0.6 m.

5.4 Regional surface geology

The surface geology (1:100,000 scale) underlying the site is classified as the Corella Formation, Paleoproterozoic aged (2500 to 1600 MYA) Calcareous siltstone, sandstone and minor limestone, passing into calc-silicate granofels, commonly scapolitic, and marble; local quartzose sandstone passing into quartzite; local breccia; minor amphibolite.

The flat top hills which rise to the southeast of the site are capped by the Mount Birnie beds, which are comprised of Neoprotozoic to early Cambrian aged massive ferruginous sandstone, cross-bedded sandstone, conglomerate, red and green shale, mudstone and dolomite; basal tillite, and middle Cambrian aged Thorntonia Limestone with laterite cap.

Figure 5

5.5 Hydrogeology

5.5.1 Registered bore search

A search was undertaken of registered groundwater bores within a 5 km radius of the site using (QldGlobe May 2023). A summary is presented in **Table 3** and bore reports are provided in **Appendix B**.

5.5.2 Aquifers and aquitards

Based on bore logs from the site, groundwater is found in fractured and weathered zones within the Proterozoic metasediments and igneous rocks of the Corella formation. Comparison of water strike and standing water levels (SWLs) indicates that the regional aquifer is semi-confined to confined. Granofels typically has little to no primary porosity. Groundwater flow will therefore mainly occur through secondary porosity including fractures and weathering, and more porous interbedded layers.

Aquifer yield would be expected to be low. Occasional high flow zones may be encountered however lack of connectivity (effective porosity, specific storage or specific yield) within the aquifer means that sufficient long-term yield to supply a production bore or water supply is unlikely.

Groundwater is neutral to slightly alkaline and moderately to highly saline. Water chemistry is dominated by sodium and magnesium, and bicarbonate and chloride.

Within the landscape around Tick Hill, groundwater recharge areas are likely to be located in the ephemeral watercourses, and the limestone capped hills to the southeast.

5.5.3 Groundwater dependent ecosystems

With reference to Groundwater Dependent Ecosystems (GDE) mapping (QldGlobe 2023) the site does not contain a GDE.

The closest off-site GDE is a cave ecosystem of the Devoncourt Limestone located 5 km to the southeast of the site. The GDE is described as a subterranean GDE of unknown confidence. The location of the GDE is shown on **Figure 6**.

5.6 Climate and meteorology

Regional meteorological data has been sourced from the Bureau of Meteorology (2023) (www.bom.gov.au, verified 17 May 2023); the Monument Airport weather station (037034 2000 - 2023), approximately 18 km from site. Mean maximum and minimum monthly temperatures and mean monthly rainfall recorded between 2000 and the present are presented in **Table 4**.

Evaporation is taken from climate data for Mount Isa Airport (029127, 1966 - 2023), presented in **Table 5**.

Table 4: Average monthly climate data – The Monument (2000- 2023)

5.7 Sensitive receptors

5.7.1 Sensitive human receptors

To identify sensitive human receptors, a review of the nearest sensitive land use, as defined in the *Planning Regulation 2017* (Queensland Government 2017), was undertaken. No sensitive land uses or receptors were identified within a 500 m radius of the site.

5.7.2 Environmentally sensitive areas

With reference to the Department of Environment and Science 'Environmentally Sensitive Areas (ESA) Map' (see **Appendix C**), the nearest identified ESA to the site is the "Stanbroke Designated Landscape Area (DLA)". This area covers the former Lot 16 on CW62 and is classified as a declared Aboriginal Site under the Relicts Act 1971.

The Stanbroke DLA covers the western area of the site within Lot 16 on SP309110. The DLA is a Category C Environmentally Sensitive Area which extends approximately 70 km east-west and 54 km north-south and surrounds the township of Dajarra.

Four areas mapped as Matters of State Environmental Significance (MSES) occur at or adjacent to the site. These include:

- Essential Habitat: Regulated vegetation map category A or B which covers the limestone hills to the southeast of the mine;
- Wildlife habitat: special least concern, one or more special least concern taxa recorded in locality, which covers the mine and surrounds;
- Wildlife habitat: endangered or vulnerable, one or more critically endangered/ endangered/ vulnerable taxa recorded in the locality which covers the mine and surrounds; and
- Regulated vegetation: defined watercourse, which includes all watercourses within the mine lease area and surrounds.

A map showing the location of MSES in the vicinity of the mine is included as **Figure 6**.

6 SITE HISTORY

The site history review includes a review of historical aerial photographs, site ownership, local and state government registers, previous reports and interviews with relevant persons. The information forthcoming from the review is described separately below.

6.1 Historical aerial photographs

A review of aerial photographs and other available imagery of the site is presented in **Table 6** and aerial photographs are provided in **Appendix E**.

Table 6: Review of aerial photographs

Year	Scale	Notes
1970	1:85,000	Black and white image. No development on site. No roads (Duchess Phosphate Hill Road not present). Small dam in creek 4 km west of future Tick Hill Site.
1981	1:25,000	Black and white image. No development on site.

Year	Scale	Notes
unknown	Aerial photo	Undated photo taken during mine operations. Colour. Image taken from low height looking east across the site. Major mine structures of the pit (centre), tailings and decant dams (front right) and waste rock dump (centre left) are present. Two flat top hills are located east of the mine. A large tank is situated at the base of the northern hill. Between the tank and the tailings dam series of buildings and structures. This image is included as **Figure 3.**
2004	1:80,000	Colour image. Major structures; pit, tailings and decant dams and waste rock dump are visible. Dams and waste rock dump appear to be capped. Tank remains on hill. Other structures have been removed. Dirt tracks into site remain. Pit flooded. Duchess Phosphate Hill Road and Phosphate Hill rail line present to the east of site.
2006	Google Earth	As above, however image clearer. Recent burn scar to vegetation north of pit and waste rock dump. Dark patch on image southwest of tank. Pit flooded.
2017	Satellite	Site as above. Poor quality image not included in appendix.
2018	Google Earth	Site as above. More vegetation growth. Dark patch near tank appears to be dense vegetation.
2020	Satellite	Poor quality image (not included in appendix). Site as above – no disturbance of tailings visible.
2021	Google Earth	Vegetation cleared from eastern tailings cell and northern part of western tailings cell. Excavation occurring in the southern part of eastern tailings cell. Some material stockpiled on the northern end of western tailings cell, however it does not appear to be tailings.
2022	Google Earth	Western tailings cell has stockpiled tailings (white) in the centre and other stockpiles in the north and western side. The eastern tailings cell has been scraped of cover to expose tailings. The southern end appears to have been excavated more deeply. The south-eastern corner is holding water.

6.2 Summary of site ownership and mining activities

A summary of lease ownership of Tick Hill and associated mining activities is presented in **Table 7**. Following the operation of the mine during the 1990s, the site has been subject to further exploration of the resource. From 2020 reprocessing of the tailings was undertaken, with some tailings processed on site and other material taken off site to Lorena Gold Mine near Cloncurry for reprocessing. Specific details related to either the original mine operation or tailings reprocessing relevant to this investigation are discussed further in the remainder of **Section 6**, and **Section 7** below.

Table 7: Mine operations at Tick Hill

Period	Owner	Activity
1991 to 1995	Carpentaria Gold Pty Ltd (MIM Holdings Ltd)	Operation of Tick Hill Gold Mine – Open cut and underground operations with processing on site.
1995 to 2004	MIM Holdings Ltd	Further exploration at Tick Hill.

Period	Owner	Activity
2004 to 2019	Diatreme Resources Ltd	Further exploration at Tick Hill.
2019 to current	Carnaby Resources Pty Ltd	Further exploration of the Tick Hill Resource. Reprocessing of tailings by Blue Cap mining, including transport of tailings to Lorena Gold Mine for extraction.

6.3 Local and state government registers relating to the site

Based on a review of DES's Enforcement Register (DES, 2023), the site has been issued with a notice to conduct or commission and environmental evaluation (EE), reference STAT1399. The EE was issued on the basis "…that an activity or proposed activity on the site is causing or is likely to cause environmental harm." The EE notice is included as **Appendix F**. A response to the EE was submitted by Carnaby Resources, which has been commented on by DES. A response to these comments has also been included in **Appendix F**.

6.4 Previous reports

The following reports and information were provided by the client for review:

- Environmental & Earth Services (1990) Assessment of cyanide decay and acid generation potential of tailings and tailings liquor, Tick Hill. Report to Kinhill Engineers Pty Ltd.
- MIM Holdings (1993) Tick Hill Gold Mine; Visit by ASARCO Directors. Summary of operations as of March 1993.
- Envirofin (2020) Tick Hill Tailings Reclamation Project. EA amendment application supporting information. Report to Carnaby Resources Ltd. 10/08/2020
- Carnaby Resources Ltd (2021) Tick Hill Mining Lease MLs 7094, 7096 & 7097. Initial Development Plan, for period 1 July 2021 to 30 June 2025.
- ATC Williams (2022) Tailings Reclamation Project – Consequence Category Assessment. Tick Hill Mine. Report to Blue Cap Mining, June 2022.
- PA Scott Consulting (2022) Tick Hill Environmental Evaluation Groundwater Geochemistry Report. ML7097, ML7094, ML7096. Environmental Authority EPML00820613. Prepared for Carnaby Resources Pty Ltd, 20 April 2022.

6.4.1 Interviews with relevant site staff

No staff were available for interviews from the original operation of the mine in the early 1990s. Information has been supplied by the current site owner regarding recent and historical site activities and is discussed in **Section 7** where relevant.

6.4.2 Assessment of cyanide degradation and acid generation potential 1990

Tailings liquor material from the site was assessed for cyanide degradation properties and acid generation potential prior to commencement of mining operations.

The cyanide decay study identified initial decay would largely occur due to volatilisation, with relatively low metal concentration not likely to significantly inhibit decay reactions as the majority of cyanide was present as free cyanide. As free cyanide is removed, cyanide decay is then limited by breakdown of metal complexes.

The maximum sulfur concentrations in the tailings material was 0.02% and therefore the material was not considered to have any potential for acid mine drainage (AMD).

6.4.3 Summary of Mine Operations 1993

A summary of mine operations is presented in the MIM Holdings Limited report (1993). At the time of this report the open pit had been mined and underground workings were under development. Schematics of the layout of the open cut and underground workings are shown in **Figures 7 and 8**.

The Tick Hill Gold Deposit was discovered in 1989 and open cut mining commence in 1991. Initially ore was transported off-site for processing. The open cut was 70 m deep and completed in 1992. While the open cut was mined, the infrastructure was under development for the underground mine. This included the vent shaft which joined each level of the underground mine, and the decline which runs off the open cut haul road, 25 m below ground surface.

A processing plant was set up on site, with ore processing involving crushing and milling followed by cyanide leach. Gold was then extracted via electrowinning and smelted in a gas furnace.

Figure 7: Schematic of open cut and planned underground workings (Tick Hill 1993)

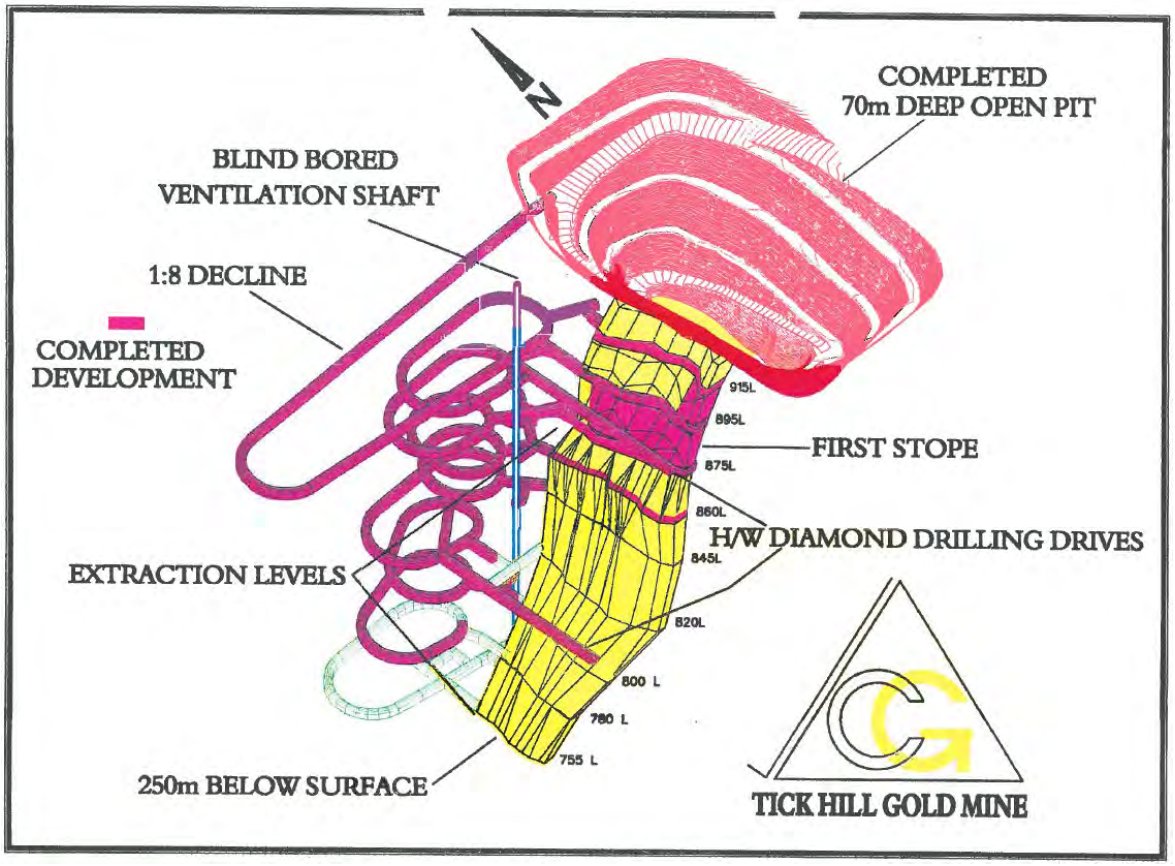

Figure 8: Cross section schematic of open cut and planned underground workings (Tick Hill 1993)

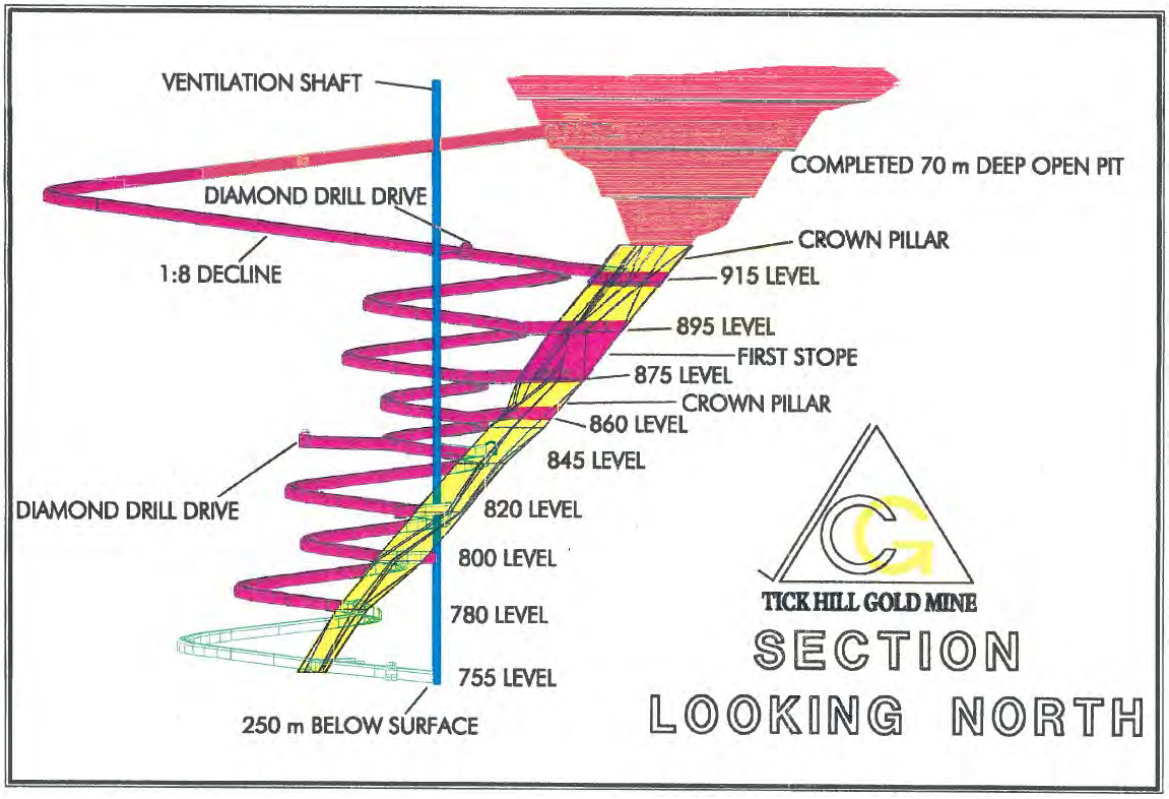

The mine aimed to operate on a total containment basis with no effluents leaving the site. The waste rock dump (WRD) was constructed in lifts of 5 m. The waste rock was assessed as containing no acid generating material or toxic properties. Topsoil from clearing the waste dump area was stockpiled for use as cover on the WRD at completion of operations.

The tailings dams were constructed of waste rock with clay sealant to comply with guidelines at the time of operations. Two tailings cells were constructed with a decant dam for return water. Planned rehabilitation of the tailings involved a waste rock cover and replacement of stockpiled topsoil.

Water for mine operations was pumped from the Pilgrims Creek borefield 15 km to the east of site.

Site staff and contractors lived at The Monument township to the south of Tick Hill.

6.4.4 Tick Hill Tailings Reclamation Project. EA amendment application supporting information 2020

In 2020 a project was developed to reclaim and reprocess tailings from Tick Hill to extract residual gold. The plan involved excavation of dry tailings for transport to a processing facility near Cloncurry. An application to amend the site EA to allow these works was prepared by Envirofin (2020).

The tailings excavation plan involved scrapping of the existing cap from the tailings and excavation of tailings for export for reprocessing. On completion, the remaining tailings were to be re-encapsulated within a smaller cell, thereby reducing the footprint of the tailings cell on site.

The EA amendment application included a summary of existing site conditions and an assessment of potential risks to environmental values, land, surface water, groundwater, air quality, noise and biodiversity at the site.

The assessment identified a potential reduction in impacts associated with cyanide in the tailings as exposure of tailings would result in further breakdown of residual cyanide. Removal of tailings volume would also reduce potential for leaching of cyanide into the surrounding environment. The report includes a discussion on the construction of the tailings dam, which will be presented further in Section 7 below.

The hydrogeological assessment of the site including description of a regolith aquifer beneath the tailings dam and surrounding valley. It is noted that subsequent bore installation near the tailings dam and elsewhere on site showed no evidence of a shallow aquifer of this type.

Characterisation of tailings material was included in the assessment, which focused on presence of cyanide, metals and oxidable sulfur. The investigation found the tailings material was alkaline and did not have the potential for acid generation. Metals concentrations were low, except for moderate concentrations of copper. Residual cyanide was present as total cyanide, with concentrations up to 583 mg/kg, with no detections of free cyanide. Cyanide concentrations increased with depth. The cyanide profile indicates that cyanide has progressively degraded within the tailings cells over the years since mine closure. The free

cyanide pool has been depleted and breakdown of metal-complexed cyanide is occurring at a faster rate closer to the cell surface.

A summary of the limited existing monitoring data for groundwater and surface water is also included in this report.

6.4.5 Tick Hill Mining Lease MLs 7094, 7096 & 7097. Initial Development Plan, for period 1 July 2021 to 30 June 2025

The Initial Development plan provides further detail on the tailings reprocessing project. Between late 2020 and early 2021, approximately 100t of tailings was transported to Lorena Gold Mine, near Cloncurry for reprocessing. Due to the cost of haulage, a gravity separation plant was installed at Tick Hill to process the tailings on site. At the time of the report the gravity plant was undergoing commissioning to optimise gold extraction.

The development plan therefore outlines the planned works on site to extract and process tailings. In addition, it was planned that residual ore in the open pit be mined and processed on site following the tailings reprocessing.

6.4.6 Tailings Reclamation Project – Consequence Category Assessment. Tick Hill Mine 2022

The consequence category assessment (CCA) outlines the proposed works associated with the on-site reprocessing of tailings and provides a risk assessment of potential impacts to human and ecological receptors. This includes assessment of potential for structural failure of loss of containment from site structures.

6.4.7 Tick Hill Environmental Evaluation Groundwater Geochemistry Report. ML7097, ML7094, ML7096. Environmental Authority EPML00820613 2022

The groundwater geochemistry report details the site hydrogeological model, and groundwater monitoring activities conducted to date. This includes assessment of potential impacts associated with cyanide, metals, acid and metalliferous drainage. The report includes available groundwater data along with geochemical characterisation of tailings and waste rock materials.

Of the installed groundwater bores, bores THGW001, THGW003 and THGW004 were described as located in fractured, mineralised host rock, while bores THGW002, THGW005 and THGW006 were in unmineralised host rock.

This assessment identified cyanide impact at bore THGW001, located downgradient of the tailings and decant dams. Concentrations have fluctuated over the period monitored. Cyanide was also detected in bores THGW003 and THGW005 and in the mine pit and mine shaft bore. The source of impact to bores THGW003 and THGW005 was not certain at the time of investigation as these bores were considered to be up and cross gradient from the tailings cell.

The report also discussed the chemistry of the pit water, noting that the pit is consistently three times more saline than the mine shaft bore, which samples water from the underground

workings. The higher salinity in the pit is due to evaporative concentration of water in the pit over time.

6.5 Previous environmental monitoring

6.5.1 Groundwater monitoring

Groundwater monitoring bores on site are summarised in **Table 8** and shown on **Figure 9**. Available borelogs are presented in **Appendix G**.

Two bores, THGW001 and THGW002, are likely to have been installed circa 2012 by Diatreme Resources (**Photo 1**). No installation details are available for these bores. These bores were sampled on six occasions between 2012 and 2017, with typical analysis including major cations and anions, total and dissolved metals and cyanide. These bores were included in the site monitoring program following the installation of four additional bores in 2020.

Four bores, THGW003 to THGW006 were installed by Carnaby Resources in 2020 (**Photo 2**). These bores have been periodically monitored since installation. Installation logs are presented in **Appendix G**. Bores THGW001 to THGW006 were sampled on nine occasions between 2020 and 2022. At this time the mine vent shaft bore was also included in the monitoring program.

Three groundwater bores, THGW007 to THGW009 were installed in June 2023 as part of this ESA, to address data gaps and further characterise groundwater at the site. One sampling event was conducted in June 2023 for all bores on site.

The mine pit was sampled in 2012, however a collapse of the north western wall removed a section of the haul road which prevented safe access to the water. A sample was collected in 2017, however it is not known how this was collected. In 2020 a flying fox arrangement was set up to allow sampling of the pit using a bailer. The pit was sampled nine times between 2020 and 2022, with both deep and shallow water sampled in June 2020.

Sampling events completed up to February 2022 were conducted by Carnaby, or the site operator at the time. Supplied results have been presented in **Table 37** in the Tables Appendix, which collates all historical results. Relevant results have been incorporated in trend graphs prepared to assess ionic balance, cyanide and metals concentrations over time.

1. Bore THGW001. Bore THGW002 has similar surface structure.

2. Bore THGW004. Bores THGW003 – THGW006 are also installed with monuments.

6.5.2 Surface water monitoring

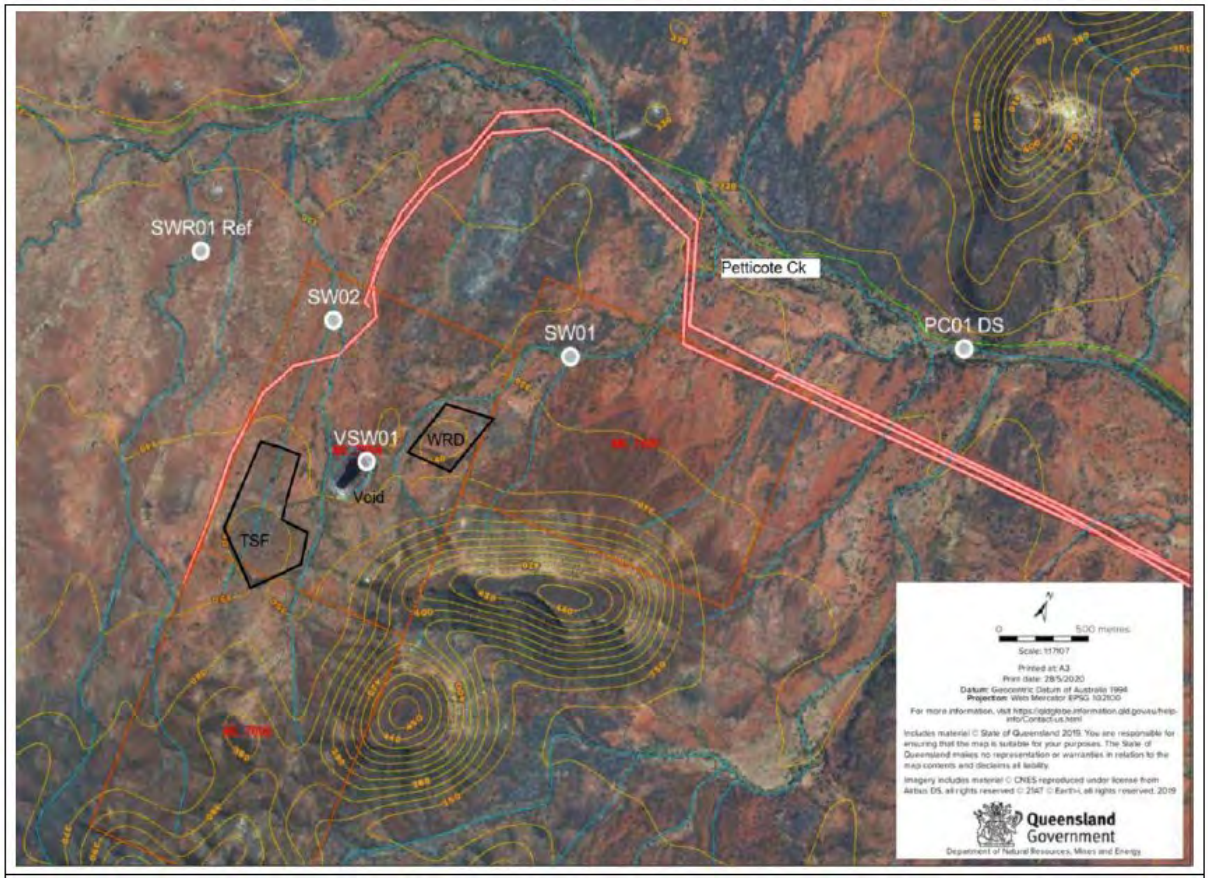
All watercourses on site are ephemeral and flow for a brief period after rainfall, consequently surface water monitoring data was only available from two sampling events, undertaken in 2015 and 2018. Surface water sample locations and their purpose are described in **Table 9** and sample locations presented on **Figure 10**.

All surface water samples were analysed for major anions and cations, nutrients, dissolved and total metals. Results are presented in **Table 38** in the Tables appendix.

Table 9: Summary of surface water monitoring locations

Location	Description	Target
THSWR01 ref	Reference site in neighbouring watercourse to the west of site. Similar conditions to on-site watercourses	Background conditions
THSW01	Ephemeral watercourse to the northeast of site, downstream of waste rock dump	Waste rock dump
THSW02	Ephemeral watercourse to the northwest of site, downstream from the tailings dam, decant dam, open pit and former processing area.	Tailings, decant and mine pit
THSWPC01 DS	Petticoat Creek, downstream of site.	Downstream of site

Figure 10: Surface water monitoring locations



7 SITE CONDITIONS

The investigation works completed between December 2022 and June 2023 included two site visits by Principal Soil Scientist and Suitably Qualified Person (SQP) Dr Anna Sheldon of Environmental Earth Sciences. These site visits occurred on 19-20 December 2022, accompanied by Carnaby Resources Geologist Neill Kite, and on 8-12 June 2023, accompanied by Environmental Earth Sciences' Environmental Scientist Sam Weiss.

The section below collates observations and photographs from these site inspections, along with relevant information from the site history.

7.1 Significant site features

The current site layout of Tick Hill is shown on **Figure 2**, with an inset showing available information on the former site layout during mine operations during the 1990s. The aerial photograph in **Figure 3** also shows the site layout during mine operations.

The mine is located at the foot of a flat topped mesa hill, on a northwest facing slope. Entry to the site is from the Duchess Phosphate Hill Road. The majority of operational structures have been removed from site, with only the major mining structures (open pit, waste rock

dump and tailings and decant dams) remaining. Some infrastructure associated with tailings reclamation works is also present on site.

7.1.1 Open pit

In the centre of the site is the open pit (**Photos 3 and 4**). The pit is elongated north-south, and 70 m deep, with water filling approximately 25 m depth. Water level varies by several meters, depending on rainfall. The former haul road into the pit collapsed in the northwest corner of the pit, preventing access to the water level. The pit rim is higher than the surrounding landscape (**Photo 5**) which means that the pit catchment is limited to the pit excavation boundary.

The area between the pit rim and bund wall drains externally, via gaps in the bund wall. These gaps are placed in locations that are not otherwise accessible so that the bund is still effective in preventing pit access (see **Photo 6**). The bund wall is surrounded by a barbed wire fence with warning signs.

Drainage flows around the open pit are shown on **Figure 11**.

3. Mine open pit – facing south from haul road.

4. Mine open pit – facing west from pit rim. Note collapse of face in north west corner.

5. View of the open pit from the hill to the southeast. Note the raised rim relative to the surrounding landscape.

6. Gap in the bund on the southwestern side to allow drainage from the pit perimeter area.

Client: Carnaby Resources | Drawn By: A Sheldon | Date: June 2023

Location: Tick Hill Mine, QLD

Figure 11

7.1.2 Waste rock dump (WRD)

The WRD is located northeast of the pit. The WRD is diamond shaped and has a flat top (**Photo 7**). There is a small V in the northeast corner and the former access ramp acts as a drainage line towards the southwest corner.

The WRD was constructed in 5 m lifts and is capped with rock mulch and topsoil. Waste rock material at the mine was assessed as not having potential for acid or metalliferous drainage and waste rock was therefore considered inert.

Observations at the time of the December 2022 and June 2023 inspections indicate that the WRD is stable and becoming integrated into the surrounding landscape. The batters are stable and well vegetated (**Photos 8 and 9**), with one minor (stable) scour observed on the northern side. On the southern (uphill) side of the WRD an area of water ponding was observed adjacent to the WRD, where a minor drainage line meets the WRD (**Photo 10**).

No evidence of scalding or seepage was observed around the perimeter of the WRD.

The top of the WRD is generally flat and well vegetated (**Photos 11 and 12**). The surface of the WRD is slightly uneven, indicating that rainwater will pond and infiltrate. As described above, an area of ponding was also observed at the top of the ramp / drainage line on the WRD during recent site inspections. Drainage flows around the WRD are shown on **Figure 11**.

7. View of the waste rock dump from the hill to the southeast.

8. Waste rock dump batter – north side.

9. Waste rock dump batter – south side.

10. Waste rock dump batter – south side, with area of local ponding at base.

11. Top of waste rock dump showing access ramp / drainage line which flows to the left of the image.

12. Top of waste rock dump showing vegetation and slightly uneven surface.

7.1.3 Tailings Storage Facility (TSF)

The TSF consists of two cells, divided in to east and west with a total capacity of 600,000 m³. The TSF cells are built as a turkey nest dam and designed as Referable dams. The cells have a 500 mm clay liner in the base, and clay core in the walls. The cells range in depth from 6 on the up-slope side to 10 m on the down-slope site. Walls were built with a batter angle of 1:3. The cells have a flat top, and the perimeter embankments are higher than the cell surface. Excess runoff was designed to be directed to a spillway on the northern end of the eastern cell. The cover material was a waste rock mulch covered with topsoil. The cover was not designed or expected to restrict water infiltration. Clay and topsoil used for lining and cover were source from borrow pits and scrapes on site (Envirofin 2020).

At the time of the site inspections the tailings reclamation project had ceased, with the eastern cell remaining open. The entire eastern cell had been removed of cover, and the southern part of the eastern tailings cell had been substantially excavated (**Photo 13**). Stockpiles of tailings were located on the western cell, surrounded by an earth bund (**Photo 14**).

The northern part of the eastern tailings cell had the cover removed but minimal excavation of tailings. Erosion scours indicated flow of surface water to the north, towards the spillway (**Photo 15**). It was not possible to determine visually whether overflow of stormwater from the TSF had occurred. The central part of the eastern tailings cell had been partially excavated, while the southern part was split into two areas. The south-western section was excavated to the base of the tailings cell (**Photo 16**). The south-eastern section was excavated to the base of tailings and a plastic liner installed. This section of the cell was being used for water storage (**Photo 17**). Areas of disturbance and water flow on the tailings and decant dams is shown on **Figure 12**.

On the western cell cover material was stockpiled across the cell. Areas of intermittent ponding were also evident (**Photo 18**). Infrastructure associated with the tailings reclamation work remained on the western tailings cell and water storage cell. This includes a screening for processing tailings (**Photo 19**) and a gravity separation unit (**Photo 20**). Also remaining were two locked shipping containers, a tractor, pumps and generators, empty IBCs for peroxide and other rubbish. Large diameter pipe was also located on and around the tailings cells and from the water supply tank. In areas of the western cell not disturbed by the tailings reclamation project, low scrubby vegetation was well established (**Photo 21**). The TSF batter slopes were vegetated and in good condition (**Photo 22**).

13. TSF from the hill east of site, the eastern cell has been excavated for tailings reclamation.

14. Stockpiled excavated tailings with earth bund on western cell.

15. Northern section of eastern cell – cover removed from tailings, and surface erosion.

16. Southern section of eastern cell where tailings have been excavated to base of cell.

17. Southeast section of eastern cell which has been plastic lined for use as water storage.

18. Stockpiled cover material and areas where water had ponded on northern end of western cell.

19. Screen used for processing excavated tailings.

20. Gravity separation unit used for processing of excavated tailings.

21. Vegetation on southern part of western tailings cell.

22. Vegetation on southern batter slope of western tailings cell.

Base map Google Earth (November 2022)

Title: Tailings and decant dam drainage. Observations June 2023. Image November 2022, contours October 2022.

Client: Carnaby Resources | Drawn By: A Sheldon | Date: June 2023

Location: Tick Hill Mine, QLD

Figure 12

7.1.4 Decant dam

The decant dam was constructed to the same specifications as the TSF, with a capacity of 93,000 m³ (Envirofin 2020). The decant dam perimeter walls were in good condition and well vegetated (**Photo 23**). The decant dam surface has been subject to areas of subsidence (**Photo 24**) and in the northern centre of the dam was an area of tunnelling indicating a preferential flow path for water to enter the decant dam. Water flows on the decant dam are shown on **Figure 12**. Vegetation on the decant dam was well established.

23. Northern wall of decant dam, looking west.

24. Top of decant dam showing uneven surface and areas of subsidence.

7.1.5 Former processing plant area and remaining infrastructure

To the east of the TSF, and up-slope, was the former processing and administration area. The general layout can be estimated based on the diagram showing the site plans (**Figure 2**) and the aerial photograph of the site taking during operations (**Figure 3**).

Uphill of the former processing plant is the site water supply tank (**Photo 25**). This tank remains in use and currently supplies stock water for the surrounding area. Water is sourced from a borefield 15 km east of site.

The slope between the tank and tailings dam has been heavily disturbed, although little direct evidence of the processing plant remains. Landforms were either modified following plant removal or have eroded over time. The area is well vegetated with grass but has notably fewer trees than the surrounding landscape.

To the south west of the tank is a causeway crossing of a gully and a remnant concrete slab (**Photo 26**). This was the only remaining infrastructure observed on the slope. The processing plant area is shown in **Photos 27, 28 and 29**. The processing plant and other site infrastructure were relocated to other mines after closure of Tick Hill.

Further to the north and south of the WRD is the core yard (**Photo 30**). Two shipping containers had been located upslope of the core yard at the time of the December site visit, however these had been removed before the June visit.

The aerial photograph from the time of mine operations indicates that the ROM was located immediately south of the WRD, however nothing remains in this area.

25. Water supply tank. Water is sourced from a borefield 15 km east. Currently used for stock watering.

26. Remnant concrete slab, southwest of the water tank.

27. Processing plant area, looking north.

28. Processing plant area, looking south.

29. Processing plant area, looking west. Tailings dam in background.

30. Core yard, located south of WRD.

7.2 Summary of site conditions

7.2.1 Site activities/ uses

The site is a former gold mine. The mine operated from 1991 to 1995. Further minerals exploration works have been undertaken at the site since mining operations ceased. A project to reclaim and reprocess tailings was undertaken between 2020 and 2022 however this has ceased with the eastern tailings cell remaining open.

7.2.2 Utility infrastructure

The only current utility infrastructure is the water pipeline that supplies the on-site water supply tank. The pipeline runs north east from the tank around the hill. This tank is currently used for suppling stock in the surrounding area.

The previous mining operation would have required electricity and gas. Gas and diesel trucked in to supply the gas furnace and onsite generators.

7.2.3 Building construction, basements and crawl spaces

All site buildings and site infrastructure associated with mining operations has been removed. One concrete slab remains. Two shipping containers remain on the western tailings cell associated with the tailings reclamation project.

Underground workings associated with mine operations were accessed via a portal in the upper haul road from the open pit. On closure the entrance portal to the underground workings was sealed.

7.2.4 Industrial processes carried out on site

During mining operations ore was processed on site. This involved crushing and milling of ore, followed by cyanide leach. Gold was reclaimed from the cyanide leach by electrowinning and smelted into gold bars. Sodium cyanide is the main reagent used in this process.

For the main part of the tailings reclamation project excavated tailings were trucked off site. Due to the cost of trucking, partial processing on site was trialled. This involved gravity separation to remove gold bearing material from the tailings. The separated material was to be taken off site for processing. No chemical extraction was involved in this process.

7.2.5 Chemical storage and transfer areas

All chemicals used in ore processing would have been trucked to site and stored on site. Details of chemical and fuel storage areas during mine operations is not known. However, it is understood the following chemicals would have been stored and used on site:

- Chemicals and reagents associated with the cyanide leach process used to extract gold included sodium cyanide, activated carbon, lime, steel ball, flocculant, antiscalant and activated carbon.
- Reagents used in the extractive section of the process (elution and gold room sections) include hydrochloric acid, caustic soda, borax, potassium nitrate, silica and soda ash (sodium carbonate).
- Explosives for mine operations; and
- Chemicals used during the tailings reprocessing works including diesel fuel and IBCs of peroxide.

7.2.6 Raw materials used

The raw material for the mining operation was the ore mined on site. Excavated tailings was the raw material for the tailings reprocessing activities.

7.2.7 Product spills, losses, incidents, accidents, fires

No information was available regarding spills, losses, incidents, accidents or fires.

7.2.8 Discharges to land and water

The mine aimed to operate as a zero-discharge site, with all mine wastes contained. No information is available regarding spills or discharges that may have occurred during mine operations.

7.2.9 Waste produced and waste storage areas, management practices and disposal areas

The main waste storage areas on site are the WRD, TSF and decant dam, as detailed above. No information is known about disposal of other wastes from site including chemical or putrescible wastes.

7.2.10 Power generation

No power is currently supplied to the site. Power supply during mine operations is not known, however the smelter was gas powered. A diesel supply would have been required for site plant and vehicles.

Recent tailings reclamation work has relied on diesel powered generators. No fuel storage was observed on site.

7.2.11 Historical earthworks and areas of fill

Major earthworks were undertaken associated with mine operations on site including excavation of the open pit and underground workings, construction of the WRD, TSF and decant dam. Around the pit bund walls have been constructed to prevent access. Earthworks were also undertaken to clear topsoil for closure works and construct roads and site access. At closure the WRD, TSF and decant dam were capped and the processing plant decommissioned.

Recent earthworks have involved scrapping capping material from the eastern TSF cell and excavation of tailings material.

7.2.12 Existing monitoring infrastructure

Existing groundwater monitoring infrastructure consisted of six groundwater bores, as described in **Section 6.5.1**. Three additional bores were installed as part of these works.

8 PRELIMINARY CONCEPTUAL SITE MODEL

A conceptual site model (CSM) of the site can be formed by considering the geophysical characteristics at play at the site, the contaminant source, potential receptors and the pathways to the receptors. The CSM, as required by the NEPC (2013), is an iterative process constantly being updated during the investigation process as more information becomes available.

Prior to constructing the exposure component of the CSM, an evaluation of geophysical factors is required. This is best achieved as follows:

1. Define the Physical Environment (**Section 5** above);
2. Define the Waste (Contaminants) and its likely origin (**Sections 6 and 7**);
3. Predict the Interaction of the Waste and the Medium to establish actual and likely modes and velocity of transport (this section); and
4. Define the Receptors that could be exposed on-site (**Section 8.1.3**), and given the outcome of the first three points, the likelihood of Exposure on the Pathways.

8.1 Preliminary receptor pathway evaluation

8.1.1 Sources

Potential sources of contamination identified within the site area include:

- Potential for soil contamination:
    - Release of fuel or chemicals associated with historical mine operations and ore processing;
    - Release of fuel or chemicals associated with recent tailings reprocessing;
    - Release of tailings from the TSF;
- Potential for groundwater contamination;
    - Release of fuel or chemicals associated with historical mine operations and ore processing;
    - Leaching of cyanide, metals or other contaminants from the TSF or WRD.

8.1.2 Pathways

The potential pathways between the sources and human receptors have been identified as:

- Dermal/ inhalation/ ingestion exposure to contaminated soil materials or groundwater for future workers and visitors to the site.

The potential pathways between the sources and environmental receptors have been identified as:

- Direct contact or uptake by flora or terrestrial fauna;
- Overland flow resulting in runoff to local soil and waterways;
- Impacted groundwater migrating towards local waterways; and
- Use of impacted groundwater for stock watering

8.1.3 Receptors

The nearest onsite and offsite human receptors of any potential land contamination are identified as:

- Owners of the neighbouring grazing property and surrounding areas;
- Future site workers involved with demolition and construction works; and
- Future site workers and visitors.

The closest environmental receptors are identified as:

- The watercourses north and west of the site draining to Petticoat Creek; and
- Off-site receptors if building wastes or contaminated soil is poorly characterised or managed.

8.2 Chemicals of Potential Concern

Chemicals of potential concern (CoPC) associated with the identified sources include:

- Cyanide (CN)– cyanide leach process and residual cyanide in tailings;
- heavy metals – metals from within processed ore and tailings, from workshops, batteries and degraded site infrastructure;
- petroleum hydrocarbons (TRH) – with fuel and oil storage;
- benzene, toluene, ethyl benzene, xylenes and naphthalene (BTEXN) – fuel storage;
- per- and poly-fluoroalkyl substances (PFAS) – fire suppression;
- polychlorinated biphenyls (PCBs) – transformer oil;
- organochlorine pesticides (OCPs)– pest control;
- acids, alkalis & other reagents – gold ore processing;
- nitrogen compounds – explosive residue; and
- nutrients in effluent and soil.

9 ADOPTED ASSESSMENT CRITERIA

Environmental Earth Sciences refers to the following guideline values for the assessment of groundwater and surface water quality at Tick Hill.

General:

- NEPC (2013), *Schedule B(1): Guideline on the Investigation Levels for Soil and Groundwater:*
    - Health investigation/screening levels for soil for the protection of Human Health (Public Open Space and Commercial / Industrial).
    - Environmental Investigation/screening levels for the protection of terrestrial ecosystems (Areas of Ecological Significance and Commercial / Industrial).
    - Groundwater Investigation Levels (GILs, Table 1C) for the protection of Aquatic Ecosystems and Drinking Water (including recreation).
- ANZG (2018*) Australian and New Zealand Guidelines for Fresh and Marine Water Quality:*
    - Ecosystems, Agricultural Water quality for irrigation and livestock.
- HEPA (2020) *PFAS National Environmental Management Plan (NEMP) – Version 2.0*. Heads of EPAs Australia and New Zealand, January 2020:
    - Human Health guidelines for drinking water and recreation.
    - Ecological screening values for freshwater; 95% and 99% species protection for slightly to moderate conservation value systems, including consideration of potential for bioaccumulation and biomagnification.
- Environmental (Water and Wetland Biodiversity) Protection Policy (2019): No environmental values and water quality objectives nominated for Lake Eyre catchment (relevant environmental values discussed in Section 5.2.1).

9.1 NEPC (2013)

Results of the site investigation were initially compared with the Tier 1 criteria from the NEPM Schedule B1. For soil human health criteria, HIL-C (public open space) criteria were applied based on the potential for visitors to access the abandoned site in the future. For tailings material, HIL-D (commercial / industrial) criteria were applied as tailings material should be encapsulated into the tailings cells and not accessible by visitors.

9.2 Ecological investigation levels (EILs) for soil

The EILs assigned by NEPC (2013) Schedule B5a - *Guideline on Ecological Risk Assessment* are adopted for this assessment. This guideline presents the methodology for deriving terrestrial EILs using both fresh and aged (i.e. >2 years old) contamination for soil with the following land use types:

- areas of ecological significance;
- urban residential/ public open space; and

- commercial/ industrial.

The methodology has been developed to protect soil processes, soil biota (flora and fauna) and terrestrial invertebrates and vertebrates. The approved land use on the site is commercial/ industrial and hence these EILs have been adopted for this assessment. A summary of information used in EIL calculations is presented in **Appendix D**. Site specific EILs were derived from soil and tailings parameters collected in June 2023.

The values presented for zinc, chromium (III), copper and lead are added contaminant limits (ACLs) based on added concentrations. The EIL is calculated from summing the ACL and the ambient background concentration (ABC) to derive the site-specific soil quality guideline (SQG) taking into account the effect caused by pH, exchangeable cations, iron and total organic carbon in soil that can affect concentration toxicity data (**Table 10**).

For soil, where direct exposure to flora and fauna is possible, screening criteria for areas of ecological significance have been derived. For tailings material, which are intended to be encapsulated within the TSF or decant dam, commercial / industrial screening criteria are derived. It is noted that EILs are typically only applicable to the upper 2 m of the soil profile, except in arid zones where 4 m applies to account for deeper potential rooting depth.

A summary of the EILs for aged contamination in soil (>2 years) for the adopted land use are presented in **Table 11**. EILs for tailings are presented in **Table 12**.

Table 10: Site Specific EIL Calculation Data

Material	CEC	Iron	Organic carbon	pH
-	meq/100g	%	%	-
Soil	16.3	2.28	<0.1	8.69
Tailings	-	1.21	<0.1	9.5

Table 11: Site Specific EILs – Soil

Analyte	Ambient background concentration (mg/kg)[1]	Added contaminant limit (mg/kg)[2]	EIL – Areas of Ecological Significance (mg/kg)
Arsenic	28.1	-	40
Chromium III	459.1	130	589
Copper	48.8	67	116
Nickel	78.6	37	116
Lead	5.6	470	476
Zinc	127.6	120	248

Notes:
1. ambient background concentrations (ABC) were calculated as per Hamon *et al*. (2004).
2. added contaminant limits were determined using Tables 1B(1-5), Schedule B1, NEPC (2013).

Table 12: Site Specific EILs – Tailings

Analyte	Ambient background concentration (mg/kg)[1]	Added contaminant limit (mg/kg)[2]	EIL – Commercial / Industrial (mg/kg)
Arsenic	14.2		160
Chromium III	119.1	310	429
Copper	21.7	140	162
Nickel	31.3	55	86
Lead	4.0	1800	1804
Zinc	45.3	360	405

Notes:
1. ambient background concentrations (ABC) were calculated as per Hamon *et al*. (2004).
2. added contaminant limits were determined using Tables 1B(1-5), Schedule B1, NEPC (2013).

Exceedances of the Tier 1 EIL for copper were observed for tailings material in the decant dam. The concentration of copper in the ASLP leachate was used to determine the bioavailability factor for copper of 0.0119, which allowed derivation of a site specific (Tier 2) copper criteria (for tailings, commercial / industrial land use) of 13,600 mg/kg. No exceedances of the site specific criteria were observed.

9.3 ANZG (2018)

This environmental monitoring program is investigating the potential for groundwater at the Tick Hill mine to be extracted or discharged to surface water (noting that no current use or discharge occurs). Therefore, groundwater and surface water analysis results have been compared with ANZG (2018) trigger values for the protection of 95% of species, with consideration of the slightly to moderately disturbed ecosystem in the area surrounding Tick Hill.

The ANZG (2018) trigger values for the protection of species in various ecosystem settings are based on conservative assumptions, so they are used as an initial basis for comparison. As the potential toxicity and bioavailability of some chemicals is dependent on the pH, organic content and hardness of the water, the ANZG (2018) trigger values also allow for correction of the trigger values based on these parameters.

Heavy metals (cadmium, chromium, lead, nickel and zinc) are potential chemicals of concern for both groundwater and surface water. The trigger values have been corrected for the average surface water hardness using the ANZG (2018) hardness dependent algorithm.

It should be noted that the ANZG (2018) trigger values are directly applicable to surface water quality but are not directly relevant to groundwater quality. In cases where groundwater concentrations exceed ANZG (2018) trigger values, further assessment is required to determine whether a given concentration of an analyte is likely to significantly or detrimentally impact on the receiving water body.

9.4 Summary of Adopted Guideline Values

Reported concentrations have therefore been compared to the following guidelines:

- Human health and ecosystems (NEPC 2013);
- Freshwater Ecosystems (ANZG 2018);
- Per- Poly Fluoroalkyl Substances (PFAS) Guideline Values for human health and freshwater ecosystems (HEPA, 2020)
- Stock water (ANZG 2018); and
- Drinking Water Quality (NHMRC/ NRMMC).

References for relevant guideline values are presented in **Table 13** below. The specific guidance values adopted for the assessment are included in the results tables in the **Tables Appendix**.

Table 13: Adopted Assessment Criteria for Groundwater and Soil

Protected beneficial use	Assessment Criteria
Human health (public access)	NEPC HIL-C public open space
Human health (site works)	NEPC HIL-D public open space
Terrestrial ecosystems (soil)	NEPC EIL – areas of ecological significance
Terrestrial ecosystems (tailings)	NEPC EIL – commercial / industrial
Maintenance of ecosystems, Freshwater	Criteria specified for protection of freshwater ecosystems (95% species protection) in ANZG (2018) and HEPA (2020).
Drinking water	Australian Drinking Water Guidelines (NHMRC / NRMMC 2011) and HEPA (2020).
Stock watering	Those specified for stock watering in ANZG (2018) / Farm supply use

9.5 PFAS Assessment Criteria

For the purposes of the monitoring program, relevant screening criteria relate to concentrations of PFAS in soil, groundwater, surface water (fresh) and biota (refer **Table 14**).

Table 14: Selected Investigation Screening Criteria (PFAS)

Criteria	PFOS[1,2]	∑ PFOS + PFHxS[1]	PFOA[1]
Soil Screening Criteria (mg/kg)			
Human Health: Public Open Space		1	10
Ecological: Indirect exposure	0.01		
Ecological: Direct exposure	1		10

Criteria	PFOS[1,2]	∑ PFOS + PFHxS[1]	PFOA[1]

10 SITE INVESTIGATION METHODOLOGY

A site investigation was undertaken to further characterise the hydrogeological and contaminated land status of the site in response to a request for further information relating to the environmental evaluation (EE) notice for the site. The scope included a background assessment of the site, data gap assessment, two rounds of groundwater monitoring, installation of three additional monitoring bores and soil and tailings assessment.

10.1 Data gap assessment

A data gap assessment was conducted to assess the extent of investigations completed to date and address these in the current investigation. A summary of the data gaps identified is presented in **Table 15** below.

Table 15: Data gap assessment

Data gap / issue	Solution
Site contamination assessment addressed remaining site features rather than potential residual hazards	Conduct a site history review to assess historical site activities to determine what contaminants might remain. Include additional CoPCs in analysis suite.
Site assessments had not considered soil contamination outside the TSF or WRD	Conduct a targeted soil assessment across the site to characterise current contamination status.
Insufficient information to support the conclusion that the open pit is a groundwater sink	Install additional monitoring bores to better characterise site hydrogeology. Improve water balance model of open pit.
Inadequate delineation of the extent of impacts associated with historical mine activities	Further delineation of site conditions and consideration of contaminant concentration trends to determine extent and stability of mine impacts.
Cyanide detected in up and cross gradient bores THGW005 and THGW003.	THGW005 may not be upgradient of former processing plant. Installation of additional bores conducted to provide background bore. Further development of hydrogeological model for site.
Inadequate detail for bore THGW001 to determine cyanide impacts to groundwater at this location	Installation of a paired bore to improved cyanide delineation below the tailings dam.

Data gap / issue	Solution
Inconsistent analysis of CoPCs between waste materials and groundwater	Extend suite of groundwater analysis to account for all CoPCs
Potential irregularities or cross contamination observed in previous monitoring data	Additional sampling with care taken to avoid cross contamination between sample locations.

10.2 Installation of three monitoring bores

Based on review of the available site data, and site observations from the December 2022 site visit, three additional groundwater monitoring bores were installed. A summary of the bore locations and justification is presented in **Table 16**. Bores were installed between 8 and 11 June 2023, using air hammer drilling. Borelogs are presented in **Appendix G**.

The soil layer comprised a red-brown gravelly clay ranged from 3 m at THGW007 on the lower slope to <0.5 m at THGW009 higher on the hill. Heavily weathered rock was encounter to 6 m at THGW009 and 3 m at THGW008. Hard rock was encountered close to the ground surface at THGW009. No evidence of shallow groundwater or weathered zones indicating ephemeral flow were encountered in any of the locations.

In all locations the water bearing lithology was extremely hard with minimal weathering. In bore THGW007, no discernible water strike was identified, however water flowed into the borehole during a pause in drilling at 33 mBGL. For bore THGW008 a water strike at 33.6 mBGL was identified as a reduction in dust produced during drilling. In bore THGW009, a water strike was encountered at 18.5 mBGL, identified as a reduction in dust, which increased to a steady flow over the next 2.5 meters.

Bores THGW008 and THGW009 were considered to have inadequate yield for airlifting and were developed using dedicated bailers. These bores were bailed on several occasions prior to sampling. Bore THGW007 was airlifted until it ran clear. Post drilling, SWLs in bores THGW007 and THGW008 were similar to the height of initial water strike, while SWLs in bore THGW009 had risen higher than the initial water strike, indicating confined conditions.

Observations during drilling indicate that groundwater occurs in fine fractures within the aquifer at depth. Bore yield is highly variable and dependent on the extent of fractures encountered. Groundwater flow paths are therefore likely to be tortuous and follow local pressure gradients along fracture lines rather than directly following the overall groundwater flow direction.

Table 16: Monitoring bore installation

Bore	Location	Justification
THGW007	Northwest of the open pit	Further delineation of groundwater impacts on the “downgradient” side of the open pit.
THGW008	Between the TSF and decant dams and the open pit.	No installation details are available for THGW001 meaning that the cyanide concentrations in this bore are difficult to interpret. A new bore provides information on the aquifer conditions at this location and allows better delineation of the cyanide impacts

Bore	Location	Justification
	Adjacent to THGW001.	
THGW009	South of the former processing plant	Background location not impacted by processing or tailings activities.

10.3 Groundwater and Pit Sampling

Groundwater and pit samples were collected from the 8 existing locations in December 2022 (8 total) and both the original 8 and 3 newly installed groundwater monitoring bores (11 total), in June 2023. These bore locations are shown in **Figure 9**.

The following water sampling methodology was employed for sampling completed by Environmental Earth Sciences. The collection of groundwater samples was undertaken in general accordance with the following publications and guidelines:

- DES (2018), *Monitoring and Sampling Manual.*
- HEPA (2020) *PFAS National Environmental Management Plan – Version 2.0.*

Prior to sampling, depth to SWL was measured an accuracy of ±0.01 m. A 12 V submersible pump and 16 mm class 12 HDPE poly tubing, or waterra with 16 mm class 12 HDPE poly tubing were used to purge and sample monitoring bores Purging involved the removal of a minimum of three bore volumes from each bore or stabilisation of aquifer parameters, whichever occurred first.

For bores THGW001, THGW002, THGW007 and THGW008 where the water levels were too deep to pump, disposable bailers were used. Monitoring bores were allowed to recharge before groundwater samples were collected and transferred to appropriately preserved and labelled sampling containers.

Field pH, temperature, redox potential (Eh), dissolved oxygen (DO) and electrical conductivity (EC) were measured using a YSI multi parameter water quality meter (WQM), which was calibrated prior to use. WQM calibration certificates are presented in **Appendix H**.

All non-dedicated sampling equipment was decontaminated prior to sampling each location, and between bores, using PFAS free decontamination solution. Water samples were collected in laboratory-supplied sampling containers appropriate for the specific analysis to be conducted. Samples collected for PFAS analysis were collected in accordance with the recommended sampling procedure as per HEPA (2020). A rinsate blank sample was collected from decontaminated sampling equipment at the completion of the sampling program.

All samples were:

- Filled from the base to remove all air;
- Stored in a chilled cooler (on ice) in the dark; and

- Delivered to the laboratory within 24 hours.

10.4 Hydraulic testing of groundwater bores

In order to assess potential infiltration and migration of groundwater at the site, along with potential impacts to receptors at points of groundwater discharge, hydraulic testing was conducted on two groundwater bores, THGW005 and THGW006.

Following sampling at each bore, a pressure transducer logger (diver) was installed into the bore and the bore pumped to extract water to be used for a slug test (falling head test). Following extraction of the required amount of water, the pump was removed and water levels were then allowed to recover, as a rising head test. Water pumped from the bore was then used to fill the bore to the top of casing, allowing a falling head test to be conducted. This process was repeated for two rounds for each bore.

Results of the hydraulic testing were used to calculate the hydraulic conductivity (K) values used in modelling and are presented in **Section 11.4** below (and **Appendix J**).

10.5 Soil investigation

The soil investigation involved sampling of soil from current or former work areas at the site, and in drainage lines subject to impact from upstream activities. Sample locations are shown **Figure 13** and detailed in **Table 17**. Samples from drainage lines were treated as soil rather than sediment as the watercourses are ephemeral and rarely inundated. Samples were collected using a hand auger.

Table 17: Soil investigation locations

Location	Type	Rationale
THS01	Sediment	Base of spillway of TSF
THS02	Sediment	Drainage line downstream of TSF and processing
THS03	Sediment	Ponded area at foot of TSF wall
THS04	Sediment	Drainage line upgradient of site
THS05	Sediment	Junction of drainage line between processing and TSF
THS06	Sediment	Junction of drainage line between processing and TSF
THS07	Sediment	Drainage line downstream of TSF and processing
THS08 – THS11	Soil	Depressions or drainage lines within the former processing plant area
THS12	Sediment	Drainage line on site boundary – downstream of TSF, processing and open pit.
THS13	Soil	Foot of decant dam
THS14	Soil	Core yard
THS15	Soil	Foot of waste rock dump wall

10.6 Tailings assessment

Tailings sample locations are shown on **Figure 14**. Samples THT01 to THT08 were collected from the eastern tailings cell using a hand auger. Samples THT09 to THT11 were collected from the western tailings cell using a push tube. Samples THTSF_DEC01 and THTSF_DEC02 were collected from the decant dam by Carnaby Resources using an excavator.

The tailings assessment aimed to characterise the nature of the tailings material in the three areas.

The following observations were made:

- Tailings material in the eastern cell and decant dam is brown and appears more oxidised than tailings material in the western cell.
- Material is finely bedded with sandy and clayey layers.
- Within the western cell more clay was observed in the northern and western locations (further from the release point).
- Tailings was saturated at depth, between 4 and 5 m.
- Rocky mulch cover on the western cell ranged from 0.7 to 1.0 m.
- Distinct topsoil cover of 0.1 m was observed in one location.

10.7 Laboratory Analysis

Samples were analysed by ALS Environmental (ALS), Eurofins and Sydney Analytical Laboratories (SAL). All laboratories are accredited with the National Association of Testing Authorities (NATA) for the methods used. Intra-laboratory duplicates (blind duplicates) and inter-laboratory duplicates (split duplicate) were analysed as part of our standard QA/ QC procedure at a rate of one blind duplicate and split duplicate per 10 samples for groundwater and one blind duplicate and split duplicate per 20 samples for soil or tailings.

10.7.1 Analytical Schedule

The analytical schedule was chosen based on the contaminants of concern identified and is summarised in **Table 18** below. Laboratory transcripts are provided in **Appendix I**.

Table 18: Project Analytical Schedule

Analyte	No. of Samples	No. of Intra-lab Duplicates	No. of Inter-lab Duplicates	Project Total
Groundwater				
Metals – Totals (extended suite)	20	2	2	24
Metals – Dissolved (extended suite)	20	2	2	24
Ionic Balance	20	2	2	24
Total, Free and Weak Acid Dissociable Cyanide	20	2	2	24
Total Phosphorus	11	1	1	13
PFAS	11	1	1	13
Total Recoverable Hydrocarbons	11*	1	1	13

Soil				
Metals (extended suite)	8	1	1	10
Total, Free and Weak Acid Dissociable Cyanide	11	1		12
Total Phosphorus	5			5
PFAS	3			3
Total Recoverable Hydrocarbons	5			5
BTEXN	5			5
pH, EC	8		1	8
Cation Exchange Capacity	3			3
Total Organic Carbon	1			1
Chromium Reducible Sulfur	3			3
Organochlorine Pesticides	4			4
PCB	4			4
Tailings & Decant				
Metals (extended suite)	24	1	1	26
Total, Free and Weak Acid Dissociable Cyanide	28	1	1	30
Total Phosphorus	3			3

Analyte	No. of Samples	No. of Intra-lab Duplicates	No. of Inter-lab Duplicates	Project Total
PFAS	2			2
pH, EC	8			8
Chromium Reducible Sulfur	23			23
ASLP Leach + metals analysis	21			21
ALSP Leach + cyanide analysis	34			34

10.7.2 Quality Assurance and Quality Control

Quality control is achieved by using NATA registered laboratories using ASTM standard methods supported by internal duplicates, the checking of high, abnormal or otherwise anomalous results against background and other chemical results for the sample concerned.

Quality assurance is achieved by confirming that field results, or anticipated results based upon comparison with field observations, are consistent with laboratory results. Also, that sampling methods are uniform and that decontamination of sampling equipment is thorough. In addition, the laboratory undertakes additional duplicate analysis as part of their internal quality assurance program on the basis of one duplicate analysis for every 10 (water) or 20 (soil) samples analysed.

Field observations are compared with laboratory results when they are not as expected. Confirmation, re-sampling and re-analysis of a sample are undertaken if the results are not consistent with field observations and/or measurements. In addition, field duplicate sample results have to be within the acceptable range of reproducibility.

A discussion of the quality of internal laboratory results and field duplicate relative percentage difference (RPD) calculations is presented below. RPD calculations are presented in **Table 35**.

The overall assessment of the data quality is as follows:

- Analysis holding time breaches were present during all monitoring rounds for pH. However, as pH is measured in the field prior to sampling in the field data quality and the ability to assess the site contamination status is not considered to have been compromised;
- RPDs were identified with four RPD exceedances for each of the groundwater QAQC sets, one for the soil sample and nine for tailings. Results indicate some heterogeneity in the tailings material, and oxidation of the split samples for groundwater. Overall correlation between primary, duplicate and split samples is good;
- Field observations and measurements were generally comparable to laboratory data;
- Internal laboratory quality data is considered acceptable;
- The use of field instruments was acceptable;

- Decontamination procedures are considered acceptable based on no detections of CoPCs in rinsate samples (**Table 36**); and
- The dataset as a whole is considered reliable.

11 RESULTS AND DISCUSSION

11.1 Groundwater results

Two rounds of groundwater monitoring were completed as part of this investigation, in December 2022 and June 2023. Results have been interpreted with consideration of historical monitoring results available. This includes data from 2012 for bores THGW001 and THGW002, and from 2020 for the remaining bores. Bores THGW007 to THGW009 were installed in June 2023 and have been sampled once.

Field parameters from the two recent monitoring rounds are presented in **Table 26** of the Tables appendix. Results for ionic balance and cyanide are presented in **Table 27**, dissolved metals in **Table 28** and Total metals in **Table 29**. Total recoverable hydrocarbons (TRH), BTEXN and PFAS results are presented in **Table 30**. All available historical results are collated in **Table 37**. One sample was also collected from the water ponded in the TSF in December 2022.

11.1.1 Field parameters

As shown in **Table 26**, groundwater at the site is neutral to slightly alkaline, with pit water and mine shaft bore slightly to moderately alkaline. Groundwater salinity ranges from low in bore THGW002 and THGW009 to moderate to high in other site bores, and the mine shaft bore. The pit is highly saline. The EC of the mine pit and mine shaft bore have fluctuated, however the pit is consistently 2.5 times the EC of the mine shaft. Redox conditions and dissolved oxygen concentrations indicate that conditions are mostly oxidising within the aquifer.

11.1.2 Water levels

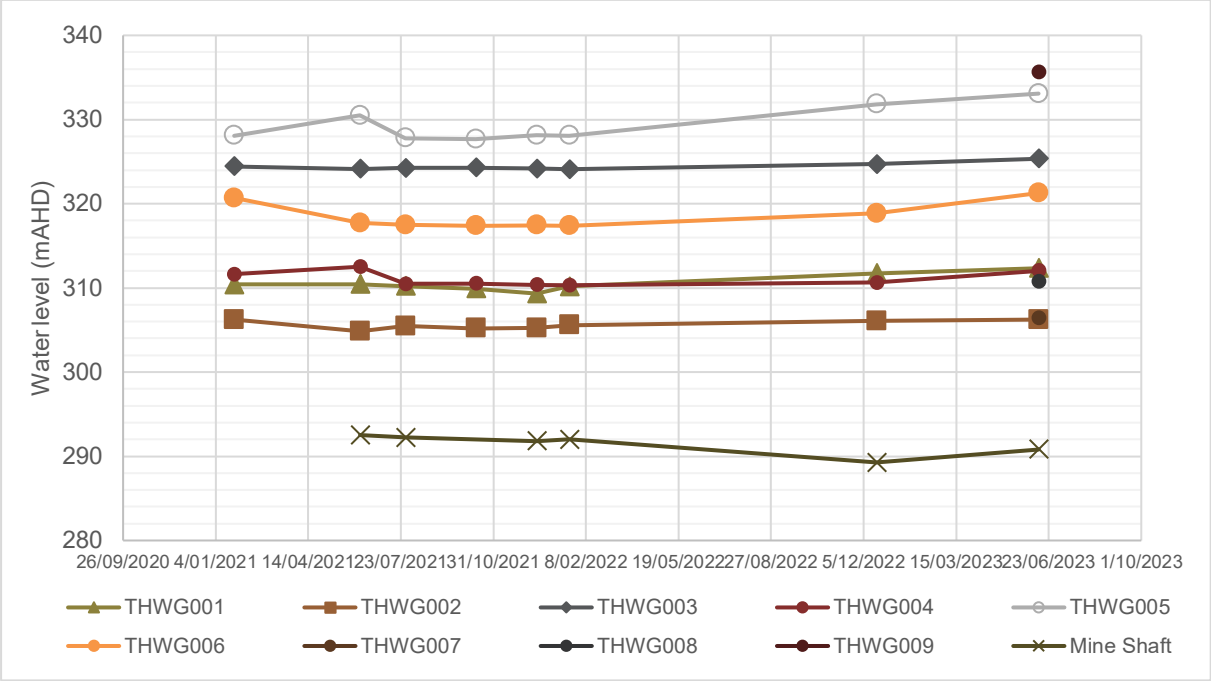
Water levels in groundwater bores and the mine shaft bore have been tracked since 2020. The mine shaft bore measures water levels within the underground workings, which are considered to be in direct connectivity with the open pit. The mine shaft bore is therefore taken as a proxy for the water level in the open pit as no direct way of measuring the pit water level is available. Water levels since 2020 are shown on **Graph 1**.

Groundwater levels have varied between 1.2 m (bore THGW003) and 5.4 m (bore THGW005) over this period. Water levels in June 2023 are higher than previously observed (since 2020), except in the pit, where water level decreased to December 2022 and subsequently increased.

Based on the SWLs measured in site bores in June 2023 and survey data provided by Carnaby Resources, groundwater contours were developed for the site. These are shown on **Figure 9** with the monitoring bore locations. The groundwater contours show the influence of the pit as a sink within the centre of the site. The hydraulic gradient from the pit

to the east (bore THGW006) is steep, while the gradient to the west is more gradual. The contours to the west show the potential influence of the underground workings in providing a preferential pathway from the aquifer to the mine pit.

Graph 1. Standing water levels – groundwater bores



Two cross sections have been prepared to show the influence of the mine pit on groundwater at the site. These run southwest to northeast (**Figure 15**) and northwest to southeast (**Figure 16**).

11.1.3 Ionic balance

Groundwater at the site is Na(Mg):Cl/HCO_3 dominated. Water is relatively elevated in fluoride. Nitrate was detected in all locations except the mine shaft, as were low concentrations of ammonia. Phosphate was detected in varying concentrations across the site. Nitrate, ammonia and phosphate have only been included in monitoring since December 2023, so trend analysis is not possible.

Water chemistry for all bores (June 2023) is shown on the Schoeller Plot in **Graph A1** in the Graphs appendix. This graph includes chemistry for rainwater and seawater for comparison.

Figure 16

Water chemistry over the period of monitoring has been presented for each bore, the mine shaft and pit in **Graphs A2 to A9**, with the exception of newly installed bores THGW007 to THGW009. A summary of observations is presented below:

- THGW001: Water is Na:Cl dominated. Water chemistry is consistent over time.
- THGW002: Water is Na:HCO_3 dominated. Salinity is stable until late 2021 when a sharp decrease occurred. This trend is observed for all major ions except sulfate. Sulfate concentrations were initially low (2012) but increased until 2014. Concentrations steadily decreased until a sharp decrease in 2021. Concentrations have subsequently increased and appear to have stabilised. Sulfate is utilised as an oxygen source by microbes. This fluctuation indicates that microbial activity is occurring to break down some compounds in groundwater at this location. The change in salinity from 2021 indicates that a fresher source of groundwater or surface water inflow is influencing chemistry in this location.
- THGW003: Water is Na:HCO_3 dominated. Chemistry is stable over time, with a decease in potassium the only significant trend.
- THGW004: Water is Na:HCO_3 dominated. Chemistry is stable over time, with the exception of a slight fluctuation in 2021.
- THGW005: Water is Na:HCO_3 dominated. No trends in water chemistry are observed.
- THGW006: Water is Na:HCO_3 dominated. No trends in water chemistry are observed.
- Mine shaft: Water is Na:Cl dominated. No trends in water chemistry are observed.
- Pit: Water is Na:Cl dominated. Concentrations of major ions increase steadily over time, however have remained relatively steady since 2021.

Exceedances of relevant criteria for human health, ecological species protection and stock watering are shown with the water chemistry data. A brief summary is provided below. For details of exceedances for specific analytes in specific bores, refer to the results tables.

Drinking water criteria were exceeded for pH, salinity (TDS), chloride, sodium, fluoride, ammonia and nitrate. Ecological criteria were exceeded for ammonia and nitrate while stock watering criteria were exceeded for fluoride.

Salinity and fluoride are considered to be naturally occurring. Water would require treatment to remove salinity to enable suitability for drinking. Slight exceedances of fluoride are considered acceptable for stock if other water sources are available.

Several potential sources of nitrate and ammonia are present on site. The highest nitrate concentrations are downgradient of the WRD and TSF (THGW001, THGW004 and THGW08). Ammonium nitrate is a commonly used explosive, and explosive residues in mine wastes is a likely source. Concentrations of nitrate and ammonia are similar between December 2022 and June 2023 monitoring events and no trends are currently evident. Ammonia and nitrate may also be present in an aquifer due to natural contributions from nitrogen fixing plants, where nitrogen is leached from the soil. Many arid zone plants are nitrogen fixing including wattles and gidgee, which are present across the site.

Ecological screening criteria for nitrogen in surface water relate to potential for eutrophication of waterways and toxicity of ammonia. As no surface expression of groundwater occurs at the site (other than the open pit), there is no complete pathway for ecological exposure. Concentrations of ammonia and nitrate in the open pit are below screening criteria. It is recommended that ammonia and nitrate be retained in future analysis suites for groundwater.

Due to elevated concentrations of phosphorus identified in tailings materials, total phosphorus and phosphate have been included in the groundwater analysis suite. Phosphate is considered the available form of P, while total P is mostly related to occurrence of P containing minerals. Phosphate concentrations are close to the LOR, with slightly higher concentrations in THGW002, and newly installed bores THGW007 to THGW009 which were observed to contain higher sediment load than other bores due to recent installation and development. Total P concentrations were also correlated with observed turbidity in samples.

There are no ANZG criteria for total P or phosphate and therefore no exceedances were observed.

11.1.4 Cyanide

Due to the presence of cyanide in mine tailings, cyanide has been included in the monitoring suite for groundwater since the commencement of monitoring. Cyanide in groundwater on site occurs as total cyanide. Free and weak acid dissociable (WAD) are generally not detected. The discussion therefore focuses on total cyanide.

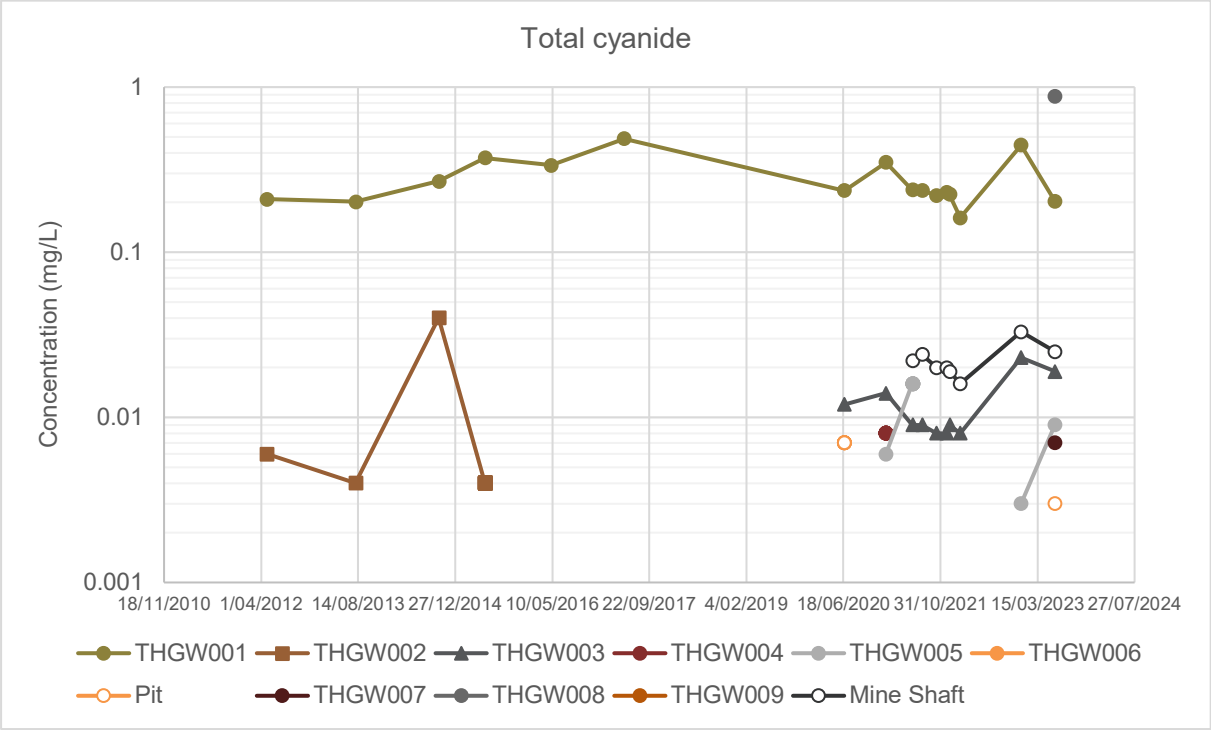
Total cyanide concentrations are presented in **Graphs 2a** (logarithmic scale)**, 2b** (linear scale) and **2c** (adjusted linear scale with bores THGW001 and THGW008 excluded) to allow ease of interpretation.

Free cyanide is shown on **Graph 3**. Exceedances of screening criteria for free cyanide have been observed at bores THGW001 and THGW008. While free cyanide is toxic, the balance of cyanide observed as total cyanide is typically iron cyanide which is non-toxic, non-reactive and moves through aquifers with minimal geochemical interaction with the aquifer matrix. Iron cyanides will also not typically degrade in alkaline conditions without light (Ghosh et. al. 1999), as occurs in the groundwater on site.

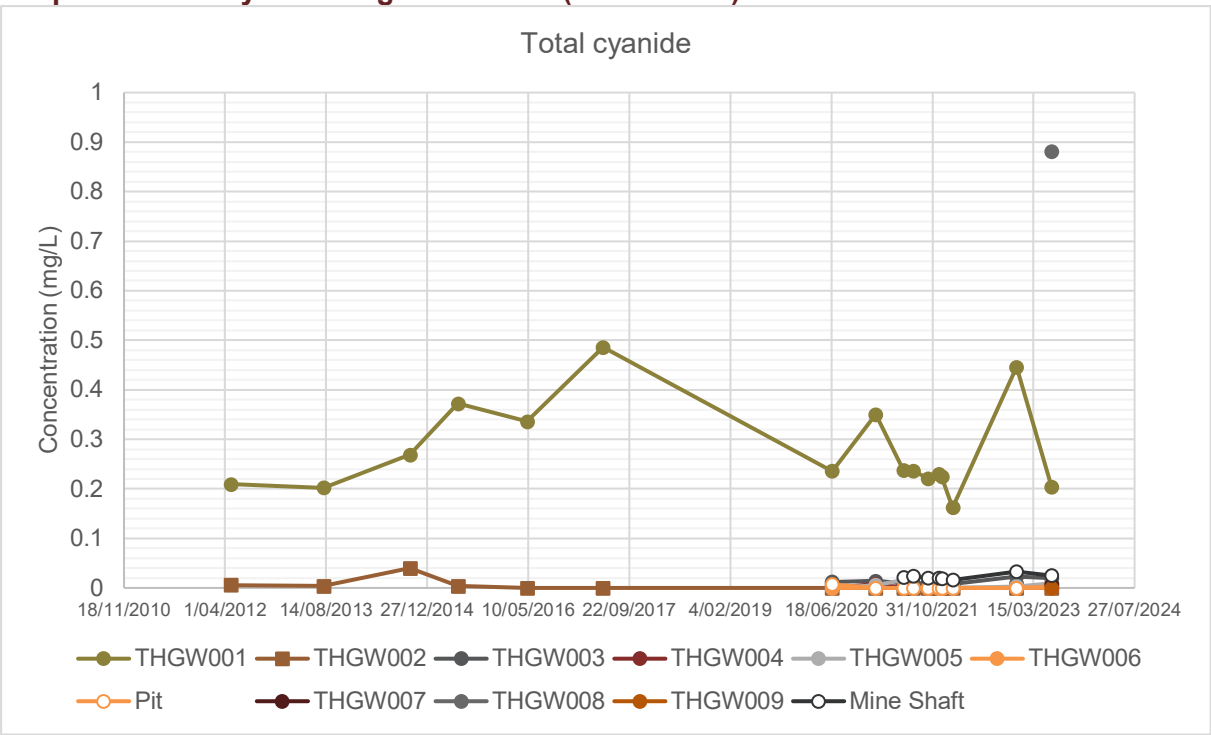
The highest concentrations of cyanide (total and free) have consistently been observed in bore THGW001. Concentrations have varied over the 11 years of monitoring, however no obvious trend is observed. As installation details of bore THGW001 are not known, characterisation of the extent of groundwater impact at bore THGW001 was difficult. Bore THGW008 was installed adjacent to bore THGW001 in the upper part of the aquifer. Bore THGW008 has higher concentrations of total and free cyanide.

The variation in concentration is consistent with vertical gradation of cyanide concentration in groundwater sourced from infiltration from the tailings dams to the south.

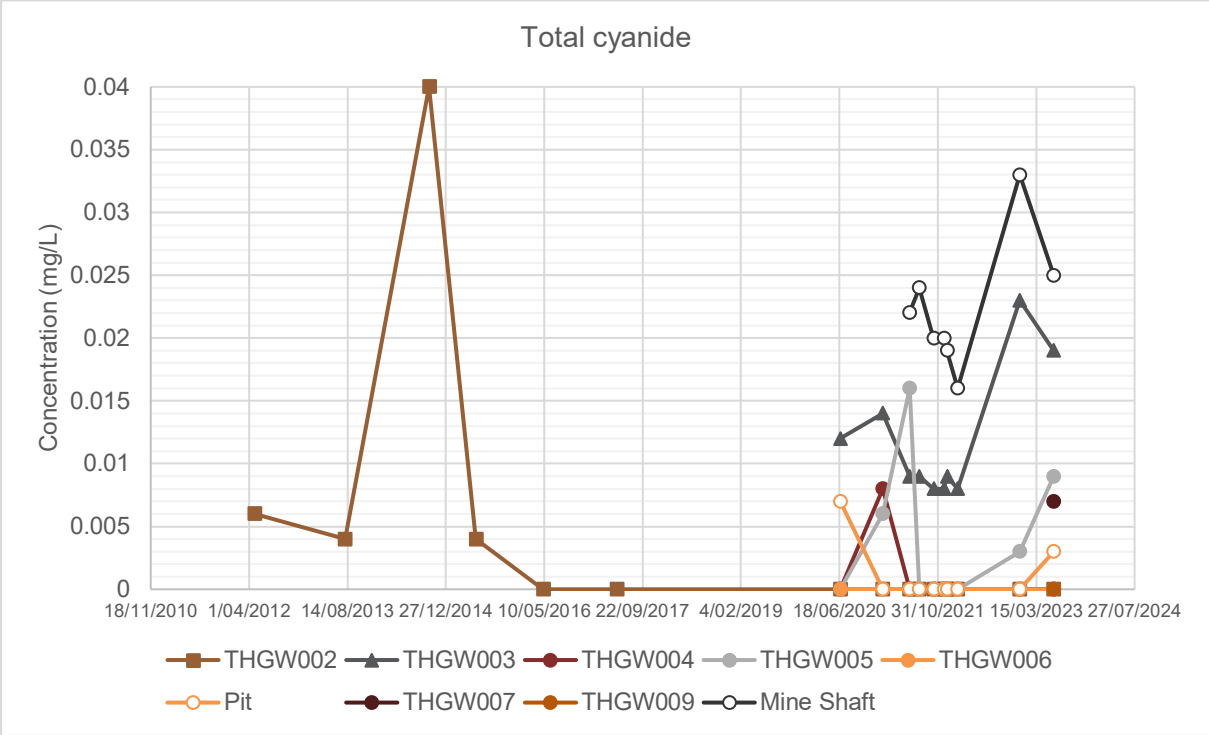
Graph 2a. Total cyanide in groundwater (logarithmic scale)



Graph 2b. Total cyanide in groundwater (linear scale)



Graph 2c. Total cyanide in groundwater (adjusted linear scale, bores THGW001 and THGW008 excluded)



Total cyanide is observed in other bores on site, but not free cyanide. Low concentrations have been observed in bore THGW003 and intermittently in bore THGW005. It is considered likely that cyanide is sourced from the tailings dam as the tailings dam acts as an infiltration zone. Due to the nature of the aquifer with water moving through irregular fractures, it is likely that low level impact to groundwater will occur radially from the TSF.

As concentrations are low and consistent, with no free cyanide detected, cyanide is not considered to have potential to impact human or ecological receptors in around the western site boundary at bore THGW003. Fluctuations in concentrations are likely to occur in response to high rainfall events resulting in increased groundwater recharge.

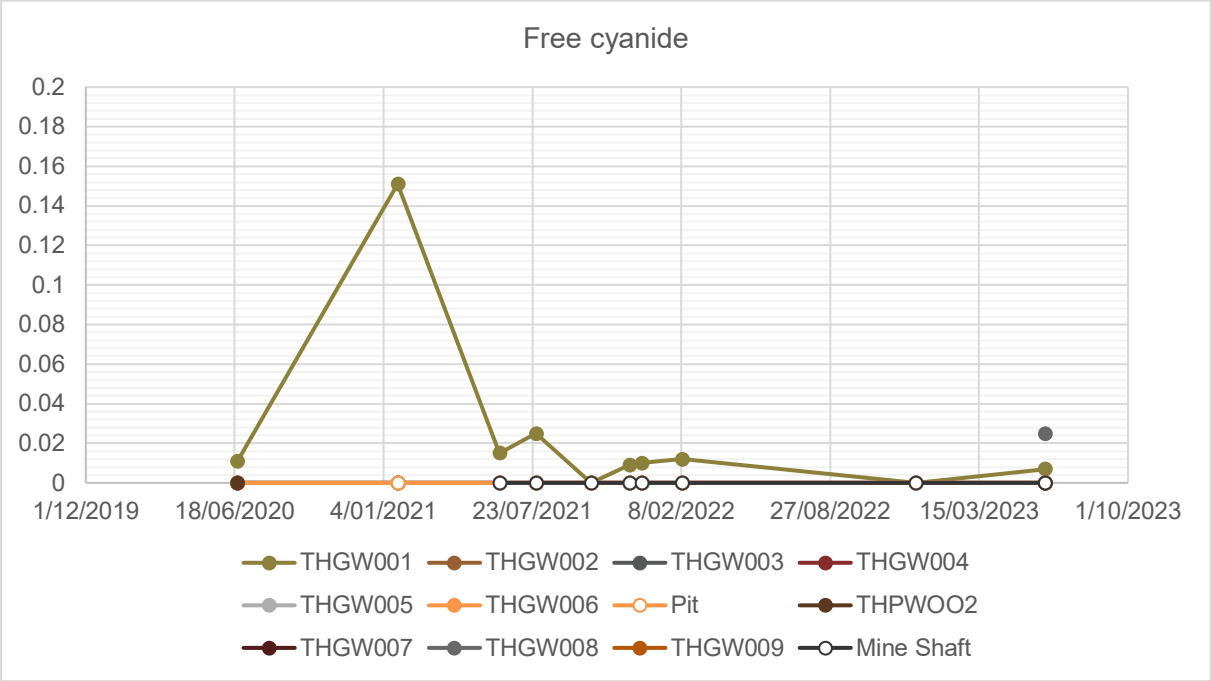
Total cyanide was previously detected at bore THGW004 in January 2021. This was considered to be due to a false positive or cross contamination. No further detections of cyanide have been made that this location, which supports the hypothesis of an anomalous result.

A low concentration of total cyanide was observed in new bore THGW007.

Other than at bores THGW001 and THGW008, the mine shaft has the highest concentrations of total cyanide. No free cyanide has been detected at this location. Concentrations of total cyanide further decrease as water migrates to the pit.

As free cyanide is only observed in locations situated between the TSF and open pit, and concentrations of total and free cyanide have been observed to vary within a consistent range, cyanide in groundwater is not considered to have the potential to cause environmental harm. While degradation of iron cyanide would occur slowly within the aquifer, any point at which cyanides are exposed to light or oxidising conditions will result in cyanide degradation.

Graph 3. Free cyanide in groundwater



11.1.5 Metals

Groundwater samples on site were analysed for an extended suite of dissolved and total metals. This includes aluminium, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, lead, manganese, molybdenum, nickel, selenium, strontium, titanium, uranium, vanadium, zinc, iron and tungsten. Concentrations of total and dissolved metals are presented in **Graphs A10 to A22** in the Graphs appendix, where sufficient data were available to assess potential trends, based on sufficient sampling events and detections of metals in samples.

Exceedances of drinking water criteria were observed for dissolved cobalt, selenium, uranium and vanadium. Ecological criteria were exceeded for aluminium, copper and selenium. Arsenic also exceeded both ecological and drinking water criteria in the TSF pond.

Uranium and vanadium exceedances are consistent across the site and are considered to be associated with natural mineralisation. The site is also known to be naturally elevated in copper. Cobalt was elevated in bores THGW001 and THGW008, located downgradient of the TSF. Exceedances of selenium were observed in bore THGW004 and the mine pit. Exceedances of ecological criteria for aluminium are due to sediment contamination of the sample, as aluminium does not occur in the dissolved phase at the pH range observed on site. Detections of dissolved aluminium can also indicate sediment contamination which is the cause of other metal exceedances.

No exceedances of stock watering criteria were observed.

When reviewing trends in metal concentrations, occasional spikes are typically associated with sediment contamination and are therefore not relevant to the overall trend. The

relationship between trend concentrations and screening criteria should also be considered as relatively elevated concentrations may not exceed screening criteria.

For metals with long term trends able to be assessed:

- Arsenic: No exceedances. Slightly higher concentrations observed in the mine pit and THGW004.
- Cadmium: No exceedances. Occasional spikes in concentration but no obvious trends.
- Chromium: No exceedances. Recent spike correlates with sediment contamination.
- Cobalt: Exceedances at bores THGW001 and THGW008. Consistently elevated concentrations at THGW001, no increasing or decreasing trend.
- Copper: Exceedances at several locations however no consistent trend observed. Considered to be due to natural site conditions.
- Lead: Occasional historical exceedances at bore THGW001. No recent exceedances or trends apparent.
- Manganese: No exceedances and no trends. Variable concentrations across site.
- Molybdenum: No exceedances. Elevated concentrations at the mine pit. Consistent concentrations at each bore which correlate with pH; No increases with pH.
- Nickel: No recent exceedances. No trends.
- Selenium: Concentrations consistently exceed at the mine pit and bore THGW004. Pit concentration decreasing, no change at bore THGW004.
- Zinc: No exceedances. High variability in concentrations – no trends.

11.1.6 Organic compounds

No hydrocarbons or BTEXN compounds were detected in groundwater at the site.

PFAS was detected in groundwater at the site, with the exception of bores THGW009 (upgradient), THGW006 and the mine pit.

PFOS exceeded the 99% ecological protection criteria at the mine shaft bore but was not detected at any other location. No other exceedances were observed.

The majority of the PFAS mass is attributed to 6:2 FTS which was found in bores THGW001, THGW002, THGW004, THGW005, THGW007 and THGW008. PFAS detections are consistent with the requirement for fire suppression at the mining operation.

As PFAS with screening criteria were only detected in the mine shaft bore, the potential for off-site impact is considered negligible.

11.2 Tailings and decant dam results

Tailings and decant material results are shown in **Table 31, 32 and 34**. Tailings and decant material were assessed to determine potential residual impacts associated with these residual waste materials. Tailings materials from the TSF and decant dam were assessed against commercial / industrial criteria on the basis that these materials should be contained with the appropriate structures.

Tailings materials are:

- Alkaline to strongly alkaline;
- Salinity ranges from low to high;
- Chromium reducible sulfur (CRS) is below the threshold for acid production. This supports several previous assessments of acid generation potential which show no acid generation risk for site waste materials, as outlined in **Section 6.4**;
- Total phosphorus is high, indicating mineral P, however available phosphate concentrations are low;
- Metals:
    - All metals were below the human health criteria;
    - All metals with the exception of copper were below the EILs developed for the material.
    - Maximum concentration was 357 mg/kg.
    - ALSP leach for metals indicated a bioavailability factor of 0.0119, giving a site specific Tier 2 EIL for copper of 13600 mg/kg. No exceedances of the Tier 2 criteria were observed.
- Cyanide:
    - No free cyanide was detected in the tailings material;
    - Average total cyanide in the eastern cell was 69 mg/kg, 185 mg/kg in the western cell and 101 mg/kg in the decant dam.
    - Maximum concentration was 564 mg/kg.
    - No depth relationship was evident.
    - ASLP leach for total cyanide showed a bioavailability fraction of 0.019.

Results for tailings material in the TSF and decant dams indicates that tailings material does not have potential to cause contamination, if material is appropriately contained within the TSF and decant dam facilities.

11.3 Soil results

Soils results are presented in **Table 33 and 34**. Soil and creek sediment results were assessed to determine potential residual impacts associated with historical and recent site operations. No visible evidence of soil contamination was identified across the site, with the exception of tailings material (discussed below). A summary of soil results is presented below:

- Soil pH is slightly to moderately alkaline;
- Salinity is low;
- Chromium reducible sulfur is below the threshold for acid production;
- Total phosphorus is high, indicating mineral P, however available phosphate concentrations are low;
- Total organic carbon is low;
- Cation exchange capacity is moderately high;
- No exceedances were observed for any metals;
- No free cyanide was detected. The sediment sample collected from below the TSF spillway contained total cyanide at 5 mg/kg indicating potential overflow or runoff from the TSF and transport of tailings material. No cyanide was detected in downstream samples;
- No pesticides or PCB were detected;
- No hydrocarbons or BTEXN compounds were detected; and
- No PFAS compounds were detected.

Soil and sediment results show no evidence of contamination across the site. The total cyanide detected downstream of the TSF indicates a lack of containment of tailings material, however no exceedances of screening criteria were observed indicating that this material does not pose a contamination risk.

11.4 Groundwater migration

Results of hydraulic testing were interpreted to determine the hydraulic conductivity (K) of the site aquifer. Interpretation of slug test results included use of bore construction data provided in borelogs (Carnaby Resources 2020) and standard values for metamorphic aquifer properties. Porosity was assumed to be 0.1. Results of slug test and solute transport modelling are presented in **Appendix J**.

For each bore, the results of two of the tests is presented below, representing the range of values obtained during test interpretation. The Hvorslev and Bouwer and Rice methods provided the most consistent results for interpretation for slug test results.

Comparison of the slug test results shows a 10x difference in hydraulic conductivity between the two bores, indicating the range of variability observed on site.

Table 19: Aquifer parameters

Bore	Lithology (water bearing zone)	Thickness (m)	K (m/d)	*i* (m/m)	V_g (m/d)	KD (m²/d)
THGW005	Corella Formation	10	0.081	0.038	0.031	0.806
			0.064	0.038	0.064	0.641
THGW006	Corella Formation	10	0.898	0.236	2.12	8.98
			0.682	0.236	1.61	6.82

Note: K – hydraulic conductivity, i – hydraulic gradient, V – velocity, KD – transmissivity

11.5 Groundwater cyanide transport and sorption mechanisms

Cyanide in groundwater at the site predominantly occurs as iron cyanide, measured as total cyanide. Under alkaline conditions with no light, iron cyanides do not typically react with the aquifer matrix and do not degrade. Iron cyanide will therefore migrate at a similar speed to groundwater, with minimal retardation. Concentrations used for calibration of the groundwater model are presented in **Table 20**.

Table 20: Concentrations used in solute transport model calibration

Location	Aquifer	Total Cyanide (mg/L)
THGW001	Regional Aquifer – upper layer	0.881
THGW008	Regional Aquifer	0.206
Retardation factor (R)		1.002

Based on the velocity (V_g) and hydraulic gradient (*i*) of groundwater calculated for the water bearing zones on site, and the retardation (R) rates determined for Cyanide (**Table 20** and **Appendix J**), the potential migration rates (V_s) for total cyanide were determined. These are presented in **Table 21**. The migration pathway was calculated based on the TSF as a source, with the hydraulic gradient between bores THGW005 and THGW001/8.

The TSF is treated as an ongoing source. Width is based on the tailings and decant dams and flow towards the pit. The model considers downward migration of 10 m into a saturated zone below the TSF. The initial source concentration is based on an estimate of cyanide concentration in fresh tailings at the time of mine operations, based on tailings material used for cyanide decay trials of 350 mg/L (Environmental & Earth Services 1990).

Table 21: Groundwater and contaminant migration rates

Unit	Pathway	Water (V_g)		Total Cyanide (V_s)	
		m/d	m/yr	m/d	m/yr
Regional Aquifer	TSF to THGW001/8	0.027	9.71	0.0265	9.69

The model was calibrated based on a measured concentration of 0.8 at bore THGW008, 200 m downgradient from the TSF. The time since release has been estimated as 30 years, based on the time since tailings were deposited in the TSF. Predicted total cyanide concentrations with distance from the source and time since release (**Graphs 4 and 5**). Total cyanide concentrations observed at bore THGW008 are shown as orange diamonds on these graphs.

The model predicts that this cyanide concentration reached the receptor (bore THGW008) after 21 years and that the plume is stable. This model represents the observed site conditions relatively well, as the concentration at bore THGW001 has remained consistent over 10 years of monitoring. However, the model assumes a constant concentration at the receptor. This is not the case as cyanide in the tailings has substantially degraded over time. While the model therefore provides a good estimate of current and recent conditions, future concentrations may decrease more quickly than modelled as the source is depleted.

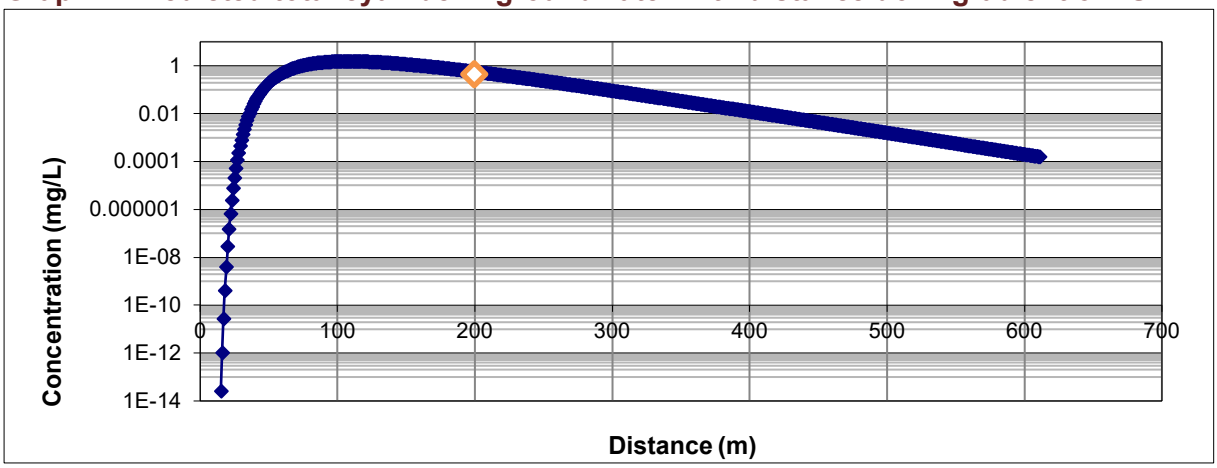
It is not expected that the cyanide impacts to groundwater would further increase pit concentrations substantially as pit inflows are sourced radially and not just from the TSF. In addition, pit water is subject to sunlight which allows breakdown of cyanide.

In summary, the groundwater model predicts that total cyanide concentrations at bores THGW001/8 are at the stable maximum of the plume migration and that depletion of the cyanide source will result in a decrease in concentrations at these bores into the future.

Cyanide in groundwater at Tick Hill is therefore limited in potential toxicity to the environment as:

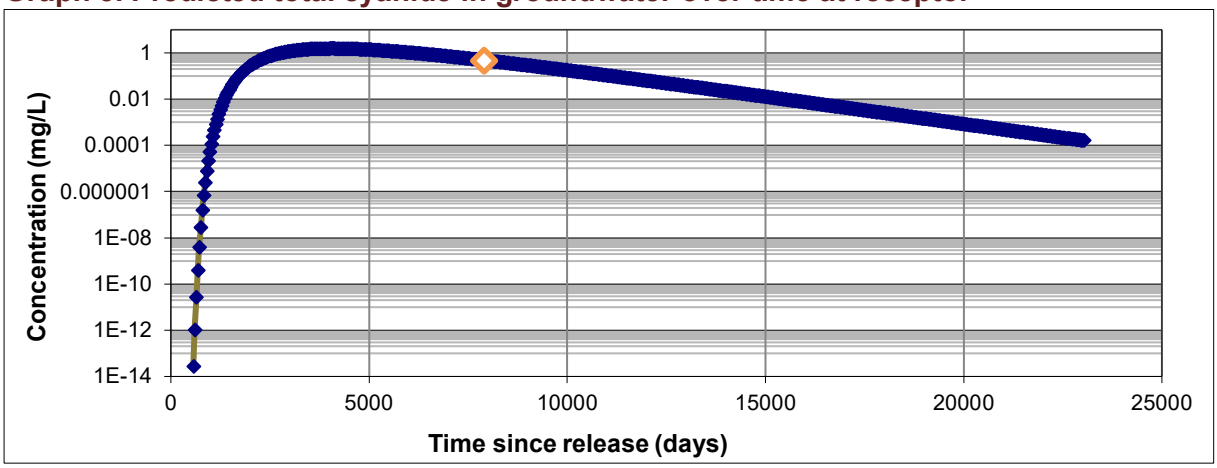
- Cyanide is almost entirely present as non-toxic, non-reactive iron cyanides, measured as total cyanide.
- Current concentrations at bores THGW001 and THGW008 represent the maximum likely concentrations over the migration of the plume.
- Bores THGW001 and THGW008 are the only locations where free cyanide exceeds criteria. These locations are well within the influence of the open pit as a sink for groundwater.
- Cyanide in the open pit is subject to breakdown in sunlight.
- Source concentrations of cyanide in the TSF are substantially depleted, with no free cyanide detected in tailings material.

Graph 4. Predicted total cyanide in groundwater with distance downgradient of TSF



Note: Orange diamond indicates concentration at bore THGW008

Graph 5. Predicted total cyanide in groundwater over time at receptor



Note: Orange diamond indicates concentration at bore THGW008

11.6 Mine void water balance

11.6.1 Current site conditions

The mine open pit acts as a groundwater sink at the site. From when mining operations in the pit ceased in the mid 1990s, the underground workings re-flooded and the water level in the pit increased to approximately 25 m from the pit base of the 70 m pit. Water levels have since fluctuated within a range of several metres. Water levels in the pit are influenced by rainfall and runoff inputs, evaporative losses and groundwater inflow. In order to estimate long term groundwater inflows, a mass balance was developed using known climatic inputs.

The mass balance calculation used the site information and data as outlined in **Table 22**.

Water inflows from rainfall and runoff were calculated under two scenarios; runoff in the catchment area after the initial 10 mm of a rainfall event, 50% runoff after 10 mm. Once the

volume of rainfall and runoff inputs and evaporative losses are calculated, the volume of groundwater discharging into the pit can be calculated. Estimated groundwater inflow volumes are presented in **Table 23.** It was initially attempted to correlate changes in pit levels to changes due to rainfall, however the rainfall inflow and groundwater flux associated with rainfall events do not synchronise. Long term average conditions were therefore assessed. The perimeter of the open pit catchment is shown on **Figure 11.**

Table 22: Mine void mass balance calculations

Parameter	Value	Notes
Mine pit surface area (pit walls and water surface) (340 mAHD)	32,000 m²	
Pit surface at 290mAHD water level	8,000 m²	Direct rainfall and evaporation
Exposed pit catchment area between 290 and 340 mAHD	24,000 m²	Runoff to pit
'Likely' runoff conditions	Runoff after 10 mm rainfall per event	Estimated likely scenario
Minimum runoff conditions	50% runoff after 10 mm rainfall event	
Rainfall data	Mean annual rainfall since 1994	The Monument - **Section 5.6**
Evaporation data	Pan evaporation	Mount Isa daily evaporation - **Section 5.6**

Using the range of estimated groundwater inflows into the pit and the standing water levels of monitoring bores at the mine, the hydraulic conductivity and transmissivity of the aquifer can be estimated (**Table 23**). The hydraulic gradient between pit water level and SWL at bore THGW001 was used to calculate inflow. Hydraulic conductivity (K) values are low compared to direct estimates based on groundwater bore measurements.

Table 23: Groundwater flux estimates

Groundwater inflow scenario	Units	High Runoff	Low runoff
Runoff Scenario		100% runoff after 10 mm	50% runoff after 10 mm
Pit area	m²	8,000	8,000
Catchment area	m²	24,000	24,000
Annual rainfall	m/yr	0.396	0.396
Annual rainfall volume to pit	m³/yr	3168	3168
Annual evaporation	m/yr	3.1	3.1
Annual evaporation volume from pit	m³/yr	24492	24492
Annual runoff from catchment	m/yr	0.257	0.257

Groundwater inflow scenario	Units	High Runoff	Low runoff
Annual runoff volume	m³/yr	6178	3089
Annual groundwater inflow	m³/yr	-15146	-18235
Daily Groundwater inflow	m³/day	-41.5	-50.0
Aquifer thickness	m	25	25
Hydraulic conductivity (K)	m/day	0.017	0.020
Transmissivity (KD)	m³/day	0.418	0.510

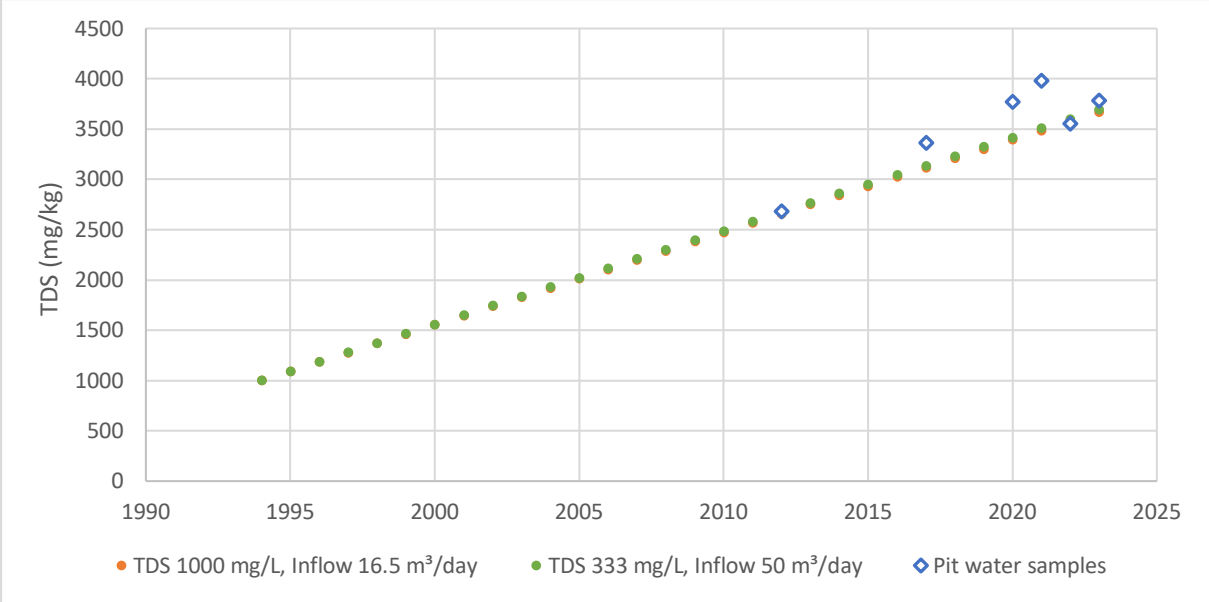
11.6.2 Salinity in the open pit

A salt balance in the open pit was estimated based on the salinity of the surrounding aquifer and observed measurements of TDS in pit water. Results are shown in **Graph 6**. Two estimates were developed, based on a starting salinity of 1000 mg/L TDS in the mid 1990s. To reach the current TDS in the pit of ~3,750 mg/L, the pit requires an addition of ~6077 kg salt per year. Rainfall salt inputs are assumed to be negligible. Two scenarios are shown on **Graph 6** to meet this requirement.

For groundwater inflows at 1000 mg/L TDS, the inflow volume would be 16 m³/day. For groundwater inflows volumes of 50 m³/day, as estimated by the pit mass balance above, the inflow TDS is 333 mg/L. This indicates that the pit is receiving lower salinity water than indicated by the shallower parts of the aquifer assessed in monitoring bores. Previous assessment of salinity with depth in the pit indicated no stratification, however sampling method details are not known.

Water quality results since 2020 indicate relatively stable salinity in the pit, however inadequate data is available to determine how this relates to long term trends. It is predicted that pit salinity will continue to increase due to evapo-concentration of pit waters.

Graph 6. Salt balance in the open pit



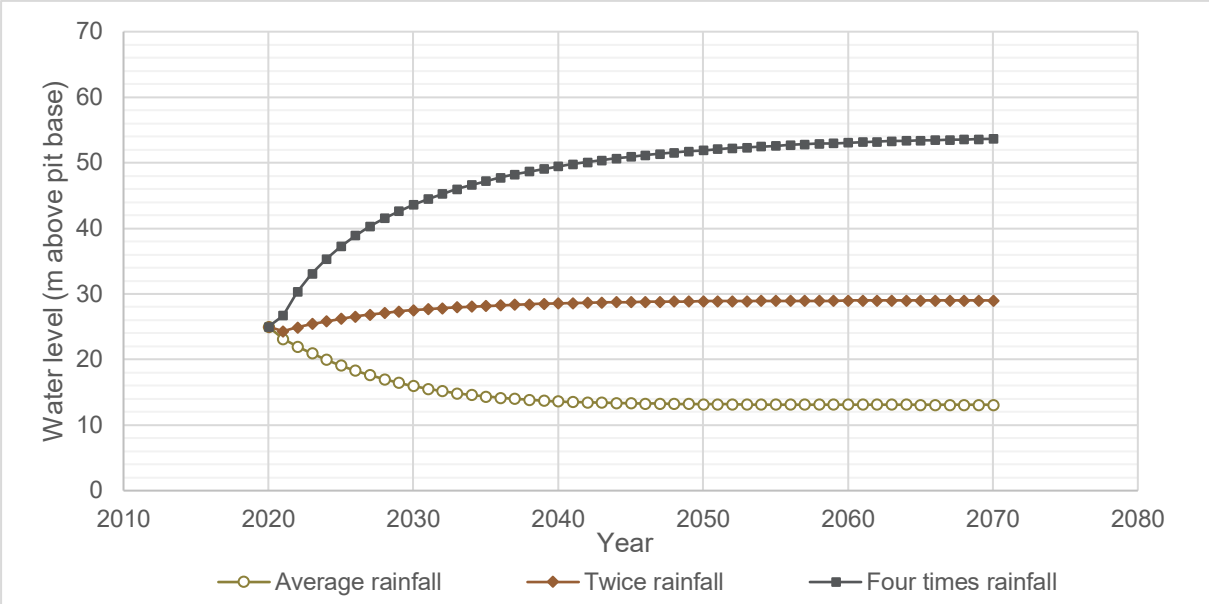
11.6.3 Future site conditions

Water level in the Tick Hill open pit has been at a stable level for many years and has acted as a groundwater sink. A mass balance calculation was conducted to examine what increased rainfall would do to the equilibrium pit level. This assessment ignored groundwater inflows on the basis that groundwater inflows steadily decrease as water level increases, due to the decreasing hydraulic gradient. Once the water level reaches the groundwater equilibrium level the pit may act as a flow through groundwater lens, at approximately 310 mAHD, or approximately 45 m above the base of pit shown in **Graph 7**.

Pit water levels over 50 years were calculated using actual annual rainfall (396 mm/year), twice annual rainfall (792 mm/year) and four times annual rainfall (1.58 mm/year), using the same catchment runoff and evaporation assumptions as in **Section 11.6.1** above. These calculations indicate that without groundwater inflow, under current rainfall conditions, the pit level would decrease to 13 m.

With double annual rainfall, pit level would stabilise at 29 m. This level is below the groundwater level in the surrounding environment and the pit would still act as a groundwater sink. With four times annual rainfall, water levels are stable at 53 m, with the pit acting as a recharge source for groundwater. Given the likelihood of these scenarios of substantially increased rainfall on a consistent basis for many years, it is evident that the pit will continue to act as a groundwater sink under all plausible site climatic conditions.

Graph 7. Water balance in the open pit under varying rainfall scenarios



12 UPDATED CONCEPTUAL SITE MODEL

A conceptual site model (CSM) of the site can be formed by considering the geophysical characteristics at play, the contaminant source, potential receptors, and the pathways to the receptors. The CSM, as required by the NEPC (2013), is an iterative process which is updated during the investigation process as more information becomes available.

12.1 Sources

Identified hazards, where relevant investigation criteria for chemicals of concern have been exceeded include:

Exposed tailings:

- Tailings material concentrations of metals and cyanide are within the relevant screening criteria for these materials, however the current nature of exposed tailings does not meet requirements for long term site management;

Groundwater:

- Groundwater exceeds drinking water criteria for salinity, sodium, chloride, ammonia, nitrate and fluoride;
- Groundwater exceeds ecological criteria for nitrate and ammonia;
- Metals exceed health and ecological screening criteria; and
- Free cyanide exceeds health and ecological criteria at bores THGW001 and THGW008.

With the exception of cyanide and nitrogen compounds, exceedances are considered to be naturally occurring and related to the natural lithology of the aquifer.

12.2 Pathways

Pathways of transport of contamination from site sources to the mine void or groundwater include:

- Seepage and groundwater migration from WRD and TSF to aquifer;
- Groundwater inflows to pit.

12.3 Receptors

The following has been identified in relation to receptors in the vicinity of site:

- The pit water is not intended to be used for stock watering or other purpose. Wildlife may consume water directly from the mine pit.
- No GDEs or groundwater discharge zones have been identified in the vicinity of site.
- For groundwater migrating from the cyanide impacted bores to the open pit, dilution and degradation of cyanide reduces concentration to below screening criteria.
- Groundwater is therefore accessed via direct pumping only.
- Groundwater impacts associated with mine activities are either subject to the direct inflow influence of the pit, or stable within the vicinity of the mine environment.

12.4 Findings of CSM refinement

The Source – Pathway – Receptor model therefore determines that there is no risk posed to sensitive receptors due to the groundwater contamination identified on site.

Exposed tailings material does not meet conditions for long term site management and requires containment.

13 QUALITATIVE RISK ASSESSMENT

This section presents an assessment of the potential physical and chemical impacts of the project, including consideration of the potential impacts to beneficial users of the groundwater.

13.1 Assessment Methodology

Potential impacts to groundwater and the surrounding environment as a result of the project have been assessed in the context of the local hydrogeological setting, i.e., the CSM, and the relevant legislation and guidelines.

The CSM was based on:

- a desktop study of existing information relating to the project site and catchment hydrogeology;
- assessment of aquifer physical properties based on site observations, and
- assessment of aquifer chemical properties at existing individual locations.

13.2 Likelihood and Consequence Matrix

A summary of the primary potential impacts of the different components of the project, based on the above discussion, has been provided in **Table 24**. The individual impacts are considered separately in terms of their likelihood and consequence; scores are attributed to both likelihood and consequence on a scale from 1 to 5 in each case. The risk is, in turn, scored as the sum of the likelihood and consequence scores.

Table 24: Risk matrix

		Likelihood				
Consequence		Very unlikely (5)	Unlikely (4)	Possible (3)	Likely (2)	Very Likely (1)
	Negligible (5)	10	9	8	7	6
	Minor (4)	9	8	7	6	5
	Moderate (3)	8	7	6	5	4
	Major (2)	7	6	5	4	3
	Critical (1)	6	5	4	3	2

Note(s):

1. Likelihood scale has five categories with scores from 5 to 1, i.e., Very Unlikely (5), Unlikely (4), Possible (3), Likely (2), Very Likely (1)
2. Consequence scale has five categories with scores from 5 to 1, i.e., Negligible (5), Minor (4), Moderate (3), Major (2), Critical (1)
3. Overall risk value = Consequence value + Likelihood value; consequence and likelihood are considered separately
4. Red denotes Extreme Risk (scores of 2-3), Orange denotes High Risk (scores of 4-5), Yellow denotes Moderate risk (scores of 6-7), Green denotes low risk (8-10)

13.3 Summary of Impacts

The risk matrix is illustrated in **Table 25** and confirms that whilst potential direct impact to the local aquifer and surface water streams is a “moderate risk”, these can be mitigated in the future as part of site management and rehabilitation.

14 SUMMARY OF FINDINGS

The findings of the investigation into groundwater, soil and tailings at Tick Hill can be summarised as follows:

- Groundwater is naturally elevated in salts and metals which make it unsuitable for potable use without treatment. Low concentrations of total cyanide are found across the site, with the highest concentrations observed at bores THGW001 and THGW008. Free cyanide exceeding screening criteria was observed in these two bores. Nitrate and ammonia attributed to explosive residue was observed in several locations, including bore THGW004, down gradient of the WRD.

- The groundwater model indicates that the open pit acts as a groundwater sink for the site, with the exception of the area north of the WRD and potentially the western site perimeter around bore THGW003. No sensitive receptors were identified that might be impacted by groundwater quality at these locations.

Table 25: Qualitative Impact Assessment

Component	Potential Impact to Receptor	Likelihood of Impact	Consequence of Impact	Level of Risk	Proposed Mitigation Measure	Observations
Contaminated groundwater reaching off site receptors	Impacts to human or ecological receptors	Unlikely (4)	Minor (4)	Low (8)	Continued monitoring of onsite groundwater.	No current known nearby receptors however groundwater may be extracted for beneficial uses, such as stock watering.
Mine pit water impact to groundwater	Contamination of groundwater	Very unlikely (5)	Minor (4)	Low (9)	Prevent contamination impacts to mine pit	Risk based on current pit water chemistry and water balance
Direct contamination of groundwater from site infrastructure or spills	Contamination of groundwater	Possible (3)	Moderate (3)	Moderate (6)	Adequate environmental controls for any future works	Future site works required to remediate TSF
Contaminated runoff from site infrastructure reaching pit	Contamination of groundwater via inflow from pit	Very Unlikely (5)	Minor (4)	Low (9)	Pit perimeter is higher than landscape. Accidental inflows unlikely	Considers subsequent impact of contamination to groundwater
Direct overflow of contaminated water from pit flowing into nearby waterways	Contamination of surface water bodies	Very unlikely (5)	Minor (4)	Low (9)	Pit contains sufficient available volume to contain extreme rainfall events	Unlikely based on pit water balance model
Direct overflow of contaminated water from TSF flowing into nearby waterways	Contamination of surface water bodies	Possible (5)	Minor (4)	Moderate (7)	Reinstate tailings into TSF and re-cover tailings.	Stream sediment indicates overflow from TSF

- The cyanide impact to groundwater between the TSF and open pit is assessed as being stable, with concentrations likely to steadily decrease over time. It is not expected that cyanide impacted groundwater will adversely impact pit water quality to any significant extent and cyanide in pit water will be degraded by sunlight.
- No evidence of soil or sediment contamination was observed on site.
- Tailings material retains some cyanide as total cyanide, which is likely present as iron cyanide. This form is non toxic. No free cyanide remains. Some elevated concentrations of copper occur within the tailings due to natural elevations of copper in the ore material. Copper concentrations are acceptable if tailings materials are managed appropriately within the TSF. No identified acid generation potential exists within tailings material.
- The waste rock dump is stable and well vegetated. The WRD appears to have been releasing nitrogen compounds from explosive residues into the surrounding landscape, however due to the age and permeability of the WRD.

15 CONCLUSIONS

Based on the above findings the following conclusion have been made:

- The mining void currently serves as a groundwater sink, influencing groundwater flow across the site, with the exception of the area around the WRD.
- The long-term scenario is that the pit will act as a groundwater sink under all plausible site conditions.
- The water quality of the pit poses no current risk of contamination to the surrounding aquifer.
- Potential for pit stratification is not currently known.
- Cyanide (free and total) at bores THGW001 and THGW008 will remain at stable concentrations for some time before decreasing.
- Free cyanide at bores THGW001 and THGW008 does not have the potential to adversely impact pit water quality or discharge to watercourses.

16 RECOMMENDATIONS

Based on the above conclusions the following recommendations have been made:

- Rectification works should be undertaken to reinstate stockpiled tailings into the eastern TSF cell and recover the TSF.

- Regular groundwater monitoring should continue, with the analysis suite extended from the current parameters to include ammonia, nitrate and phosphate. Bi-annual monitoring is recommended until at least after the TSF rectification works are completed.

17 LIMITATIONS

This report has been prepared by Environmental Earth Sciences QLD ACN 109 442 284 in response to and subject to the following limitations:

1. The specific instructions received from Carnaby Resources;
2. The specific scope of works set out in PO722108 issued by Environmental Earth Sciences for and on behalf of Carnaby Resources Ltd, is included in Section 3 (Scope of Work) of this report;
3. May not be relied upon by any third party not named in this report for any purpose except with the prior written consent of Environmental Earth Sciences QLD (which consent may or may not be given at the discretion of Environmental Earth Sciences QLD);
4. This report comprises the formal report, documentation sections, tables, figures and appendices as referred to in the index to this report and must not be released to any third party or copied in part without all the material included in this report for any reason;
5. The report only relates to the site referred to in the scope of works being located at the Tick Hill Gold Mine, Dajarra, QLD ("the site");
6. The report relates to the site as at the date of the report as conditions may change thereafter due to natural processes and/or site activities;
7. No warranty or guarantee is made in regard to any other use than as specified in the scope of works and only applies to the depth tested and reported in this report;
8. Fill, soil, groundwater and rock to the depth tested on the site may be fit for the use specified in this report. Unless it is expressly stated in this report, the fill, soil and/or rock may not be suitable for classification as clean fill if deposited off site;
9. This report is not a geotechnical or planning report suitable for planning or zoning purposes; and
10. Our General Limitations set out at the back of the body of this report.

19 GLOSSARY OF TERMS

The following descriptions are of terms used in the text of this report.

Alluvial. Describes material deposited by, or in transit in, flowing water.

Anaerobic. Reducing or without oxygen.

Aquifer. A rock or sediment in a formation, group of formations, or part of a formation which is saturated and sufficiently permeable to transmit economic quantities of water to bores and springs.

Aquifer, confined. An aquifer that is overlain by a confining bed with significantly lower hydraulic conductivity than the aquifer.

Aquifer, perched. A region in the unsaturated zone where the soil is locally saturated because it overlies soil or rock of low permeability.

Background. The natural level of a property.

Baseline. An initial value of a measure.

Biodegradation. A biochemical process of microbial oxidation of complex organic compounds, to simpler chemical products. Micro-organisms derive the energy and cell carbon for growth from oxidation of organic compounds.

Bore. A hydraulic structure that facilitates the monitoring of groundwater level, collection of groundwater samples, or the extraction (or injection) of groundwater. Also known as a well, monitoring bore or piezometer, although piezometers are typically of small diameter and only used for measuring the groundwater elevation or potentiometric surface.

Borehole. An uncased well drill hole.

Cation Exchange Capacity (CEC). The maximum positive charge required to balance the negative charge on colloids (clays and other charged particles). The units are milli-equivalents per 100 grams of material or centimoles of charge per kilogram of exchanger.

Clay. A soil material composed of particles finer than 0.002 mm. When used as a soil texture group such soils contain at least 35% clay.

Colluvial. Unconsolidated soil and rock material moved down-slope by gravity.

Confined Aquifer. An aquifer that is confined between two low-permeability aquitards. The groundwater in these aquifers is usually under hydraulic pressure, i.e. its hydraulic head is above the top of the aquifer.

Confining layer. A layer with low vertical hydraulic conductivity that is stratigraphically adjacent to one or more aquifers. A confining layer is an aquitard. It may lie above or below the aquifer.

Contaminant. Generally, any chemical species introduced into the soil or water. More particularly relates to those species that render soil or water unfit for beneficial use.

Contamination. Is considered to have occurred when the concentration of a specific element or compound is established as being greater than the normally expected (or actually quantified) background concentration.

Diffusion. A process by which species in solution move, driven by concentration gradients (from high to low).

Dilution. The mixing of a small volume of contaminated leachate with a large volume of uncontaminated water. The concentration of contaminants is reduced by the volume of the lower concentrated water. However the physical process of dilution often causes chemical disequilibria resulting in the destruction of ligand bonds, the alteration of solubility products and the alteration of water pH. This usually causes precipitation by different chemical means of various species.

Discrete sample. Samples collected from different locations and depths that will not be composited but analysed individually.

Dispersion. A process by which species in solution mix with a second solution, thus reducing in concentration. In particular, relates to the reduction in concentration resulting from the movement of flowing groundwater.

Dissolved Oxygen (DO). Oxygen in the gaseous phase dissolved in water. Measured either as a concentration in mg/L or as a percentage of the theoretical saturation point, which is inversely related to temperature. At 19, 20 and 21 degrees Celsius, the oxygen concentrations in mg/L corresponding to 100% saturation are 9.4, 9.2 and 9.0 respectively.

Electrical Conductivity (EC). The EC of water is a measure of its ability to conduct an electric current. This property is related to the ionic content of the sample, which is in turn a function of the total dissolved (ionisable) solids (TDS) concentration. An estimate of TDS in fresh water can be obtained by multiplying EC by 0.65.

Flow path. The direction in which groundwater is moving.

Fluvial. A material deposited by, or in transit, in streams or watercourses.

Fracture. A break in the geological formation, e.g. a shear or a fault.

Gradient. The rate of inclination of a slope. The degree of deviation from the horizontal; also refers to pressure.

Groundwater. The water held in the pores in the ground below the water table.

Groundwater Elevation. The elevation of the groundwater surface measured relative to a specified datum such as the Australian Height Datum (mAHD) or an arbitrary survey datum onsite, or "reduced level" (mRL).

Head space. The air space at the top of a soil or water sample.

Heavy Metals. All metallic elements whose atomic mass exceeds that of calcium (20). Typical analysis for heavy metals includes cadmium (Cd), chromium (Cr), copper (Cu), nickel (Ni), lead (Pb), zinc (Zn), and the metalloid arsenic (As).

Heterogeneous. A condition of having different characteristics in proximate locations. Non-uniform. (Opposite of homogeneous).

Hydraulic Conductivity (K). A coefficient describing the rate at which water can move through a permeable medium. It has units of length per time. The units for hydraulic conductivity are typically $m^3/day/m^2$ or m/day.

Hydraulic Gradient (i). The rate of change in total head per unit of distance of flow in a given direction – the direction is that which yields a maximum rate of decrease in head. Hydraulic Gradient is unit less.

Hydraulic Head (h). The sum of the elevation head and the pressure head at a point in an aquifer. This is typically reported as an elevation above a fixed datum, such as sea level.

Infiltration. The passage of water, under the influence of gravity, from the land surface into the subsurface.

Ionic Exchange. Adsorption occurs when a particle with a charge imbalance, neutralises this charge by the attraction (and subsequent adherence of) ions of opposite charge from solution. There are two types of such a charge: pH dependent; and pH independent or crystalline charge. Metal hydroxides and oxy-hydroxides represent examples of the former type, whilst clay minerals are representative of the latter and are normally associated with cation exchange.

Ions. An ion is a charged element or compound as a result of an excess or deficit of electrons. Positively charged ions are called cations, whilst negatively charged ions are called anions. Cations are written with superscript $^+$, whilst anions use $^-$ as the superscript. The major aqueous ions are those that dominate total dissolved solids (TDS). These ions include: Cl^-, SO_4^{2-}, HCO_3^-, Na^+, Ca^{2+}, Mg^{2+}, K^+, NH_4^+, NO_3^-, NO_2^-, F^-, PO_4^{3-} and the heavy metals.

Perched Groundwater. Unconfined groundwater separated from an underlying main body of groundwater by an unsaturated zone. Perched groundwater typically occurs in discontinuous, often ephemeral, lenses, with unsaturated conditions both above and below.

Permeability (k). Property of porous medium relating to its ability to transmit or conduct liquid (usually water) under the influence of a driving force. Where water is the fluid, this is effectively the hydraulic conductivity. A function of the connectivity of pore spaces.

Piezometric or Potentiometric Surface. A surface that represents the level to which water will rise in cased bores. The water table is the potentiometric surface in an unconfined aquifer.

pH. A logarithmic index for the concentration of hydrogen ions in an aqueous solution, which is used as a measure of acidity.

Porosity (n). The ratio of the volume of void spaces in a rock or sediment to the total volume of the rock or sediment. Typically given as a percentage.

Porosity, effective (ne). The volume of the void spaces through which water or other fluids can travel in a rock or sediment divided by the total volume of the rock or sediment.

Precipitation (chemical). There are two types of precipitation, pH dependent precipitation and solubility controlled precipitation. As the pH is raised beyond a threshold level the precipitation of metal cations such as oxy-hydroxides and hydroxides occur. As the pH is raised further precipitation continues until there are very few metal cations remaining in solution. This reaction is entirely reversible. Solubility controlled precipitation occurs between two ions when, at a given temperature and pressure, the concentration of one of the ions exceeds a certain level.

Purge (bores). The pumping out of monitoring bore water to remove drilling debris or impurities; also conducted to bring fresh groundwater into the casing for sample collection. The later ensures that a more representative sample of an aquifer is taken.

QA/QC. Quality Assurance / Quality Control.

Recharge Area. Location of the replenishment of an aquifer by a natural process such as addition of water at the ground surface, or by an artificial system such as addition through a well

Recovery. The rate at which a water level in a bore rises after pumping ceases.

Saturated Zone. A zone in which the rock or soil pores are filled (saturated) with water.

Standing Water Level (SWL). The depth to the groundwater surface in a well or bore measured below a specific reference point – usually recorded as metres below the top of the well casing or below the ground surface.

Stratigraphy. A vertical sequence of geological units.

Total Dissolved Salts (TDS). The total dissolved salts comprise dissociated compounds and undissociated compounds, but not suspended material, colloids or dissolved gases.

Toxicity. The inherent potential or capacity of a material to cause adverse effects in a living organism.

Unsaturated Zone. The zone between the land surface and the water table, in which the rock or soil pores contain both air and water (water in the unsaturated zone is present at less than atmospheric pressure). It includes the root zone, intermediate zone and capillary fringe. Saturated bodies such as perched groundwater may exist in the unsaturated zone. Also referred to as the Vadose Zone.

Volatile. Having a low boiling or subliming pressure (a high vapour pressure).

Water table. Interface between the saturated zone and unsaturated zones. The surface in an aquifer at which pore water pressure is equal to atmospheric pressure.

Well. See **Bore** (monitoring bore).

CONTAMINATION RESOLVED

ENVIRONMENTAL EARTH SCIENCES GENERAL LIMITATIONS

Scope of services
The work presented in this report is Environmental Earth Sciences response to the specific scope of works requested by, planned with and approved by the client. It cannot be relied on by any other third party for any purpose except with our prior written consent. Client may distribute this report to other parties and in doing so warrants that the report is suitable for the purpose it was intended for. However, any party wishing to rely on this report should contact us to determine the suitability of this report for their specific purpose.

Data should not be separated from the report
A report is provided inclusive of all documentation sections, limitations, tables, figures and appendices and should not be provided or copied in part without all supporting documentation for any reason, because misinterpretation may occur.

Subsurface conditions change
Understanding an environmental study will reduce exposure to the risk of the presence of contaminated soil and or groundwater. However, contaminants may be present in areas that were not investigated, or may migrate to other areas. Analysis cannot cover every type of contaminant that could possibly be present. When combined with field observations, field measurements and professional judgement, this approach increases the probability of identifying contaminated soil and or groundwater. Under no circumstances can it be considered that these findings represent the actual condition of the site at all points.

Environmental studies identify actual sub-surface conditions only at those points where samples are taken, when they are taken. Actual conditions between sampling locations differ from those inferred because no professional, no matter how qualified, and no sub-surface exploration program, no matter how comprehensive, can reveal what is hidden below the ground surface. The actual interface between materials may be far more gradual or abrupt than an assessment indicates. Actual conditions in areas not sampled may differ from that predicted. Nothing can be done to prevent the unanticipated. However, steps can be taken to help minimize the impact. For this reason, site owners should retain our services.

Problems with interpretation by others
Advice and interpretation is provided on the basis that subsequent work will be undertaken by Environmental Earth Sciences QLD. This will identify variances, maintain consistency in how data is interpreted, conduct additional tests that may be necessary and recommend solutions to problems encountered on site. Other parties may misinterpret our work and we cannot be responsible for how the information in this report is used. If further data is collected or comes to light we reserve the right to alter their conclusions.

Obtain regulatory approval
The investigation and remediation of contaminated sites is a field in which legislation and interpretation of legislation is changing rapidly. Our interpretation of the investigation findings should not be taken to be that of any other party. When approval from a statutory authority is required for a project, that approval should be directly sought by the client.

Limit of liability
This study has been carried out to a particular scope of works at a specified site and should not be used for any other purpose. This report is provided on the condition that Environmental Earth Sciences QLD disclaims all liability to any person or entity other than the client in respect of anything done or omitted to be done and of the consequence of anything done or omitted to be done by any such person in reliance, whether in whole or in part, on the contents of this report. Furthermore, Environmental Earth Sciences QLD disclaims all liability in respect of anything done or omitted to be done and of the consequence of anything done or omitted to be done by the client, or any such person in reliance, whether in whole or any part of the contents of this report of all matters not stated in the brief outlined in Environmental Earth Sciences QLD's proposal number and according to Environmental Earth Sciences general terms and conditions and special terms and conditions for contaminated sites.

To the maximum extent permitted by law, we exclude all liability of whatever nature, whether in contract, tort or otherwise, for the acts, omissions or default, whether negligent or otherwise for any loss or damage whatsoever that may arise in any way in connection with the supply of services. Under circumstances where liability cannot be excluded, such liability is limited to the value of the purchased service.

APPENDIX A: ENVIRONMENTAL AUTHORITY

Permit

Environmental Protection Act 1994

Environmental authority EPML00820613

This DRAFT environmental authority is issued by the administering authority under Chapter 5 of the Environmental Protection Act 1994.

Environmental authority number: EPML00820613

Environmental authority takes effect on

The anniversary date of this environmental authority is 5 April each year.

Environmental authority holder(s)

Name(s)	Registered address
Carnaby Resources (Holdings) Pty Ltd	Office 1 Level 2 16 Ord St WEST PERTH WA 6005 Australia

Environmentally relevant activity and location details

Environmentally relevant activity/activities	Location(s)
Resource Activity, Schedule 3, 21: A mining activity that is an ineligible ERA, other than a mining activity mentioned in items 9 to 20	ML7097
Resource Activity, Schedule 3, 21: A mining activity that is an ineligible ERA, other than a mining activity mentioned in items 9 to 20	ML7094
Resource Activity, Schedule 3, 21: A mining activity that is an ineligible ERA, other than a mining activity mentioned in items 9 to 20	ML7096
Ancillary, Schedule 2, 31: Mineral processing 2(a) - Processing, in a year, the following quantities of mineral products, other than coke – 1,000t to 100,000t	ML7094
Ancillary, Schedule 2, 60 – Waste Disposal 2: Operating a facility for disposing of, in a year, the following quantity of waste mentioned in subsection (1)(b)(a) less than 2,000 t.	ML7094

Queensland Government

Additional information for applicants

Environmentally relevant activities

The description of any environmentally relevant activity (ERA) for which an environmental authority (EA) is issued is a restatement of the ERA as defined by legislation at the time the EA is issued. Where there is any inconsistency between that description of an ERA and the conditions stated by an EA as to the scale, intensity or manner of carrying out an ERA, the conditions prevail to the extent of the inconsistency.

An EA authorises the carrying out of an ERA and does not authorise any environmental harm unless a condition stated by the EA specifically authorises environmental harm.

A person carrying out an ERA must also be a registered suitable operator under the *Environmental Protection Act 1994* (EP Act).

Contaminated land

It is a requirement of the EP Act that an owner or occupier of contaminated land give written notice to the administering authority if they become aware of the following:

- the happening of an event involving a hazardous contaminant on the contaminated land (notice must be given within 24 hours); or
- a change in the condition of the contaminated land (notice must be given within 24 hours); or
- a notifiable activity (as defined in Schedule 3) having been carried out, or is being carried out, on the contaminated land (notice must be given within 20 business days)

that is causing, or is reasonably likely to cause, serious or material environmental harm.

For further information, including the form for giving written notice, refer to the Queensland Government website www.qld.gov.au, using the search term 'duty to notify'.

Take effect

Please note that, in accordance with section 200 of the EP Act, an EA has effect:

a) if the authority is for a prescribed ERA and it states that it takes effect on the day nominated by the holder of the authority in a written notice given to the administering authority-on the nominated day; or

b) if the authority states a day or an event for it to take effect-on the stated day or when the stated event happens; or

c) otherwise- one the day the authority is issued.

However, if the EA is authorising an activity that requires an additional authorisation (a relevant tenure for a resource activity, a development permit under the *Planning Act 2016* or an SDA Approval under the *State Development and Public Works Organisation Act 1971*), this EA will not take effect until the additional authorisation has taken effect.

If this EA takes effect when the additional authorisation takes effect, you must provide the administering authority written notice within 5 business days of receiving notification of the related additional authorisation taking effect.

The payment of the annual fee will be due each year on the anniversary day of this environmental authority. An annual return will be due each year on 1 April.

If you have incorrectly claimed that an additional authorisation is not required, carrying out the ERA without the additional authorisation is not legal and could result in your prosecution for providing false or misleading information or operating without a valid environmental authority.

Obligations under the *Environmental Protection Act 1994*

In addition to the requirements found in the conditions of this environmental authority, the holder must also meet their obligations under the EP Act, and the regulations made under the EP Act. For example, the holder must comply with the following provisions of the Act:

- general environmental duty (section 319)
- duty to notify environmental harm (section 320-320G)
- offence of causing serious or material environmental harm (sections 437-439)
- offence of causing environmental nuisance (section 440)
- offence of depositing prescribed water contaminants in waters and related matters (section 440ZG)
- offence to place contaminant where environmental harm or nuisance may be caused (section 443)

Other permits required

This permit only provides an approval under the *Environmental Protection Act 1994*. In order to lawfully operate you may also require permits / approvals from your local government authority, other business units within the department and other State Government agencies prior to commencing any activity at the site. For example, this may include permits / approvals with your local Council (for planning approval), the Department of Transport and Main Roads (to access state controlled roads), the Department of Natural Resources, Mines and Energy (to clear vegetation), and the Department of Agriculture and Fisheries (to clear marine plants or to obtain a quarry material allocation).

Conditions of environmental authority

Relevant activity: The environmentally relevant activity conducted at the location as described above must be conducted in accordance with the following site specific conditions of approval.

Condition number	Condition
A1	This **environmental authority** authorises **environmental harm** referred to in the conditions. Where there is no condition or this **environmental authority** is silent on a matter, the lack of a condition or silence does not authorise **environmental harm**.
A2	**Contaminants** resulting from the authorised mining activities must not be released to the **receiving environment**.
A3	The **environmental authority** holder will not cause **environmental nuisance** outside the mining lease boundaries.
A4	In carrying out the mining activity authorised by this **environmental authority**, the holder of this **environmental authority** must comply with Schedule A – Table 1 (Authorised Activities).
A5	The holder of this **environmental authority** must: a) Install all measures, plant and equipment necessary to ensure compliance with the conditions of this **environmental authority**; b) Maintain such measures, plant and equipment in a proper and efficient condition; c) Operate such measures, plant and equipment in a proper and efficient manner; and d) Ensure all instruments and devices used for the measurement or monitoring of any parameter under any condition of this **environmental authority** are properly calibrated.
A6	The activities authorised by this **environmental authority** are limited to: a) **Care and maintenance** as defined in the definitions of this **environmental authority**; and b) The reclamation of tailings from the Tailings Storage Facility defined in Schedule A Figure 1a (Project Infrastructure Layout – Mine area) and Schedule A Figure 1b (Project Infrastructure Layout – Support Infrastructure) for processing on site, in accordance with the following criteria: i. a maximum re-disturbance area of 6.5 hectares; ii. processing using **gravity separation** methods only; c) Exploration activities in accordance with condition A15 of this **environmental authority**.
A7	The **environmental authority** holder must ensure that an estimated rehabilitation cost decision is in effect for the activity; and a) a contribution has been paid to the scheme fund in the amount and form required; or b) a surety has been given for the authority in the amount and form required.
A8	Where a change in activities will, or is likely to, increase the maximum amount of disturbance caused by the activity, or the estimated rehabilitation cost for the activity, the holder must re-apply for an estimated rehabilitation cost decision.
A9	The holder of this **environmental authority** must notify the **administering authority** by written notification within twenty-four (24) hours, after becoming aware of any emergency or incident which results in the **release** of **contaminants** not in accordance, or reasonably expected to be not in accordance with the conditions of this **environmental authority**.

A10	Within ten (10) business days following the initial notification of an emergency or incident, or receipt of monitoring results, whichever is the latter, further written advice must be provided to the **administering authority**, including the following: a) Results and interpretation of any samples taken and analysed; b) Outcomes of actions taken at the time to prevent or minimise unlawful **environmental harm**; and c) Proposed actions to prevent a recurrence of the emergency or incident.
A11	The holder of this **environmental authority** must record all environmental complaints received about the mining activities including the following details: a) Name, address and contact number of the complainant; b) Time and date of complaint; c) Reasons for the complaint; d) Investigations undertaken; e) Conclusions formed; f) Actions taken to resolve the complaint; g) Any abatement measures implemented; and h) Person responsible for resolving the complaint.
A12	The holder of this **environmental authority** must, when requested by the **administering authority**, undertake relevant specified monitoring within a reasonable timeframe nominated or agreed to by the **administering authority** to investigate any complaint of **environmental harm**. The results of the investigation (including an analysis and interpretation of the monitoring results) and abatement measures, where implemented, must be provided to the **administering authority** within ten (10) business days of completion of the investigation, or no later than ten (10) business days after the end of the timeframe nominated by the **administering authority** to undertake the investigation.
A13	By 11 October 2021, the holder of this environmental authority must: a) obtain from an appropriately qualified person a report on compliance with the conditions of this environmental authority b) obtain further such reports at regular intervals, not exceeding three yearly intervals, from the completion of the report referred to above c) provide each report to the administering authority within ninety (90) days of its completion.

A14	Where a condition of this **environmental authority** requires compliance with a standard, policy or guideline published externally to this **environmental authority** and the standard is amended or changed subsequent to the issue of this **environmental authority** the holder of this **environmental authority** must: a) Comply with the amended or changed standard within two (2) years of the amendment or change being made, unless a different period is specified in the amended standard or relevant legislation; and b) Until compliance with the amended or changed standard is achieved, continue to remain in compliance with the standard that was current immediately prior to the relevant amendment or change.
A15	All exploration activity carried out on a mining lease listed in this **environmental authority** must comply with the provisions detailed in the **administering authority's** *Code of Environmental Compliance for Exploration and Mineral Development Projects* (*the Code*). Where there is a discrepancy between *the Code* and this **environmental authority**, the conditions of this **environmental authority** apply.
A16	Land disturbance must be rehabilitated in accordance with the most recent edition of the **administering authority's** guideline *Rehabilitation requirements for mining projects.*
A17	All buildings, structures, mining equipment and plant erected and/or used for the mining activities must be removed from the site prior to surrender, except where agreed in writing by the **administering authority** and the landowner.
A18	The environmental authority holder may dispose of up to 15 tonne per year of general waste generated at the mine for mining activities into the waste disposal trench facility located on ML7094 and identified in Schedule A Figure 2 (Latitude 21.642937, Longitude 131.928231).
A19	The environmental authority holder must bury general waste using the following or similar measures: - locate the waste pit so as to ensure that the waste will not contaminate any watercourse, waterway, groundwater, wetland or lake; - divert stormwater runoff from entering the pit; - crush drums and other containers to reduce the volume of waste; - make the pit safe and protect it from scavengers; - backfill the pit when the level of rubbish in the pit is not less than 1m below the surface; and - sufficiently overfill the pit to allow for settlement.
A20	All regulated waste must be removed from the site to a facility that is lawfully able to accept the waste under the *Environmental Protection Act 1994*.
A21	Contaminants that will, or have the potential to cause environmental harm must not be released directly or indirectly to any waters as a result of the authorised mining activities, except as permitted under the conditions of this environmental authority.
A22	All regulated **dams** must be designed, operated, maintained and decommissioned in accordance with the most recent edition of the **administering authority's** guideline *Manual for Assessing Hazard Categories and Hydraulic Performance of Dams.*

A23	The **environmental authority** holder must develop and implement an environmental monitoring program sufficient to demonstrate compliance with the conditions of this **environmental authority** by **1 December 2020** or prior to commencement of reclaimation of tailings activities (whichever comes first).
A24	The environmental monitoring program required by Condition A23 must include quarterly surface water monitoring of the open cut pit and reclaimed TSF footprint for the parameters listed in Table B2.
A25	Except where specified otherwise in another condition of this authority, all monitoring records or reports required by this **environmental authority** must be kept for a period of not less than five (5) years.
A26	The environmental authority holder must ensure analyses and tests required to be conducted under this **environmental authority** are carried out by an **appropriately qualified person** and analysed by a laboratory that has NATA accreditation for such analyses and tests, except as otherwise authorised by the **administering authority.**
A27	**Significant residual impacts** to prescribed environmental matters are not authorised under this environmental authority or the *Environmental Offsets Act 2014*.
A28	Records demonstrating that each impact to a **prescribed environmental matter** did not, or is not likely to, result in a significant residual impact to that matter must be: a) completed by an appropriately qualified person; and b) kept for the life of the **environmental authority**.
B1	The holder of the environmental authority must not directly or indirectly release fuels, oils, lubricants or other contaminants to land.
B2	The holder of the environmental authority must ensure that all chemical, fuel and oil storage facilities less than 10 000L on a mining tenement, must be designed and operated in accordance with Australian Standard 1940 – 'The storage and handling of flammable and combustible liquids', Section 2, Minor Storage.
B3	Contaminants must not be released directly or indirectly to any groundwater.
B4	Groundwater must be monitored: (a) at the locations specified in **Table B1 - Groundwater monitoring locations and frequency**; and (b) at the frequencies specified in **Table B1 - Groundwater monitoring locations and frequency**; and (c) for the quality characteristics identified in **Table B2 - Groundwater contaminant limits** for the aquifer in which the bore is located.
B5	Groundwater measured from any monitoring bore specified in **Table B1 - Groundwater monitoring locations and frequency** must not exceed the corresponding Limit A specified in **Table B2 – Groundwater contaminant limits** on any five (5) consecutive sampling occasions as defined in **Table B1 - Groundwater monitoring locations and frequency.**

B6	Groundwater measured from any monitoring bore specified in **Table B1 - Groundwater monitoring locations and frequency** must not exceed the corresponding Limit B specified in **Table B2 – Groundwater quality limits** on any three consecutive sampling occasions.

	Nitrate	mg/L	TBA[1]	TBA[1]
	Nitrite	mg/L	TBA[1]	TBA[1]
	[1] TBA means to be advised by means of an EA amendment application made by the environmental authority holder to the administering authority by 21 April 2022 and calculated in accordance with the methodology outlined in the DSITI guideline “Using monitoring data to assess groundwater quality an potential environmental impacts, March 2017, Version 1”.			
B7	If groundwater measured from any bore specified in T**able B1 - Groundwater monitoring locations and frequency** exceeds the corresponding Limit specified in **Table B2 – Groundwater contaminant limits** on any one (1) sampling occasion the environmental authority holder must resample the groundwater within the compliance bore for all exceeding parameters within 10 business days of receipt of results.			
B8	Monitoring and sampling must be carried out in accordance with the requirements of the latest version of the following documents unless otherwise approved by the administering authority: a) for waters and aquatic environments, the Queensland Government’s Monitoring and Sampling Manual 2009 – Environmental Protection (Water) Policy 2009; and b) for groundwater, Groundwater Sampling and Analysis – A Field Guide (2009:27 GeoCat#6890.1) and Australian Standard AS/NZS 5667.11:1998 Water Quality – Sampling – Guidance on sampling of groundwaters; and c) for subterranean aquatic fauna, the Guideline for the Environmental Assessment of Subterranean Aquatic Fauna.			

B9	The consequence category of any structure, including existing structures, must be assessed by a suitably qualified and experienced person in accordance with the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933 – the Manual) at the following times: a) prior to the commencement of the reclamation activities under condition A6; or b) prior to any change in its purpose or the nature of its stored contents.
B10	The consequence category assessment completed under Condition B9 must be submitted to the administering authority at least 30 days (unless otherwise agreed to a shorter period) prior to the commencement of the activities that triggered the preparation of the consequence category assessment.
B11	All existing structures must comply with the timetable for any further assessments in accordance with Condition B9 and specified in **Table B3 – Transitional hydraulic performance requirements for existing structures**, depending on the consequence category for each existing structure assessed in the most recent previous certification for that structure.
B12	Table B3 ceases to apply for a structure once any of the following events has occurred: a) it has been brought into compliance with the hydraulic performance criteria applicable to the structure under the Manual; or b) it has been decommissioned; or c) it has been certified as no longer being assessed as a regulated structure.

Table B3

Table B3 – Transitional hydraulic performance requirements for existing structures

Transition period required for existing structures to achieve the requirements of the Manual for Assessing Consequence Categories and Hydraulic Performance of Dams			
Compliance with criteria	High consequence	Significant consequence	Low consequence
>90% and a history of good compliance performance in last 5 years	No transition required	No transition required	No transitional conditions apply. Review consequence assessment every 7 years.
>70%-≤90%	Within 7 years, unless otherwise agreed with the administering authority, based on no history of unauthorised releases.	Within 10 years, unless otherwise agreed with the administering authority, based on no history of unauthorised releases.	No transitional conditions apply. Review consequence assessment every 7 years.
>50-≤70%	Within 5 years unless otherwise agreed with the administering authority, based on no history of unauthorised releases.	Within 7 years unless otherwise agreed with the administering authority, based on no history of unauthorised releases.	Review consequence assessment every 7 years.
≤50%	Within 5 years or as per compliance requirements (e.g. TEP timing)	Within 5 years or as per compliance requirements (e.g. TEP timing).	Review consequence assessment every 5 years.
Regulated levee designed to prevent the ingress of clean flood water <100% compliant	Within 5 years unless otherwise agreed with the administering authority.		

B13

Certification of the transitional assessment required by condition B11 (as applicable) must be provided to the administering authority by 4 October 2022.

Definitions

Key terms and/or phrases used in this document are defined in this section. Where a term is not defined, the definition in the *Environmental Protection Act 1994*, its regulations or environmental protection policies must be used. If a word remains undefined it has its ordinary meaning.

"administering authority" means the Department of Environment and Resource Management or its successor.

"appropriately qualified person" means a person who has professional qualifications, training, skills or experience relevant to the nominated subject matter and can give authoritative assessment, advice and analysis on performance relative to the subject matter using the relevant protocols, standards, methods or literature.

"care and maintenance" means a mining project where production has ceased (whether temporary or permanent) and the mining activity is limited to maintenance of mine infrastructure, rehabilitation and any other environmental management of significantly disturbed land.

"consecutive sampling occasions" means successive sampling events and includes resampling of groundwaters that is required under condition B7.

"contaminant" has the same meaning given in section 10 of the *Environmental Protection Act 1994*.

"dam" means a land-based structure or a void that is designed to contain, divert or control flowable substances, and includes any substances that are thereby contained, diverted or controlled by that land-based structure or void and associated works. However; a dam does *not* mean a fabricated or manufactured tank or container designed to a recognised standard, *nor* does a dam mean a land-based structure where that structure is designed to an Australian Standard. In case there is any doubt, a levee (dyke or bund) is a dam, but (for example) a bund designed for spill containment to AS1940 is *not* a dam.

"environmental authority" means an environmental authority granted in relation to an environmentally relevant activity under the *Environmental Protection Act 1994*.

"environmental harm" has the same meaning given in section 14 of the *Environmental Protection Act 1994*.

"environmental nuisance" has the same meaning given in section 15 of the *Environmental Protection Act 1994*.

"**existing structure**" means a structure that prior to the issue of this environmental authority meets any or both of the following, a structure:

(a) with a design that is in accordance with the Manual for Assessing Consequence Categories and Hydraulic Performance of Structures (ESR/2016/1933) and that is considerably in progress;

(b) that is under considerable construction or that is constructed.

"flowable substance" means matter or a mixture of materials which can flow under any conditions potentially affecting that substance. Constituents of a flowable substance can include water, other liquids fluids or solids, or a mixture that includes water and any other liquids fluids or solids either in solution or suspension.

"**gravity separation**" means mineral processing that excludes the use of any reagent such as cyanide and onsite heavy metal processing such as refining and smelting.

"hazard" in relation to a dam as defined, means the potential for environmental harm resulting from the collapse or failure of the dam to perform its primary purpose of containing, diverting or controlling flowable substances.

“hazard category” means a category, either low significant or high, into which a dam is assessed as a result of the application of tables and other criteria in “Manual for Assessing Hazard Categories and Hydraulic Performance of Dams”, prepared by the Department of Environment and Resource Management, as amended from time to time.

‘**prescribed environmental matters’** has the meaning in section 10 of *the Environmental Offsets Act 2014*, limited to the matters of State environmental significant listed in schedule 2 of the *Environmental Offsets Regulation 2014.*

"regulated dam" means any dam in the significant or high hazard category as assessed using the *Manual for Assessing Hazard Categories and Hydraulic Performance of Dams* published by the administering authority.

“receiving environment” in relation to an activity that causes or may cause environmental harm, means the part of the environment to which the harm is, or may be, caused. The receiving environment includes (but is not limited to):

(a) a watercourse;
(b) groundwater; and
(c) an area that is not specified in Schedule A – Table 1 (Authorised Activities)of this environmental authority

“release” in relation to release of a contaminant to the receiving environment has the same meaning given in Schedule 4 of the *Environmental Protection Act 1994*.

‘**significant residual impact’** has meaning in section 8 of the *Environmental Offsets Act 2014.*

"watercourse" has the same meaning given in the *Water Act 2000*.

“waters” Includes river, stream, lake, lagoon, pond, swamp, wetland, unconfined surface water, unconfined water in natural or artificial watercourses, bed and bank of any waters, dams, non-tidal or tidal waters (including the sea), stormwater channel, stormwater drain, roadside gutter, stormwater run-off, and groundwater or any part-thereof**.**

APPENDIX C: ENVIRONMENTALLY SENSITIVE AREAS

ENVIRONMENTALLY SENSITIVE AREAS - Mining Activities

Selected Mining Lease (ML)

CATEGORY A

- National Parks
- Conservation Parks
- Forest Reserves
- Special Wildlife Reserve
- Wet Tropics World Heritage Area
- Great Barrier Reef Marine Park Area
- Marine Parks other than General Use Zones

CATEGORY B

- Queensland Heritage Register Places
- Ramsar Sites
- Cultural Heritage Registered Areas and DLA's other than Stanbroke
- Special Forestry Areas
- Seaward Side of Highest Astronomical Tide
- Fish Habitat Areas
- Coordinated Conservation Areas
- Endangered Regional Ecosystems - regrowth and remnant (Biodiversity Status)
- General Use Zones of Marine Parks
- Marine Plants

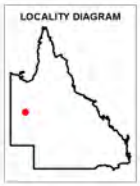
CATEGORY C

- Nature Refuges
- Resources Reserve
- State Forests
- Timber Reserves
- River Improvement Areas
- Stanbroke DLA
- Coastal Management District
- Dams and Weirs

OTHERS

- Towns
- Roads
- Repealed Wild River Nominated Waterways
- Repealed Wild River Preservation Areas
- Repealed Wild River High Preservation Areas
- Mahogany Glider Habitat
- Directory of Important Wetlands
- Queensland

LOCALITY DIAGRAM



N

0 110 220 330 440 550 m

This product is projected into GDA 1994 MGA Zone 54

Information presented on this product is distributed by the Queensland Government as an information source only. While every care is taken to ensure the accuracy of this data, The State of Queensland makes no statements, representations or warranties about the accuracy, reliability, completeness or suitability of any information contained in this product.

The State of Queensland disclaims all responsibility for information contained in this product and all liability (including without limitation, liability in negligence) for all expenses, losses, damages and costs you may incur as a result of the information being inaccurate or incomplete in any way for any reason.

NOTE TO USER: Themes presented in this map are indicative only. Field survey may be required to verify the 'true' spatial extent and value. Not all environmentally sensitive areas are presented in this map. A user should refer to the particular circumstances relevant to their situation to assess the 'completeness' of themes provided.

The user should note that some boundaries and indicated values are ambient and may change over time (e.g. regional ecosystem boundaries and conservation status, watercourse mapping etc).

The user should be aware that due to multiple overlapping themes/ layers present, some themes/layers may be obscured by others. Ordering in the Legend does not accurately reflect the order by which themes/layers are displayed.

APPENDIX F: RESPONSE TO ENVIRONMENTAL EVALUATION NOTICE

ENVIRONMENTAL EARTH SCIENCES
CONTAMINATION RESOLVED

To: **Paul Tan**, Carnaby Resources Pty Ltd

From: Dr Anna Sheldon, Principal Soil Scientist (Author)
Kat Spruth, Principal Environmental Scientist (Reviewer)

Date: 13 July 2023

Subject: Technical Memo, 722092
722092 Response to EE comments on Environmental Evaluation Groundwater Geochemistry Report

---

1 Introduction

The attached comments (Appendix A) provide brief responses to the Department of Environment and Science (DES) comments on the Environmental Evaluation Groundwater Geochemistry Report.

Please also refer to the environmental site assessment (ESA) (Environmental Earth Sciences, 2023) for detailed data interrogation, interpretation and updated conceptual site model. This additional investigation was completed to address the further comments in response to the EE and address data gaps that remained after previous assessments.

2 References

PA Scott Consulting (2022) Tick Hill Environmental Evaluation Groundwater Geochemistry Report. ML7097, ML7094, ML7096. Environmental Authority EPML00820613. Prepared for Carnaby Resources Pty Ltd, 20 April 2022.

3 Limitations

This report has been prepared by Environmental Earth Sciences QLD ACN 109 442 284 in response to and subject to the following limitations:

1. The specific instructions received from Carnaby Resources Pty Ltd;

2. The specific scope of works set out in PO722108 V2 issued by Environmental Earth Sciences for and on behalf of Carnaby Resources;

3. May not be relied upon by any third party not named in this report for any purpose except with the prior written consent of Environmental Earth Sciences QLD (which consent may or may not be given at the discretion of Environmental Earth Sciences QLD);

4. This report comprises the formal report, documentation sections, tables, figures and appendices as referred to in the index to this report and must not be released to any third party or copied in part without all the material included in this report for any reason;

5. The report only relates to the site referred to in the scope of works being located at Tick Hill Gold Mine ("the site");

6. The report relates to the site as at the date of the report as conditions may change thereafter due to natural processes and/or site activities;

7. No warranty or guarantee is made in regard to any other use than as specified in the scope of works and only applies to the depth tested and reported in this report;

8. Fill, soil, groundwater and rock to the depth tested on the site may be fit for the use specified in this report. Unless it is expressly stated in this report, the fill, soil and/or rock may not be suitable for classification as clean fill if deposited off site;

9. This report is not a geotechnical or planning report suitable for planning or zoning purposes; and

10. Our General Limitations set out at the back of the body of this report.

ENVIRONMENTAL EARTH SCIENCES
CONTAMINATION RESOLVED

ENVIRONMENTAL EARTH SCIENCES GENERAL LIMITATIONS

Scope of services
The work presented in this report is Environmental Earth Sciences response to the specific scope of works requested by, planned with and approved by the client. It cannot be relied on by any other third party for any purpose except with our prior written consent. Client may distribute this report to other parties and in doing so warrants that the report is suitable for the purpose it was intended for. However, any party wishing to rely on this report should contact us to determine the suitability of this report for their specific purpose.

Data should not be separated from the report
A report is provided inclusive of all documentation sections, limitations, tables, figures and appendices and should not be provided or copied in part without all supporting documentation for any reason, because misinterpretation may occur.

Subsurface conditions change
Understanding an environmental study will reduce exposure to the risk of the presence of contaminated soil and or groundwater. However, contaminants may be present in areas that were not investigated, or may migrate to other areas. Analysis cannot cover every type of contaminant that could possibly be present. When combined with field observations, field measurements and professional judgement, this approach increases the probability of identifying contaminated soil and or groundwater. Under no circumstances can it be considered that these findings represent the actual condition of the site at all points.

Environmental studies identify actual sub-surface conditions only at those points where samples are taken, when they are taken. Actual conditions between sampling locations differ from those inferred because no professional, no matter how qualified, and no sub-surface exploration program, no matter how comprehensive, can reveal what is hidden below the ground surface. The actual interface between materials may be far more gradual or abrupt than an assessment indicates. Actual conditions in areas not sampled may differ from that predicted. Nothing can be done to prevent the unanticipated. However, steps can be taken to help minimize the impact. For this reason, site owners should retain our services.

Problems with interpretation by others
Advice and interpretation is provided on the basis that subsequent work will be undertaken by Environmental Earth Sciences QLD. This will identify variances, maintain consistency in how data is interpreted, conduct additional tests that may be necessary and recommend solutions to problems encountered on site. Other parties may misinterpret our work and we cannot be responsible for how the information in this report is used. If further data is collected or comes to light we reserve the right to alter their conclusions.

Obtain regulatory approval
The investigation and remediation of contaminated sites is a field in which legislation and interpretation of legislation is changing rapidly. Our interpretation of the investigation findings should not be taken to be that of any other party. When approval from a statutory authority is required for a project, that approval should be directly sought by the client.

Limit of liability
This study has been carried out to a particular scope of works at a specified site and should not be used for any other purpose. This report is provided on the condition that Environmental Earth Sciences QLD disclaims all liability to any person or entity other than the client in respect of anything done or omitted to be done and of the consequence of anything done or omitted to be done by any such person in reliance, whether in whole or in part, on the contents of this report. Furthermore, Environmental Earth Sciences QLD disclaims all liability in respect of anything done or omitted to be done and of the consequence of anything done or omitted to be done by the client, or any such person in reliance, whether in whole or any part of the contents of this report of all matters not stated in the brief outlined in Environmental Earth Sciences QLD's proposal number and according to Environmental Earth Sciences general terms and conditions and special terms and conditions for contaminated sites.

To the maximum extent permitted by law, we exclude all liability of whatever nature, whether in contract, tort or otherwise, for the acts, omissions or default, whether negligent or otherwise for any loss or damage whatsoever that may arise in any way in connection with the supply of services. Under circumstances where liability cannot be excluded, such liability is limited to the value of the purchased service.

ENVIRONMENTAL EARTH SCIENCES
CONTAMINATION RESOLVED

APPENDIX A: RESPONSE TO ENVIRONMENTAL EVALUATION COMMENTS

Table 1: Response to DES comments on Environmental Evaluation requirements

Requirement	DES Comment	Response
1. Develop a conceptual groundwater model that identifies all groundwater systems, which may be impacted on as a result of activities conducted under environmental authority EPML00820613, with reference to all mine features, depth to groundwater, and direction of groundwater flow.	a) The report does not adequately identify and characterise all groundwater systems which may be impacted at the site. Based on the results of the model, the report concludes the groundwater system is limited to a fractured hard-rock aquifer under unconfined conditions. The report then goes onto identify a regolith aquifer present above the fractured rock in section 2.6 of the report, however there are no details regarding its hydrogeology and no monitoring bores present within this geological unit. b) Groundwater flow direction has not been sufficiently determined. The report states that due to scarce groundwater information available for the site, groundwater flow directions for intermediate and regional scale groundwater systems are conjectural. Furthermore, the conceptual model infers that groundwater flows west from groundwater bore THGW002 and regional groundwater flows south. However, the report states that groundwater bore 5 is upgradient of the mine site and the Tailings Storage Facility (TSF) and decant pond are upgradient of the open cut pit, indicating groundwater flow may be to the north. c) The report concludes that the pit is likely acting as a groundwater sink, however then goes onto state further assessment of the hydrogeological model is required using the recently acquired monitoring data. From the conceptual model presented, it appears that THGW002 is not within the influence of the pit and that THGW006 is at the edge of pit influence, based on the water table. Further evidence is required to support the conceptual model and the extent of drawdown or radial flow towards the pit.	a) The site hydrogeological model has been substantially updated based on review of available data and installation of additional monitoring bores. The updated hydrogeological conceptual site model (CSM) is developed within the environmental site assessment (ESA) report (Environmental Earth Sciences [EES], 2023). b) The groundwater flow direction has been recalculated in consideration of existing infrastructure and data obtained from newly installed monitoring bores. This is presented in Figure 9. The available data and recalculated contours indicate that the pit is a groundwater sink for the majority of the site, although influence of the open pit as a sink in the southwestern corner of the site may be limited, and groundwater in the area of the waste rock dump is not substantially influenced by the pit. Groundwater in the pit vicinity appears to be influenced by the underground workings to the northwest. Regional groundwater flow is to the northwest, as would be expected based on topography. Groundwater flow from the TSF and decant dam are within the hydrogeological influence of the open pit. Conceptual cross sections (Figures 15 and 16) are used to further illustrate the hydrogeological influence of the pit. c) The conditions described are not supported by the current CSM.

Requirement	DES Comment	Response
2. Identify all contaminants potentially generated by mine features, including characterisation of materials contained in mine features.	The Report does not explicitly identify all contaminants of concern. The report provides some characterisation of materials contained in the TSF, decant pond and open cut pit. However, it does not characterise materials in other mine features, such as the waste rock dump (WRD).	Chemicals of potential concern (CoPCs) were identified via desktop review (identification of historical and current potentially contaminating activities) and site inspection. These CoPCs were then incorporated into the supplementary soil and groundwater assessment undertaken at the site in 2023 (EES, 2023). Previous investigations have characterised the waste rock dump and potential associated issues. This investigation (EES, 2023) identified residual impacts to groundwater due to nitrate leaching, likely due to explosive residue in waste rock.
3. Consider all environmental values and identify those that are potentially impacted. Consider groundwater migration, interaction with surface water, and any	a. Environmental values have been identified in section 2.3 of the report, however groundwater migration, interaction with surface water, and any potential future use of the water have not been sufficiently considered. b. Insufficient justification is provided in the report in determining potentially affected groundwater environmental values, for example the applicability of aquatic ecosystems groundwater environmental values.	a) Potential interactions between groundwater and surface water are further developed when discussing site impacts. b) Selection of relevant environmental values is further discussed.
4. By 21 July 2020, design and implement a groundwater monitoring program, capable of detecting and assessing impacts from mining activities to groundwater	a. Groundwater monitoring bores have been nominated in the report, however insufficient justification has been provided to demonstrate their geographic locations and geology are adequate for their intended purpose, including their suitability as reference and impact bores based on groundwater flow direction. Furthermore, the report contains inconsistencies in relation to groundwater bore classifications and naming conventions, for example in section 2.2 of the report THGW006 is referred to as an impact bore, however, is then presented as a reference bore in the report. b. Sample results obtained from the TSF and decant pond detected contaminants including barium, iron, strontium, vanadium, phosphorus and titanium. These contaminants were not tested for in the groundwater monitoring	a) The purpose and relevance of groundwater monitoring bores to characterise hydrogeological conditions at the site is further discussed, along with the justification for locations of additional monitoring bores. b) Tailings, soil and groundwater were analysed for the same metals suite. Total and available phosphorus were also analysed. The distribution of metal concentrations and trends is discussed in the report, along with the potential for environmental harm. Several of the metals that exceed screening criteria show evidence of natural mineralisation across the site.

Requirement	DES Comment	Response
	program. Furthermore, the notice issued on 14 May 2020 identified elevated concentrations of vanadium in monitoring bores.	
5. Identify the source(s) of all contaminants that are being, or have been released from mine features to groundwater	a. Graphs are presented in the report depicting concentrations of some contaminants at some bores, however minimal interpretation or analysis of other results is provided. Furthermore, the data presented is restricted to sampling conducted post 2020 and does not consider monitoring data prior to this. b. An assessment of groundwater chemistry against stock water guideline values derived from ANZECC & ARMCANZ (2000) water quality guidelines (ANZECC 2000) is provided in section 2.4 of the report, however this is limited to one sampling occasion (i.e. 22 June 2020), does not consider other potentially relevant guidelines values such as aquatic ecosystems, and does not adequately consider their sources for example relevant mine features. c. Section 2.5 of the report states the: detection of cyanide in groundwater bores 2, 4 and 5 is most likely due to cross-contamination from sampling equipment or water level measuring equipment. Although the raw data does not show a detection of cyanide in groundwater bore THGW002, further information is required to justify the source of the cyanide results detected in groundwater bores THGW004 and THGW005.	a) Where sufficient data are available, graphs of monitoring results have been presented to aid in the interpretation of results. Interpretation of trends and exceedances for all graphed data is supplied. Where available, monitoring data from 2012 is included. b) Monitoring results are compared with relevant screening criteria for human health, ecosystems and stock watering. Exceedances are discussed in relation to source and potential for impact to the relevant sensitive receptors. c) Distribution and concentrations of cyanide across the site is discussed, along with potential impacts to sensitive receptors. Previous potentially anomalous results are discussed in the context of long term trends.
6. Identify and describe the pathways and mechanisms for the release and transport of contaminants to groundwater from mine features. Include a description of any existing barriers incorporated in mine features (e.g. Capping and lining of features containing contaminants) and assess their integrity.	a. The report concludes that local groundwater flow is towards the pit, however the following indicates uncertainty and additional potential pathways which have not been described: i. The pit maybe acting as a storage sink, however further assessment of the hydrogeological model is required using contemporary monitoring data. ii. Based on the PSM (2020) investigation, the larger fraction of TSF seepage migrates down-valley and to lower aquifers.	a) The influence of the pit as a sink in relation to groundwater across the site is further discussed and modelled. The comments relating to down-valley flow and regolith flow are not supported by the updated CSM. b) Assessment of waste materials at the site since prior to commencement of mine operations has indicated that total sulfur concentrations are low and

Requirement	DES Comment	Response
	iii. Regolith is present above the fractured rock, however no details are presented regarding its hydrogeology and no monitoring bores are present within this geological unit. b. The report concludes that the contribution of metals and sulfate from the WRD and TSF to the pit is minor to limited, however there is no justification provided to support this statement. c. A description of existing barriers incorporated into mine features and their integrity, is not included in the report.	there is no potential for sulfide oxidation and associated acid generation. Sulfate is not considered to be a chemical of potential concern associated with mine operations. Concentrations of major anions and cations, along with overall salinity increase between the aquifer and open pit due to evapo-concentration. Exceedances and trends of metal concentrations in groundwater are discussed. While the pit is the sink for groundwater in the vicinity of the TSF, groundwater in the area around the WRD flows towards the north, as illustrated in Figure 9. c) Current condition of the waste rock dump, tailings storage facility and decant dam is discussed.
7. Estimate the current lateral and vertical geographical extents of contaminants released to groundwater, from mine features.	The report concludes that the extent of contaminants is confined to the mine site and is controlled by the open cut pit acting as a groundwater sink, however based on the groundwater monitoring data presented in the report, this statement requires further justification. For example, groundwater bore THGW003 is off-lease and is considered to be a mine influenced bore. In addition, groundwater bores THGW004 (northernmost) and THGW005 (southernmost) have detected cyanide which indicates all groundwater systems may not flow to the open cut pit.	The extent of impacts to groundwater at and about the mine are evaluated and discussed, with consideration of the extent of influence of the pit as a groundwater sink. Groundwater impacts should be considered in the context of the nearly 30 years since mine operations ceased and that current conditions are reflective of stable or decreasing impacts. Minor detections of chemicals of concern along site boundaries are therefore not indicative of potential for off-site environmental harm.
8. To the extent necessary to prevent environmental harm, identify and prioritise potential options for a) the prevention of further contaminant releases from the premises to groundwater and b) remedial measures to reduce contaminant concentrations in groundwater.	The report concludes that further monitoring and assessment is required to define the source, cause and extent of contamination and suggests cyanide contamination is likely from the TSF, decant pond, or both. Remedial options are identified; however, no options analysis, prioritisation or evaluation for these options was presented.	Rectification works are required for the exposed tailings in the TSF, with a range of potential remediation options available which may reduce the footprint of the TSF and decant dam. These works are primarily required to stabilise the site and prevent dispersal of tailings material. As the source of free cyanide in the TSF and decant dam is assessed as being substantially depleted, further remediation or modification of other site structures, such as the WRD is not required.

Requirement	DES Comment	Response
9. The final report must include the results of all studies, assessments or analyses that were carried out during this investigation.	The assessment of environmental values in section 2.3 of the report, references '**Annexure 11 Envirofin 2020**', however this is not attached to the report.	This report can be supplied on request.
10. The final report must include the raw data for all results drawn upon in this investigation.	a. Groundwater monitoring raw data collected between 2020 and 2022 has been attached to the report in Appendix C and Appendix D, however the report indicates that data for THGW001 and THGW002 are available from 30 April 2012 to 22 June 2020. This data has not been provided with the raw data. b. Groundwater monitoring bore depths and associated groundwater water depth measurements are provided in the report, however the raw data, including groundwater bore logs and screened intervals, were not provided in support of these measurements. c. Section 3.3 of Appendix A of the report summarises surface water monitoring data collected in 2015 and 2018, however this raw data has not been provided in the report.	a) Data from 2012 has been included in the data tables and graphs. b) All available information relating to groundwater bore logs and installation are provided. c) Surface water data is provided in the tables appendix.
11. The final report must include nomination of appropriate water quality objectives to determine if environmental harm is being caused.	Water quality objectives for the site are nominated in section 2.9 of the report as livestock drinking water (sourced from ANZECC 2000), however insufficient details of the methodology and assessment has been provided in the report to justify this. Groundwater water quality objectives should be based on site-specific groundwater quality data with the objective to protect groundwater quality. Furthermore, the environmental value assessment provided in section 2.3 of the report identifies aquatic ecosystems as an applicable environmental value for surface waters. Where multiple environmental values have been identified, surface or groundwater quality should be managed to comply with the most conservative water quality guideline.	The applicability of various water quality guidelines in relation to identified exposure pathways to potential receptors is discussed, along with the potential for environmental harm in relation to exceedances of relevant screening criteria.

ENVIRONMENTAL EARTH SCIENCES

Equipment Calibration Record – TPS

This equipment calibration record is to be stored in your job folder

Equipment type/model:	~~TPS Water Quality Meter – 90FL(MV)~~T
Equipment number:	451.
Date calibrated:	18/12/2022
Fieldwork date:	19/12/2022
Calibrated by:	AS
Job number:	722092

Details of Calibration	Reading after calibration	Units	Acceptable range	Conclusion
Visual electrode check (condition):	N/A	N/A	N/A	
Battery reading:	N/A	Volts	6.5 – 8.5	
Temperature reading:	24.9	°C	±1 °C	
pH in 4.01 Solution:	4.01	pH units	3.91 – 4.11	
pH in 7.01 Solution:	7.00	pH units	6.91 – 7.11	
pH in 10.01 Solution:		pH units	9.91 – 10.11	
ORP in 240mV Redox solution:	232.4	mV	205 – 275	temp adjusted.
EC in 2.5 µS cm^{-1} deionised water:		µS cm^{-1}	0 – 7.0	
EC in 2,760 µS cm^{-1} solution:	2706	µS cm^{-1}	2,600 – 2,900	
EC in 12,880 µS cm^{-1} solution:	12520	µS cm^{-1}	12,500 – 13,200	
DO in 0.0% Water & $NaSO_4$ solution:		% DO	0.0 – 1.5	
DO in 100% air saturation:		% DO	99.0 – 101.0	

APPENDIX I: LABORATORY CERTIFICATES AND CHAIN OF CUSTODY DOCUMENTATION

CERTIFICATE OF ANALYSIS

Work Order	: **EB2317957**	Page	: 1 of 46
Amendment	: **1**		
Client	: **ENVIRONMENTAL EARTH SCIENCES**	Laboratory	: Environmental Division Brisbane
Contact	: MS ANNA SHELDON	Contact	: David Wall
Address	: PO BOX 3207 NEWSTEAD 4006	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: 07 3852 6666	Telephone	: +61-7-3243 7222
Project	: 722092	Date Samples Received	: 14-Jun-2023 10:35
Order number	: ----	Date Analysis Commenced	: 16-Jun-2023
C-O-C number	: COC#3/4/5-AAE-BR	Issue Date	: 07-Jul-2023 15:50
Sampler	: AS / SW		
Site	: Tick Hill		
Quote number	: EB23ENVEAR0004		
No. of samples received	: 65		
No. of samples analysed	: 55		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results
- Surrogate Control Limits

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Beatriz Llarinas	Senior Chemist - Inorganics	Brisbane Acid Sulphate Soils, Stafford, QLD
Beatriz Llarinas	Senior Chemist - Inorganics	Brisbane Inorganics, Stafford, QLD
Ben Felgendrejeris	Senior Acid Sulfate Soil Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Keegan Mullane	Senior Chemist - Organics	Brisbane Organics, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Mark Hallas	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Matt Frost	Assistant Laboratory Manager	Brisbane Organics, Stafford, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- It is recognised that EK028SF (WAD Cyanide by SFA) is less than EK025SF (Free Cyanide) for sample GWBD01 (EB2317957-012). However, the difference is within experimental variation of the methods.
- It is recognised that EK028SF (WAD Cyanide by SFA) is less than EK025SF (Free Cyanide) for sample THGW08 (EB2317957-008). However, the difference is within experimental variation of the methods.
- It is recognised that EK028SF (WAD Cyanide by SFA) is less than EK025SF (Free Cyanide) for sample THGW01 (EB2317957-001). However, the difference is within experimental variation of the methods.
- EP231X-LL PFAS Low Level: High LCS recovery deemed acceptable as all associated analyte results are less than LOR.
- EK067G (Total Phosphorus as P): Sample EB2318164-001 shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.
- EP231X - Per- and Polyfluoroalkyl Substances (PFAS): Samples received in 20ml or 125ml bottles have been tested in accordance with the QSM5.3 compliant, NATA accredited method. 60mL or 250mL bottles have been tested to the legacy QSM 5.1 aligned, NATA accredited method.
- EP080: Where reported, Total Xylenes is the sum of the reported concentrations of m&p-Xylene and o-Xylene at or above the LOR.
- EP068: Where reported, Total Chlordane (sum) is the sum of the reported concentrations of cis-Chlordane and trans-Chlordane at or above the LOR.
- EP068: Where reported, Total OCP is the sum of the reported concentrations of all Organochlorine Pesticides at or above LOR.
- As per QWI – EN55-3 Data Interpreting Procedures, Ionic balances are typically calculated using Major Anions - Chloride, Alkalinity and Sulfate; and Major Cations - Calcium, Magnesium, Potassium and Sodium. Where applicable and dependent upon sample matrix, the Ionic Balance may also include the additional contribution of Ammonia, Dissolved Metals by ICPMS and H+ to the Cations and Nitrate, SiO2 and Fluoride to the Anions.
- Amendment (DD/MM/YYYY): This report has been amended and re-released to allow the reporting of additional analytical data, specifically method Free, Total and WAD Cyanide (EK026SF, EK025SF, EK028SF) and Metals EG020T for sample <client ID>> EB2317957_062 (BD01).
- It is recognised that EG020T (Total Metals by ICP-MS) is less than EG020F (Dissolved Metals by ICP-MS) for some samples. However, the difference is within experimental variation of the methods.
- EG020-T (Total Metals by ICP-MS): Sample THS01 0-0.1 (EB2317957-014) shows poor duplicate results due to sample heterogeneity. Confirmed by visual inspection.
- EP231X-LL PFAS Low level: The LOR values for PFHxS and PFOS have been raised in sample ‘GWBD01’ (EB2317957-012) due to matrix interference.
- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.
- EP231: Stable isotope enriched internal standards are added to samples prior to extraction. Target compounds have a direct analogous internal standard with the exception of PFPeS, PFHpA, PFDS, PFTrDA and 10:2 FTS. These compounds use an internal standard that is chemically related and has a retention time close to that of the target compound. The DQO for internal standard response is 50-150% of that established at initial calibration. PFOS is quantified using a certified, traceable standard consisting of linear and branched PFOS isomers. These practices are in line with recommendations in the National Environmental Management Plan for PFAS (Australian HEPA) and also conform to QSM 5.3 (US DoD) requirements.

Analytical Results

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Sub-Matrix: **SOIL**

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

Amendment	: **1**		
Client	: **ENVIRONMENTAL EARTH SCIENCES**	Laboratory	: Environmental Division Brisbane
Contact	: MS ANNA SHELDON	Telephone	: +61-7-3243 7222
Project	: 722092	Date Samples Received	: 14-Jun-2023
Site	: Tick Hill	Issue Date	: 07-Jul-2023
Sampler	: AS / SW	No. of samples received	: 65
Order number	: ----	No. of samples analysed	: 55

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **Duplicate outliers exist - please see following pages for full details.**
- **Laboratory Control outliers exist - please see following pages for full details.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **Quality Control Sample Frequency Outliers exist - please see following pages for full details.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **SOIL**

Compound Group Name	Laboratory Sample ID	Client Sample ID	Analyte	CAS Number	Data	Limits	Comment
Duplicate (DUP) RPDs							
EG020T: Total Metals by ICP-MS	EB2317957--014	THS01 0-0.1	**Arsenic**	7440-38-2	23.3 %	0% - 20%	**RPD exceeds LOR based limits**
EK067G: Total Phosphorus as P by Discrete Analyser	EB2318164--001	Anonymous	**Total Phosphorus as P**	----	55.3 %	0% - 20%	**RPD exceeds LOR based limits**
Matrix Spike (MS) Recoveries							
EK067G: Total Phosphorus as P by Discrete Analyser	EB2317806--004	Anonymous	**Total Phosphorus as P**	----	Not Determined	----	**MS recovery not determined, background level greater than or equal to 4x spike level.**

Matrix: **WATER**

Compound Group Name	Laboratory Sample ID	Client Sample ID	Analyte	CAS Number	Data	Limits	Comment
Laboratory Control Spike (LCS) Recoveries

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: ✗ = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Quality Control Sample Type		Count		Rate (%)			Quality Control Specification
Analytical Methods	Method	QC	Regular	Actual	Expected	Evaluation

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH (1:5)	EA002	SOIL	In house: Referenced to Rayment and Lyons 4A1 and APHA 4500H+. pH is determined on soil samples after a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Chromium Reducible Sulphur	EA026	SOIL	In house: Referenced to Sullivan et al (1998) The CRS method converts reduced inorganic sulfur to H2S by CrCl2 solution ; the evolved H2S is trapped in a zinc acetate solution as ZnS which is quantified by iodometric titration.
Moisture Content	EA055	SOIL	In house: A gravimetric procedure based on weight loss over a 12 hour drying period at 105-110 degrees C. This method is compliant with NEPM Schedule B(3).
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3)
Water Leachable Metals by ICP-MS - Suite A	EG020A-W	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, AS 4439.3, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Water Leachable Metals by ICP-MS - Suite B	EG020B-W	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Water Leachable Metals by ICP-MS - Suite E	EG020E-W	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite R	EG020R-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020. Metals in solids are determined following an appropriate acid digestion. The ICPMS technique ionizes selected elements. Ions are passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass / charge ratios prior to measurement by a discrete dynode ion detector. This method is compliant with NEPM Schedule B(3)
Total Metals by ICP-MS - Suite V	EG020V-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Metals in solids are determined following an appropriate acid digestion. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.

Analytical Methods	Method	Matrix	Method Descriptions
Total Metals by ICP-MS - Suite X	EG020X-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite Y	EG020Y-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Free Cyanide by Segmented Flow Analyser	EK025SF	SOIL	In house: Referenced to ASTM D7237, APHA 4500-CN-C&O and ISO 14403: Using an automated segmented flow analyser, a sample at high pH (caustic leach of a soil) is buffered to pH 6.0. The hydrogen cyanide present passes across a gas dialysis membrane into an acceptor stream consisting of 0.01 M sodium hydroxide. The acceptor stream mixes with a buffer at pH 5.2 and reacts with chloramine-T to form cyanogen chloride. Cyanogen chloride reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour. This is measured at 600nm. This method is compliant with NEPM Schedule B(3).
Total Cyanide by Segmented Flow Analyser	EK026SF	SOIL	In house: Referenced to APHA 4500-CN C / ASTM D7511 / ISO 14403. Caustic leachates of soil samples are introduced into an automated segmented flow analyser. Complex bound cyanide is decomposed in a continuously flowing stream, at a pH of 3.8, by the effect of UV light. A UV-B lamp (312 nm) and a decomposition spiral of borosilicate glass are used to filter out UV light with a wavelength of less than 290 nm thus preventing the conversion of thiocyanate into cyanide. The hydrogen cyanide present at a pH of 3.8 is separated by gas dialysis. The hydrogen cyanide is then determined photometrically, based on the reaction of cyanide with chloramine-T to form cyanogen chloride. This then reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour which is measured at 600 nm. This method is compliant with NEPM Schedule B(3).
WAD Cyanide by Segmented Flow Analyser	EK028SF	SOIL	In house: Referenced to APHA 4500-CN C&O / ISO 14403. Caustic leachates of soil samples are introduced into an automated segmented flow analyser. Hydrogen cyanide is liberated from a slightly acidified (pH 4.5) and is dialysed. Tight cyanide complexes that would not be amenable to oxidation by chlorine are not converted. Iron cyanide complexes are precipitated with zinc acetate. Liberated HCN diffuses through a membrane into a stream of sodium hydroxide where it is carried as CN- The cyanide in caustic solution is buffered to pH 5.2 and further converted to cyanogen chloride by reaction with chloramine-T. Cyanogen chloride subsequently reacts with 4-pyridine carboxylic and 1,3-dimethylbarbituric acids to give a red colour complex. This colour is measured at 600 nm. This method is compliant with NEPM Schedule B(3).
Total Phosphorus By Discrete Analyser	EK067G	SOIL	In house: Referenced to APHA 4500 P-B&F This procedure involves sulfuric acid digestion and quantification using Discrete Analyser.
Reactive Phosphorus as P-Soluble By Discrete Analyser	EK071G	SOIL	In house: Referenced to APHA 4500 P-F Ammonium molybdate and potassium antimonyl tartrate reacts in acid medium with othophosphate to form a heteropoly acid -phosphomolybdic acid - which is reduced to intensely coloured molybdenum blue by ascorbic acid. Quantification is by Discrete Analyser. This method is compliant with NEPM Schedule B(3).
Polychlorinated Biphenyls (PCB)	EP066	SOIL	In house: Referenced to USEPA SW 846 - 8270 Extracts are analysed by Capillary GC/MS and quantification is by comparison against an established 5 point calibration curve. This method is compliant with NEPM Schedule B(3).

Analytical Methods	Method	Matrix	Method Descriptions
Pesticides by GCMS	EP068	SOIL	In house: Referenced to USEPA SW 846 - 8270 Extracts are analysed by Capillary GC/MS and quantification is by comparison against an established 5 point calibration curve. This technique is compliant with NEPM Schedule B(3).
TRH - Semivolatile Fraction	EP071	SOIL	In house: Referenced to USEPA SW 846 - 8015 Sample extracts are analysed by Capillary GC/FID and quantified against alkane standards over the range C10 - C40. Compliant with NEPM Schedule B(3).
TRH Volatiles/BTEX	EP080	SOIL	In house: Referenced to USEPA SW 846 - 8260. Extracts are analysed by Purge and Trap, Capillary GC/MS. Quantification is by comparison against an established 5 point calibration curve. Compliant with NEPM Schedule B(3) amended.
Per- and Polyfluoroalkyl Substances (PFAS) by LCMSMS	EP231X	SOIL	In-house: Analysis of soils by solvent extraction followed by LC-Electrospray-MS-MS, Negative Mode using MRM using internal standard quantitation. Isotopically labelled analogues of target analytes used as internal standards and surrogates are added to a portion of soil which is then extracted with MTBE and an ion pairing reagent. A portion of extract is exchanged into the analytical solvent mixture, combined with an equal volume reagent water and filtered for analysis. Method procedures and data quality objectives conform to US DoD QSM 5.3, table B-15 requirements.
pH by Auto Titrator	EA005-P	WATER	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM Schedule B(3)
Total Dissolved Solids (High Level)	EA015H	WATER	In house: Referenced to APHA 2540C. A gravimetric procedure that determines the amount of `filterable` residue in an aqueous sample. A well-mixed sample is filtered through a glass fibre filter (1.2um). The filtrate is evaporated to dryness and dried to constant weight at 180+/-5C. This method is compliant with NEPM Schedule B(3)
Alkalinity by Auto Titrator	ED037-P	WATER	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) on a settled supernatant aliquot of the sample using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM Schedule B(3)
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	WATER	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM Schedule B(3)
Chloride by Discrete Analyser	ED045G	WATER	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride. In the presence of ferric ions the liberated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm.
Major Cations - Dissolved	ED093F	WATER	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations are determined by either ICP-AES or ICP-MS techniques. This method is compliant with NEPM Schedule B(3) Sodium Adsorption Ratio is calculated from Ca, Mg and Na which determined by ALS in house method QWI-EN/ED093F. This method is compliant with NEPM Schedule B(3) Hardness parameters are calculated based on APHA 2340 B. This method is compliant with NEPM Schedule B(3)
Dissolved Metals by ICP-MS - Suite A	EG020A-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.

Analytical Methods	Method	Matrix	Method Descriptions
Total Metals by ICP-MS - Suite A	EG020A-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Dissolved Metals by ICP-MS - Suite B	EG020B-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite B	EG020B-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Dissolved Metals by ICP-MS - Suite E	EG020E-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite E	EG020E-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Dissolved Mercury by FIMS	EG035F	WATER	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) Samples are 0.45µm filtered prior to analysis. FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the filtered sample. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Total Mercury by FIMS	EG035T	WATER	In house: Referenced to APHA 3112 Hg - B (Flow-injection (SnCl2)(Cold Vapour generation) AAS) FIM-AAS is an automated flameless atomic absorption technique. A bromate/bromide reagent is used to oxidise any organic mercury compounds in the unfiltered sample. The ionic mercury is reduced online to atomic mercury vapour by SnCl2 which is then purged into a heated quartz cell. Quantification is by comparing absorbance against a calibration curve. This method is compliant with NEPM Schedule B(3).
Free CN by Segmented Flow Analyser	EK025SF	WATER	In house: Referenced to ASTM D7237, APHA 4500-CN-C&O and ISO 14403: Using an automated segmented flow analyser, a sample at high pH (sodium hydroxide preserved) is buffered to pH 6.0. The hydrogen cyanide present passes across a gas dialysis membrane into an acceptor stream consisting of 0.01 M sodium hydroxide. The acceptor stream mixes with a buffer at pH 5.2 and reacts with chloramine-T to form cyanogen chloride. Cyanogen chloride reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour, measured at 600nm. This method is compliant with NEPM Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Total Cyanide by Segmented Flow Analyser	EK026SF	WATER	In house: Referenced to APHA 4500-CN C&O / ASTM D7511 / ISO 14403. Sodium hydroxide preserved samples are introduced into an automated segmented flow analyser. Complex bound cyanide is decomposed in a continuously flowing stream, at a pH of 3.8, by the effect of UV light. A UV-B lamp (312 nm) and a decomposition spiral of borosilicate glass are used to filter out UV light with a wavelength of less than 290 nm thus preventing the conversion of thiocyanate into cyanide. The hydrogen cyanide present at a pH of 3.8 is separated by gas dialysis. The hydrogen cyanide is then determined photometrically, based on the reaction of cyanide with chloramine-T to form cyanogen chloride. This then reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour which is measured at 600 nm. This method is compliant with NEPM Schedule B(3)
Weak Acid Dissociable Cyanide by Segmented Flow Analyser	EK028SF	WATER	In house: Referenced to APHA 4500-CN C&O / ISO 14403. Samples preserved with sodium hydroxide are introduced into an automated segmented flow analyser. Hydrogen cyanide is liberated from a slightly acidified (pH 4.5) and is dialysed. Tight cyanide complexes that would not be amenable to oxidation by chlorine are not converted. Iron cyanide complexes are precipitated with zinc acetate. Liberated HCN diffuses through a membrane into a stream of sodium hydroxide where it is carried as CN- The cyanide in caustic solution is buffered to pH 5.2 and further converted to cyanogen chloride by reaction with chloramine-T. Cyanogen chloride subsequently reacts with 4-pyridine carboxylic and 1,3-dimethylbarbituric acids to give a red colour complex. This colour is measured at 600 nm. This method is compliant with NEPM Schedule B(3)
Fluoride by Auto Titrator	EK040P	WATER	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM Schedule B(3)
Ammonia as N by Discrete analyser	EK055G	WATER	In house: Referenced to APHA 4500-NH3 G Ammonia is determined by direct colorimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Nitrite as N by Discrete Analyser	EK057G	WATER	In house: Referenced to APHA 4500-NO2- B. Nitrite is determined by direct colourimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Nitrate as N by Discrete Analyser	EK058G	WATER	In house: Referenced to APHA 4500-NO3- F. Nitrate is reduced to nitrite by way of a chemical reduction followed by quantification by Discrete Analyser. Nitrite is determined seperately by direct colourimetry and result for Nitrate calculated as the difference between the two results. This method is compliant with NEPM Schedule B(3)
Total Phosphorus as P By Discrete Analyser	EK067G	WATER	In house: Referenced to APHA 4500-P H, Jirka et al, Zhang et al. This procedure involves sulphuric acid digestion of a sample aliquot to break phosphorus down to orthophosphate. The orthophosphate reacts with ammonium molybdate and antimony potassium tartrate to form a complex which is then reduced and its concentration measured at 880nm using discrete analyser. This method is compliant with NEPM Schedule B(3)
Reactive Phosphorus as P-By Discrete Analyser	EK071G	WATER	In house: Referenced to APHA 4500-P F Ammonium molybdate and potassium antimonyl tartrate reacts in acid medium with othophosphate to form a heteropoly acid -phosphomolybdic acid - which is reduced to intensely coloured molybdenum blue by ascorbic acid. Quantification is by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Ionic Balance by PCT DA and Turbi SO4 DA	* EN055 - PG	WATER	In house: Referenced to APHA 1030F. This method is compliant with NEPM Schedule B(3)
TRH - Semivolatile Fraction	EP071	WATER	In house: Referenced to USEPA SW 846 - 8015 The sample extract is analysed by Capillary GC/FID and quantification is by comparison against an established 5 point calibration curve of n-Alkane standards. This method is compliant with the QC requirements of NEPM Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
TRH Volatiles/BTEX	EP080	WATER	In house: Referenced to USEPA SW 846 - 8260 Water samples are directly purged prior to analysis by Capillary GC/MS and quantification is by comparison against an established 5 point calibration curve. Alternatively, a sample is equilibrated in a headspace vial and a portion of the headspace determined by GCMS analysis. This method is compliant with the QC requirements of NEPM Schedule B(3)
Per- and Polyfluoroalkyl Substances (PFAS by LCMSMS	EP231X-LL	WATER	In-house: Analysis of fresh and saline waters by Solid Phase Extraction (SPE) followed by LC-Electrospray-MS-MS, Negative Mode using MRM and internal standard quantitation. Isotopically labelled analogues of target analytes used as internal standards and surrogates are added to the sample container. The entire contents are transferred to a solid phase extraction (SPE) cartridge. The sample container is successively rinsed with aliquots of the elution solvent. The eluted extract is concentrated, combined with an equal volume of reagent water and filtered for analysis. Method procedures and data quality objectives conform to US DoD QSM 5.3, table B-15 requirements.

Preparation Methods	Method	Matrix	Method Descriptions
NaOH leach for CN in Soils	CN-PR	SOIL	In house: APHA 4500 CN. Samples are extracted by end-over-end tumbling with NaOH.
TKN/TP Digestion	EK061/EK067	SOIL	In house: Referenced to APHA 4500 Norg- D; APHA 4500 P - H. Macro Kjeldahl digestion.
Drying at 85 degrees, bagging and labelling (ASS)	EN020PR	SOIL	In house
Digestion for Total Recoverable Metals in DI Water Leachate	EN25W	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
ASLP for Non & Semivolatile Analytes - Glass Leaching Vessel	EN60a-G	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates
ASLP for Volatile Analytes (Zero Headspace Extraction)	EN60Za	SOIL	In house QWI-EN/60 referenced to AS4439.2 Preparation of Leachates
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM Schedule B(3).
Methanolic Extraction of Soils for Purge and Trap	ORG16	SOIL	In house: Referenced to USEPA SW 846 - 5030A. 5g of solid is shaken with surrogate and 10mL methanol prior to analysis by Purge and Trap - GC/MS.
Tumbler Extraction of Solids	ORG17	SOIL	In house: Mechanical agitation (tumbler). 10g of sample, Na2SO4 and surrogate are extracted with 30mL 1:1 DCM/Acetone by end over end tumble. The solvent is decanted, dehydrated and concentrated (by KD) to the desired volume for analysis.
QuECheRS Extraction of Solids	ORG71	SOIL	In house: Sequential extractions with Acetonitrile/Methanol by shaking. Extraction efficiency aided by the addition of salts under acidic conditions. Where relevant, interferences from co-extracted organics are removed with dispersive clean-up media (dSPE). The extract is either diluted or concentrated and exchanged into the analytical solvent.
TKN/TP Digestion	EK061/EK067	WATER	In house: Referenced to APHA 4500 Norg - D; APHA 4500 P - H. This method is compliant with NEPM Schedule B(3)

Preparation Methods	*Method*	*Matrix*	*Method Descriptions*
Digestion for Total Recoverable Metals	EN25	WATER	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
Separatory Funnel Extraction of Liquids	ORG14	WATER	In house: Referenced to USEPA SW 846 - 3510 100 mL to 1L of sample is transferred to a separatory funnel and serially extracted three times using DCM for each extract. The resultant extracts are combined, dehydrated and concentrated for analysis. This method is compliant with NEPM Schedule B(3) . ALS default excludes sediment which may be resident in the container.
Volatiles Water Preparation	ORG16-W	WATER	A 5 mL aliquot or 5 mL of a diluted sample is added to a 40 mL VOC vial for purging.
Solid Phase Extraction (SPE) for PFAS in water	ORG72	WATER	In-house: Isotopically labelled analogues of target analytes used as internal standards and surrogates are added to the sample container. The entire contents are transferred to a solid phase extraction (SPE) cartridge. The sample container is successively rinsed with aliquots of the elution solvent. The eluted extract is combined with an equal volume of reagent water and a portion is filtered for analysis. Method procedures conform to US DoD QSM 5.3, table B-15 requirements.

Ben Felgendrejeris	Senior Acid Sulfate Soil Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Timothy Creagh	Senior Chemist - Organics	Brisbane Inorganics, Stafford, QLD
Timothy Creagh	Senior Chemist - Organics	Brisbane Organics, Stafford, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- Particular samples have been crushed prior to preparation and analysis as per client request on the Chain of Custody. Please refer to SRN for further details.
- EG020X-T (Total Metals by ICP-MS): Sample 'THTSF_DEC_02_600_900' (EB2318849-011) shows poor duplicate results due to sample heterogeneity. Confirmed by re-extraction and re-analysis.

Project	: 722092	Date Samples Received	: 22-Jun-2023
Order number	: ----	Date Analysis Commenced	: 23-Jun-2023
C-O-C number	: ----	Issue Date	: 04-Jul-2023
Sampler	: PAUL TAN		
Site	: Tick Hill		
Quote number	: EB23ENVEAR0004		
No. of samples received	: 19		
No. of samples analysed	: 19		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Beatriz Llarinas	Senior Chemist - Inorganics	Brisbane Inorganics, Stafford, QLD
Ben Felgendrejeris	Senior Acid Sulfate Soil Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Timothy Creagh	Senior Chemist - Organics	Brisbane Inorganics, Stafford, QLD
Timothy Creagh	Senior Chemist - Organics	Brisbane Organics, Stafford, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Sub-Matrix: **SOIL**

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

Sampler	: PAUL TAN	No. of samples received	: 19
Order number	: ----	No. of samples analysed	: 19

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Laboratory Control outliers occur.**
- **NO Matrix Spike outliers occur.**
- **Duplicate outliers exist - please see following pages for full details.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **Quality Control Sample Frequency Outliers exist - please see following pages for full details.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **SOIL**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **SOIL**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH (1:5)	EA002	SOIL	In house: Referenced to Rayment and Lyons 4A1 and APHA 4500H+. pH is determined on soil samples after a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Electrical Conductivity (1:5)	EA010	SOIL	In house: Referenced to Rayment and Lyons 3A1 and APHA 2510. Conductivity is determined on soil samples using a 1:5 soil/water leach. This method is compliant with NEPM Schedule B(3).
Chromium Reducible Sulphur	EA026	SOIL	In house: Referenced to Sullivan et al (1998) The CRS method converts reduced inorganic sulfur to H2S by CrCl2 solution ; the evolved H2S is trapped in a zinc acetate solution as ZnS which is quantified by iodometric titration.
Total Metals by ICP-AES	EG005T	SOIL	In house: Referenced to APHA 3120; USEPA SW 846 - 6010. Metals are determined following an appropriate acid digestion of the soil. The ICPAES technique ionises samples in a plasma, emitting a characteristic spectrum based on metals present. Intensities at selected wavelengths are compared against those of matrix matched standards. This method is compliant with NEPM Schedule B(3)
Water Leachable Metals by ICP-MS - Suite A	EG020A-W	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, AS 4439.3, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Water Leachable Metals by ICP-MS - Suite B	EG020B-W	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Water Leachable Metals by ICP-MS - Suite E	EG020E-W	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite R	EG020R-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020. Metals in solids are determined following an appropriate acid digestion. The ICPMS technique ionizes selected elements. Ions are passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass / charge ratios prior to measurement by a discrete dynode ion detector. This method is compliant with NEPM Schedule B(3)
Total Metals by ICP-MS - Suite V	EG020V-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Metals in solids are determined following an appropriate acid digestion. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite X	EG020X-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.

Analytical Methods	Method	Matrix	Method Descriptions
Total Metals by ICP-MS - Suite Y	EG020Y-T	SOIL	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Free Cyanide by Segmented Flow Analyser	EK025SF	SOIL	In house: Referenced to ASTM D7237, APHA 4500-CN-C&O and ISO 14403: Using an automated segmented flow analyser, a sample at high pH (caustic leach of a soil) is buffered to pH 6.0. The hydrogen cyanide present passes across a gas dialysis membrane into an acceptor stream consisting of 0.01 M sodium hydroxide. The acceptor stream mixes with a buffer at pH 5.2 and reacts with chloramine-T to form cyanogen chloride. Cyanogen chloride reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour. This is measured at 600nm. This method is compliant with NEPM Schedule B(3).
Total Cyanide by Segmented Flow Analyser	EK026SF	SOIL	In house: Referenced to APHA 4500-CN C / ASTM D7511 / ISO 14403. Caustic leachates of soil samples are introduced into an automated segmented flow analyser. Complex bound cyanide is decomposed in a continuously flowing stream, at a pH of 3.8, by the effect of UV light. A UV-B lamp (312 nm) and a decomposition spiral of borosilicate glass are used to filter out UV light with a wavelength of less than 290 nm thus preventing the conversion of thiocyanate into cyanide. The hydrogen cyanide present at a pH of 3.8 is separated by gas dialysis. The hydrogen cyanide is then determined photometrically, based on the reaction of cyanide with chloramine-T to form cyanogen chloride. This then reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour which is measured at 600 nm. This method is compliant with NEPM Schedule B(3).
WAD Cyanide by Segmented Flow Analyser	EK028SF	SOIL	In house: Referenced to APHA 4500-CN C&O / ISO 14403. Caustic leachates of soil samples are introduced into an automated segmented flow analyser. Hydrogen cyanide is liberated from a slightly acidified (pH 4.5) and is dialysed. Tight cyanide complexes that would not be amenable to oxidation by chlorine are not converted. Iron cyanide complexes are precipitated with zinc acetate. Liberated HCN diffuses through a membrane into a stream of sodium hydroxide where it is carried as CN- The cyanide in caustic solution is buffered to pH 5.2 and further converted to cyanogen chloride by reaction with chloramine-T. Cyanogen chloride subsequently reacts with 4-pyridine carboxylic and 1,3-dimethylbarbituric acids to give a red colour complex. This colour is measured at 600 nm. This method is compliant with NEPM Schedule B(3).

Preparation Methods	Method	Matrix	Method Descriptions
NaOH leach for CN in Soils	CN-PR	SOIL	In house: APHA 4500 CN. Samples are extracted by end-over-end tumbling with NaOH.
Drying at 85 degrees, bagging and labelling (ASS)	EN020PR	SOIL	In house
Digestion for Total Recoverable Metals in DI Water Leachate	EN25W	SOIL	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)
1:5 solid / water leach for soluble analytes	EN34	SOIL	10 g of soil is mixed with 50 mL of reagent grade water and tumbled end over end for 1 hour. Water soluble salts are leached from the soil by the continuous suspension. Samples are settled and the water filtered off for analysis.
Deionised Water Leach - Glass Leaching Vessel	EN60-DIa-G	SOIL	In house QWI-EN/60 referenced to AS4439.3 Preparation of Leachates
Deionised Water Leach - Zero Headspace Extraction	EN60Z-DIa	SOIL	In house QWI-EN/60 referenced to AS4439.2 Preparation of Leachates

Preparation Methods	*Method*	*Matrix*	*Method Descriptions*
Hot Block Digest for metals in soils sediments and sludges	EN69	SOIL	In house: Referenced to USEPA 200.2. Hot Block Acid Digestion 1.0g of sample is heated with Nitric and Hydrochloric acids, then cooled. Peroxide is added and samples heated and cooled again before being filtered and bulked to volume for analysis. Digest is appropriate for determination of selected metals in sludge, sediments, and soils. This method is compliant with NEPM Schedule B(3).
Dry and Crush	EN84	SOIL	In house

Sample Information

- ✓ A detailed list of analytes logged into our LIMS, is included in the attached summary table.
- ✓ All samples have been received as described on the above COC.
- ✓ COC has been completed correctly.
- ✓ Attempt to chill was evident.
- ✓ Appropriately preserved sample containers have been used.
- ✓ All samples were received in good condition.
- ✓ Samples have been provided with adequate time to commence analysis in accordance with the relevant holding times.
- ✓ Appropriate sample containers have been used.
- ✓ Sample containers for volatile analysis received with zero headspace.
- ✗ Split sample sent to requested external lab.
- ✗ Some samples have been subcontracted.
- N/A Custody Seals intact (if used).

Notes

Contact

If you have any questions with respect to these samples, please contact your Analytical Services Manager:

Peter Brand on phone : 0436 360 123 or by email: PeterBrand@eurofins.com

Results will be delivered electronically via email to Anna Sheldon - asheldon@environmentalearthsciences.com.

Note: A copy of these results will also be delivered to the general Environmental Earth Sciences QLD email address.

Global Leader - Results you can trust

Internal Quality Control Review and Glossary

General

1. Laboratory QC results for Method Blanks, Duplicates, Matrix Spikes, and Laboratory Control Samples follows guidelines delineated in the National Environment Protection (Assessment of Site Contamination) Measure 1999, as amended May 2013 and are included in this QC report where applicable. Additional QC data may be available on request.
2. All soil/sediment/solid results are reported on a dry basis, unless otherwise stated.
3. All biota/food results are reported on a wet weight basis on the edible portion, unless otherwise stated.
4. Actual LORs are matrix dependant. Quoted LORs may be raised where sample extracts are diluted due to interferences.
5. Results are uncorrected for matrix spikes or surrogate recoveries except for PFAS compounds.
6. SVOC analysis on waters are performed on homogenised, unfiltered samples, unless noted otherwise.
7. Samples were analysed on an 'as received' basis.
8. Information identified on this report with blue colour, indicates data provided by customer that may have an impact on the results.
9. This report replaces any interim results previously issued.

Holding Times

Please refer to 'Sample Preservation and Container Guide' for holding times (QS3001).

For samples received on the last day of holding time, notification of testing requirements should have been received at least 6 hours prior to sample receipt deadlines as stated on the SRA.

If the Laboratory did not receive the information in the required timeframe, and regardless of any other integrity issues, suitably qualified results may still be reported.

Holding times apply from the date of sampling, therefore compliance to these may be outside the laboratory's control.

For VOCs containing vinyl chloride, styrene and 2-chloroethyl vinyl ether the holding time is 7 days however for all other VOCs such as BTEX or C6-10 TRH then the holding time is 14 days.

Units

mg/kg: milligrams per kilogram
mg/L: milligrams per litre
µg/L: micrograms per litre
ppm: parts per million
ppb: parts per billion
%: Percentage
org/100 mL: Organisms per 100 millilitres
NTU: Nephelometric Turbidity Units
MPN/100 mL: Most Probable Number of organisms per 100 millilitres
CFU: Colony forming unit

Terms

APHA	American Public Health Association
COC	Chain of Custody
CP	Client Parent - QC was performed on samples pertaining to this report
CRM	Certified Reference Material (ISO17034) - reported as percent recovery.
Dry	Where a moisture has been determined on a solid sample the result is expressed on a dry basis.
Duplicate	A second piece of analysis from the same sample and reported in the same units as the result to show comparison.
LOR	Limit of Reporting.
LCS	Laboratory Control Sample - reported as percent recovery.
Method Blank	In the case of solid samples these are performed on laboratory certified clean sands and in the case of water samples these are performed on de-ionised water.
NCP	Non-Client Parent - QC performed on samples not pertaining to this report, QC is representative of the sequence or batch that client samples were analysed within.
RPD	Relative Percent Difference between two Duplicate pieces of analysis.
SPIKE	Addition of the analyte to the sample and reported as percentage recovery.
SRA	Sample Receipt Advice
Surr - Surrogate	The addition of a like compound to the analyte target and reported as percentage recovery.
TBTO	Tributyltin oxide (*bis*-tributyltin oxide) - individual tributyltin compounds cannot be identified separately in the environment however free tributyltin was measured and its values were converted stoichiometrically into tributyltin oxide for comparison with regulatory limits.
TCLP	Toxicity Characteristic Leaching Procedure
TEQ	Toxic Equivalency Quotient or Total Equivalence
QSM	US Department of Defense Quality Systems Manual Version 5.4
US EPA	United States Environmental Protection Agency
WA DWER	Sum of PFBA, PFPeA, PFHxA, PFHpA, PFOA, PFBS, PFHxS, PFOS, 6:2 FTSA, 8:2 FTSA

QC - Acceptance Criteria

The acceptance criteria should be used as a guide only and may be different when site specific Sampling Analysis and Quality Plan (SAQP) have been implemented

RPD Duplicates: Global RPD Duplicates Acceptance Criteria is 30% however the following acceptance guidelines are equally applicable:

Results <10 times the LOR: No Limit

Results between 10-20 times the LOR: RPD must lie between 0-50%

Results >20 times the LOR: RPD must lie between 0-30%

NOTE: pH duplicates are reported as a range not as RPD

Surrogate Recoveries: Recoveries must lie between 20-130% for Speciated Phenols & 50-150% for PFAS. SVOCs recoveries 20 – 150%

PFAS field samples that contain surrogate recoveries in excess of the QC limit designated in QSM 5.4 where no positive PFAS results have been reported have been reviewed and no data was affected.

QC Data General Comments

1. Where a result is reported as a less than (<), higher than the nominated LOR, this is due to either matrix interference, extract dilution required due to interferences or contaminant levels within the sample, high moisture content or insufficient sample provided.
2. Duplicate data shown within this report that states the word "BATCH" is a Batch Duplicate from outside of your sample batch, but within the laboratory sample batch at a 1:10 ratio. The Parent and Duplicate data shown is not data from your samples.
3. pH and Free Chlorine analysed in the laboratory - Analysis on this test must begin within 30 minutes of sampling. Therefore, laboratory analysis is unlikely to be completed within holding time.Analysis will begin as soon as possible after sample receipt.
4. Recovery Data (Spikes & Surrogates) - where chromatographic interference does not allow the determination of recovery the term "INT" appears against that analyte.
5. For Matrix Spikes and LCS results a dash "-" in the report means that the specific analyte was not added to the QC sample.
6. Duplicate RPDs are calculated from raw analytical data thus it is possible to have two sets of data.

Sample History

Where samples are submitted/analysed over several days, the last date of extraction is reported.

If the date and time of sampling are not provided, the Laboratory will not be responsible for compromised results should testing be performed outside the recommended holding time.

Description	Testing Site	Extracted	Holding Time
Total Recoverable Hydrocarbons - 1999 NEPM Fractions	Brisbane	Jun 26, 2023	7 Days
- Method: LTM-ORG-2010 TRH C6-C40			
BTEX	Brisbane	Jun 26, 2023	14 Days
- Method: USEPA SW846 8260			
Total Recoverable Hydrocarbons - 2013 NEPM Fractions	Brisbane	Jun 26, 2023	7 Days
- Method: LTM-ORG-2010 TRH C6-C40			
Total Recoverable Hydrocarbons - 2013 NEPM Fractions	Brisbane	Jun 26, 2023	7 Days
- Method: LTM-ORG-2010 TRH C6-C40			
Ammonia (as N)	Melbourne	Jun 22, 2023	28 Days
- Method: LTM-INO-4450 Determination of Nitrogen Species by Discrete Analyser			
Chloride	Melbourne	Jun 22, 2023	28 Days
- Method: LTM-INO-4090 Chloride by Discrete Analyser			
Conductivity (at 25 °C)	Melbourne	Jun 22, 2023	28 Days
- Method: LTM-INO-4030 Conductivity			
Fluoride	Melbourne	Jun 22, 2023	28 Days
- Method: Ion selective electrode (ISE) by APHA 4500-F B, C and in-house method LTM-INO-4150			
Nitrate (as N)	Melbourne	Jun 22, 2023	28 Days
- Method: LTM-INO-4450 Determination of Nitrogen Species by Discrete Analyser			
Nitrite (as N)	Melbourne	Jun 22, 2023	2 Days
- Method: LTM-INO-4450 Determination of Nitrogen Species by Discrete Analyser			
pH (at 25 °C)	Melbourne	Jun 22, 2023	0 Hours
- Method: LTM-GEN-7090 pH in water by ISE			
Phosphorus reactive (as P)	Melbourne	Jun 22, 2023	2 Days
- Method: APHA 4500-P			
Sulphate (as S)	Melbourne	Jun 22, 2023	28 Days
- Method: LTM-INO-4110 Sulfate by Discrete Analyser			
Total Dissolved Solids Dried at 180 °C ± 2 °C	Melbourne	Jul 05, 2023	28 Days
- Method: LTM-INO-4170 Total Dissolved Solids in Water			
Alkalinity (speciated)	Melbourne	Jun 22, 2023	14 Days
- Method: LTM-INO-4250 Alkalinity by Electrometric Titration			
Alkali Metals	Melbourne	Jun 22, 2023	180 Days
- Method: LTM-MET-3010 Alkali Metals Sulfur Silicon Phosphorus by ICP-AES			
Cyanide (free)	Melbourne	Jun 22, 2023	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
Cyanide (total)	Melbourne	Jun 22, 2023	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
Cyanide (weak acid dissoc.)	Melbourne	Jun 22, 2023	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
Heavy Metals	Brisbane	Jun 26, 2023	28 Days
- Method: LTM-MET-3040 Metals in Waters, Soils & Sediments by ICP-MS			
Heavy Metals (filtered)	Brisbane	Jun 26, 2023	180 Days
- Method: LTM-MET-3040 Metals in Waters, Soils & Sediments by ICP-MS			
Metals M7	Brisbane	Jun 21, 2023	180 Days
- Method: USEPA 6010/6020 Heavy Metals			
Metals M7 filtered	Brisbane	Jun 21, 2023	180 Days
- Method: USEPA 6010/6020 Heavy Metals			
Per- and Polyfluoroalkyl Substances (PFASs)			
Perfluoroalkyl carboxylic acids (PFCAs)	Brisbane	Jun 26, 2023	28 Days
- Method: LTM-ORG-2100 Per- and Polyfluoroalkyl Substances (PFAS)			
Perfluoroalkyl sulfonamido substances	Brisbane	Jun 26, 2023	28 Days
- Method: LTM-ORG-2100 Per- and Polyfluoroalkyl Substances (PFAS)			

Description	Testing Site	Extracted	Holding Time
Perfluoroalkyl sulfonic acids (PFSAs)	Brisbane	Jun 26, 2023	28 Days
- Method: LTM-ORG-2100 Per- and Polyfluoroalkyl Substances (PFAS)			
n:2 Fluorotelomer sulfonic acids (n:2 FTSAs)	Brisbane	Jun 26, 2023	28 Days

Internal Quality Control Review and Glossary

General

1. Laboratory QC results for Method Blanks, Duplicates, Matrix Spikes, and Laboratory Control Samples follows guidelines delineated in the National Environment Protection (Assessment of Site Contamination) Measure 1999, as amended May 2013 and are included in this QC report where applicable. Additional QC data may be available on request.
2. All soil/sediment/solid results are reported on a dry basis, unless otherwise stated.
3. All biota/food results are reported on a wet weight basis on the edible portion, unless otherwise stated.
4. Actual LORs are matrix dependant. Quoted LORs may be raised where sample extracts are diluted due to interferences.
5. Results are uncorrected for matrix spikes or surrogate recoveries except for PFAS compounds.
6. SVOC analysis on waters are performed on homogenised, unfiltered samples, unless noted otherwise.
7. Samples were analysed on an 'as received' basis.
8. Information identified on this report with blue colour, indicates data provided by customer that may have an impact on the results.
9. This report replaces any interim results previously issued.

Holding Times

Please refer to 'Sample Preservation and Container Guide' for holding times (QS3001).

For samples received on the last day of holding time, notification of testing requirements should have been received at least 6 hours prior to sample receipt deadlines as stated on the SRA.

If the Laboratory did not receive the information in the required timeframe, and regardless of any other integrity issues, suitably qualified results may still be reported.

Holding times apply from the date of sampling, therefore compliance to these may be outside the laboratory's control.

For VOCs containing vinyl chloride, styrene and 2-chloroethyl vinyl ether the holding time is 7 days however for all other VOCs such as BTEX or C6-10 TRH then the holding time is 14 days.

Units

mg/kg: milligrams per kilogram
mg/L: milligrams per litre
µg/L: micrograms per litre
ppm: parts per million
ppb: parts per billion
%: Percentage
org/100 mL: Organisms per 100 millilitres
NTU: Nephelometric Turbidity Units
MPN/100 mL: Most Probable Number of organisms per 100 millilitres
CFU: Colony forming unit

Terms

APHA	American Public Health Association
COC	Chain of Custody
CP	Client Parent - QC was performed on samples pertaining to this report
CRM	Certified Reference Material (ISO17034) - reported as percent recovery.
Dry	Where a moisture has been determined on a solid sample the result is expressed on a dry basis.
Duplicate	A second piece of analysis from the same sample and reported in the same units as the result to show comparison.
LOR	Limit of Reporting.
LCS	Laboratory Control Sample - reported as percent recovery.
Method Blank	In the case of solid samples these are performed on laboratory certified clean sands and in the case of water samples these are performed on de-ionised water.
NCP	Non-Client Parent - QC performed on samples not pertaining to this report, QC is representative of the sequence or batch that client samples were analysed within.
RPD	Relative Percent Difference between two Duplicate pieces of analysis.
SPIKE	Addition of the analyte to the sample and reported as percentage recovery.
SRA	Sample Receipt Advice
Surr - Surrogate	The addition of a like compound to the analyte target and reported as percentage recovery.
TBTO	Tributyltin oxide (*bis*-tributyltin oxide) - individual tributyltin compounds cannot be identified separately in the environment however free tributyltin was measured and its values were converted stoichiometrically into tributyltin oxide for comparison with regulatory limits.
TCLP	Toxicity Characteristic Leaching Procedure
TEQ	Toxic Equivalency Quotient or Total Equivalence
QSM	US Department of Defense Quality Systems Manual Version 5.4
US EPA	United States Environmental Protection Agency
WA DWER	Sum of PFBA, PFPeA, PFHxA, PFHpA, PFOA, PFBS, PFHxS, PFOS, 6:2 FTSA, 8:2 FTSA

QC - Acceptance Criteria

The acceptance criteria should be used as a guide only and may be different when site specific Sampling Analysis and Quality Plan (SAQP) have been implemented

RPD Duplicates: Global RPD Duplicates Acceptance Criteria is 30% however the following acceptance guidelines are equally applicable:

Results <10 times the LOR: No Limit

Results between 10-20 times the LOR: RPD must lie between 0-50%

Results >20 times the LOR: RPD must lie between 0-30%

NOTE: pH duplicates are reported as a range not as RPD

Surrogate Recoveries: Recoveries must lie between 20-130% for Speciated Phenols & 50-150% for PFAS. SVOCs recoveries 20 – 150%

PFAS field samples that contain surrogate recoveries in excess of the QC limit designated in QSM 5.4 where no positive PFAS results have been reported have been reviewed and no data was affected.

QC Data General Comments

1. Where a result is reported as a less than (<), higher than the nominated LOR, this is due to either matrix interference, extract dilution required due to interferences or contaminant levels within the sample, high moisture content or insufficient sample provided.
2. Duplicate data shown within this report that states the word "BATCH" is a Batch Duplicate from outside of your sample batch, but within the laboratory sample batch at a 1:10 ratio. The Parent and Duplicate data shown is not data from your samples.
3. pH and Free Chlorine analysed in the laboratory - Analysis on this test must begin within 30 minutes of sampling. Therefore, laboratory analysis is unlikely to be completed within holding time.Analysis will begin as soon as possible after sample receipt.
4. Recovery Data (Spikes & Surrogates) - where chromatographic interference does not allow the determination of recovery the term "INT" appears against that analyte.
5. For Matrix Spikes and LCS results a dash "-" in the report means that the specific analyte was not added to the QC sample.
6. Duplicate RPDs are calculated from raw analytical data thus it is possible to have two sets of data.

Comments

V2 issued to include repeat results for TDS

Sample Integrity

Custody Seals Intact (if used)	N/A
Attempt to Chill was evident	Yes
Sample correctly preserved	Yes
Appropriate sample containers have been used	Yes
Sample containers for volatile analysis received with minimal headspace	Yes
Samples received within HoldingTime	Yes
Some samples have been subcontracted	No

Qualifier Codes/Comments

Code	Description
N01	F2 is determined by arithmetically subtracting the "naphthalene" value from the ">C10-C16" value. The naphthalene value used in this calculation is obtained from volatiles (Purge & Trap analysis).
N02	Where we have reported both volatile (P&T GCMS) and semivolatile (GCMS) naphthalene data, results may not be identical. Provided correct sample handling protocols have been followed, any observed differences in results are likely to be due to procedural differences within each methodology. Results determined by both techniques have passed all QAQC acceptance criteria, and are entirely technically valid.
N04	F1 is determined by arithmetically subtracting the "Total BTEX" value from the "C6-C10" value. The "Total BTEX" value is obtained by summing the concentrations of BTEX analytes. The "C6-C10" value is obtained by quantitating against a standard of mixed aromatic/aliphatic analytes.
N11	Isotope dilution is used for calibration of each native compound for which an exact labelled analogue is available (Isotope Dilution Quantitation). The isotopically labelled analogues allow identification and recovery correction of the concentration of the associated native PFAS compounds.
N15	Where the native PFAS compound does not have labelled analogue then the quantification is made using the Extracted Internal Standard Analyte with the closest retention time to the analyte and no recovery correction has been made (Internal Standard Quantitation).
Q15	The RPD reported passes Eurofins Environment Testing's QC - Acceptance Criteria as defined in the Internal Quality Control Review and Glossary page of this report.
R05	Theoretically the total result should be greater or equal to the dissolved concentration. However the difference reported is within the uncertainty of the individual tests

All results are within the acceptance criteria

Note: The hot acid digest does not always determine 'total' metals. Refractory elements such as Iron and Aluminium and some base metals (particularly Chromium) show lower recoveries depending on their form within the sample matrix. Silicates and oxides are normally less soluble than elements in metallic or salt forms. The acceptance criteria for this reference material is based on histories of analyte recoveries using the nitric acid based digestion procedures.

ANALYTICAL REPORT

JOB NO: SAL28618
CLIENT ORDER: 722092

METHODS OF PREPARATION AND ANALYSIS

The tests contained in this report have been carried out on the samples as received by the laboratory. In the case where an analyte or group of analytes are received outside of recommended holding times, the analysis will proceed and the report annotated. Analysis is carried out within analyte holding times where possible.

P3	Sample dried, jaw crushed and sieved at 1mm
WA1	pH - In House Method A8.40 (1:5 soil/water extract) Determined by APHA 4500B
WA2	Conductivity-In House Method A8.25 (1:5 soil/water extract) Determined by APHA 2510B
C48	Total Organic Carbon - AS1289.4.1.1
S7	Cation Exchange Capacity & Exchangeable/Soluble Cations Determined by Silver Thiourea Method CEC-1
M4	Refractory Element - Digestion Method 3050 (HNO_3/H_2O_2) Element determined by APHA 3111D (Flame AAS)
M7	Hydride Element - Digestion Method 7061 (HNO_3/H_2SO_4) Element determined by APHA 3114B (Hydride Generation AAS)
M1	Base Metal - Digestion Method 3050 (HNO_3/H_2O_2) Element determined by APHA 3111B (Flame AAS)

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- As per QWI – EN55-3 Data Interpreting Procedures, Ionic balances are typically calculated using Major Anions - Chloride, Alkalinity and Sulfate; and Major Cations - Calcium, Magnesium, Potassium and Sodium. Where applicable and dependent upon sample matrix, the Ionic Balance may also include the additional contribution of Ammonia, Dissolved Metals by ICPMS and H+ to the Cations and Nitrate, SiO2 and Fluoride to the Anions.
- It has been noted that EK025SF (Free Cyanide by SFA) is greater than EK028SF (WAD Cyanide by SFA) for some samples, however this difference is within the limits of experimental variation.
- EK058G, EA005-P, EA015H, ED037-P, ED041G, ED045G, EK040P, EK055G, EK057G, EK059G, EK071G conducted by ALS Townsville, NATA accreditation no. 825, (Site no. 23472 for Chemical Testing and Site no. 23313 for Biological Testing)
- All remaining analysis will be conducted by ALS Environmental, Brisbane, NATA accreditation no. 825, Site No. 818.
- It is recognised that EG020T (Total Metals by ICP-MS) is less than EG020F (Dissolved Metals by ICP-MS) for some samples. However, the difference is within experimental variation of the methods.
- Please be aware that APHA/NEPM recommends water and soil samples be chilled to less than or equal to 6°C for chemical analysis, and less than or equal to 10°C but unfrozen for Microbiological analysis. Where samples are received above this temperature, it should be taken into consideration when interpreting results.
- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percentage Difference (RPD) and Acceptance Limits
- Method Blank (MB) and Laboratory Control Spike (LCS) Report; Recovery and Acceptance Limits
- Matrix Spike (MS) Report; Recovery and Acceptance Limits

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Narelle Drummond	Laboratory Manager	Townsville Inorganics, Townsville, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis. Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Key : Anonymous = Refers to samples which are not specifically part of this work order but formed part of the QC process lot
CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
RPD = Relative Percentage Difference
# = Indicates failed QC

Laboratory Duplicate (DUP) Report

The quality control term Laboratory Duplicate refers to a randomly selected intralaboratory split. Laboratory duplicates provide information regarding method precision and sample heterogeneity. The permitted ranges for the Relative Percent Deviation (RPD) of Laboratory Duplicates are specified in ALS Method QWI-EN/38 and are dependent on the magnitude of results in comparison to the level of reporting: Result < 10 times LOR: No Limit; Result between 10 and 20 times LOR: 0% - 50%; Result > 20 times LOR: 0% - 20%.

Method Blank (MB) and Laboratory Control Sample (LCS) Report

The quality control term Method / Laboratory Blank refers to an analyte free matrix to which all reagents are added in the same volumes or proportions as used in standard sample preparation. The purpose of this QC parameter is to monitor potential laboratory contamination. The quality control term Laboratory Control Sample (LCS) refers to a certified reference material, or a known interference free matrix spiked with target analytes. The purpose of this QC parameter is to monitor method precision and accuracy independent of sample matrix. Dynamic Recovery Limits are based on statistical evaluation of processed LCS.

Matrix Spike (MS) Report

The quality control term Matrix Spike (MS) refers to an intralaboratory split sample spiked with a representative set of target analytes. The purpose of this QC parameter is to monitor potential matrix effects on analyte recoveries. Static Recovery Limits as per laboratory Data Quality Objectives (DQOs). Ideal recovery ranges stated may be waived in the event of sample matrix interference.

ALS Environmental

QA/QC Compliance Assessment to assist with Quality Review

Work Order	: **ET2206834**	Page	: 1 of 14
Client	: **ENVIRONMENTAL EARTH SCIENCES**	Laboratory	: Environmental Division Townsville
Contact	: MS ANNA SHELDON	Telephone	: +61 7 4773 0000
Project	: 722092	Date Samples Received	: 23-Dec-2022
Site	: Tick Hill	Issue Date	: 09-Jan-2023
Sampler	: A.S	No. of samples received	: 10
Order number	: ----	No. of samples analysed	: 10

This report is automatically generated by the ALS LIMS through interpretation of the ALS Quality Control Report and several Quality Assurance parameters measured by ALS. This automated reporting highlights any non-conformances, facilitates faster and more accurate data validation and is designed to assist internal expert and external Auditor review. Many components of this report contribute to the overall DQO assessment and reporting for guideline compliance.

Brief method summaries and references are also provided to assist in traceability.

Summary of Outliers

Outliers : Quality Control Samples

This report highlights outliers flagged in the Quality Control (QC) Report.

- **NO Method Blank value outliers occur.**
- **NO Duplicate outliers occur.**
- **NO Laboratory Control outliers occur.**
- **Matrix Spike outliers exist - please see following pages for full details.**
- **For all regular sample matrices, NO surrogate recovery outliers occur.**

Outliers : Analysis Holding Time Compliance

- **Analysis Holding Time Outliers exist - please see following pages for full details.**

Outliers : Frequency of Quality Control Samples

- **NO Quality Control Sample Frequency Outliers exist.**

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **WATER**

Analysis Holding Time Compliance

If samples are identified below as having been analysed or extracted outside of recommended holding times, this should be taken into consideration when interpreting results.

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times (referencing USEPA SW 846, APHA, AS and NEPM) based on the sample container provided. Dates reported represent first date of extraction or analysis and preclude subsequent dilutions and reruns. A listing of breaches (if any) is provided herein.

Holding time for leachate methods (e.g. TCLP) vary according to the analytes reported. Assessment compares the leach date with the shortest analyte holding time for the equivalent soil method. These are: organics 14 days, mercury 28 days & other metals 180 days. A recorded breach does not guarantee a breach for all non-volatile parameters.

Holding times for ***VOC in soils*** vary according to analytes of interest. Vinyl Chloride and Styrene holding time is 7 days; others 14 days. A recorded breach does not guarantee a breach for all VOC analytes and should be verified in case the reported breach is a false positive or Vinyl Chloride and Styrene are not key analytes of interest/concern.

Matrix: **WATER**

Evaluation: × = Holding time breach ; ✓ = Within holding time.

Quality Control Parameter Frequency Compliance

The following report summarises the frequency of laboratory QC samples analysed within the analytical lot(s) in which the submitted sample(s) was(were) processed. Actual rate should be greater than or equal to the expected rate. A listing of breaches is provided in the Summary of Outliers.

Matrix: **WATER**

Evaluation: × = Quality Control frequency not within specification ; ✓ = Quality Control frequency within specification.

Quality Control Sample Type		Count		Rate (%)			Quality Control Specification

Brief Method Summaries

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the US EPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request. The following report provides brief descriptions of the analytical procedures employed for results reported in the Certificate of Analysis. Sources from which ALS methods have been developed are provided within the Method Descriptions.

Analytical Methods	Method	Matrix	Method Descriptions
pH by Auto Titrator	EA005-P	WATER	In house: Referenced to APHA 4500 H+ B. This procedure determines pH of water samples by automated ISE. This method is compliant with NEPM Schedule B(3)
Total Dissolved Solids (High Level)	EA015H	WATER	In house: Referenced to APHA 2540C. A gravimetric procedure that determines the amount of `filterable` residue in an aqueous sample. A well-mixed sample is filtered through a glass fibre filter (1.2um). The filtrate is evaporated to dryness and dried to constant weight at 180+/-5C. This method is compliant with NEPM Schedule B(3)
Standard Anions - by IC	ED009	WATER	In house: Referenced to APHA 4110. This method is compliant with NEPM Schedule B(3)
Alkalinity by Auto Titrator	ED037-P	WATER	In house: Referenced to APHA 2320 B This procedure determines alkalinity by automated measurement (e.g. PC Titrate) on a settled supernatant aliquot of the sample using pH 4.5 for indicating the total alkalinity end-point. This method is compliant with NEPM Schedule B(3)
Sulfate (Turbidimetric) as SO4 2- by Discrete Analyser	ED041G	WATER	In house: Referenced to APHA 4500-SO4. Dissolved sulfate is determined in a 0.45um filtered sample. Sulfate ions are converted to a barium sulfate suspension in an acetic acid medium with barium chloride. Light absorbance of the BaSO4 suspension is measured by a photometer and the SO4-2 concentration is determined by comparison of the reading with a standard curve. This method is compliant with NEPM Schedule B(3)
Chloride by Discrete Analyser	ED045G	WATER	In house: Referenced to APHA 4500 Cl - G.The thiocyanate ion is liberated from mercuric thiocyanate through sequestration of mercury by the chloride ion to form non-ionised mercuric chloride. In the presence of ferric ions the liberated thiocynate forms highly-coloured ferric thiocynate which is measured at 480 nm.
Major Cations - Dissolved	ED093F	WATER	In house: Referenced to APHA 3120 and 3125; USEPA SW 846 - 6010 and 6020; Cations are determined by either ICP-AES or ICP-MS techniques. This method is compliant with NEPM Schedule B(3) Sodium Adsorption Ratio is calculated from Ca, Mg and Na which determined by ALS in house method QWI-EN/ED093F. This method is compliant with NEPM Schedule B(3) Hardness parameters are calculated based on APHA 2340 B. This method is compliant with NEPM Schedule B(3)
Dissolved Metals by ICP-MS - Suite A	EG020A-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite A	EG020A-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Dissolved Metals by ICP-MS - Suite B	EG020B-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.

Analytical Methods	Method	Matrix	Method Descriptions
Total Metals by ICP-MS - Suite B	EG020B-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Dissolved Metals by ICP-MS - Suite E	EG020E-F	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. Samples are 0.45µm filtered prior to analysis. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Total Metals by ICP-MS - Suite E	EG020E-T	WATER	In house: Referenced to APHA 3125; USEPA SW846 - 6020, ALS QWI-EN/EG020. The ICPMS technique utilizes a highly efficient argon plasma to ionize selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector.
Free CN by Segmented Flow Analyser	EK025SF	WATER	In house: Referenced to ASTM D7237, APHA 4500-CN-C&O and ISO 14403: Using an automated segmented flow analyser, a sample at high pH (sodium hydroxide preserved) is buffered to pH 6.0. The hydrogen cyanide present passes across a gas dialysis membrane into an acceptor stream consisting of 0.01 M sodium hydroxide. The acceptor stream mixes with a buffer at pH 5.2 and reacts with chloramine-T to form cyanogen chloride. Cyanogen chloride reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour, measured at 600nm. This method is compliant with NEPM Schedule B(3)
Total Cyanide by Segmented Flow Analyser	EK026SF	WATER	In house: Referenced to APHA 4500-CN C&O / ASTM D7511 / ISO 14403. Sodium hydroxide preserved samples are introduced into an automated segmented flow analyser. Complex bound cyanide is decomposed in a continuously flowing stream, at a pH of 3.8, by the effect of UV light. A UV-B lamp (312 nm) and a decomposition spiral of borosilicate glass are used to filter out UV light with a wavelength of less than 290 nm thus preventing the conversion of thiocyanate into cyanide. The hydrogen cyanide present at a pH of 3.8 is separated by gas dialysis. The hydrogen cyanide is then determined photometrically, based on the reaction of cyanide with chloramine-T to form cyanogen chloride. This then reacts with 4-pyridine carboxylic acid and 1,3-dimethylbarbituric acid to give a red colour which is measured at 600 nm. This method is compliant with NEPM Schedule B(3)
Weak Acid Dissociable Cyanide by Segmented Flow Analyser	EK028SF	WATER	In house: Referenced to APHA 4500-CN C&O / ISO 14403. Samples preserved with sodium hydroxide are introduced into an automated segmented flow analyser. Hydrogen cyanide is liberated from a slightly acidified (pH 4.5) and is dialysed. Tight cyanide complexes that would not be amenable to oxidation by chlorine are not converted. Iron cyanide complexes are precipitated with zinc acetate. Liberated HCN diffuses through a membrane into a stream of sodium hydroxide where it is carried as CN- The cyanide in caustic solution is buffered to pH 5.2 and further converted to cyanogen chloride by reaction with chloramine-T. Cyanogen chloride subsequently reacts with 4 ¿pyridine carboxylic and 1,3 - dimethylbarbituric acids to give a red colour complex. This colour is measured at 600 nm. This method is compliant with NEPM Schedule B(3)
Fluoride by Auto Titrator	EK040P	WATER	In house: Referenced to APHA 4500-F C: CDTA is added to the sample to provide a uniform ionic strength background, adjust pH, and break up complexes. Fluoride concentration is determined by either manual or automatic ISE measurement. This method is compliant with NEPM Schedule B(3)
Ammonia as N by Discrete analyser	EK055G	WATER	In house: Referenced to APHA 4500-NH3 G Ammonia is determined by direct colorimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)

Analytical Methods	Method	Matrix	Method Descriptions
Nitrite as N by Discrete Analyser	EK057G	WATER	In house: Referenced to APHA 4500-NO2- B. Nitrite is determined by direct colourimetry by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Nitrate as N by Discrete Analyser	EK058G	WATER	In house: Referenced to APHA 4500-NO3- F. Nitrate is reduced to nitrite by way of a chemical reduction followed by quantification by Discrete Analyser. Nitrite is determined seperately by direct colourimetry and result for Nitrate calculated as the difference between the two results. This method is compliant with NEPM Schedule B(3)
Reactive Phosphorus as P-By Discrete Analyser	EK071G	WATER	In house: Referenced to APHA 4500-P F Ammonium molybdate and potassium antimonyl tartrate reacts in acid medium with othophosphate to form a heteropoly acid -phosphomolybdic acid - which is reduced to intensely coloured molybdenum blue by ascorbic acid. Quantification is by Discrete Analyser. This method is compliant with NEPM Schedule B(3)
Ionic Balance by PCT DA and Turbi SO4 DA	* EN055 - PG	WATER	In house: Referenced to APHA 1030F. This method is compliant with NEPM Schedule B(3)

Preparation Methods	Method	Matrix	Method Descriptions
Digestion for Total Recoverable Metals	EN25	WATER	In house: Referenced to USEPA SW846-3005. Method 3005 is a Nitric/Hydrochloric acid digestion procedure used to prepare surface and ground water samples for analysis by ICPAES or ICPMS. This method is compliant with NEPM Schedule B(3)

Dates

Date Samples Received	: 23-Dec-2022 08:35	Issue Date	: 23-Dec-2022
Client Requested Due Date	: 09-Jan-2023	Scheduled Reporting Date	: **09-Jan-2023**

Delivery Details

Mode of Delivery	: Carrier	Security Seal	: Intact.
No. of coolers/boxes	: 1	Temperature	: 16.7°C - Ice Bricks present
Receipt Detail	: Large Esky	No. of samples received / analysed	: 10 / 10

General Comments

- This report contains the following information:
  - Sample Container(s)/Preservation Non-Compliances
  - Summary of Sample(s) and Requested Analysis
  - Proactive Holding Time Report
  - Requested Deliverables
- Please be advised, fluro yellow bottles were provided, however there is no analysis requested for the bottles. Bottles have been put on hold in Townsville. If this is incorrect please contact Client Services at alsenviroTownsville@alsglobal.com.
- **23/12/2022: SRN has been resent to acknowledge that that low level CN has been added and Bromide. For any further information regarding these adjustments please contact client services at ALSEnviro.Brisbane@alsglobal.com.**
- Discounted Package Prices apply only when specific ALS Group Codes ('W', 'S', 'NT' suites) are referenced on COCs.
- EK058G, EA005-P, EA015H, ED037-P, ED041G, ED045G, EK040P, EK055G, EK057G, EK059G, EK071G conducted by ALS Townsville, NATA accreditation no. 825, (Site no. 23472 for Chemical Testing and Site no. 23313 for Biological Testing)
- Please direct any turn around / technical queries to the laboratory contact designated above.
- Sample Disposal - Aqueous (3 weeks), Solid (2 months ± 1 week) from receipt of samples.
- All remaining analysis will be conducted by ALS Environmental, Brisbane, NATA accreditation no. 825, Site No. 818.
- Please be aware that APHA/NEPM recommends water and soil samples be chilled to less than or equal to 6°C for chemical analysis, and less than or equal to 10°C but unfrozen for Microbiological analysis. Where samples are received above this temperature, it should be taken into consideration when interpreting results. Refer to ALS EnviroMail 85 for ALS recommendations of the best practice for chilling samples after sampling and for maintaining a cool temperature during transit.
- **Please refer to the Proactive Holding Time Report table below which summarises breaches of recommended holding times that have occurred prior to samples/instructions being received at the laboratory. The laboratory will process these samples unless instructions are received from you indicating you do not wish to proceed. The absence of this summary table indicates that all samples have been received within the recommended holding times for the analysis requested.**

Sample Container(s)/Preservation Non-Compliances

All comparisons are made against pretreatment/preservation AS, APHA, USEPA standards.

Summary of Sample(s) and Requested Analysis

Some items described below may be part of a laboratory process necessary for the execution of client requested tasks. Packages may contain additional analyses, such as the determination of moisture content and preparation tasks, that are included in the package.
If no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component

Sample Receipt Advice

Company name:	Environmental Earth Sciences QLD
Contact name:	Anna Sheldon
Project name:	TICK HILL
Project ID:	722092
Turnaround time:	10 Day
Date/Time received	Dec 29, 2022 1:05 PM
Eurofins reference	953272

Sample Information

- ✓ A detailed list of analytes logged into our LIMS, is included in the attached summary table.
- ✓ All samples have been received as described on the above COC.
- ✓ COC has been completed correctly.
- ✓ Attempt to chill was evident.
- ✓ Appropriately preserved sample containers have been used.
- ✓ All samples were received in good condition.
- ✓ Samples have been provided with adequate time to commence analysis in accordance with the relevant holding times.
- ✓ Appropriate sample containers have been used.
- ✓ Sample containers for volatile analysis received with zero headspace.
- ✗ Split sample sent to requested external lab.
- ✗ Some samples have been subcontracted.
- N/A Custody Seals intact (if used).

Notes

As these samples were received after the 15th, a 10 day TAT has been applied due to the holiday period. Tungsten (W) analysis is not able to be performed.

Contact

If you have any questions with respect to these samples, please contact your Analytical Services Manager:

Peter Brand on phone : 0436 360 123 or by email: PeterBrand@eurofins.com

Results will be delivered electronically via email to Anna Sheldon - asheldon@environmentalearthsciences.com.

Note: A copy of these results will also be delivered to the general Environmental Earth Sciences QLD email address.

Global Leader - Results you can trust

Sample History

Where samples are submitted/analysed over several days, the last date of extraction is reported.

If the date and time of sampling are not provided, the Laboratory will not be responsible for compromised results should testing be performed outside the recommended holding time.

Description	Testing Site	Extracted	Holding Time
Eurofins Suite B19C: NO3/NO2/NOx/Reactive P/NH3			
Ammonia (as N)	Melbourne	Jan 03, 2023	28 Days
- Method: APHA 4500-NH3 Ammonia Nitrogen by FIA			
Nitrate & Nitrite (as N)	Melbourne	Jan 03, 2023	28 Days
- Method: LTM-INO-4120 Analysis of NOx NO2 NH3 by FIA			
Nitrate (as N)	Melbourne	Jan 03, 2023	28 Days
- Method: LTM-INO-4120 Analysis of NOx NO2 NH3 by FIA			
Nitrite (as N)	Melbourne	Jan 03, 2023	2 Days
- Method: LTM-INO-4120 Analysis of NOx NO2 NH3 by FIA			
Phosphorus reactive (as P)	Melbourne	Jan 03, 2023	2 Days
- Method: APHA 4500-P			
Eurofins Suite B11F: Cl/SO4/Alkalinity/Total F			
Chloride	Melbourne	Jan 03, 2023	28 Days
- Method: LTM-INO-4090 Chloride by Discrete Analyser			
Fluoride	Melbourne	Jan 03, 2023	28 Days
- Method: in-house method LTM-INO-4390 Fluoride by Discrete Analyser			
Sulphate (as SO4)	Melbourne	Jan 03, 2023	28 Days
- Method: LTM-INO-4110 Sulfate by Discrete Analyser			
Alkalinity (speciated)	Melbourne	Jan 03, 2023	14 Days
- Method: LTM-INO-4250 Alkalinity by Electrometric Titration			
Conductivity (at 25 °C)	Melbourne	Jan 03, 2023	28 Days
- Method: LTM-INO-4030 Conductivity			
Cyanide (free)	Melbourne	Jan 03, 2023	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
Cyanide (total)	Melbourne	Jan 03, 2023	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
Cyanide (weak acid dissoc.)	Melbourne	Jan 03, 2023	14 Days
- Method: LTM-INO-4020 Total Free WAD Cyanide by CFA			
pH (at 25 °C)	Melbourne	Jan 03, 2023	0 Hours
- Method: LTM-GEN-7090 pH in water by ISE			
Heavy Metals	Melbourne	Jan 03, 2023	28 Days
- Method: LTM-MET-3040 Metals in Waters, Soils & Sediments by ICP-MS			
Heavy Metals (filtered)	Melbourne	Jan 03, 2023	180 Days
- Method: LTM-MET-3040 Metals in Waters, Soils & Sediments by ICP-MS			
Eurofins Suite B11C: Na/K/Ca/Mg	Melbourne	Jan 03, 2023	180 Days
- Method: LTM-MET-3010 Alkali Metals by ICP-AES

Internal Quality Control Review and Glossary

General

1. Laboratory QC results for Method Blanks, Duplicates, Matrix Spikes, and Laboratory Control Samples follows guidelines delineated in the National Environment Protection (Assessment of Site Contamination) Measure 1999, as amended May 2013 and are included in this QC report where applicable. Additional QC data may be available on request.
2. All soil/sediment/solid results are reported on a dry basis, unless otherwise stated.
3. All biota/food results are reported on a wet weight basis on the edible portion, unless otherwise stated.
4. Actual LORs are matrix dependant. Quoted LORs may be raised where sample extracts are diluted due to interferences.
5. Results are uncorrected for matrix spikes or surrogate recoveries except for PFAS compounds.
6. SVOC analysis on waters are performed on homogenised, unfiltered samples, unless noted otherwise.
7. Samples were analysed on an 'as received' basis.
8. Information identified on this report with blue colour, indicates data provided by customer that may have an impact on the results.
9. This report replaces any interim results previously issued.

Holding Times

Please refer to 'Sample Preservation and Container Guide' for holding times (QS3001).

For samples received on the last day of holding time, notification of testing requirements should have been received at least 6 hours prior to sample receipt deadlines as stated on the SRA.

If the Laboratory did not receive the information in the required timeframe, and regardless of any other integrity issues, suitably qualified results may still be reported.

Holding times apply from the date of sampling, therefore compliance to these may be outside the laboratory's control.

For VOCs containing vinyl chloride, styrene and 2-chloroethyl vinyl ether the holding time is 7 days however for all other VOCs such as BTEX or C6-10 TRH then the holding time is 14 days.

Units

mg/kg: milligrams per kilogram
mg/L: milligrams per litre
µg/L: micrograms per litre
ppm: parts per million
ppb: parts per billion
%: Percentage
org/100 mL: Organisms per 100 millilitres
NTU: Nephelometric Turbidity Units
MPN/100 mL: Most Probable Number of organisms per 100 millilitres
CFU: Colony forming unit

Terms

APHA	American Public Health Association
COC	Chain of Custody
CP	Client Parent - QC was performed on samples pertaining to this report
CRM	Certified Reference Material (ISO17034) - reported as percent recovery.
Dry	Where a moisture has been determined on a solid sample the result is expressed on a dry basis.
Duplicate	A second piece of analysis from the same sample and reported in the same units as the result to show comparison.
LOR	Limit of Reporting.
LCS	Laboratory Control Sample - reported as percent recovery.
Method Blank	In the case of solid samples these are performed on laboratory certified clean sands and in the case of water samples these are performed on de-ionised water.
NCP	Non-Client Parent - QC performed on samples not pertaining to this report, QC is representative of the sequence or batch that client samples were analysed within.
RPD	Relative Percent Difference between two Duplicate pieces of analysis.
SPIKE	Addition of the analyte to the sample and reported as percentage recovery.
SRA	Sample Receipt Advice
Surr - Surrogate	The addition of a like compound to the analyte target and reported as percentage recovery.
TBTO	Tributyltin oxide (*bis*-tributyltin oxide) - individual tributyltin compounds cannot be identified separately in the environment however free tributyltin was measured and its values were converted stoichiometrically into tributyltin oxide for comparison with regulatory limits.
TCLP	Toxicity Characteristic Leaching Procedure
TEQ	Toxic Equivalency Quotient or Total Equivalence
QSM	US Department of Defense Quality Systems Manual Version 5.4
US EPA	United States Environmental Protection Agency
WA DWER	Sum of PFBA, PFPeA, PFHxA, PFHpA, PFOA, PFBS, PFHxS, PFOS, 6:2 FTSA, 8:2 FTSA

QC - Acceptance Criteria

The acceptance criteria should be used as a guide only and may be different when site specific Sampling Analysis and Quality Plan (SAQP) have been implemented

RPD Duplicates: Global RPD Duplicates Acceptance Criteria is 30% however the following acceptance guidelines are equally applicable:

Results <10 times the LOR: No Limit

Results between 10-20 times the LOR: RPD must lie between 0-50%

Results >20 times the LOR : RPD must lie between 0-30%

NOTE: pH duplicates are reported as a range not as RPD

Surrogate Recoveries: Recoveries must lie between 20-130% for Speciated Phenols & 50-150% for PFAS

PFAS field samples that contain surrogate recoveries in excess of the QC limit designated in QSM 5.4 where no positive PFAS results have been reported have been reviewed and no data was affected.

QC Data General Comments

1. Where a result is reported as a less than (<), higher than the nominated LOR, this is due to either matrix interference, extract dilution required due to interferences or contaminant levels within the sample, high moisture content or insufficient sample provided.
2. Duplicate data shown within this report that states the word "BATCH" is a Batch Duplicate from outside of your sample batch, but within the laboratory sample batch at a 1:10 ratio. The Parent and Duplicate data shown is not data from your samples.
3. pH and Free Chlorine analysed in the laboratory - Analysis on this test must begin within 30 minutes of sampling. Therefore, laboratory analysis is unlikely to be completed within holding time.Analysis will begin as soon as possible after sample receipt.
4. Recovery Data (Spikes & Surrogates) - where chromatographic interference does not allow the determination of recovery the term "INT" appears against that analyte.
5. For Matrix Spikes and LCS results a dash "-" in the report means that the specific analyte was not added to the QC sample.
6. Duplicate RPDs are calculated from raw analytical data thus it is possible to have two sets of data.

Comments

Sample Integrity

Custody Seals Intact (if used)	N/A
Attempt to Chill was evident	Yes
Sample correctly preserved	Yes
Appropriate sample containers have been used	Yes
Sample containers for volatile analysis received with minimal headspace	Yes
Samples received within HoldingTime	Yes
Some samples have been subcontracted	No

Qualifier Codes/Comments

Code	Description
Q15	The RPD reported passes Eurofins Environment Testing's QC - Acceptance Criteria as defined in the Internal Quality Control Review and Glossary page of this report.

Authorised by:

Project: 722092 Tick Hill
Scenario: Migration from tailings dam
Chemical of concern: Cyanide
Model Source: Domenico 1987

Introduction:

As contaminated groundwater flows through the environment the actual rate of contaminant migration will be affected by diffusion, advestion and retardation. The acual concentrations of the pollutant generally reduces with distance from the source as a result of various attenuation factors. These include hydrodynamic dispersion and biological or chemical breakdown. This model is a three dimentional steady state model. As such it presumes an ongoing source. If the source has actually diminished with time or has been remediated then application of this model would be ultra conservative and an instantaneous point source model would be more appropriate. However as remediation at this site has not yet occured and there may be residual sources we feel this model is applicable.
The model calculated an attenuation factor based on the ratio of the modeled concentration at some distance from the source, with the inital concentration at the source. When the criteria at the receptor (abstraction well, river or in this case river bank) is multiplied by the attenuation factor a groundwater criteria can be derived for groundwater at the centre of the plume.

$$C(x,y,z,t) = \frac{C_0}{8}\exp\left\{\left(\frac{x}{2\alpha_x}\right)\left[1-\sqrt{\left(1+\frac{4\lambda\alpha_x}{v}\right)}\right]\right\}\mathrm{erfc}\left[\frac{x-vt\sqrt{(1+4\lambda\alpha_x/v)}}{\sqrt{2(\alpha_x vt)}}\right]\left\{\mathrm{erf}\left[\frac{(y+Y/2)}{2\sqrt{(\alpha_y x)}}\right]-\mathrm{erf}\left[\frac{(y-Y/2)}{2\sqrt{(\alpha_y x)}}\right]\right\}\left\{\mathrm{erf}\left[\frac{(z+Z)}{2\sqrt{(\alpha_z x)}}\right]-\mathrm{erf}\left[\frac{(z-Z)}{2\sqrt{(\alpha_z x)}}\right]\right\}$$

EXECUTIVE SUMMARY

Introduction and objectives

Environmental Earth Sciences QLD was commissioned by Tick Hill Mining Ptd Ltd to develop a hydrogeological model for Tick Hill Gold Mine, Dajarra, Queensland (the site). The site occupies mining leases ML7094, 7096 and 7097 and is located approximately 40 km south of Duchess and 140 km southeast of Mount Isa. The site covers an area of approximately 390 hectares (ha).

The investigation was required to meet the requirements of the progressive rehabilitation and closure plan (PRCP), specifically in response to a request for information (RFI) issued by the Department of Environment, Science and Innovation (DESI) in relation to the long-term pit water balance and pit water quality. The site is currently non-operational, however was previously an operational gold mine between 1990 and 1994 and tailings have been extracted for reprocessing between 2020 and 2022. The site is managed under Environmental Authority EPML00820613.

The objectives of the development of the hydrogeological model include the following:

- To use an analytical approach to determine the relationship between the mine pit and the surrounding aquifer in the long-term, including under extreme conditions;
- To determine the long-term water quality of the pit lake; and
- To determine whether there is any potential for the pit lake to impact on nearby sensitive receptors.

Findings

The findings of the development of a hydrogeological model of the pit lake at Tick Hill can be summarised as follows:

- The hydrogeological model indicates that the mine pit acts as a groundwater sink for the site, and will continue to do so under a wide range of climatic conditions.
- No plausible rainfall scenario was identified which raised the pit water level to either the level of the surrounding water-table, or to the top of the pit.
- The pit water level is controlled by the limited rainfall runoff due to the small catchment area around the pit.
- As the pit lake acts as a groundwater sink and evaporation dominates the water balance, salinity and associated dissolved ion and metal concentrations are predicted to increase over time. The expected pit salinity after 250 years was modelled at 28,000 mg/L TDS.
- Precipitation of calcite, dolomite and iron minerals is expected within the pit lake.
- No sensitive human or ecological receptors were identified that might be impacted by mine pit water quality.

Recommendations

Based on the hydrogeological model developed for the Tick Hill mine pit, the following recommendations are made:

- That the pit continue to be fenced to prevent access by visitors or stock.
- That the pit catchment continue to be controlled so that runoff inflow is limited.
- That pit water not be extracted for beneficial use without testing to determine its suitability for that use. Extracted pit water should not be discharged to watercourses.

1 INTRODUCTION

Environmental Earth Sciences QLD was commissioned by Tick Hill Mining Ptd Ltd to develop a hydrogeological model for Tick Hill Gold Mine, Dajarra, Queensland (the site). The site occupies mining leases ML7094, 7096 and 7097 and is located approximately 40 km south of Duchess and 140 km southeast of Mount Isa. The site covers an area of approximately 390 hectares (ha).

The investigation was required to meet the requirements of the progressive rehabilitation and closure plan (PRCP), specifically in response to a request for information (RFI) issued by the Department of Environment, Science and Innovation (DESI) in relation to the long-term pit water balance and pit water quality. The site is currently non-operational, however was previously an operational gold mine between 1990 and 1994 and tailings have been extracted for reprocessing between 2020 and 2022. The site is managed under Environmental Authority EPML00820613.

2 OBJECTIVES

The objectives of the development of the hydrogeological model include the following:

- To use an analytical approach to determine the relationship between the mine pit and the surrounding aquifer in the long-term, including under extreme conditions;
- To determine the long-term water quality of the pit lake; and
- To determine whether there is any potential for the pit lake to impact on nearby sensitive receptors.

3 SCOPE OF WORK

In order to achieve our objective, Environmental Earth Sciences has identified that the scope of works will comprise the following:

- Long-term pit water quality model:
    - The previous salt balance for the pit included calibration of the potential range of groundwater inflows together with groundwater salinity.
    - The pit water quality model will be updated for a period of 250 years into the future, with consideration of groundwater inflows (including typical groundwater chemistry and seepage from the tailings storage facility [TSF]), evaporation, and mineral weathering of the pit walls.

    - Relevant inputs will include groundwater and pit water chemical results, mine geochemical information and waste rock weathering data.
    - The pit water quality model will include consideration of a subset of water level scenarios developed from the pit water balance below.
- Long-term pit water balance:
    - The previous pit water balance model predicted water levels for 50 years, based on a range of rainfall scenarios. This water balance model will be updated for a period of 250 years.
    - Climatic scenarios to be included in the model will be based on recently observed conditions (data from nearby weather stations), extremes of conditions observed at nearby weather stations, and predicted potential changes to regional climatic conditions over the modelled period.
    - Examine the potential behaviour of the pit as a source or sink of groundwater in relation to the surrounding landscape under the various climatic scenarios.
    - Also included in the model will be consideration of the influence of maximum extreme short-term events and whether these have the potential to cause the pit to act as a source zone for groundwater recharge (in response to DESI RFI Item 11).
- Preparation of a report detailing the works undertaken and recommendations for further investigation, management or remediation works (if required).

4 SITE SETTING

4.1 Site identification

Site identification details are provided in **Table 1**. A plan of the regional locality of the site, along with site lot configuration is provided in **Figure 1**. **Figure 2** presents the site layout, investigation area and surrounding land-use, including the layout during operations.

4.2 Site description and layout

The site is located approximately 40 km south of the locality of Duchess, and approximately 140 km southeast of Mount Isa. Tick Hill is accessed via the Duchess Phosphate Hill Road which runs north-south 5 km to the east of the site.

The site is currently comprised of the former mine features including the flooded open pit, the tailings and decant dams and the waste rock dump. Site features are shown on **Figure 2**. Also present are the water supply tank, located on the hill to the east of site and the core yard, located south of the waste rock dump (WRD). Adjacent to the core yard are shipping containers for storage of maintenance equipment. Almost all other mining infrastructure from the original operations has been removed from site.

Table 1: Site Identification

Item	Details
Site Owner	Tick Hill Mining Pty Ltd
Address	Tick Hill Gold Mine, Dajarra, QLD
Mine leases	ML7094, ML7096, ML7097
Lot & Plan number	Lot 13 on SP309109 (part), Lot 16 on SP309110 (part)
Area (Mining lease)	390 ha lease area + 8.5 km road access
Zoning	Rural – Extractive and Mineral Resource
Current land use	Non-operational gold mine
Proposed future land use	Rehabilitated mining land
Local Government Authority	Cloncurry Shire
Coordinates (site centre)	-21.64645 Lat, 139.92561 Long
Site Location and Layout	**Figure 1 and Figure 2**

The former site layout is shown in **Figure 3** below. This aerial photograph shows the open pit (centre), tailings and decant dam to the right (south) and WRD on the left (north). Also evident is the processing plant and mine operations to the east of the tailings dams.

Recent tailings re-working has included stripping and excavation of the eastern tailings cell. Cover material and some of the tailings are stockpiled on the western tailings cell. Some tailings material has been removed from site. Equipment involved in the tailings re-working project is present on and about the tailings cells, including screening and processing plant, pumps and pipe.

For the purposes of clarity in further discussion regarding site setting or nearby activities, distances as shown on **Figure 4** are taken from the Tick Hill mine pit.

4.3 Surrounding land use

The following adjacent land uses were observed at the time of the site inspection and based on the desktop assessment:

- North: Low density grazing land. The former Trekelano Copper mine is located 19 km to the north;
- South: Low density grazing land. The Monument / Phosphate Hill mine, airstrip and village are located 12 – 26 km south of the site;
- East: Low density grazing land, Duchess Phosphate Hill Road and the Phosphate Hill branch line of the Mount Isa Railway; and
- West: Low density grazing land.

Surrounding land uses are shown on **Figure 2**. Nearby mining and exploration leases are shown on **Figure 4**.

Figure 3: Aerial photograph of site during operations (from west to east)

4.4 Environmentally Relevant Activities

The site is managed under Environmental Authority (EA) EPML00820613 for the following Environmentally Relevant Activities (ERAs):

- Resource Activity, Schedule 3, 21: A mining activity that is an ineligible ERA, other than a mining activity mentioned in items 9 to 20 (ML7094, ML7096 and ML7097);
- Ancillary, Schedule 2, 31: Mineral processing 2(a) - Processing, in a year, the following quantities of mineral products, other than coke – 1,000t to 100,000t (ML7094); and
- Ancillary, Schedule 2, 60 – Waste Disposal 2: Operating a facility for disposing of, in a year, the following quantity of waste mentioned in subsection (1)(b)(a) less than 2,000 t (ML7094).

The EA is held by Tick Hill Mining Pty Ltd.

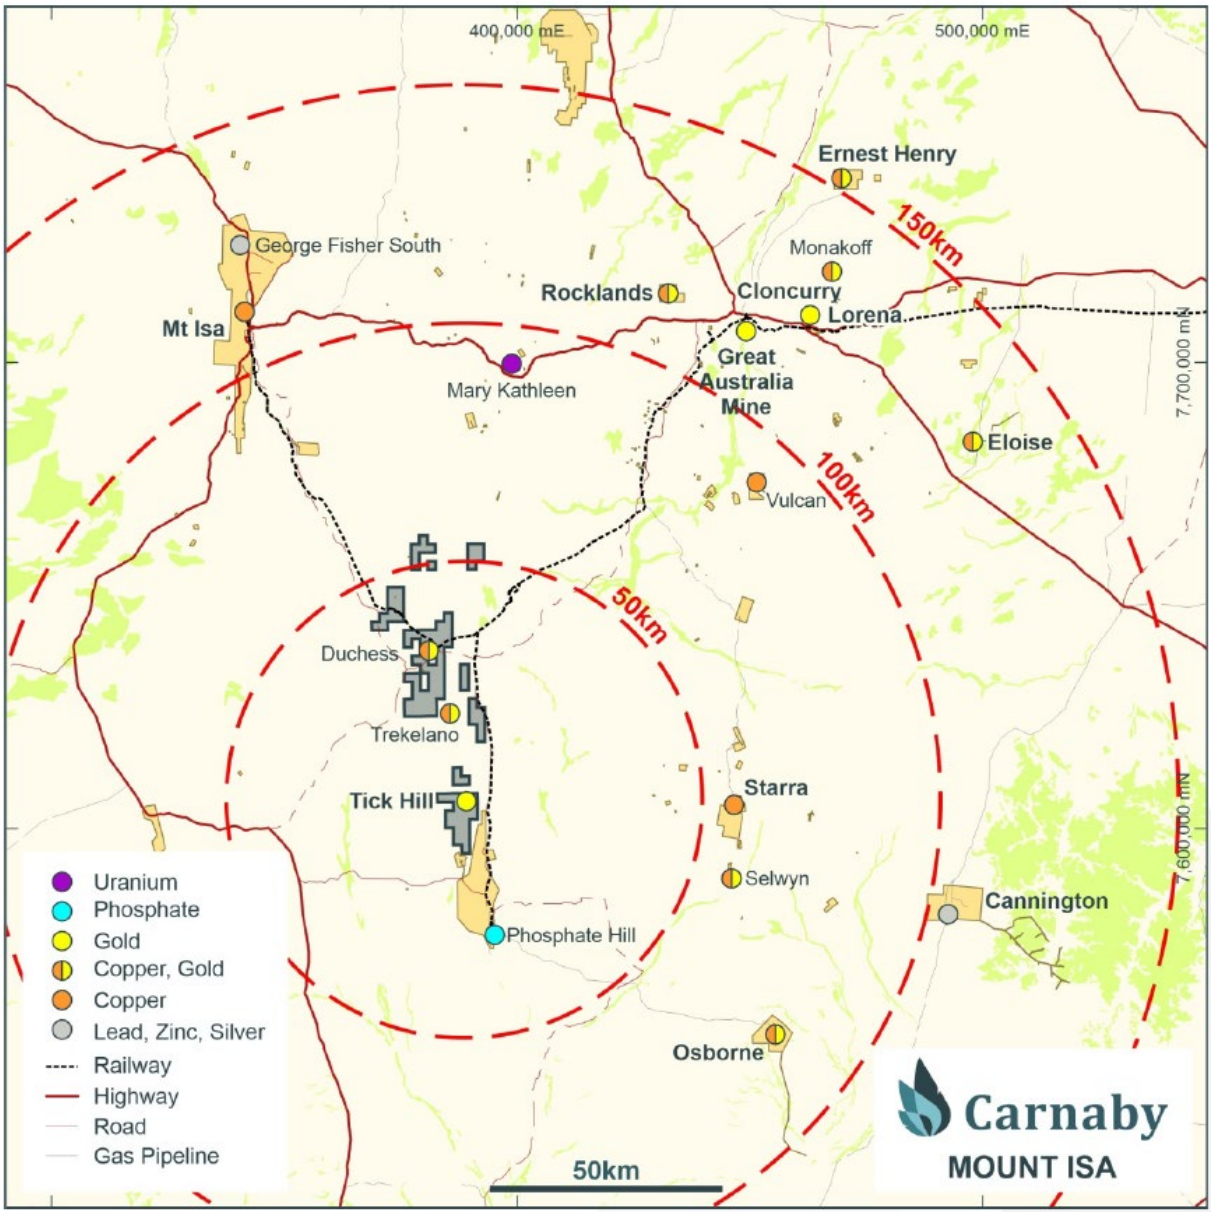

Figure 4: Mining and exploration leases within 150 km of the site

5 SITE ENVIRONMENTAL SETTING

5.1 Topography and vegetation

The regional topography is described as gently rolling to hilly terrain with flat top mesas. The site's elevation within the lease areas ranges from 320 to 450 m Australian Height Datum (mAHD) although the former operational areas of the site were between 320 and 360 mAHD (**Figure 5**). The site slopes gently to the northwest, bound by steep hills to the southeast.

Title: 1:100,000 Topography and surface water bodies

Location: Tick Hill Mine, QLD

Client: Tick Hill Mining Pty Ltd

Drawn By: A Sheldon

Date: May 2023

Figure 5

Vegetation at the site consists of regrowth open woodlands, shrubs and grasses. Vegetation type are typically described as low open woodlands dominated by Eucalyptus leucophylla (Cloncurry box) or less extensively Corymbia terminalis (long-fruited bloodwood), low open woodlands and related associations, mainly lower slopes and valleys. Open plains to the west are described as Tussock grasslands dominated by Astrebla spp. (Mitchell grass) or Dichanthium spp. (bluegrass) often with Iseilema spp. on undulating downs or clay plains.

An aerial photograph from the time of site operations indicates that the site was extensively cleared, with topsoil scraped around the tailings dams. Recent site observations indicate that site vegetation has recovered well, particularly along drainage lines and in sheltered areas, and that significant weed infestation has not occurred.

5.2 Surface water drainage and hydrology

The site is drained by several ephemeral watercourses which flow to the north and northwest. These join the larger ephemeral watercourse Petticoat Creek around 1.5 km downstream. Petticoat Creek drains the area surrounding the mine and flows east into the Burke River which flows south into the Georgina River and into Lake Eyre. Watercourses are shown on **Figure 5**.

On site water bodies include the open pit, which has partially refilled to form a permanent water body. Part of the eastern tailings cell which has been excavated for tailings reclamation also intermittently holds water.

Ephemeral watercourses at the site are potentially losing streams which contribute to groundwater recharge.

5.2.1 Surface water environmental values

Surface water quality is managed according to the Environmental Protection (Water and Wetland Biodiversity Protection) Policy 2019 (EPP[WWD] 2019). The site is located within the Lake Eyre Basin, for which water quality objectives (WQOs) have not yet been nominated. When assessing the environmental values (EVs) for the site and surrounds, site and regional conditions, observed land uses and proximity of human and environmental receptors is considered.

Relevant environmental values are presented in **Table 2**. Relevant assessment guidelines have been adopted with consideration of these environmental values.

Where groundwaters interact with surface waters, groundwater quality should not compromise identified EVs and WQOs for those waters.

The pit lake is not utilised for water supply for any purpose. The pit lake is not accessible due to partial collapse of the northwestern section of the pit wall.

Table 2: Environmental Values for water

Environmental Value	Surface Water	Applicability	
		Water courses	Pit lake
Aquatic Ecosystems	While all water courses at or near the site are ephemeral, surface water quality is important to maintaining these ecosystems. Due to the regional land use for grazing, ephemeral waterways would be considered slightly to moderately disturbed. No mapped riverine aquatic conservation areas occur within the vicinity of the site. The site is mapped as having low conservation significance.	**Yes**	No
Irrigation	No irrigated agriculture occurs in the vicinity of the site	No	No
Farm Supply use	Farm Supply within this area is primarily for stock watering. Occupied residential properties are located 17 km and 23 km from site (see drinking water below).	**Yes**	No
Stock Water	Stock will utilise available surface water.	**Yes**	No
Aquaculture	Surface water in the area is not used for aquaculture.	No	No
Human Consumer	Surface water in the area is not used for the production of food.	No	No
Primary Recreation	Surface water in the area is highly ephemeral; the area is very isolated from common human recreational pursuits and is not used for primary, secondary or visual recreational use.	No	No
Secondary Recreation		No	No
Visual Recreation		No	No
Drinking water	The nearest residences are located approximately 17 km to the SE and 23 km W, both adjoining significant waterways isolated from the Petticoat Creek system. Therefore, no drinking water is sourced in the vicinity of the site, nor would site activities impact local surface waters at these locations.	No	No
Industrial Use	There are numerous mining operations in the region, but none within 30 km of the site. It is therefore no considered possible that site activities would impact on surface water at other mines. Site water supply is sourced from a borefield 15 km E.	No	No
Cultural, Spiritual and Ceremonial Values	There are no known environmental values in relation to cultural and spiritual values of surface water in the vicinity of the site.	No	No

5.2.2 Flood risk

No flood risk has been identified at the site. The pit catchment does not receive flow from any nearby watercourses.

5.3 Regional geology

The surface geology (1:100,000 scale) underlying the site is classified as the Corella Formation, Paleoproterozoic aged (2500 to 1600 MYA) Calcareous siltstone, sandstone and minor limestone, passing into calc-silicate granofels, commonly scapolitic, and marble; local quartzose sandstone passing into quartzite; local breccia; minor amphibolite.

The flat top hills which rise to the southeast of the site are capped by the Mount Birnie beds, which are comprised of Neoprotozoic to early Cambrian aged massive ferruginous sandstone, cross-bedded sandstone, conglomerate, red and green shale, mudstone and dolomite; basal tillite, and middle Cambrian aged Thorntonia Limestone with laterite cap.

5.4 Hydrogeology

5.4.1 Registered bore search

A search was undertaken of registered groundwater bores within a 5 km radius of the site using (QldGlobe May 2023). A summary is presented in **Table 3** and bore reports are provided in **Appendix A**.

5.4.2 Aquifers and aquitards

Based on bore logs from the site, groundwater is found in fractured and weathered zones within the Proterozoic metasediments and igneous rocks of the Corella formation. Comparison of water strike and standing water levels (SWLs) indicates that the regional aquifer is semi-confined to confined. Granofels typically has little to no primary porosity. Groundwater flow will therefore mainly occur through secondary porosity including fractures and weathering, and more porous interbedded layers.

Aquifer yield would be expected to be low. Occasional high flow zones may be encountered however lack of connectivity (effective porosity, specific storage or specific yield) within the aquifer means that sufficient long-term yield to supply a production bore or water supply is unlikely.

Groundwater is neutral to slightly alkaline and moderately to highly saline. Water chemistry is dominated by sodium and magnesium, and bicarbonate and chloride.

Within the landscape around Tick Hill, groundwater recharge areas are likely to be located in the ephemeral watercourses, and the limestone capped hills to the southeast.

5.4.3 Groundwater dependent ecosystems

With reference to Groundwater Dependent Ecosystems (GDE) mapping (QldGlobe 2023) the site does not contain a GDE.

The closest off-site GDE is a cave ecosystem of the Devoncourt Limestone located 5 km to the southeast of the site. The GDE is described as a subterranean GDE of unknown confidence. The location of the GDE is shown on **Figure 6**.

Table 3: Registered groundwater bores

5.5 Climate and meteorology

Regional meteorological data has been sourced from the Bureau of Meteorology (BOM, 2024) (www.bom.gov.au, verified 10 September 2024). Due to the limited availability and continuity of data, several weather stations have been used. The Monument Airport weather station (037034 2000 – 2023), approximately 18 km from site has records since 2000. Mean maximum and minimum monthly temperatures and mean monthly rainfall recorded between 2000 and the present are presented in **Table 4**.

Evaporation is taken from climate data for Mount Isa Airport (029127, 1966 - 2023), presented in **Table 5**.

Annual rainfall data was sourced from Phosphate Hill (037106, 27 km S) and Devoncourt Station (029129, 62 km NNE) utilising data between 1994 and 2023. Summary data presented in **Table 6**.

Extreme event predictions were taken from the BOM 2016 Annual Exceedance Probability data for rare events, for the grid location of Tick Hill. AEP data are presented in the Tables Appendix.

Table 4: Average monthly climate data – The Monument (2000-2023)

5.6 Sensitive receptors

5.6.1 Sensitive human receptors

To identify sensitive human receptors, a review of the nearest sensitive land use, as defined in the *Planning Regulation 2017* (Queensland Government 2017), was undertaken. No sensitive land-uses or receptors were identified within a 500 m radius of the site.

5.6.2 Environmentally sensitive areas

With reference to the Department of Environment and Science 'Environmentally Sensitive Areas (ESA) Map' (see **Appendix B**), the nearest identified ESA to the site is the "Stanbroke Designated Landscape Area (DLA)". This area covers the former Lot 16 on CW62 and is classified as a declared Aboriginal Site under the Relicts Act 1971.

The Stanbroke DLA covers the western area of the site within Lot 16 on SP309110. The DLA is a Category C Environmentally Sensitive Area which extends approximately 70 km east-west and 54 km north-south and surrounds the township of Dajarra.

Four areas mapped as Matters of State Environmental Significance (MSES) occur at or adjacent to the site. These include:

- Essential Habitat: Regulated vegetation map category A or B which covers the limestone hills to the southeast of the mine;
- Wildlife habitat: special least concern, one or more special least concern taxa recorded in locality, which covers the mine and surrounds;
- Wildlife habitat: endangered or vulnerable, one or more critically endangered/ endangered/ vulnerable taxa recorded in the locality which covers the mine and surrounds; and
- Regulated vegetation: defined watercourse, which includes all watercourses within the mine lease area and surrounds.

A map showing the location of MSES in the vicinity of the mine is included as **Figure 6**.

6 MINE OPERATIONS

A detailed summary of site history was completed with the Environmental Site Assessment report (Environmental Earth Sciences 2023). That report includes a review of historical aerial photographs, site ownership, local and state government registers, previous reports and interviews with relevant persons. A limited extract is provided below with information relevant to development of the pit hydrogeological model.

6.1 Summary of Mine Operations 1993

A summary of mine operations is presented in the MIM Holdings Limited report (1993). At the time of this report the open pit had been mined and underground workings were under development. Schematics of the layout of the open cut and underground workings are shown in **Figures 7 and 8**.

The Tick Hill Gold Deposit was discovered in 1989 and open cut mining commence in 1991. Initially ore was transported off-site for processing. The open cut was 70 m deep and completed in 1992. While the open cut was mined, the infrastructure was under development for the underground mine. This included the vent shaft which joined each level of the underground mine, and the decline which runs off the open cut haul road, 25 m below ground surface.

A processing plant was set up on site, with ore processing involving crushing and milling followed by cyanide leach. Gold was then extracted via electrowinning and smelted in a gas furnace.

The mine aimed to operate on a total containment basis with no effluents leaving the site. The waste rock dump (WRD) was constructed in lifts of 5 m. The waste rock was assessed as containing no acid generating material or toxic properties. Topsoil from clearing the waste dump area was stockpiled for use as cover on the WRD at completion of operations.

The tailings dams were constructed of waste rock with clay sealant to comply with guidelines at the time of operations. Two tailings cells were constructed with a decant dam for return water. Planned rehabilitation of the tailings involved a waste rock cover and replacement of stockpiled topsoil.

Water for mine operations was pumped from the Pilgrims Creek borefield 15 km to the east of site.

Site staff and contractors lived at The Monument township to the south of Tick Hill.

Figure 7: Schematic of open cut and planned underground workings (Tick Hill 1993)

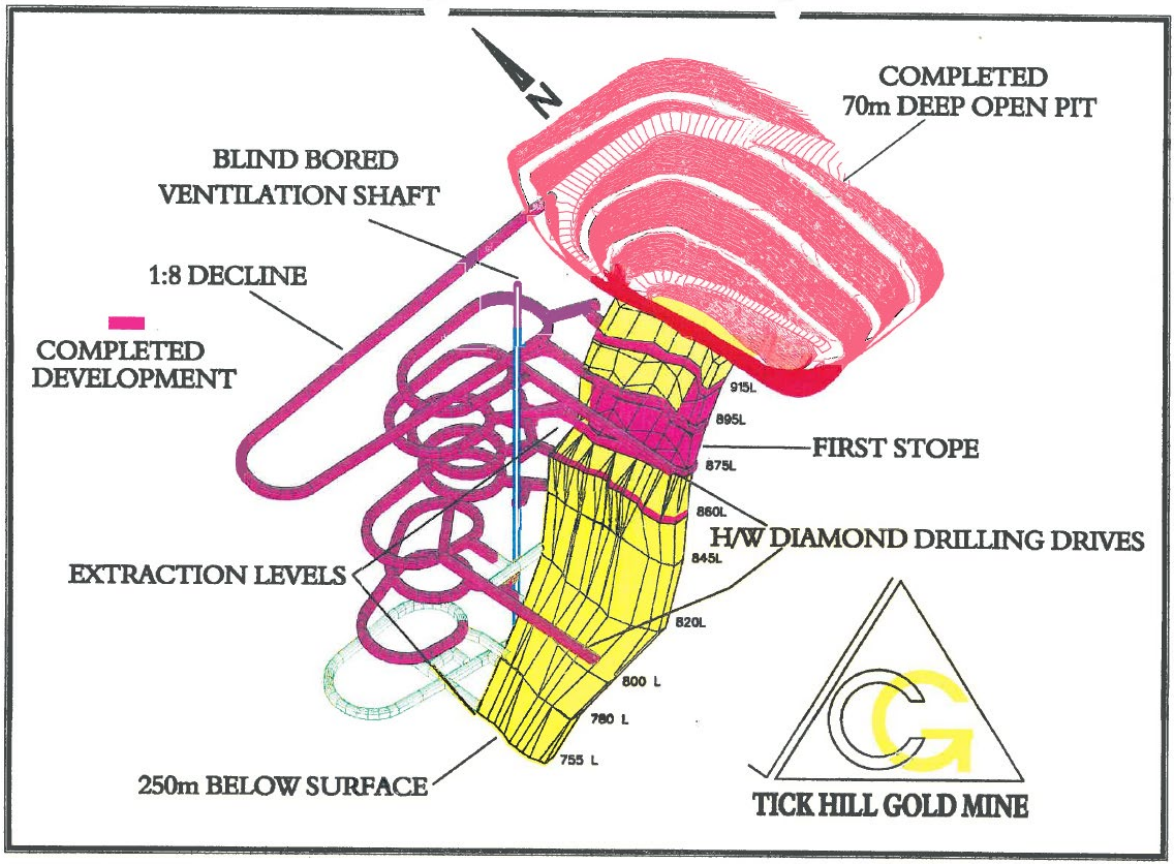

Figure 8: Cross section schematic of open cut and planned underground workings (Tick Hill 1993)

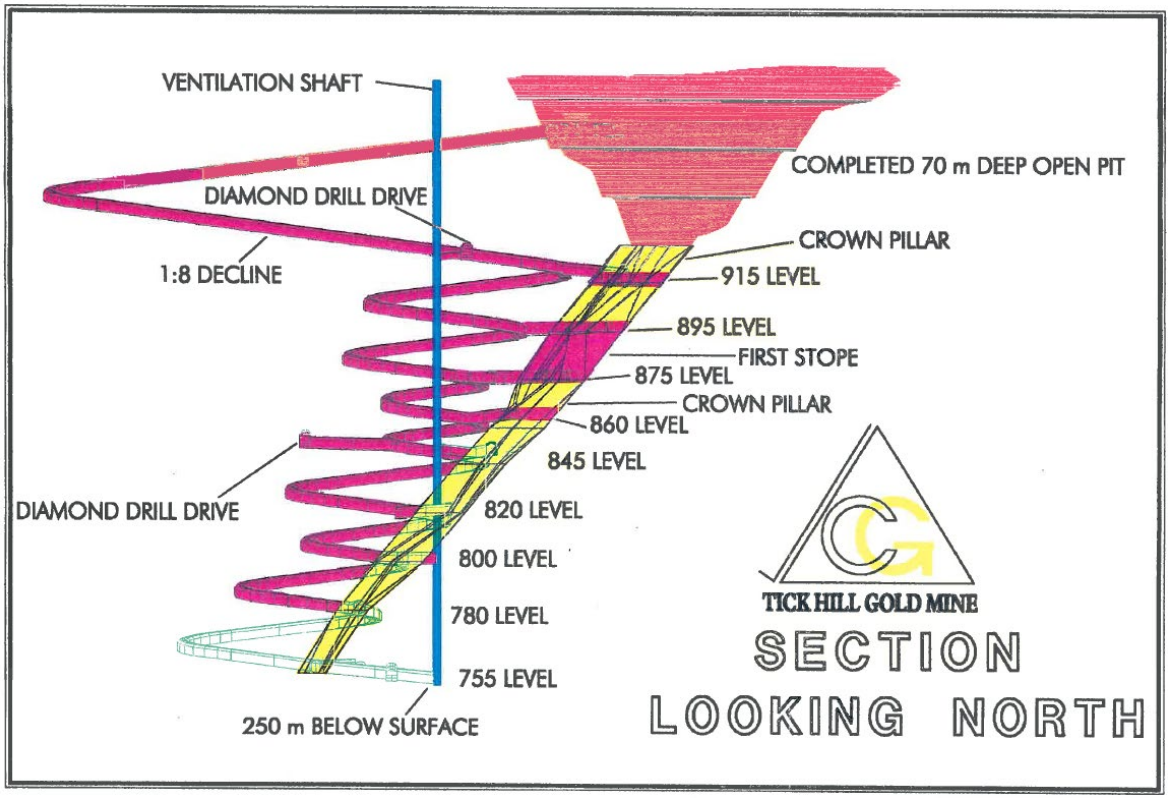

6.2 Previous environmental monitoring

6.2.1 Groundwater monitoring

Groundwater monitoring bores on site are summarised in **Table 7** and shown on **Figure 9**. Available borelogs are presented in **Appendix C**. Two bores, THGW001 and THGW002, are likely to have been installed circa 2012 by Diatreme Resources (**Photo 1**). No installation details are available for these bores. These bores were sampled on six occasions between 2012 and 2017, with typical analysis including major cations and anions, total and dissolved metals and cyanide. These bores were included in the site monitoring program following the installation of four additional bores in 2020.

Four bores, THGW003 to THGW006, were installed by Carnaby Resources in 2020 (**Photo 2**). These bores have been periodically monitored since installation. Installation logs are presented in **Appendix C**. Bores THGW001 to THGW006 were sampled on nine occasions between 2020 and 2022. At this time the mine vent shaft bore was also included in the monitoring program.

Three groundwater bores, THGW007 to THGW009, were installed in June 2023 as part of the ESA (Environmental Earth Sciences 2023), to address data gaps and further characterise groundwater at the site. One sampling event was conducted in June 2023 for all bores on site (bores TGHW001-THGW009).

The mine pit was sampled in 2012, however a collapse of the north-western wall removed a section of the haul road which prevented safe access to the water. A sample was collected in 2017, however it is not known how this was collected. In 2020 a flying fox arrangement was set up to allow sampling of the pit using a bailer. The pit was sampled nine times between 2020 and 2022, with both deep and shallow water sampled in June 2020.

Sampling events completed up to February 2022 were conducted by Carnaby, or the site operator at the time. Supplied results have been presented in **Table 37** in the Tables Appendix of Environmental Earth Sciences (2023), which collates all historical results. Relevant results have been incorporated in trend graphs prepared to assess ionic balance, cyanide and metals concentrations over time. Two additional groundwater sampling events were conducted by Environmental Earth Sciences, in December 2022 and June 2023.

Two cross sections have been prepared to show the influence of the mine pit on groundwater at the site. These run southwest to northeast (**Figure 10**) and northwest to southeast (**Figure 11**).

1. Bore THGW001. Bore THGW002 has similar surface structure.

2. Bore THGW004. Bores THGW003 – THGW006 are also installed with monuments.

6.2.2 Surface water monitoring

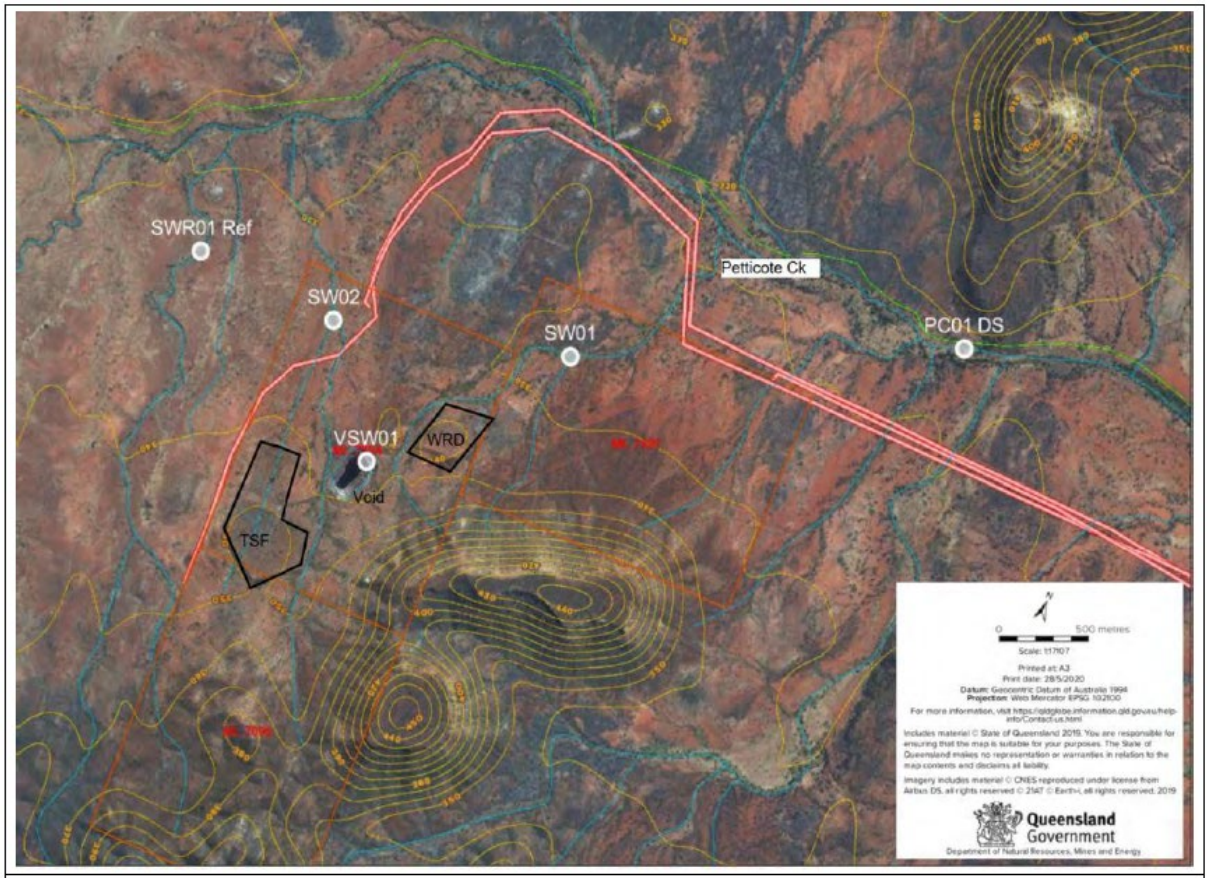
All watercourses on site are ephemeral and flow for a brief period after rainfall, consequently surface water monitoring data was only available from two sampling events, undertaken in 2015 and 2018. Surface water sample locations and their purpose are described in **Table 8** and sample locations presented on **Figure 12**.

All surface water samples were analysed for major anions and cations, nutrients, dissolved and total metals. Results are presented in **Table 38** in the Tables appendix of Environmental Earth Sciences (2023).

Table 8: Summary of surface water monitoring locations

Location	Description	Target
THSWR01 ref	Reference site in neighbouring watercourse to the west of site. Similar conditions to on-site watercourses	Background conditions
THSW01	Ephemeral watercourse to the northeast of site, downstream of waste rock dump	Waste rock dump
THSW02	Ephemeral watercourse to the northwest of site, downstream from the tailings dam, decant dam, open pit and former processing area.	Tailings, decant and mine pit
THSWPC01 DS	Petticoat Creek, downstream of site.	Downstream of site

Figure 12: Surface water monitoring locations



7 SITE CONDITIONS

The investigation works completed between December 2022 and June 2023 included two site visits by Principal Soil Scientist and Suitably Qualified Person (SQP) Dr Anna Sheldon of Environmental Earth Sciences. These site visits occurred on 19-20 December 2022, accompanied by Carnaby Resources Geologist Neill Kite, and on 8-12 June 2023, accompanied by Environmental Earth Sciences' Environmental Scientist Sam Weiss.

The section below collates observations and photographs from these site inspections, along with relevant information from the site history.

7.1 Significant site features

The current site layout of Tick Hill is shown on **Figure 2**, with an inset showing available information on the former site layout during mine operations during the 1990s. The aerial photograph in **Figure 3** also shows the site layout during mine operations.

The mine is located at the foot of a flat-topped mesa hill, on a northwest facing slope. Entry to the site is from the Duchess Phosphate Hill Road. The majority of operational structures have been removed from site, with only the major mining structures (open pit, waste rock

dump and tailings and decant dams) remaining. Some infrastructure associated with tailings reclamation works is also present on site.

7.1.1 Open pit

In the centre of the site is the open pit (**Photos 3 and 4**). The pit is elongated north-south, and 70 m deep, with water filling approximately 25 m depth. Water level varies by several meters, depending on rainfall. The former haul road into the pit collapsed in the northwest corner of the pit, preventing access to the water level. The pit rim is higher than the surrounding landscape (**Photo 5**) which means that the pit catchment is limited to the pit excavation boundary.

The area between the pit rim and bund wall drains externally, via gaps in the bund wall. These gaps are placed in locations that are not otherwise accessible so that the bund is still effective in preventing pit access (see **Photo 6**). The bund wall is surrounded by a barbed wire fence with warning signs.

Drainage flows around the open pit are shown on **Figure 13**.

3. Mine open pit – facing south from haul road.

4. Mine open pit – facing west from pit rim. Note collapse of face in north west corner.

5. View of the open pit from the hill to the southeast. Note the raised rim relative to the surrounding landscape.

6. Gap in the bund on the southwestern side to allow drainage from the pit perimeter area.

Client: Tick Hill Mining Pty Ltd | Drawn By: A Sheldon | Date: June 2023

Location: Tick Hill Mine, QLD

Figure 13

7.1.2 Waste rock dump (WRD)

The WRD is located northeast of the pit. The WRD is diamond shaped and has a flat top (**Photo 7**). There is a small V in the northeast corner and the former access ramp acts as a drainage line towards the southwest corner.

The WRD was constructed in 5 m lifts and is capped with rock mulch and topsoil. Waste rock material at the mine was assessed as not having potential for acid or metalliferous drainage and waste rock was therefore considered inert.

Observations at the time of the December 2022 and June 2023 inspections indicate that the WRD is stable and becoming integrated into the surrounding landscape. The batters are stable and well vegetated (**Photos 8 and 9**), with one minor (stable) scour observed on the northern side. On the southern (uphill) side of the WRD an area of water ponding was observed adjacent to the WRD, where a minor drainage line meets the WRD (**Photo 10**).

No evidence of scalding or seepage was observed around the perimeter of the WRD.

The top of the WRD is generally flat and well vegetated (**Photos 11 and 12**). The surface of the WRD is slightly uneven, indicating that rainwater will pond and infiltrate. As described above, an area of ponding was also observed at the top of the ramp / drainage line on the WRD during recent site inspections. Drainage flows around the WRD are shown on **Figure 13**.

7. View of the waste rock dump from the hill to the southeast.

8. Waste rock dump batter – north side.

10. Waste rock dump batter – south side, with area of local ponding at base.

11. Top of waste rock dump showing access ramp / drainage line which flows to the left of the image.

12. Top of waste rock dump showing vegetation and slightly uneven surface.

7.1.3 Tailings Storage Facility (TSF)

The TSF consists of two cells, divided in to east and west with a total capacity of 600,000 m³. The TSF cells are built as a turkey nest dam and designed as Referable dams. The cells have a 500 mm clay liner in the base, and clay core in the walls. The cells range in depth from 6 on the up-slope side to 10 m on the down-slope site. Walls were built with a batter angle of 1:3. The cells have a flat top, and the perimeter embankments are higher than the cell surface. Excess runoff was designed to be directed to a spillway on the northern end of the eastern cell. The cover material was a waste rock mulch covered with topsoil. The cover was not designed or expected to restrict water infiltration. Clay and topsoil used for lining and cover were source from borrow pits and scrapes on site (Envirofin 2020).

At the time of the site inspections the tailings reclamation project had ceased, with the eastern cell remaining open. The entire eastern cell had been removed of cover, and the southern part of the eastern tailings cell had been substantially excavated (**Photo 13**). Stockpiles of tailings were located on the western cell, surrounded by an earth bund (**Photo 14**).

The northern part of the eastern tailings cell had the cover removed but minimal excavation of tailings. Erosion scours indicated flow of surface water to the north, towards the spillway (**Photo 15**). It was not possible to determine visually whether overflow of stormwater from the TSF had occurred. The central part of the eastern tailings cell had been partially excavated, while the southern part was split into two areas. The south-western section was excavated to the base of the tailings cell (**Photo 16**). The south-eastern section was excavated to the base of tailings and a plastic liner installed. This section of the cell was being used for water storage (**Photo 17**). Areas of disturbance and water flow on the tailings and decant dams is shown on **Figure 14**.

On the western cell cover material was stockpiled across the cell. Areas of intermittent ponding were also evident (**Photo 18**). Infrastructure associated with the tailings reclamation work remained on the western tailings cell and water storage cell. This includes a screening for processing tailings (**Photo 19**) and a gravity separation unit (**Photo 20**). Also remaining were two locked shipping containers, a tractor, pumps and generators, empty IBCs for peroxide and other rubbish. Large diameter pipe was also located on and around the tailings cells and from the water supply tank. In areas of the western cell not disturbed by the tailings reclamation project, low scrubby vegetation was well established (**Photo 21**). The TSF batter slopes were vegetated and in good condition (**Photo 22**).

13. TSF from the hill east of site, the eastern cell has been excavated for tailings reclamation.

14. Stockpiled excavated tailings with earth bund on western cell.

15. Northern section of eastern cell – cover removed from tailings, and surface erosion.

16. Southern section of eastern cell where tailings have been excavated to base of cell.

17. Southeast section of eastern cell which has been plastic lined for use as water storage.

18. Stockpiled cover material and areas where water had ponded on northern end of western cell.

19. Screen used for processing excavated tailings.

20. Gravity separation unit used for processing of excavated tailings.

21. Vegetation on southern part of western tailings cell.

22. Vegetation on southern batter slope of western tailings cell.

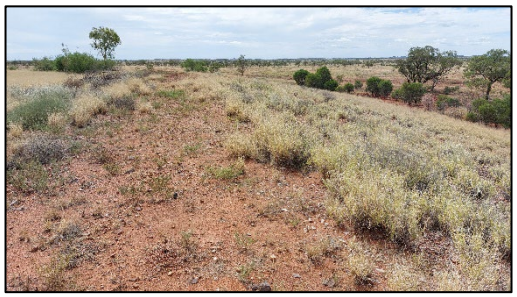
Location: Tick Hill Mine, QLD

Figure 14

7.1.4 Decant dam

The decant dam was constructed to the same specifications as the TSF, with a capacity of 93,000 m³ (Envirofin 2020). The decant dam perimeter walls were in good condition and well vegetated (**Photo 23**). The decant dam surface has been subject to areas of subsidence (**Photo 24**) and in the northern centre of the dam was an area of tunnelling indicating a preferential flow path for water to enter the decant dam. Water flows on the decant dam are shown on **Figure 14**. Vegetation on the decant dam was well established.



23. Northern wall of decant dam, looking west.

24. Top of decant dam showing uneven surface and areas of subsidence.

7.1.5 Former processing plant area and remaining infrastructure

To the east of the TSF, and up-slope, was the former processing and administration area. The general layout can be estimated based on the diagram showing the site plans (**Figure 2**) and the aerial photograph of the site taking during operations (**Figure 3**).

Uphill of the former processing plant is the site water supply tank (**Photo 25**). This tank remains in use and currently supplies stock water for the surrounding area. Water is sourced from a borefield 15 km east of site.

The slope between the tank and tailings dam has been heavily disturbed, although little direct evidence of the processing plant remains. Landforms were either modified following plant removal or have eroded over time. The area is well vegetated with grass but has notably fewer trees than the surrounding landscape.

To the south west of the tank is a causeway crossing of a gully and a remnant concrete slab (**Photo 26**). This was the only remaining infrastructure observed on the slope. The processing plant area is shown in **Photos 27, 28 and 29**. The processing plant and other site infrastructure were relocated to other mines after closure of Tick Hill.

Further to the north and south of the WRD is the core yard (**Photo 30**). Two shipping containers had been located upslope of the core yard at the time of the December site visit, however these had been removed before the June visit.

The aerial photograph from the time of mine operations indicates that the ROM was located immediately south of the WRD, however nothing remains in this area.

25. Water supply tank. Water is sourced from a borefield 15 km east. Currently used for stock watering.

26. Remnant concrete slab, southwest of the water tank.

27. Processing plant area, looking north.

28. Processing plant area, looking south.

29. Processing plant area, looking west. Tailings dam in background.

30. Core yard, located south of WRD.

8 PIT HYDROGEOLOGICAL MODEL DEVELOPMENT

A hydrogeological model for the site was developed as part of the ESA completed in 2023. This was submitted with the PRCP. Following review of the PRCP submission, DESI issued an RFI for further information relating to the long-term pit chemistry and pit water balance. These were:

- Item 10. Further details are required regarding the predicted changes overtime in the water quality within the final void.
- Item 11. Update the water balance by providing consequence scenarios for extreme rainfall events on the pit equilibrium level.

The hydrogeological model for the mine pit has therefore been updated to address the RFI. As the pit water balance informs the chemical model, Item 11 is discussed prior to Item 10.

8.1 Groundwater migration

In order to assess potential infiltration and migration of groundwater at the site, along with potential impacts to receptors at points of groundwater discharge, hydraulic testing was conducted on two groundwater bores, THGW005 and THGW006.

Following sampling at each bore, a pressure transducer logger (diver) was installed into the bore and the bore pumped to extract water to be used for a slug test (falling head test). Following extraction of the required amount of water, the pump was removed and water levels were then allowed to recover, as a rising head test. Water pumped from the bore was then used to fill the bore to the top of casing, allowing a falling head test to be conducted. This process was repeated for two rounds for each bore.

Results of hydraulic testing were interpreted to determine the hydraulic conductivity (K) of the site aquifer, as summarised in **Table 9**. Interpretation of slug test results included use of bore construction data provided in borelogs (Carnaby Resources 2020) and standard values for metamorphic aquifer properties. Porosity was assumed to be 0.1.

For each bore, the results of two of the tests is presented below, representing the range of values obtained during test interpretation. The Hvorslev and Bouwer and Rice methods provided the most consistent results for interpretation for slug test results.

Comparison of the slug test results shows a 10x difference in K between the two bores, indicating the range of variability observed on site. This variability in K is not unexpected due to the Corella Formation geology of the site and the associated aquifer properties (**Section 5.4.2**).

In addition to the slug tests at individual bores, a mass balance model of the mine pit was developed to determine groundwater inflow from the aquifer. Details of the mass balance calculations are discussed in **Section 8.2**. Once the groundwater inflow component of the mass balance was determined, the Thiem equation was used to calculate K of the aquifer, using the hydraulic gradient between the pit wall and bore THGW001.

Table 9: Aquifer parameters

Bore	Lithology (water bearing zone)	Thickness (m)	K (m/d)	*i* (m/m)	V_g (m/d)	KD (m^2/d)
THGW005	Corella Formation	10	0.081	0.038	0.031	0.806
			0.064	0.038	0.064	0.641
THGW006	Corella Formation	10	0.898	0.236	2.12	8.98
			0.682	0.236	1.61	6.82
Pit	Corella Formation	25	0.0084	0.308	0.0284	0.21

Note: K – hydraulic conductivity, i – hydraulic gradient, V – velocity, KD – transmissivity

8.2 Pit water balance

The mine pit at Tick Hill has been abandoned and left to fill since mine closure in 1994. The pit lake is inaccessible due to collapse of the haul road in the northwest corner of the pit. Pit water levels are measured using the 'mine shaft' bore which is installed into the underground workings adjacent to the pit. Pit water levels have been measured since 2021 and have fluctuated within a range of 3.5 m. The fluctuations indicate that the pit lake has filled to the extent that the water level is now predominantly influenced by recent weather rather than pit refilling. The pit water level from 2021 to 2023 has therefore been used as the basis for the pit water balance.

8.2.1 Water balance components

The pit water balance can be calculated with the following equation:

$$\Delta Lv = (Gi - Go) + Rp + Rr - E - Wu$$

Where:

- ΔLv = the change in pit water level
- *Gi* = groundwater inflow, and *Go* = groundwater outflow
- *Rp* = rainfall into the pit lake
- *Rr* = rainfall runoff from the pit catchment into the pit
- *E* = evaporation from the pit lake
- *Wu* = water use (extraction) from the pit lake

Water balance components for the Tick Hill Pit lake are summarised in **Table 10** and area calculations provided in **Table 11** below.

Table 10: Water balance components

Component	Estimate method	Comments on uncertainty
Inflows		
Direct rainfall – pit lake	Rainfall x pit area	Rainfall estimates for various climate scenarios. Pit lake area adjustment with water level based on pit dimensions.
Surface runoff – pit catchment	Rainfall x catchment area with 0.65 runoff coefficient	Rainfall estimates for various climate scenarios.
Groundwater inflow	Thiem equation	Baseline estimate from current stable conditions. Groundwater inflow model incorporated into other scenarios.
Other inflows	Zero	No additional pit inflows.

Component	Estimate method	Comments on uncertainty
Outflows		
Evaporation from pit lake	Evaporation x pit lake area with 0.7 evaporation coefficient	Evaporation estimated from weather data. Coefficient to account for shading and wind protection of pit walls.
Water use / pumped outflow	Zero	No pit water extraction occurring.
Groundwater outflow	Zero	Pit water level well below surrounding aquifer. Assumed to be acting as groundwater sink.

Table 11: Mine void mass balance calculations

Parameter	Value	Notes
Mine pit catchment surface area (pit walls, catchment and water surface) (340 mAHD)	32,000 m²	
Pit surface at 290 mAHD water level	8,000 m²	Direct rainfall and evaporation
Exposed pit catchment area between 290 and 340 mAHD	24,000 m²	Runoff to pit
'Likely' runoff conditions	Runoff after 10 mm rainfall per event	Estimated likely scenario. Calibrates with runoff coefficient of 0.65.

8.2.2 Weather data used in water balance model

Due to the location of Tick Hill in northwest Queensland, available weather data is limited in either proximity to the site, or type and duration of data collected. The climate and weather data reviewed for the project was summarised in **Section 5.5**. For the purposes of developing the initial water balance model, the following data was used:

- Evaporation – Mount Isa Airport long term climate records.
- Annual rainfall (average rainfall) – Average of Phosphate Hill and Devoncourt Station, average of all data between 1994 and 2023.

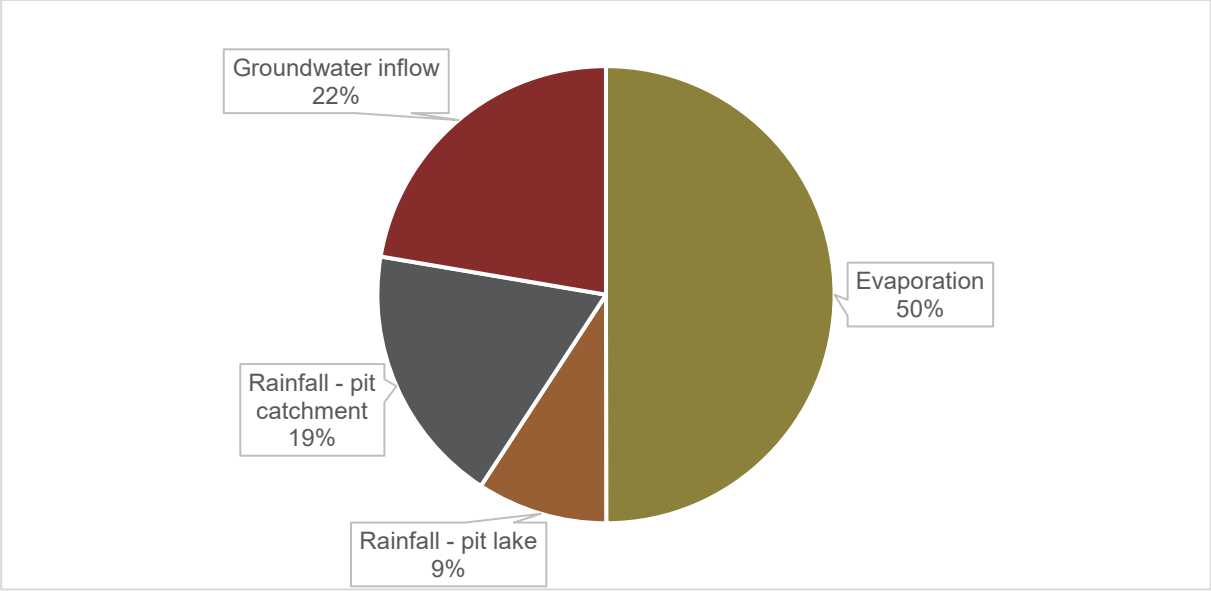
For the purposes of developing the water balance models under varying climate scenarios, the following data and estimates were used:

- Evaporation – Mount Isa Airport long term climate records.
- Twice annual rainfall (Twice rainfall) – Double the average of Phosphate Hill and Devoncourt Station, average of all data between 1994 and 2023.

- Maximum annual rainfall (Max rainfall) – Maximum recorded value from the average of Phosphate Hill and Devoncourt Station, all data between 1994 and 2023.
- Low range rainfall (Low rainfall) – 150 mm annual rainfall, estimate based on 10th percentile annual rainfall for Phosphate Hill and Devoncourt Station (**Table 6**).
- Annual rainfall (30 year cycle) – Yearly average of Phosphate Hill and Devoncourt Station, between 1994 and 2023, repeated for model duration.
- Annual rainfall (30 year cycle x 150%) – Yearly average x150% of Phosphate Hill and Devoncourt Station, between 1994 and 2023, repeated for model duration.
- Equilibrium rainfall – value adjusted in model until pit water level equal with surrounding aquifer level (45 m above base of pit | 310 mAHD).
- Extreme event data – BOM AEP grid data for Tick Hill, 1 in 2000 year 168 hour event.

8.2.3 Current pit conditions

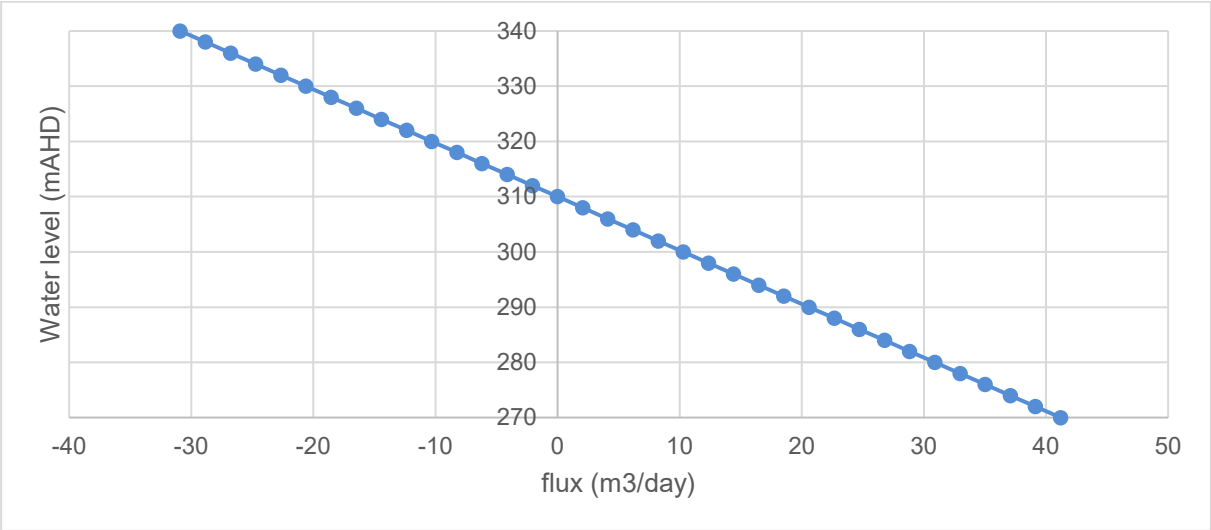
The current pit water balance was calculated using the conditions described in **Sections 8.2.1 and 8.2.2** above. The pit water balance components are summarised in **Graph 1**. This model was used to determine the rate of groundwater inflow into the pit, and therefore the K of the surrounding aquifer supplying water to the pit.



Graph 1. Pit water balance components – current stable conditions

The relationship between pit water level and groundwater inflow into the pit was then used to determine the flux of groundwater to or from the pit at different pit water levels. This is shown in **Graph 2**. When the water level in the pit lake is equal with the surrounding aquifer, at 310 mAHD, there is no net flux to or from groundwater. This is a 'flow through' pit lake scenario. When the pit water level is lower than the surrounding aquifer (<310 mAHD), groundwater flows into the pit in a 'groundwater sink' scenario. If the pit lake level is higher than the surrounding aquifer (>310 mAHD), water will flow from the pit into groundwater, and

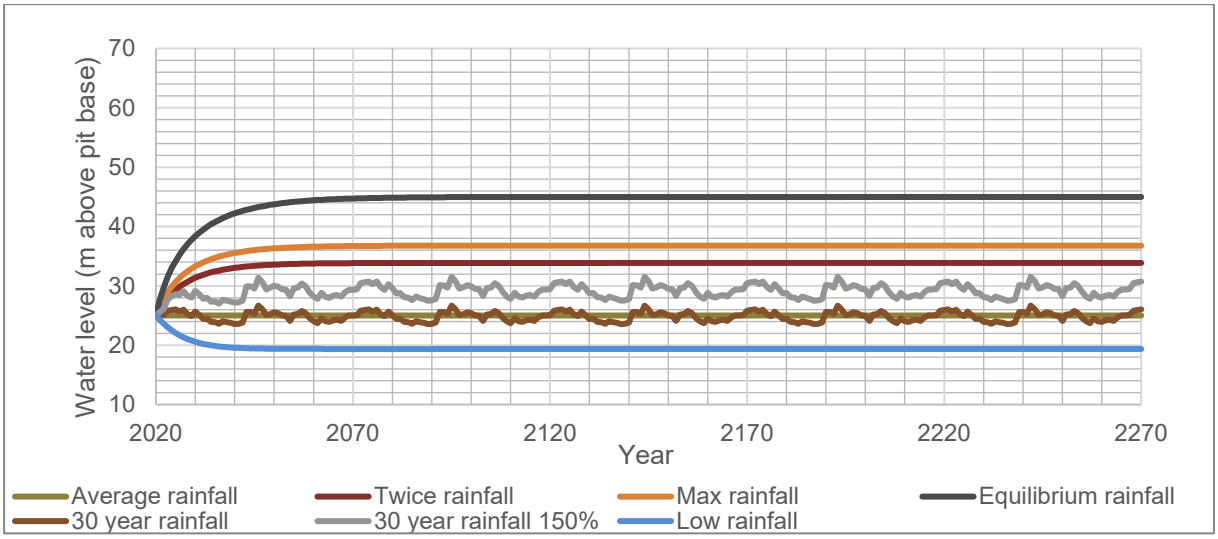
the pit lake acts as a 'groundwater source'. The current pit water level is approximately 290 mAHD, and the pit acts as a groundwater sink.



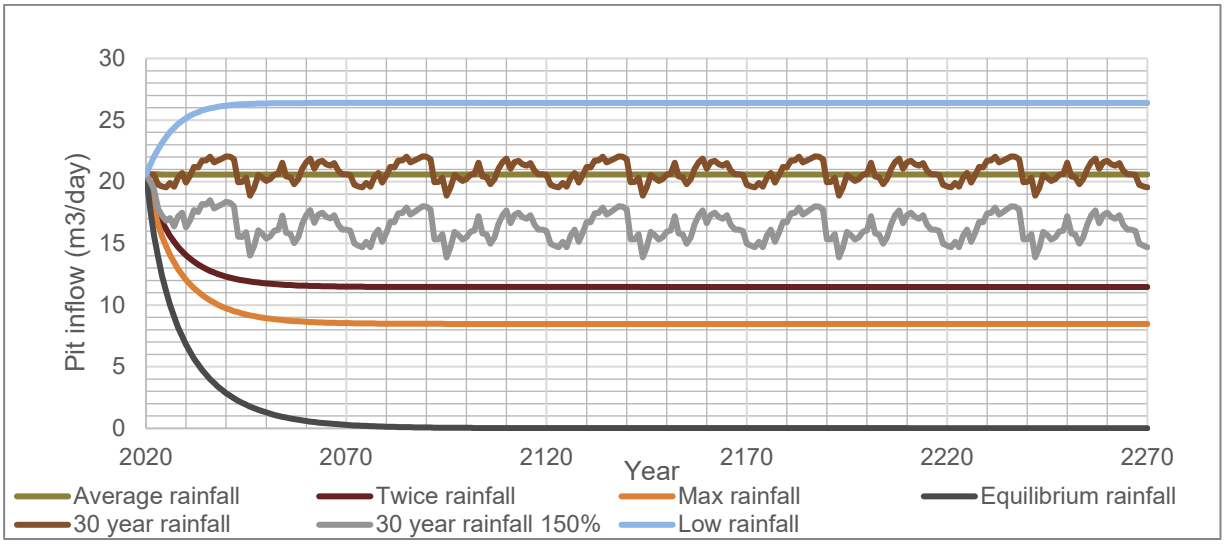
Graph 2. Groundwater flux into or out of pit depending on pit water level.

8.2.4 Pit water balance under various rainfall scenarios

Pit water levels and groundwater flux were modelled under a range of rainfall scenarios. Each scenario was modelled for a 250 year period, from 2020. All modelled conditions stabilised within approximately 70 years. Rainfall conditions used in the modelled scenarios are described in **Section 8.2.2** above. Pit water levels are presented in **Graph 3**, and associated groundwater inflows in **Graph 4**. The water balance values once the scenarios stabilise is presented in **Table 12**. Complete spreadsheets with the model calculations are presented in **Appendix D**.



Graph 3. Long term pit water level under various rainfall scenarios



Graph 4. Long term groundwater flux into pit under various rainfall scenarios

Comparison of pit water level and groundwater inflow response to the different rainfall scenarios shows that higher rainfall results in higher pit water levels, and subsequent lower groundwater inflow. The modelled conditions show that even with substantially higher rainfall than would be plausible for this location, there is no possibility that the pit water level would increase so that the pit can act as a source to recharge groundwater. The long-term average rainfall required to bring the pit water level in equilibrium with the regional aquifer is more than four times the current average rainfall.

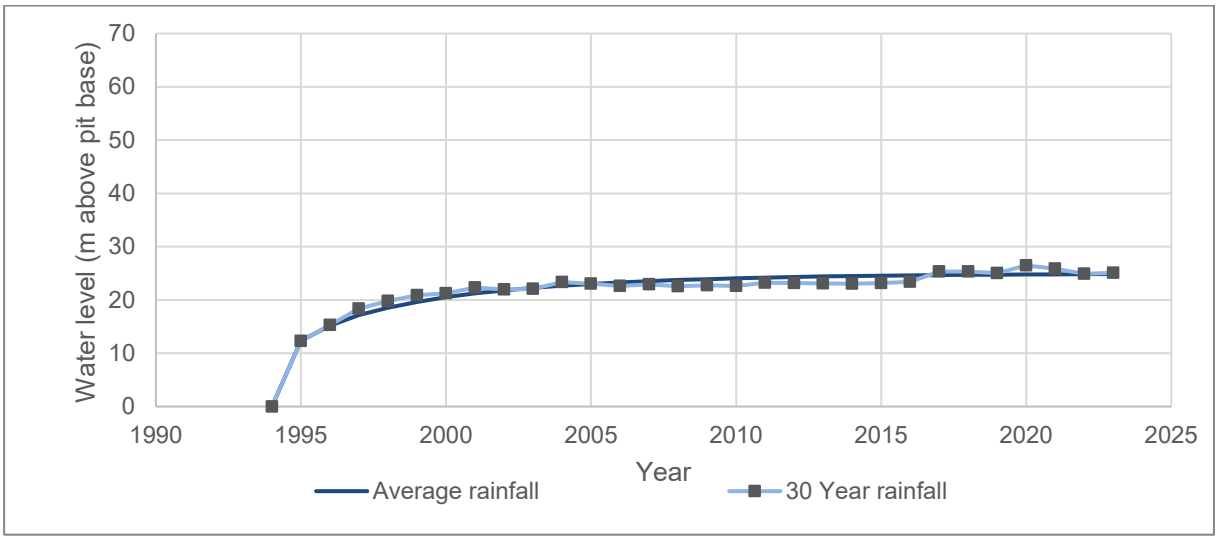
Table 12: Summary of pit water level model conditions

Model scenario	Rainfall	Evaporation	Pit direct rainfall	Pit catchment rainfall	Groundwater inflow	
Units	m/year	m^3/year	m^3/year	m^3/year	m^3/year	m^3/day
Average rainfall	0.396	16841	3112	6214	7515	20.6
Twice rainfall	0.792	23727	8767	10774	4184	11.5
Maximum rainfall	0.923	26245	11304	11851	3090	8.5
Equilibrium rainfall	1.219	34034	20502	13526	0	0
Low rainfall	0.15	13073	915	2525	9633	26.4
30 year rainfall	0.0953-0.923	15841-18047	792-7005	1474-14718	6888-8051	18.9-22.1
30 year 150% rainfall	0.143-1.38	18665-21797	1409-12559	2055-20877	5062-6575	13.9-18.0

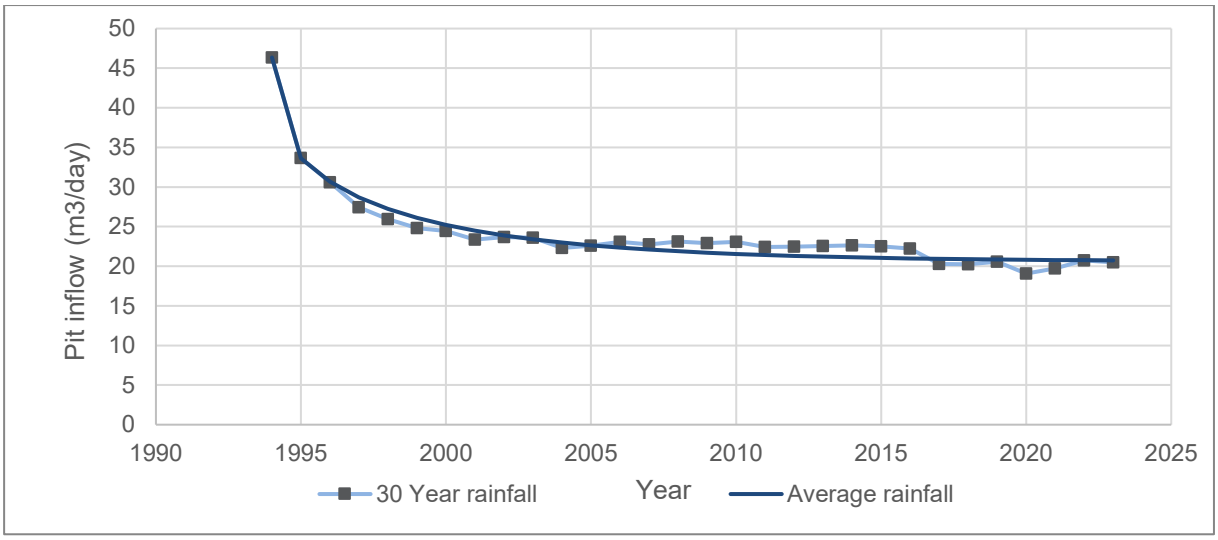
8.2.5 Pit filling since mine closure

The groundwater mass balance was used to model the filling of the mine pit after mine closure. Water level is shown in **Graph 5** and groundwater inflow is shown in **Graph 6**. Model results are presented in **Appendix D**. The 30 year rainfall data used in this model is

the averaged data between Phosphate Hill and Devoncourt Station for that period (1994 – 2023). Comparison of the long-term fluctuation in water levels from the '30 year rainfall' scenario above with the pit filling model indicates that seasonal variation was a greater influence on pit water level than pit filling from 2012.



Graph 5. Pit water level since 1994



Graph 6. Groundwater flux into pit since 1994

8.2.6 Extreme event water level response

A modified version of the mass balance model was used to determine the influence of short-term extreme rainfall events on pit water level. The rainfall events that were modelled were the 1 in 2000 year event for Tick Hill location (BOM 2016) for 168 hours (598 mm, see **Table 16**), and an event double that size (1,196 mm).

Because these events would take place over a short time frame it is assumed that no evaporation would occur, and short-term groundwater flux would be negligible. It is also assumed that in a continuous rainfall event a higher proportion would be shed as runoff, therefore no runoff coefficient has been applied. Three starting levels for the pit lake water level were modelled; 25 m is the current pit water level, 30 m would be the stable pit level for

more than 150% of the current rainfall, and 35 m is just below the pit level for a long-term average rainfall equal to the maximum rainfall. Results are shown in **Table 13**. All scenarios show that the water level of the pit does not reach equilibrium and does not become a groundwater source.

Table 13: Extreme rainfall event response – pit water level

Event Rainfall	Pit start height	Rainfall volume	Increase in pit level	Buffer to pit equilibrium level
m	m	m^3	m	m
0.598	25	19136	2.44	17.56
0.598	30	19136	1.99	13.01
0.598	35	19136	1.66	8.34
1.196	25	38272	4.87	15.13
1.196	30	38272	3.99	11.01
1.196	35	38272	3.32	6.68

8.3 Pit geochemical model

A mine pit geochemical model was developed to provide further detail on long-term water quality of the mine pit lake. The model used available geochemical data for the site to predict water quality over 250 years. The mine pit geochemical model utilised the mine water balance model scenarios developed above to determine the various potential influences on pit water composition over time.

A solute transport model to determine the influence of cyanide leaching on pit water quality was developed for the Environmental Site Assessment (Environmental Earth Sciences 2023). This found that the cyanide impact to groundwater between the TSF and open pit is stable, with concentrations likely to steadily decrease over time. It is not expected that cyanide impacted groundwater will adversely impact pit water quality to any significant extent and cyanide in pit water will be degraded by sunlight. As cyanide will not accumulate in the pit due to degradation, it is not included in the long-term pit water quality model.

8.3.1 Influences on pit water chemistry

The water chemistry of a mine pit after closure is influenced by a variety of physical, chemical, and environmental factors. Understanding these factors is required for predicting and managing water quality in closed mine pits and ensuring long-term environmental safety. Key factors may include:

- Geochemistry of the surrounding rocks:
    - **Acid mine drainage (AMD)**: When sulfide minerals (e.g., pyrite) are exposed to air and water, they can oxidize and produce sulfuric acid, which leads to the

release of metals (e.g., iron, copper, zinc) into the water, due to lowering of the pH of the pit water.

    - **Neutralising minerals**: The presence of minerals like limestone can buffer or neutralise acidity, limiting acid generation.

- Groundwater and surface water interactions:
    - **Influx of groundwater**: Groundwater entering the pit may bring dissolved minerals, metals, and contaminants, affecting water quality.
    - **Surface water runoff**: Rainwater or surface water flowing into the pit may introduce sediment, nutrients, or pollutants (e.g., pit wall runoff, mine waste).
- Pit lake hydrodynamics:
    - **Stratification**: Mine pits can form stratified layers of water, with different chemical properties at varying depths (e.g., oxygen-rich surface water vs. oxygen-deprived deeper layers).
    - **Mixing**: Natural or artificial mixing of water layers can lead to changes in water chemistry.
- Climate and precipitation:
    - **Rainfall**: Heavy precipitation can dilute concentrations of salts or chemicals in the water, but it may also increase runoff from nearby contaminated areas, leading to water quality changes.
    - **Evaporation**: In arid regions, evaporation can concentrate dissolved substances, increasing the salinity and mineral content of the water.
- Presence of biological activity:
    - **Microbial processes**: Microorganisms can influence water chemistry by driving processes like sulfate reduction (leading to hydrogen sulfide formation) or metal precipitation.
    - **Algal growth**: Nutrient-rich water may promote algal blooms, which can affect oxygen levels and lead to changes in water chemistry.
- Mining waste and tailings:
    - **Residual tailings**: Leftover tailings or waste materials can leach metals, acids, or other contaminants into the water over time.
    - **Waste rock piles**: Water percolating through waste rock piles may pick up contaminants before entering the pit lake.

- Remediation efforts:
    - **Water treatment**: Active treatment processes (e.g., adding lime to neutralize acid) or passive treatment systems (e.g., constructed wetlands) can influence the water chemistry after mine closure.
    - **Capping**: Covering exposed reactive materials can prevent water contamination and control water chemistry.

An initial review of these factors in relation to the Tick Hill pit lake is presented below.

8.3.2 Influences on pit water chemistry at Tick Hill

Geochemistry of the surrounding rocks:

The general influence of the geology of the regional aquifer on groundwater composition is discussed further below.

The potential for AMD associated with mine waste materials has been assessed on several occasions and found to not contain potential for acid generation. The Corella Formation contains units of limestone and calcareous sandstone which provide neutralising capacity.

Groundwater and surface water interactions:

The mine water balance indicates that groundwater inflow, surface water runoff from the pit catchment and rainfall are the main sources of water entering the pit. Groundwater and surface water quality will therefore influence pit water quality.

The pit catchment is limited to the area immediately surround the pit and does not include any mine waste materials, or any watercourse inflows.

Pit lake hydrodynamics:

Stratification and mixing have not been specifically addressed in this model. Factors which limit potential for stratification include low rainfall input and high evaporation. Meanwhile, the steep sides of the pit wall and depth of the pit limit mixing within the pit. Comparison of the mine shaft bore and pit lake water quality indicate that mixing between the underground workings and pit lake is limited.

Climate and precipitation:

The site is located in an arid climatic zone and evaporation is a major component of the pit water balance. Evaporation drives concentration of salts in the pit lake, and far exceeds the dilution influence of rainfall.

Rainfall runoff may wash sediments from the catchment into the pit lake, however due to the limited reactivity of the site geology it is not considered to be a significant source of salts or dissolved metals.

Presence of biological activity:

No evidence of algae was observed in the pit lake. Influence of microbial processes has not been considered in this model.

Mining waste and tailings:

The TSF is located upgradient of the mine pit, and is known to have influenced pit water chemistry as trace cyanide is detected in pit water samples, although it has been determined that concentrations will not accumulate to levels which have the potential for environmental harm (Environmental Earth Sciences 2023).

The WRD is located beyond the area of influence of inflow for the mine pit, and is not considered to have the potential to influence mine pit chemistry.

Remediation efforts:

No active or passive treatment processes are occurring to alter the water chemistry in the Tick Hill mine pit lake. The pit catchment does not contain any areas of capped mine waste materials that may alter water chemistry of runoff.

The TSF is currently partially uncapped, which may influence leaching to groundwater, however it is considered that the major influence of the TSF on groundwater quality is likely to have occurred during operations and soon after. Discussion of leach testing of the tailings material is discussed further below.

8.3.3 Comparison of groundwater and pit water quality

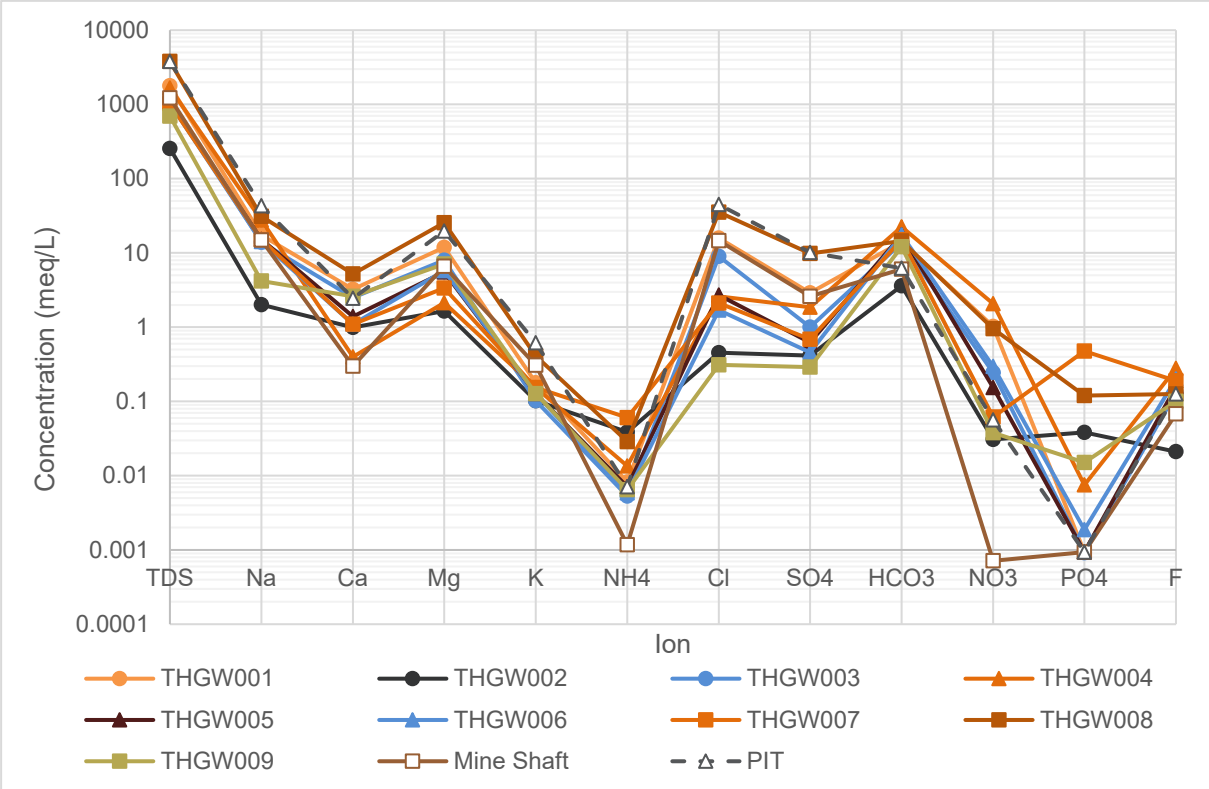
Review of the site water balance and potential influences on pit chemistry indicate that rainfall, runoff and groundwater inflows will have influenced the composition of pit water, while evaporation has caused concentration of salts in the pit over time.

As the pit has been refilling since 1994, the pit water composition provides an indication of how the different inflow components have influenced water quality over time. In order to determine how inflow chemistry should be attributed, pit water quality has been compared with groundwater and leach test results for mine tailings and mine waste rock.

Groundwater and pit water ionic composition are shown on a Schoeller plot in **Graph 7**. The aquifer occurs within the Corella Formation which is comprised of near-vertically bedded metasediments, with high variability between units. Hydraulic conductivity (K) is highly variable, with groundwater flow dominated by fractures and weathered zones.

While the pit receives water radially from the surrounding aquifer, groundwater contours indicate a steeper hydraulic gradient to the east (towards bore THGW006) and shallower gradients to the north and south (bores THGW001 and THGW008 to the south). This indicates that water inflow into the pit is dominated by flows that occur with the bedding (north-south) rather than against the bedding (particularly from the east). In addition to the open pit, there is a network of underground workings and access shafts which are situated below and to the west of the pit (**Figure 7**). These workings would intersect the aquifer and provide a component of groundwater inflow.

Groundwater is neutral to slightly alkaline and moderately to highly saline. Water chemistry is dominated by sodium and magnesium, and bicarbonate and chloride. The high sodium and chloride concentrations indicate the presence of connate sea water.



Graph 7. Schoeller plot of groundwater and pit chemistry – June 2023

Comparison of groundwater composition between monitoring bores and the mine pit indicates the following:

- Salinity of groundwater bores is generally correlated with depth, indicating that the deeper aquifer is less saline.
- The pit is more saline than all bores except bore THGW008.
- The pit has higher concentrations of sodium, magnesium, potassium, chloride and sulfate than most bores.
- The pit has lower or mid-range concentrations of calcium, ammonia, bicarbonate, nitrate, phosphate and fluoride compared to most bores.

While the majority of ions will accumulate in the pit via evapo-concentration, ammonia and nitrate will be lost via denitrification reactions and volatilisation. Bicarbonate concentrations will vary with pH. The overall salinity of the pit is well below the level at which precipitation of major ion minerals (such as gypsum) would occur.

Comparison of the mine pit and groundwater chemistry also indicates that dewatering and re-flooding of the mine workings and surrounding lithology during mine operations did not result in generation of acid via AMD reactions. This is consistent with the characterisation of the waste rock as not-acid forming (NAF).

Overall comparison between groundwater and pit water indicates that while general correlations are observed, no particular groundwater sample indicates a direct source for pit water accumulation. It was also not possible to determine a ratio of groundwater inputs to pit composition.

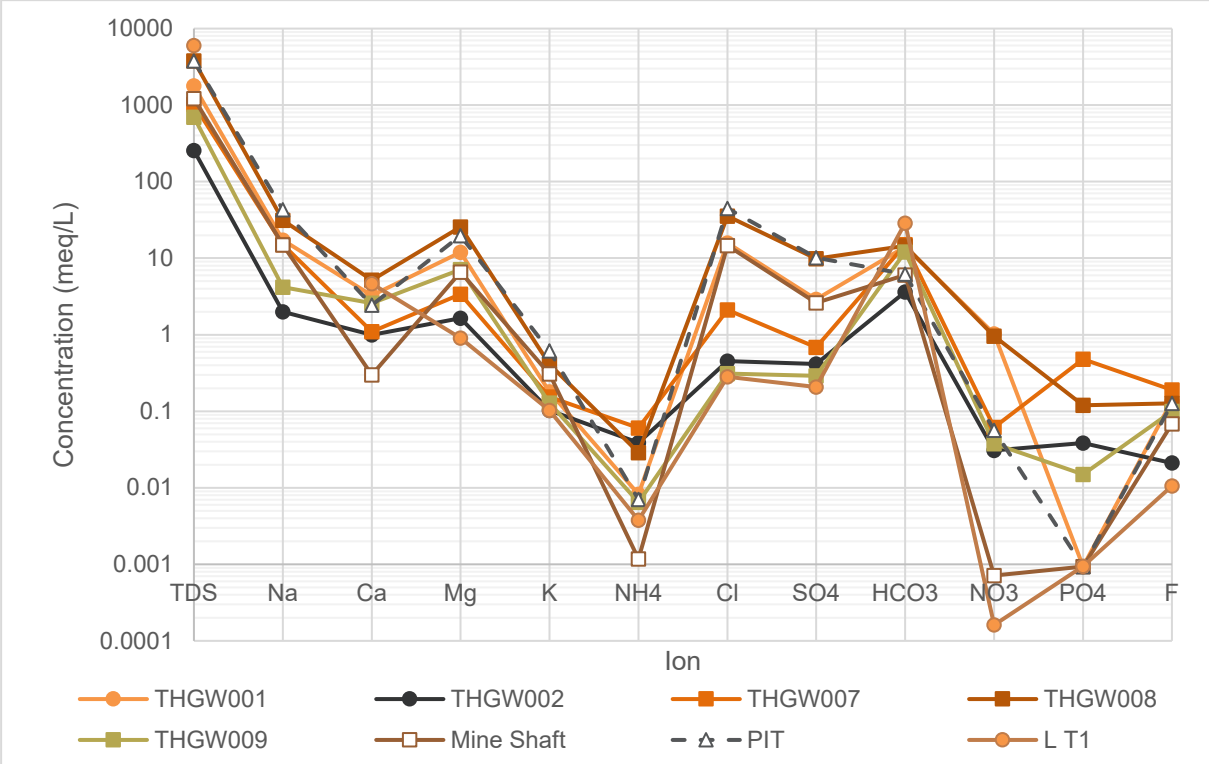
8.3.4 Comparison of leach test results and pit water quality

Due to the potential influence of rainfall runoff or infiltration on pit water quality, leach tests were conducted on waste rock and tailings samples. Waste rock was tested as a surrogate for runoff from the pit walls and tailings and tailings cover material as an indicator of potential leaching to groundwater from the TSF. The leach test completed was the Australian Standard Leach Procedure (ASLP) using deionised water. Results of the leach testing are presented in **Table 17** in the Tables Appendix (total concentration results for the same samples are provided in **Table 18**).

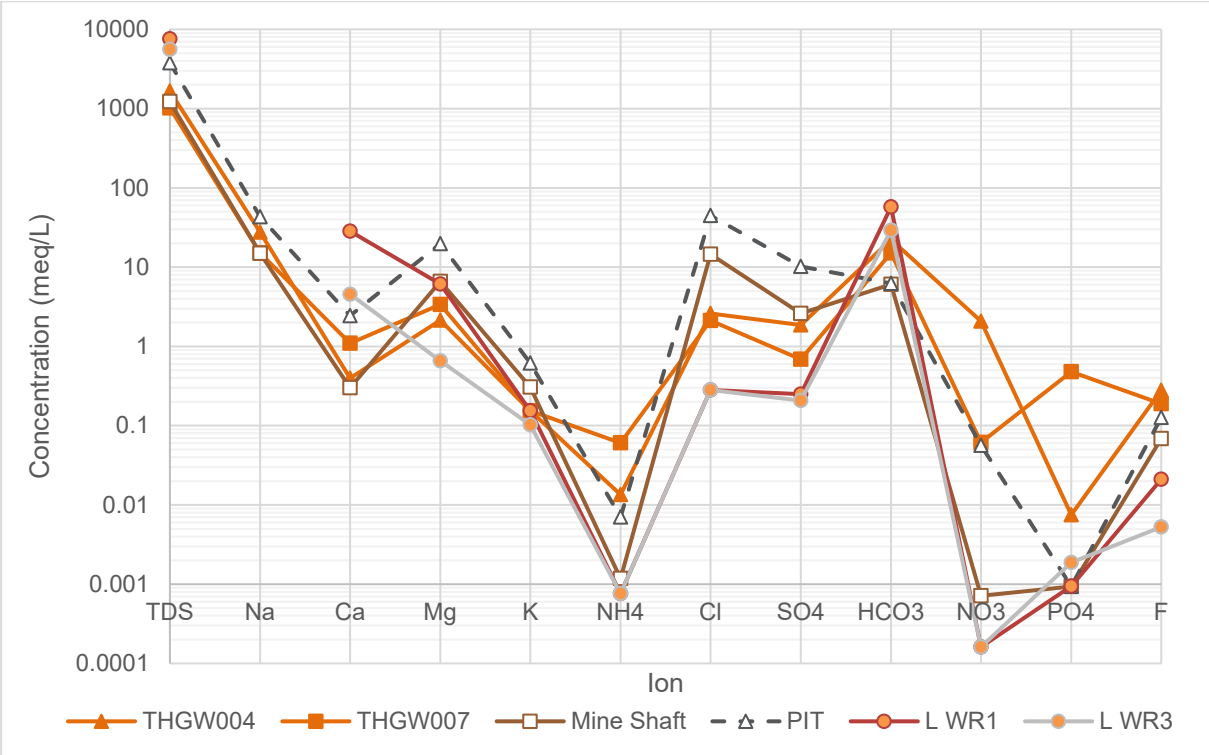
Leach test results are presented with pit water and selected groundwater results for the tailings material [L T1] (**Graph 8**) and waste rock [L WR1 and L WR3] (**Graph 9**).

The tailings leachate results had high salinity, calcium and bicarbonate results compared to groundwater and pit water, but had lower concentration of other ions. Of particular note were the very low concentrations of chloride and sulfate in the leachate. The waste rock samples also contained high salinity, calcium and bicarbonate, but low concentrations of other ions.

Overall, the leachate results indicate poor correlation with groundwater or pit water quality. If these samples are representative of runoff from the pit walls, this indicates that this is not a significant influence on pit water quality.



Graph 8. Schoeller plot of groundwater and pit chemistry with tailings leachate



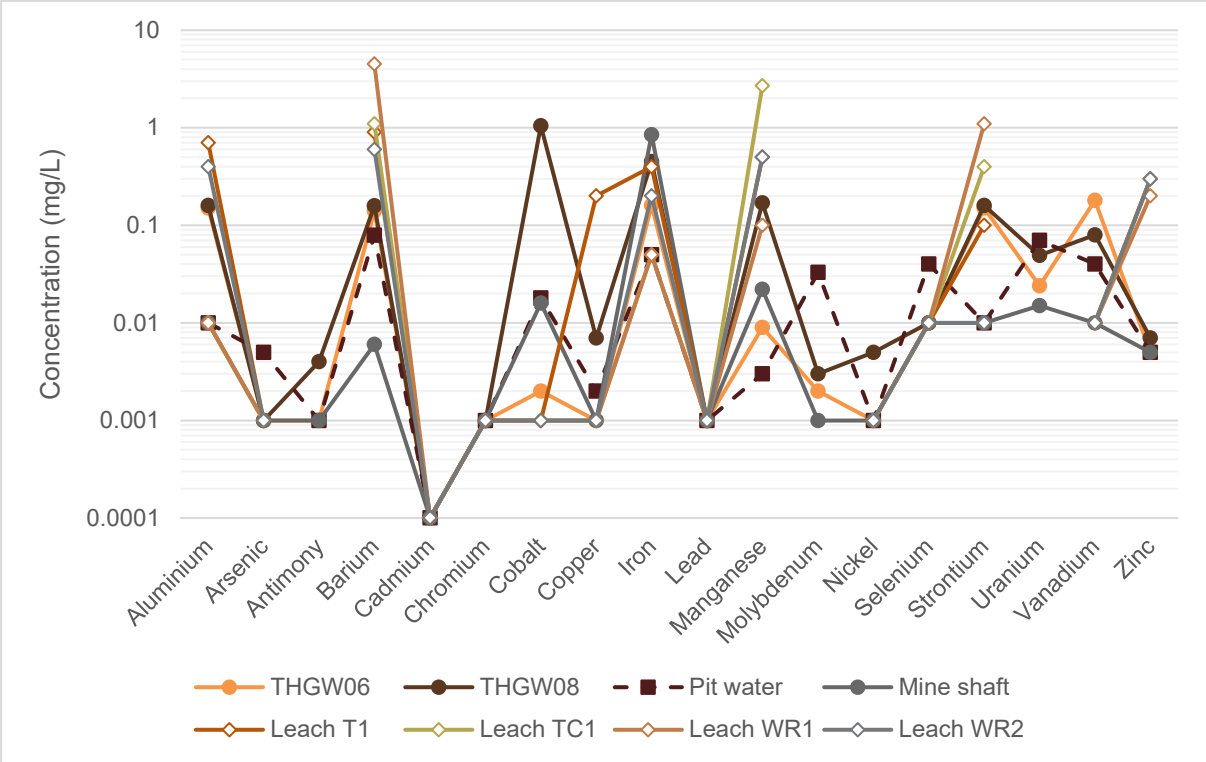
Graph 9. Schoeller plot of groundwater and pit chemistry with waste rock leachate

8.3.5 Metal concentrations in groundwater and pit water

Dissolved metal concentrations of pit water, groundwater and waste leachate were compared (**Graph 10**). For clarity, only the closest groundwater bores are included, however the full results are shown in **Tables 28 and 37** in the Tables Appendix od Environmental Earth Sciences (2023).

Results indicate that for the metals present, such as barium, iron and strontium, these were consistently observed between pit water, groundwater and leachate. Other metals, such as cadmium, chromium and lead were not detected in any locations. Leachate samples tended to have the highest metal concentrations, while the pit water and mine shaft location had lower concentrations than groundwater.

Overall metals concentrations are low, and sediment and pH may be significant in influencing minor variability between locations.



Graph 10. Dissolved metals concentrations in groundwater, pit and waste leachate

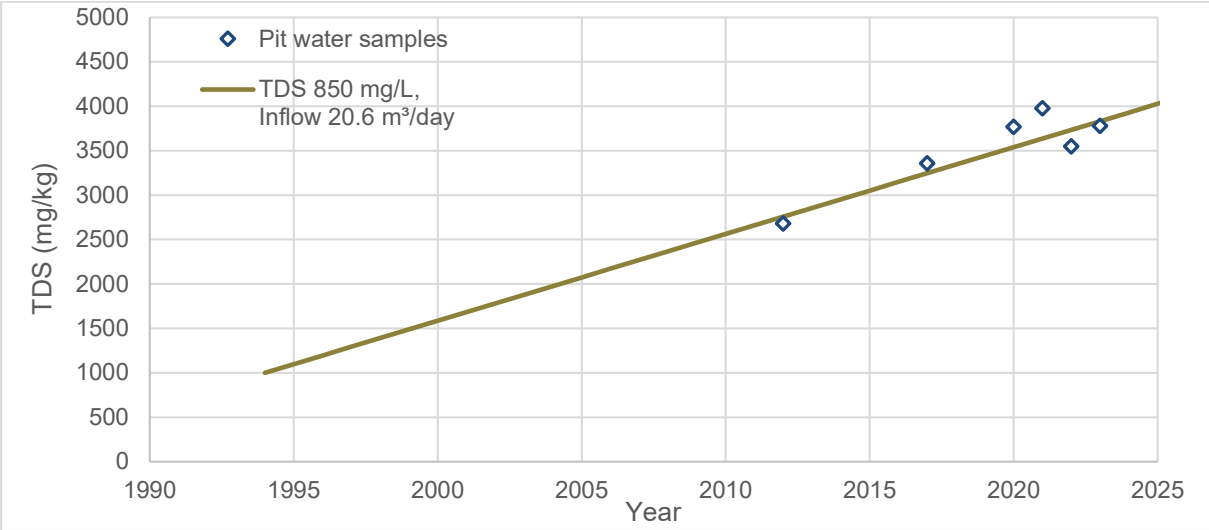
8.3.6 Pit salt balance

Analysis of groundwater and leachate (as a surrogate for runoff) samples indicates that while these correlate with pit water quality, they do not provide a consistent prediction for accumulation of ions or metals in the pit over time. For Tick Hill, the pit has been filling for 30 years, and has reached a stable water level. This differs from a current operational mine, where all pit water quality calculations require predictions.

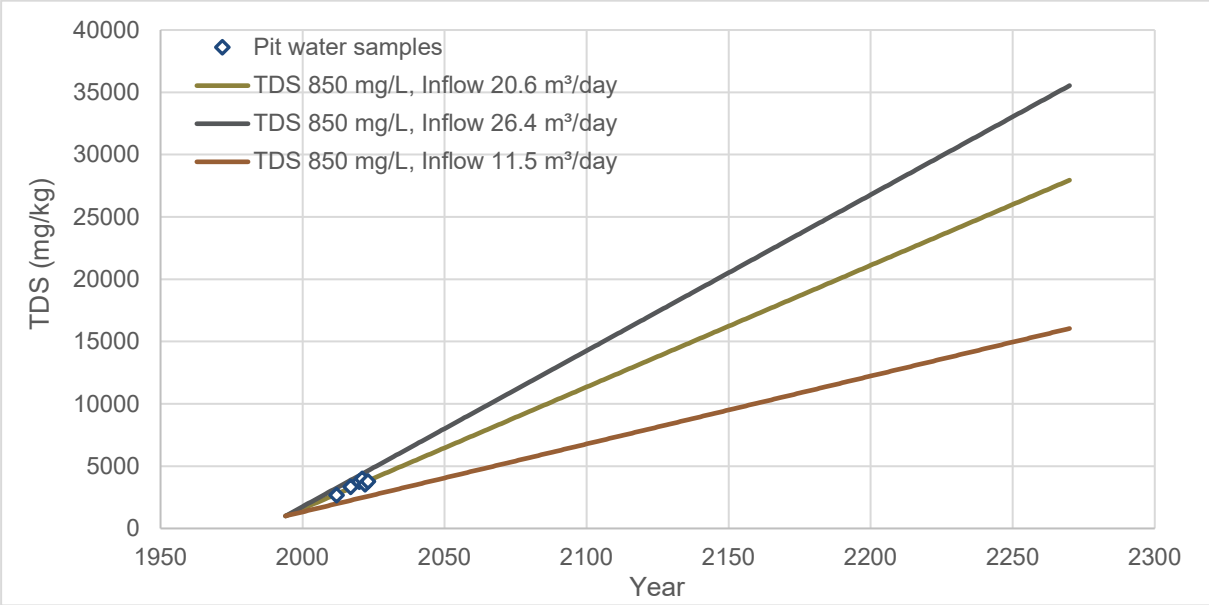
It is therefore considered that the current pit water quality provides the best available indication of how the various water sources combine to influence pit water composition. In order to determine how this would change into the future, a mass balance was developed using the pit water inflow (20.6 m^3/day) and estimate for groundwater inflow salinity. This was modelled from the initial filling with results shown in **Graph 11**, along with actual measurements of pit salinity between 2012 and 2023. Individual ion and metal concentrations were modelled with a direct concentration/ dilution from the 2021 to 2023 pit water quality results.

The pit water quality model was then extended for 250 years. Other groundwater inflow scenarios were also modelled. These were low groundwater inflow (11.5 m^3/day), which would occur under higher rainfall conditions (twice rainfall scenario – **Table 12**), and high groundwater inflow (26.4 m^3/day) which would occur under lower rainfall conditions (low rainfall scenario – **Table 12**). Predicted pit salinity for these models is shown in **Graph 12**. Of these, the low rainfall / high pit inflow scenario reaches TDS similar to seawater (35,000 mg/L) after 250 years. Continuation of current conditions results in a salinity of approximately 28,000 mg/L.

Calculated ion and metal concentrations for input into PHREEQC are presented in **Appendix E**.



Graph 11. Salt accumulation in pit since 1994, with measured values



Graph 12. Predicted salt accumulation in pit, with high and low groundwater inflow scenarios

8.3.7 Model of future groundwater chemistry

Groundwater composition over the 250-year period under the three scenarios was modelled in PHREEQC V3 (USGS 2021). Input data is presented in **Appendix E**, output is presented in **Appendix F**. Calculation intervals are approximately 9-10 years, calibrated against the overall pit salinity.

As the ion and metal concentrations in the pit concentrate over time, PHREEQC calculates the concentration of particular compounds in the pit water, including what compounds are likely to precipitate.

The saturation index (SI) indicates the potential for a compound to precipitate, with negative values indicating that a compound will remain in the dissolved phase and positive values indicating potential precipitation. As the overall ionic strength (salinity) of a solution increases, the saturation index of compounds will tend to increase.

The concentration of particular ions or compounds will also increase as the overall concentration of the pit water increases. Variation from strict concentration/ dilution effects occur when precipitation occurs. A selection of SIs and concentrations are presented below for ions and compounds. Note that concentrations are presented as log molality, which allows for comparison between compounds i.e., 4.0E-04 Ca is equivalent to 4.0E-04 $CaSO_4$. To summarise:

- Gypsum ($CaSO_4.2H_2O$) (**Graph 13**) has a solubility of 2530 mg/L in water. The SI is negative over the duration of the modelled period indicating that gypsum will predominately stay in solution. The modelled concentration of $CaSO_4$ (**Graph 14**) indicates that concentrations remain low but increase linearly.

- Calcite ($CaCO_3$) and Dolomite ($CaMg[CO_3]_2$) have low solubility and the SI values are positive from early in the modelled period (**Graphs 15 and 16**). Relative concentration of $CaCO_3$ and $MgCO_3$ increase over time as the SI becomes more positive (**Graphs 17 and 18**).

- Overall concentrations of carbonate and carbonate compounds (**Graph 19**), and calcium and calcium compounds (**Graph 20**) and sulfate and sulfate compounds (**Graph 21**) increase linearly and are not significantly impacted by calcite, dolomite or gypsum precipitation.

- The SI values for Goethite (FeOOH) (**Graph 22**) and $Fe(OH)_3$ (**Graph 23**) (and other iron compounds) are positive, indicating precipitation.

- Concentrations of $Fe(OH)_3$ (**Graph 24**) and ferric iron (**Graph 25**) compounds increase linearly.

- Concentrations of ferrous iron compounds (**Graph 26**) and Fe^{2+} (**Graph 27**) are substantially lower than the oxidised iron form, however relative concentrations increase as pit water concentrations increase. This is likely due to a shift in redox conditions as the pit becomes more saline and oxygen demand increases.

Modelling of pit water composition indicates that precipitation of calcite, dolomite and iron compounds is likely to occur. Gypsum and other salts are predicted to stay in solution. This is typical of moderate to high salinity water bodies. Within this range of salinity salt efflorescence is unlikely to occur around the pit lake perimeter.

8.3.8 Potential for exceedances of guideline values

As the salinity of the pit lake increases, the salinity, ion and metal concentrations will exceed various screening criteria. However, as the pit lake acts as a groundwater sink, is not accessible, and is not extracted for any beneficial use, these guideline value exceedances are not considered to be significant. While the pit lake may currently have incidental visitation by birds and wildlife, there are nearby stock-watering troughs which would provide an alternate water source when the pit lake becomes too saline.

9 QUALITATIVE RISK ASSESSMENT

9.1 Assessment Methodology

This section presents an assessment of the potential impacts to beneficial users of the pit lake. Potential impacts to groundwater and the surrounding environment as a result of the project have been assessed in the context of the mine pit and local hydrogeological setting, i.e., the CSM, and the relevant legislation and guidelines. The CSM was based on:

- a desktop study of existing information relating to the project site and catchment hydrogeology;
- assessment of mine pit water balance model, and
- assessment of mine pit geochemical model.

9.2 Likelihood and Consequence Matrix

A summary of the primary potential impacts of the different components of the project, based on the above discussion, has been provided in **Table 14**. The individual impacts are considered separately in terms of their likelihood and consequence; scores are attributed to both likelihood and consequence on a scale from 1 to 5 in each case. The risk is, in turn, scored as the sum of the likelihood and consequence scores.

Table 14: Risk matrix

		Likelihood				
Consequence		**Very unlikely (5)**	**Unlikely (4)**	**Possible (3)**	**Likely (2)**	**Very Likely (1)**
	Negligible (5)	10	9	8	7	6
	Minor (4)	9	8	7	6	5
	Moderate (3)	8	7	6	5	4
	Major (2)	7	6	5	4	3
	Critical (1)	6	5	4	3	2

Note(s):

1. Likelihood scale has five categories with scores from 5 to 1, i.e., Very Unlikely (5), Unlikely (4), Possible (3), Likely (2), Very Likely (1)
2. Consequence scale has five categories with scores from 5 to 1, i.e., Negligible (5), Minor (4), Moderate (3), Major (2), Critical (1)
3. Overall risk value = Consequence value + Likelihood value; consequence and likelihood are considered separately
4. Red denotes Extreme Risk (scores of 2-3), Orange denotes High Risk (scores of 4-5), Yellow denotes Moderate risk (scores of 6-7), Green denotes low risk (8-10)

9.3 Summary of Impacts

The risk matrix is illustrated in **Table 15** and confirms that potential impact of the pit lake to the local aquifer and nearby sensitive ecological receptors is low risk.

Table 15: Qualitative Impact Assessment

Component	Potential Impact to Receptor	Likelihood of Impact	Consequence of Impact	Level of Risk	Proposed Mitigation Measure	Observations
Mine pit to act as recharge source to groundwater	Contamination of groundwater	Very unlikely (5)	Minor (4)	Low (9)	Pit water level controlled by limited area of pit catchment	Pit water level not likely to increase to equilibrium with water table under any plausible rainfall scenario
Mine pit water impact to groundwater	Contamination of groundwater	Very unlikely (5)	Minor (4)	Low (9)	Prevent contamination impacts to mine pit	Risk based on current pit water chemistry and water balance
Direct overflow of contaminated water from pit flowing into nearby waterways	Contamination of surface water bodies	Very unlikely (5)	Minor (4)	Low (9)	Pit contains sufficient available volume to contain extreme rainfall events	Pit water level not likely to increase to top of pit under any plausible rainfall scenario
Pit water impacting on human or ecological receptors	Toxicity to human or ecological receptors	Very unlikely (5)	Minor (4)	Low (9)	Avoid extraction of pit water for beneficial uses	No known exposure pathway between pit and human or ecological receptors

10 SUMMARY OF FINDINGS

The findings of the development of a hydrogeological model of the pit lake at Tick Hill can be summarised as follows:

- The hydrogeological model indicates that the mine pit acts as a groundwater sink for the site, and will continue to do under a wide range of climatic conditions.
- No plausible rainfall scenario was identified which raised the water level to either the level of the surrounding water table, or to the top of the pit.
- The pit water level is controlled by the limited rainfall runoff due to the small catchment area around the pit.
- As the pit lake acts as a groundwater sink and evaporation dominates the water balance, salinity and associated dissolved ion and metal concentrations are predicted to increase over time. The expected pit salinity after 250 years is modelled as 28,000 mg/L TDS.
- Precipitation of calcite, dolomite and iron minerals is expected within the pit lake.
- No sensitive human or ecological receptors were identified that might be impacted by mine pit water quality.

11 RECOMMENDATIONS

Based on the hydrogeological model developed for the Tick Hill mine pit, the following recommendations are made:

- That the pit continue to be fenced to prevent access by visitors or stock.
- That the pit catchment continue to be controlled so that runoff inflow is limited.
- That pit water not be extracted for beneficial use without testing to determine its suitability for that use. Extracted pit water should not be discharged to watercourses.

12 LIMITATIONS

This report has been prepared by Environmental Earth Sciences QLD ACN 109 442 284 in response to and subject to the following limitations:

1. The specific instructions received from Tick Hill Mining Pty Ltd;

2. The specific scope of works set out in PO724067 issued by Environmental Earth Sciences for and on behalf of Tick Hill Mining Pty Ltd, is included in Section 3 (Scope of Work) of this report;

3. May not be relied upon by any third party not named in this report for any purpose except with the prior written consent of Environmental Earth Sciences QLD (which consent may or may not be given at the discretion of Environmental Earth Sciences QLD);

4. This report comprises the formal report, documentation sections, tables, figures and appendices as referred to in the index to this report and must not be released to any third party or copied in part without all the material included in this report for any reason;

5. The report only relates to the site referred to in the scope of works being located at Tick Hill Gold Mine ("the site");

6. The report relates to the site as at the date of the report as conditions may change thereafter due to natural processes and/or site activities;

7. No warranty or guarantee is made in regard to any other use than as specified in the scope of works and only applies to the depth tested and reported in this report;

8. Fill, soil, groundwater and rock to the depth tested on the site may be fit for the use specified in this report. Unless it is expressly stated in this report, the fill, soil and/or rock may not be suitable for classification as clean fill if deposited off site;

9. This report is not a geotechnical or planning report suitable for planning or zoning purposes; and

10. Our General Limitations set out at the back of the body of this report.

14 GLOSSARY OF TERMS

The following descriptions are of terms used in the text of this report.

Alluvial. Describes material deposited by, or in transit in, flowing water.

Anaerobic. Reducing or without oxygen.

Aquifer. A rock or sediment in a formation, group of formations, or part of a formation which is saturated and sufficiently permeable to transmit economic quantities of water to bores and springs.

Aquifer, confined. An aquifer that is overlain by a confining bed with significantly lower hydraulic conductivity than the aquifer.

Aquifer, perched. A region in the unsaturated zone where the soil is locally saturated because it overlies soil or rock of low permeability.

Background. The natural level of a property.

Baseline. An initial value of a measure.

Biodegradation. A biochemical process of microbial oxidation of complex organic compounds, to simpler chemical products. Micro-organisms derive the energy and cell carbon for growth from oxidation of organic compounds.

Bore. A hydraulic structure that facilitates the monitoring of groundwater level, collection of groundwater samples, or the extraction (or injection) of groundwater. Also known as a well, monitoring bore or piezometer, although piezometers are typically of small diameter and only used for measuring the groundwater elevation or potentiometric surface.

Borehole. An uncased well drill hole.

Cation Exchange Capacity (CEC). The maximum positive charge required to balance the negative charge on colloids (clays and other charged particles). The units are milli-equivalents per 100 grams of material or centimoles of charge per kilogram of exchanger.

Clay. A soil material composed of particles finer than 0.002 mm. When used as a soil texture group such soils contain at least 35% clay.

Colluvial. Unconsolidated soil and rock material moved down-slope by gravity.

Confined Aquifer. An aquifer that is confined between two low-permeability aquitards. The groundwater in these aquifers is usually under hydraulic pressure, i.e. its hydraulic head is above the top of the aquifer.

Confining layer. A layer with low vertical hydraulic conductivity that is stratigraphically adjacent to one or more aquifers. A confining layer is an aquitard. It may lie above or below the aquifer.

Contaminant. Generally, any chemical species introduced into the soil or water. More particularly relates to those species that render soil or water unfit for beneficial use.

Contamination. Is considered to have occurred when the concentration of a specific element or compound is established as being greater than the normally expected (or actually quantified) background concentration.

Diffusion. A process by which species in solution move, driven by concentration gradients (from high to low).

Dilution. The mixing of a small volume of contaminated leachate with a large volume of uncontaminated water. The concentration of contaminants is reduced by the volume of the lower concentrated water. However the physical process of dilution often causes chemical disequilibria resulting in the destruction of ligand bonds, the alteration of solubility products and the alteration of water pH. This usually causes precipitation by different chemical means of various species.

Discrete sample. Samples collected from different locations and depths that will not be composited but analysed individually.

Dispersion. A process by which species in solution mix with a second solution, thus reducing in concentration. In particular, relates to the reduction in concentration resulting from the movement of flowing groundwater.

Dissolved Oxygen (DO). Oxygen in the gaseous phase dissolved in water. Measured either as a concentration in mg/L or as a percentage of the theoretical saturation point, which is inversely related to temperature. At 19, 20 and 21 degrees Celsius, the oxygen concentrations in mg/L corresponding to 100% saturation are 9.4, 9.2 and 9.0 respectively.

Electrical Conductivity (EC). The EC of water is a measure of its ability to conduct an electric current. This property is related to the ionic content of the sample, which is in turn a function of the total dissolved (ionisable) solids (TDS) concentration. An estimate of TDS in fresh water can be obtained by multiplying EC by 0.65.

Flow path. The direction in which groundwater is moving.

Fluvial. A material deposited by, or in transit, in streams or watercourses.

Fracture. A break in the geological formation, e.g. a shear or a fault.

Gradient. The rate of inclination of a slope. The degree of deviation from the horizontal; also refers to pressure.

Groundwater. The water held in the pores in the ground below the water table.

Groundwater Elevation. The elevation of the groundwater surface measured relative to a specified datum such as the Australian Height Datum (mAHD) or an arbitrary survey datum onsite, or “reduced level” (mRL).

Head space. The air space at the top of a soil or water sample.

Heavy Metals. All metallic elements whose atomic mass exceeds that of calcium (20). Typical analysis for heavy metals includes cadmium (Cd), chromium (Cr), copper (Cu), nickel (Ni), lead (Pb), zinc (Zn), and the metalloid arsenic (As).

Heterogeneous. A condition of having different characteristics in proximate locations. Non-uniform. (Opposite of homogeneous).

Hydraulic Conductivity (K). A coefficient describing the rate at which water can move through a permeable medium. It has units of length per time. The units for hydraulic conductivity are typically $m^3/day/m^2$ or m/day.

Hydraulic Gradient (i). The rate of change in total head per unit of distance of flow in a given direction – the direction is that which yields a maximum rate of decrease in head. Hydraulic Gradient is unit less.

Hydraulic Head (h). The sum of the elevation head and the pressure head at a point in an aquifer. This is typically reported as an elevation above a fixed datum, such as sea level.

Infiltration. The passage of water, under the influence of gravity, from the land surface into the subsurface.

Ionic Exchange. Adsorption occurs when a particle with a charge imbalance, neutralises this charge by the attraction (and subsequent adherence of) ions of opposite charge from solution. There are two types of such a charge: pH dependent; and pH independent or crystalline charge. Metal hydroxides and oxy-hydroxides represent examples of the former type, whilst clay minerals are representative of the latter and are normally associated with cation exchange.

Ions. An ion is a charged element or compound as a result of an excess or deficit of electrons. Positively charged ions are called cations, whilst negatively charged ions are called anions. Cations are written with superscript $^{+}$, whilst anions use $^{-}$ as the superscript. The major aqueous ions are those that dominate total dissolved solids (TDS). These ions include: Cl^-, SO_4^{2-}, HCO_3^-, Na^+, Ca^{2+}, Mg^{2+}, K^+, NH_4^+, NO_3^-, NO_2^-, F^-, PO_4^{3-} and the heavy metals.

Perched Groundwater. Unconfined groundwater separated from an underlying main body of groundwater by an unsaturated zone. Perched groundwater typically occurs in discontinuous, often ephemeral, lenses, with unsaturated conditions both above and below.

Permeability (k). Property of porous medium relating to its ability to transmit or conduct liquid (usually water) under the influence of a driving force. Where water is the fluid, this is effectively the hydraulic conductivity. A function of the connectivity of pore spaces.

Piezometric or Potentiometric Surface. A surface that represents the level to which water will rise in cased bores. The water table is the potentiometric surface in an unconfined aquifer.

pH. A logarithmic index for the concentration of hydrogen ions in an aqueous solution, which is used as a measure of acidity.

Porosity (n). The ratio of the volume of void spaces in a rock or sediment to the total volume of the rock or sediment. Typically given as a percentage.

Porosity, effective (ne). The volume of the void spaces through which water or other fluids can travel in a rock or sediment divided by the total volume of the rock or sediment.

Precipitation (chemical). There are two types of precipitation, pH dependent precipitation and solubility controlled precipitation. As the pH is raised beyond a threshold level the precipitation of metal cations such as oxy-hydroxides and hydroxides occur. As the pH is raised further precipitation continues until there are very few metal cations remaining in solution. This reaction is entirely reversible. Solubility controlled precipitation occurs between two ions when, at a given temperature and pressure, the concentration of one of the ions exceeds a certain level.

Purge (bores). The pumping out of monitoring bore water to remove drilling debris or impurities; also conducted to bring fresh groundwater into the casing for sample collection. The later ensures that a more representative sample of an aquifer is taken.

QA/QC. Quality Assurance / Quality Control.

Recharge Area. Location of the replenishment of an aquifer by a natural process such as addition of water at the ground surface, or by an artificial system such as addition through a well

Recovery. The rate at which a water level in a bore rises after pumping ceases.

Saturated Zone. A zone in which the rock or soil pores are filled (saturated) with water.

Standing Water Level (SWL). The depth to the groundwater surface in a well or bore measured below a specific reference point – usually recorded as metres below the top of the well casing or below the ground surface.

Stratigraphy. A vertical sequence of geological units.

Total Dissolved Salts (TDS). The total dissolved salts comprise dissociated compounds and undissociated compounds, but not suspended material, colloids or dissolved gases.

Toxicity. The inherent potential or capacity of a material to cause adverse effects in a living organism.

Unsaturated Zone. The zone between the land surface and the water table, in which the rock or soil pores contain both air and water (water in the unsaturated zone is present at less than atmospheric pressure). It includes the root zone, intermediate zone and capillary fringe. Saturated bodies such as perched groundwater may exist in the unsaturated zone. Also referred to as the Vadose Zone.

Volatile. Having a low boiling or subliming pressure (a high vapour pressure).

Water table. Interface between the saturated zone and unsaturated zones. The surface in an aquifer at which pore water pressure is equal to atmospheric pressure.

Well. See **Bore** (monitoring bore).

ENVIRONMENTAL EARTH SCIENCES
CONTAMINATION RESOLVED

ENVIRONMENTAL EARTH SCIENCES GENERAL LIMITATIONS

Scope of services
The work presented in this report is Environmental Earth Sciences response to the specific scope of works requested by, planned with and approved by the client. It cannot be relied on by any other third party for any purpose except with our prior written consent. Client may distribute this report to other parties and in doing so warrants that the report is suitable for the purpose it was intended for. However, any party wishing to rely on this report should contact us to determine the suitability of this report for their specific purpose.

Data should not be separated from the report
A report is provided inclusive of all documentation sections, limitations, tables, figures and appendices and should not be provided or copied in part without all supporting documentation for any reason, because misinterpretation may occur.

Subsurface conditions change
Understanding an environmental study will reduce exposure to the risk of the presence of contaminated soil and or groundwater. However, contaminants may be present in areas that were not investigated, or may migrate to other areas. Analysis cannot cover every type of contaminant that could possibly be present. When combined with field observations, field measurements and professional judgement, this approach increases the probability of identifying contaminated soil and or groundwater. Under no circumstances can it be considered that these findings represent the actual condition of the site at all points.

Environmental studies identify actual sub-surface conditions only at those points where samples are taken, when they are taken. Actual conditions between sampling locations differ from those inferred because no professional, no matter how qualified, and no sub-surface exploration program, no matter how comprehensive, can reveal what is hidden below the ground surface. The actual interface between materials may be far more gradual or abrupt than an assessment indicates. Actual conditions in areas not sampled may differ from that predicted. Nothing can be done to prevent the unanticipated. However, steps can be taken to help minimize the impact. For this reason, site owners should retain our services.

Problems with interpretation by others
Advice and interpretation is provided on the basis that subsequent work will be undertaken by Environmental Earth Sciences QLD. This will identify variances, maintain consistency in how data is interpreted, conduct additional tests that may be necessary and recommend solutions to problems encountered on site. Other parties may misinterpret our work and we cannot be responsible for how the information in this report is used. If further data is collected or comes to light we reserve the right to alter their conclusions.

Obtain regulatory approval
The investigation and remediation of contaminated sites is a field in which legislation and interpretation of legislation is changing rapidly. Our interpretation of the investigation findings should not be taken to be that of any other party. When approval from a statutory authority is required for a project, that approval should be directly sought by the client.

Limit of liability
This study has been carried out to a particular scope of works at a specified site and should not be used for any other purpose. This report is provided on the condition that Environmental Earth Sciences QLD disclaims all liability to any person or entity other than the client in respect of anything done or omitted to be done and of the consequence of anything done or omitted to be done by any such person in reliance, whether in whole or in part, on the contents of this report. Furthermore, Environmental Earth Sciences QLD disclaims all liability in respect of anything done or omitted to be done and of the consequence of anything done or omitted to be done by the client, or any such person in reliance, whether in whole or any part of the contents of this report of all matters not stated in the brief outlined in Environmental Earth Sciences QLD's proposal number and according to Environmental Earth Sciences general terms and conditions and special terms and conditions for contaminated sites.

To the maximum extent permitted by law, we exclude all liability of whatever nature, whether in contract, tort or otherwise, for the acts, omissions or default, whether negligent or otherwise for any loss or damage whatsoever that may arise in any way in connection with the supply of services. Under circumstances where liability cannot be excluded, such liability is limited to the value of the purchased service.

APPENDIX B: ENVIRONMENTALLY SENSITIVE AREAS

ENVIRONMENTALLY SENSITIVE AREAS - Mining Activities

Selected Mining Lease (ML)

CATEGORY A

- National Parks
- Conservation Parks
- Forest Reserves
- Special Wildlife Reserve
- Wet Tropics World Heritage Area
- Great Barrier Reef Marine Park Area
- Marine Parks other than General Use Zones

CATEGORY B

- Queensland Heritage Register Places
- Ramsar Sites
- Cultural Heritage Registered Areas and DLA's other than Stanbroke
- Special Forestry Areas
- Seaward Side of Highest Astronomical Tide
- Fish Habitat Areas
- Coordinated Conservation Areas
- Endangered Regional Ecosystems - regrowth and remnant (Biodiversity Status)
- General Use Zones of Marine Parks
- Marine Plants

CATEGORY C

- Nature Refuges
- Resources Reserve
- State Forests
- Timber Reserves
- River Improvement Areas
- Stanbroke DLA
- Coastal Management District
- Dams and Weirs

OTHERS

- Towns
- Roads
- Repealed Wild River Nominated Waterways
- Repealed Wild River Preservation Areas
- Repealed Wild River High Preservation Areas
- Mahogany Glider Habitat
- Directory of Important Wetlands
- Queensland

LOCALITY DIAGRAM

0 110 220 330 440 550 m

This product is projected into GDA 1994 MGA Zone 54

Information presented on this product is distributed by the Queensland Government as an information source only. While every care is taken to ensure the accuracy of this data, The State of Queensland makes no statements, representations or warranties about the accuracy, reliability, completeness or suitability of any information contained in this product.

The State of Queensland disclaims all responsibility for information contained in this product and all liability (including without limitation, liability in negligence) for all expenses, losses, damages and costs you may incur as a result of the information being inaccurate or incomplete in any way for any reason.

NOTE TO USER: Themes presented in this map are indicative only. Field survey may be required to verify the 'true' spatial extent and value. Not all environmentally sensitive areas are presented in this map. A user should refer to the particular circumstances relevant to their situation to assess the 'completeness' of themes provided.

The user should note that some boundaries and indicated values are ambient and may change over time (e.g. regional ecosystem boundaries and conservation status, watercourse mapping etc).

The user should be aware that due to multiple overlapping themes/ layers present, some themes/layers may be obscured by others. Ordering in the Legend does not accurately reflect the order by which themes/layers are displayed.
