1 Introduction

AARC Environmental Solutions Pty Ltd (AARC) has been commissioned by Magnetic South Pty Ltd to develop a Progressive Rehabilitation and Closure Plan (PRCP) for the Gemini Project (the Project) in accordance with the requirements of the *Environmental Protection Act 1994* (EP Act).

The Gemini Project is a greenfield open cut metallurgical coal mine designed to produce pulverised coal injection (PCI) coal and coking coal for export to the international steel-making industry. The open cut mine will develop the coal seams in the Rangal Coal Measures.

An Environmental Authority (EA) (P-EA-100114292) for the Project was issued to Magnetic South Pty Ltd on 6 June 2024. The EA authorises the environmentally relevant activity (ERA) of Mining black coal under Schedule 3 of the Environmental Protection Regulation 2019. This PRCP is applicable to Mining Lease (ML) ML700056. The current version of the Environmental Authority (EA) P-EA-100114292 for the Project was issued on 29 October 2024.

A transition notice under s 754 of the EP Act was issued to Magnetic South on 6 June 2024, with the requirement to submit a proposed PRCP to the administering authority by 6 December 2024. This PRCP meets the legislative requirements under sections 126C, 126D and 754 of the EP Act as well as the Department of Environment, Tourism, Science and Innovation (DETSI) 'Progressive Rehabilitation and Closure Plan Guideline' (PRCP Guideline) (DESI 2024).

2 Scope and objective

The purpose of this PRCP is to describe how progressive rehabilitation will be carried out at the Project. The PRCP has been developed in accordance with the requirements of the PRCP Guideline, which states that the PRCP must include the following parts.

Rehabilitation Planning part:

The purpose of the rehabilitation planning part of the PRCP is to support and justify the development of the proposed PRCP schedule. This part must detail how progressive rehabilitation and closure will be carried out over the entire Project site. The critical components of the rehabilitation planning part for the Project are:

- community consultation information (refer to section 3.2);
- post-mining land use (PMLU) determination (refer to section 3.3);
- voids in floodplains (refer to section 3.1.8);
- rehabilitation and management methodology (refer to section 3.5);
- risk assessment (refer to section 3.6); and
- a monitoring and maintenance program (refer to section 3.7).

Rehabilitation Schedule part:

The Rehabilitation schedule is a required element of a PRCP. Once approved, the schedule becomes a legally binding and enforceable instrument with which the EA holder must comply. The schedule must include:

- nomination of either a PMLU or non-use management area (NUMA) for all land within the relevant resource tenures, including land uses for undisturbed land;
- identification of when land becomes available for rehabilitation or improvement;
- rehabilitation or management milestones to achieve the PMLU or NUMA outcomes;
- milestone criteria that demonstrate when each milestone has been completed;
- completion dates for each milestone to be achieved; and
- any conditions considered necessary or desirable.

Two deemed conditions are to be included in all PRCP schedules per section 206A of the EP Act. The first condition states that when carrying out a relevant activity under the PRCP schedule, the holder must comply with a requirement stated in the EA relevant to carrying out the activity. This condition applies even if the EA is suspended. The second condition states that the holder must comply with the following matters stated in the schedule:

- each rehabilitation milestone and management milestone; and
- when each rehabilitation milestone and management milestone is to be achieved.

The administering authority may impose a condition on a PRCP schedule if it considers the condition necessary or desirable (section 4.2 of the PRCP Guideline).

3 Project planning part

3.1 Project planning

3.1.1 Project description

The Project is situated within the Bowen Basin, approximately 110 km east of Emerald and 125 km southwest of Rockhampton, in central Queensland. The project location is shown in Figure 1. The Project is comprised of a single Mining Lease (ML 700056), which covers a total area of 6121 ha.

The Gemini open cut metallurgical coal mine will produce PCI coal and coking coal for export to the international steel-making industry. The Project targets a mining output of 1.9 Mtpa ROM and is scheduled to operate 24 hours a day, 7 days a week, during its operating life.

The open cut mining areas will be developed using a conventional truck and shovel mining method with excavators and haul trucks. The coal product will be transported via the Blackwater railway to the Port of Gladstone for export to international markets. The overall Project term is anticipated to be 37 years from the grant of the ML, including initial construction, mine operation, and rehabilitation activities. On Project commencement, mine construction activities are expected to take approximately six months to establish the necessary infrastructure for overburden removal, followed by an additional 18 months to initiate coal production.

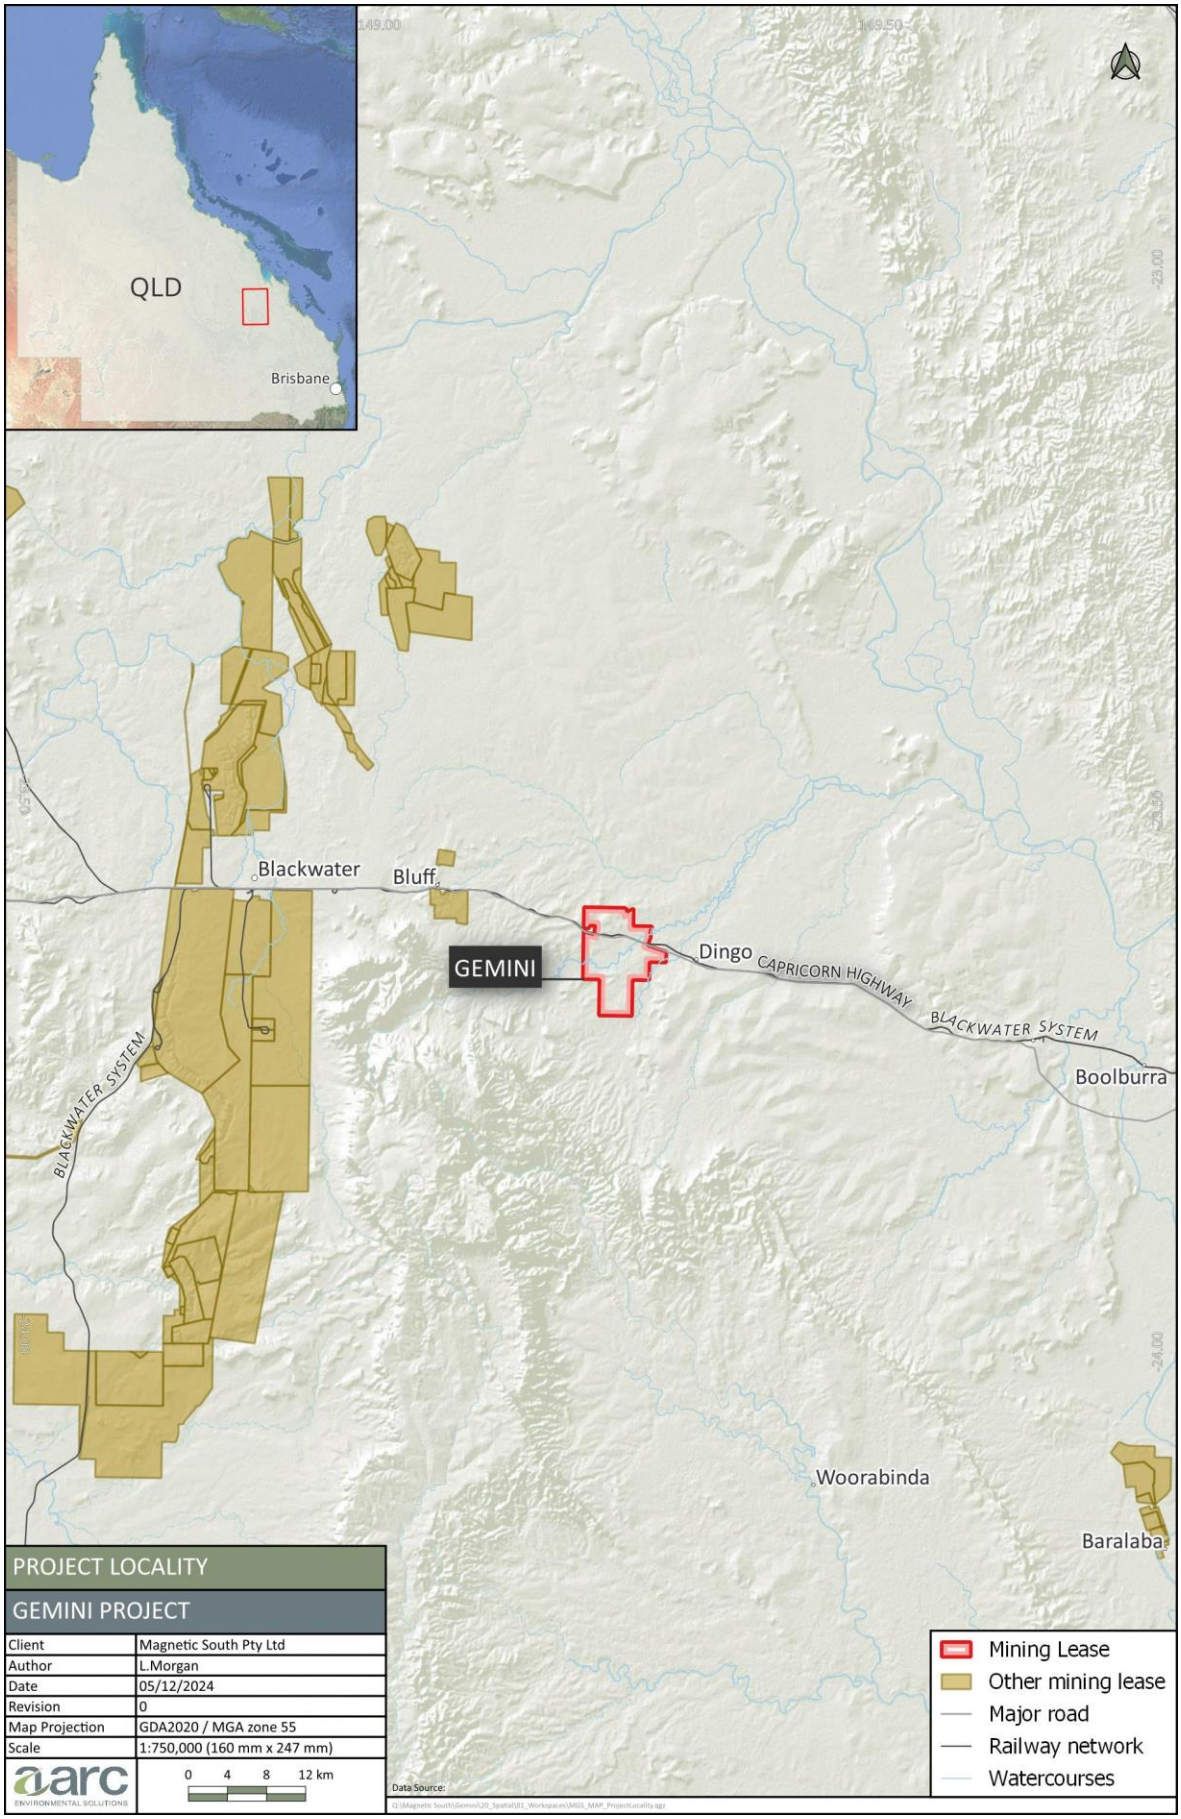

Figure 1: Project locality

3.1.1.1 Project activities

The Project will include the resource activity of 'mining black coal' as well as the ancillary activities outlined in Table 1, all of which are authorised under the EA. Notifiable activities relevant to the Project are identified in Table 2.

Table 1: Applicable ERAs for the Project

Environmentally Relevant Activity	Description
Schedule 3 (Resource Activity)	
13 Mining black coal	Mining black coal
Schedule 2 (Prescribed ERAs)	
8 (3) (iii) Chemical storage	Chemical storage (the ***relevant activity***) consists of storing more than 500 m^3 of class C1 or C2 combustible liquids under AS 1940 or dangerous goods class 3 under subsection (1)(c).
31 (2) (b) Mineral processing	Mineral processing (the ***relevant activity***) processing, in a year, the following quantity of mineral products, other than coke — more than 100,000t
33 Crushing, milling, grinding or screening	Crushing, milling, grinding or screening (the relevant activity) consists of crushing, grinding, milling or screening more than 5,000 t of material in a year.
60 (2) subsection (1)(b)–(h) Waste disposal	Waste disposal (the relevant activity) consists of operating a facility for disposing of, in a year, more than 200,000t of waste.
63 (1)(b)(i) Sewage treatment	Sewage treatment (the relevant activity) consists of operating sewage treatment works, other than no-release works, with a total daily peak design capacity of more than 100 but not more than 1,500 EP if treated effluent is discharged from the works to an infiltration trench or through an irrigation scheme

Table 2: Notifiable activities applicable to the Project as per the EP Act 1994

Notifiable Activities	Description
Schedule 3	
1 Abrasive Blasting	Carrying out abrasive blast cleaning (other than cleaning carried out in fully enclosed booths) or disposing of abrasive blasting material.
7 Chemical Storage	Storing more than 10 t of chemicals (other than compressed or liquefied gases) that are dangerous goods under the dangerous goods code.
15 Explosives production or storage	Operating an explosives factory under the *Explosives Act 1999.*
24 Mine Wastes	• storing hazardous mine or exploration wastes, including, for example, tailing dams, overburden or waste rock dumps containing hazardous contaminants; or • exploring for, or mining or process, minerals in a way that exposes faces, or releases groundwater, containing hazardous contaminants.
29 Petroleum Product or Oil Storage	Storing petroleum products or oil: a) in underground tanks with more than 200 litre (L) capacity; or b) in above ground tanks with: a) for petroleum products or oil in class 3 in packaging groups 1 and 2 of the dangerous goods code – more than 2,500 L capacity; or b) for petroleum products or oil in class 3 in packaging groups 3 of the dangerous goods code – more than 5,000 L capacity; or c) for petroleum products that are combustible liquids in class C1 or C2 in *Australian Standard AS1940 The storage and handling of flammable and combustible liquids* published by Standards Australia – more than 25,000 L capacity.
37 Waste Storage, treatment of disposal	Storing, treating, reprocessing or disposing of waste prescribed under a regulation to be regulated waste for this item (other than at the place it is generated), including operating a nightsoil disposal site or sewage treatment plant where the site or plant has a design capacity that is more than the equivalent of 50,000 persons having sludge drying beds or on-site disposal facilities.

3.1.1.2 Resource tenements

The Project is located entirely within ML700056, which is underlain by an exploration permit for coal (EPC) 881, as shown in Figure 2. Both the surface rights within ML700056 and the exploration rights within EPC881 are held by Magnetic South, as described in Table 3 and Table 4, respectively.

The project area has no petroleum tenements overlapping or adjoining the ML. Other tenements proximal to the ML include EPC 960 and mineral development licence (MDL) 505 held by Walton Coal Pty Ltd (Figure 2). The coal tenements that overlap or occur adjacent to the Project are listed in Table 4.

Table 3: Resource tenement details

Resource tenement	Grant date	Expiry date	Area (ha)
ML700056	29/10/2024	30 September 2049	6121

Table 4: Coal tenements

Authorised tenement	Tenement number	Location in relation to the Project
Exploration permit of coal		
Walton Coal Pty Ltd	EPC 960	Adjacent to Lot 1/RP904099
Magnetic South Pty Ltd	EPC 881	Overlapping Lot 4/RP801280
Mineral development licence		
Walton Coal Pty Ltd	MDL 505	Adjacent to 100SP325594

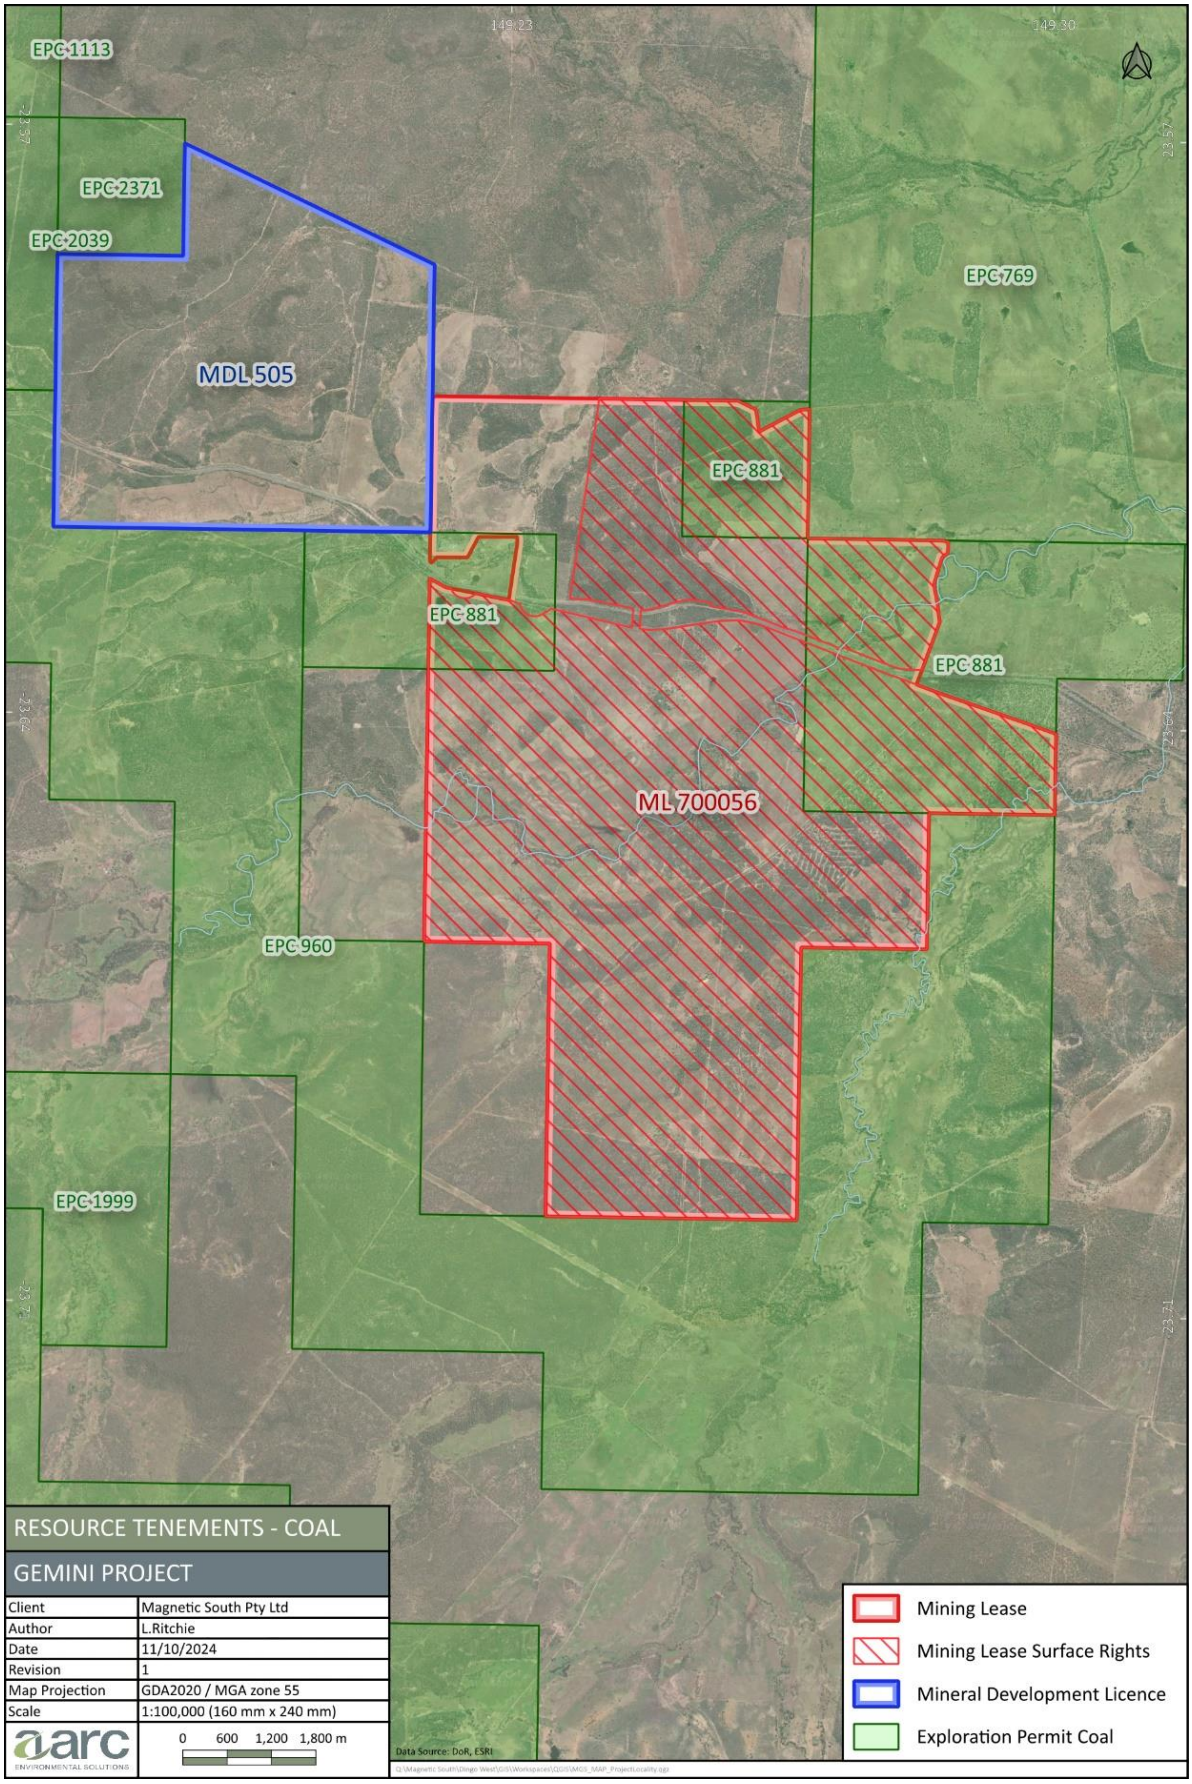

Figure 2: Resource tenements coal

3.1.1.3 Mining operations and site layout

The open cut mine will be developed using a conventional truck and shovel mining method with excavators and haul trucks. Coal will be handled, prepared, stockpiled on-site, and transferred via conveyor to a train load out (TLO) facility for transport. The coal product will then be transported via rail to the Port of Gladstone for export to international markets.

The main activities associated with the Project include:

- ongoing exploration activities to support mine planning;
- development of a mine infrastructure area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, wash bay, laydown area, sewage, effluent and liquid waste storage, and a helipad;
- construction and operation of a coal handling and preparation plant (CHPP) and coal handling facilities adjacent to the MIA, including run-of-mine (ROM) coal and product coal stockpiles and rejects bin/overflow (coarse and fine rejects);
- construction and operation of a surface conveyor from the product stockpiles to a TLO facility and rail loop connecting to the Blackwater Railway to transport product coal to coal terminals at Gladstone for export;
- construction of an accommodation facility, sewage treatment plant and effluent irrigation area within the northwest bounds of the MLA;
- construction of access roads from the Capricorn Highway to the MIA and from the Capricorn Highway to the TLO facility;
- installation of a raw water supply pipeline to connect to the Blackwater Pipeline network;
- construction of a 66 kV transmission line and switching/substation to connect to the existing regional network;
- other associated minor infrastructure, plant, equipment and activities;
- development of mine areas (open cut pits) and out-of-pit waste rock emplacements;
- drilling and blasting of competent waste material;
- mine operations using conventional surface mining equipment (excavators, front-end loaders, rear dump trucks, dozers);
- mining up to 1.9 Mtpa ROM coal (average of 1.8 Mtpa) for a construction/production period of approximately 20 years;
- progressive placement of waste rock in:
    - emplacements adjacent to and near the open cut voids; and
    - mine voids, behind the advancing open cut mining operations;
- progressive rehabilitation of waste rock emplacement areas and mined voids;
- progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works; material will be sourced from local quarries where required);
- disposal of CHPP rejects (coarse and fine rejects) in out-of-pit waste rock dumps and in-pit behind the mining void;
- progressive development of internal roads and haul roads, including a causeway over Charlevue Creek to enable coal haulage and pit access; and
- development of water storage and sediment dams and the installation of pumps, pipelines, and other water management equipment and structures, including temporary levees, diversions and drains.

Existing local and regional infrastructure, facilities and services would be used to support Project activities. These include the Sunwater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and the Gladstone export coal terminals.

The conceptual mine layout showing mine infrastructure and the authorised disturbance footprint is provided in Figure 3. The conceptual Project layout represents the total area to be disturbed by mine operations only and does not equate to the disturbance footprint at any one point in time.

The total disturbance footprint for the Project is 1,968.0 ha, which incorporates all mining and infrastructure components as described in Table 5.

Open cut mining areas will be progressively rehabilitated over the life of the mine. A key component of the rehabilitation methodology is the progressive backfilling of open cut pits with the excavated overburden or waste rock material. The proposed staging for the progressive rehabilitation of the Project's disturbance areas is demonstrated through Figure 4 to Figure 14.

Future exploration drilling will be performed and rehabilitated in accordance with the EA and standard conditions contained in the *Eligibility criteria and standard conditions for exploration and mineral development projects—ESR/2016/1985 (formerly EM586)*.

Table 5: Total disturbance area at end of operational mine life

Proposed Disturbance	**Approximate Area (ha)**
Waste rock emplacement (>3° slope)	530.9
Waste rock emplacement (<3° slope)	207.3
Residual void high walls	132.8
Residual void low walls	186.8
Rehabilitated dams	35.8
Retained dams	34
Diversion drains	14.3
Mine Infrastructure areas*	734.6
Retained infrastructure	13.8
Riparian corridor	1.4
Residual void lakes	76.3
Total	**1,968.0**

*Infrastructure disturbance includes a nominal 100m buffer around the perimeter of the disturbance footprint.

3.1.2 Climate

According to the Bureau of Meteorology's (BoM) modified Köppen climate classification system, the Project area has a climate classification of 'subtropical' (moderately dry winter). The local region experiences a subtropical climate characterised by high seasonal rainfall variability, subject to cyclic wet summer and dry winter seasons, with variable temperature and evaporation. Wind blows predominantly from the southeast and east in the region.

Local meteorological conditions have been compiled using data from the Scientific Information for Landowners (SILO) Data Drill from the year 1990 to 2024 (35 years). The Data Drill accesses grids of climate data from surrounding BoM point observations and then creates interpolated climate values for the requested location. The SILO climate data was obtained for coordinates that correspond to the approximate centre of the Gemini Project ML, referred to herein as the Gemini Grid. Moreover, rainfall and temperature data have been sourced from the nearest BoM station to the Project location.

3.1.2.1 Rainfall

The mean annual rainfall for the Project region is approximately 677.26 mm. Rainfall in the Project region is highly seasonal, with November to March generally accepted as the 'wet season' and rainfall during this time accounting for approximately 68% of the region's total yearly rainfall. The 'dry season' usually occurs from April through to October, with monthly rainfall totals below 45 mm consistently throughout this period. The rainfall data for this region is consistent with the Köppen classification of 'subtropical' (moderately dry winter).

Mean monthly rainfall records from 1990 to 2024 for the Project region are derived from the BOM database – Dingo Post Office (035025) (BOM 2024) and are shown in Figure 15.

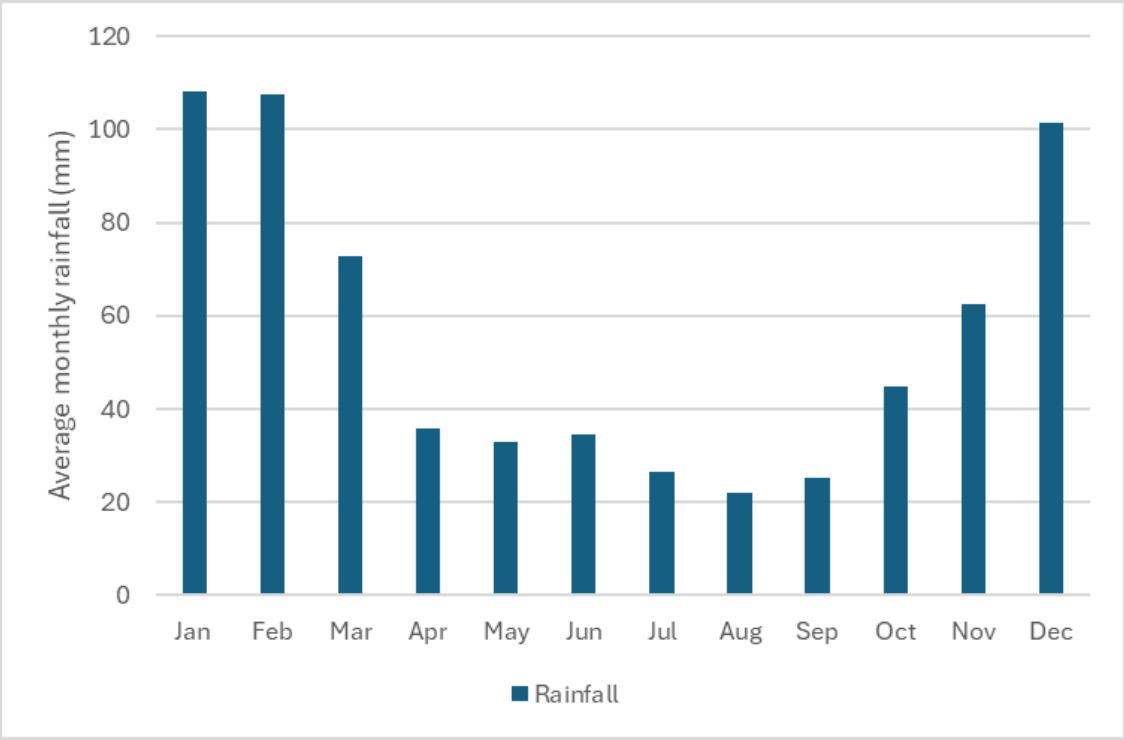

Figure 15: Mean monthly rainfall at Dingo Post Office (Source: BoM 2024)

3.1.2.2 Evaporation

The average annual (pan) evaporation estimated from the Gemini Grid is 2,018.9 mm, more than three times higher than the average annual rainfall (677.2 mm). Mean monthly evaporation exceeds mean monthly rainfall during every month from 1990 to 2024 as shown in Figure 16.

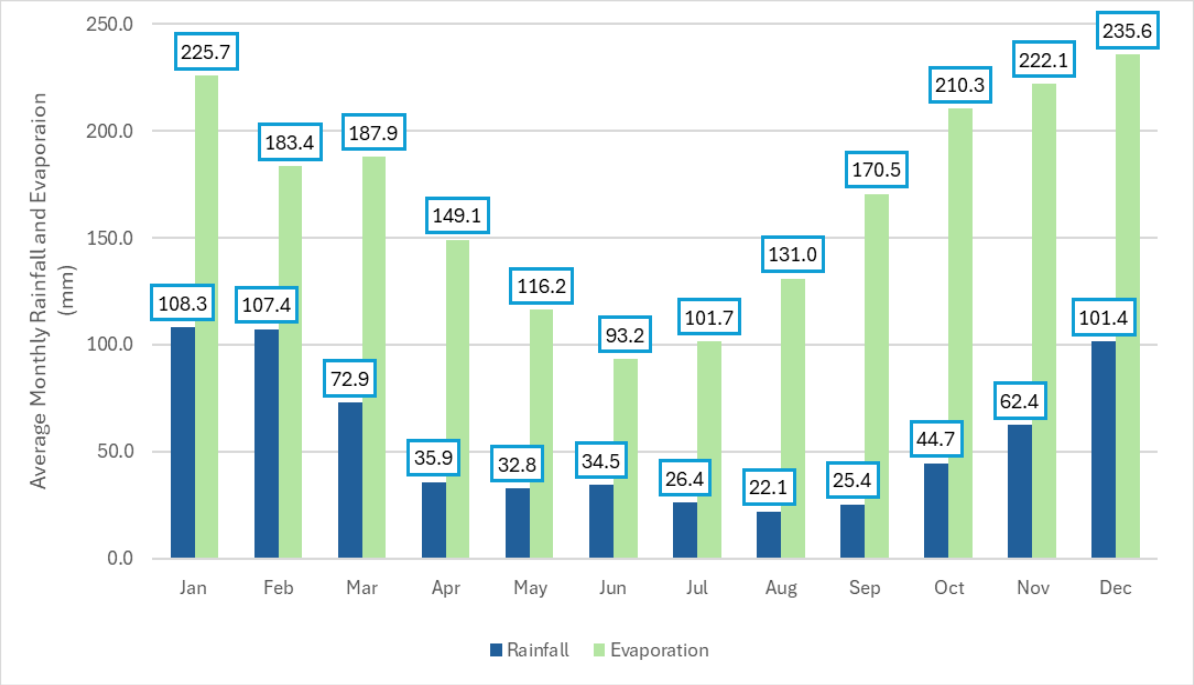

Figure 16: Mean monthly rainfall and evaporation at Dingo Post Office (Source: SILO 2024)

3.1.2.3 Temperature

Daily temperature records are available from the BoM Blackwater Airport Station (035134), which is located 40 km from the Project area, and interpolated monthly temperature data for the Gemini Grid has been obtained from the SILO database.

As per (BOM 2024) for the period May 2013 to July 2024, mean monthly temperatures were recorded in the range of 9.4 °C (min.) to 34.4 °C (max.) at Blackwater Airport (Figure 17).

While for the period between 1997 and 2024, the SILO database interpolates mean temperatures of 8.7 °C (min.) to 34.8 °C (max.) for the Project Grid.

To demonstrate the mean monthly minimum and maximum temperatures of the study area and the surrounding areas, temperature data obtained from the BoM Blackwater Airport Station (035134) has been compared to the SILO Gemini Grid data, as shown in Figure 17 (BoM 2024).

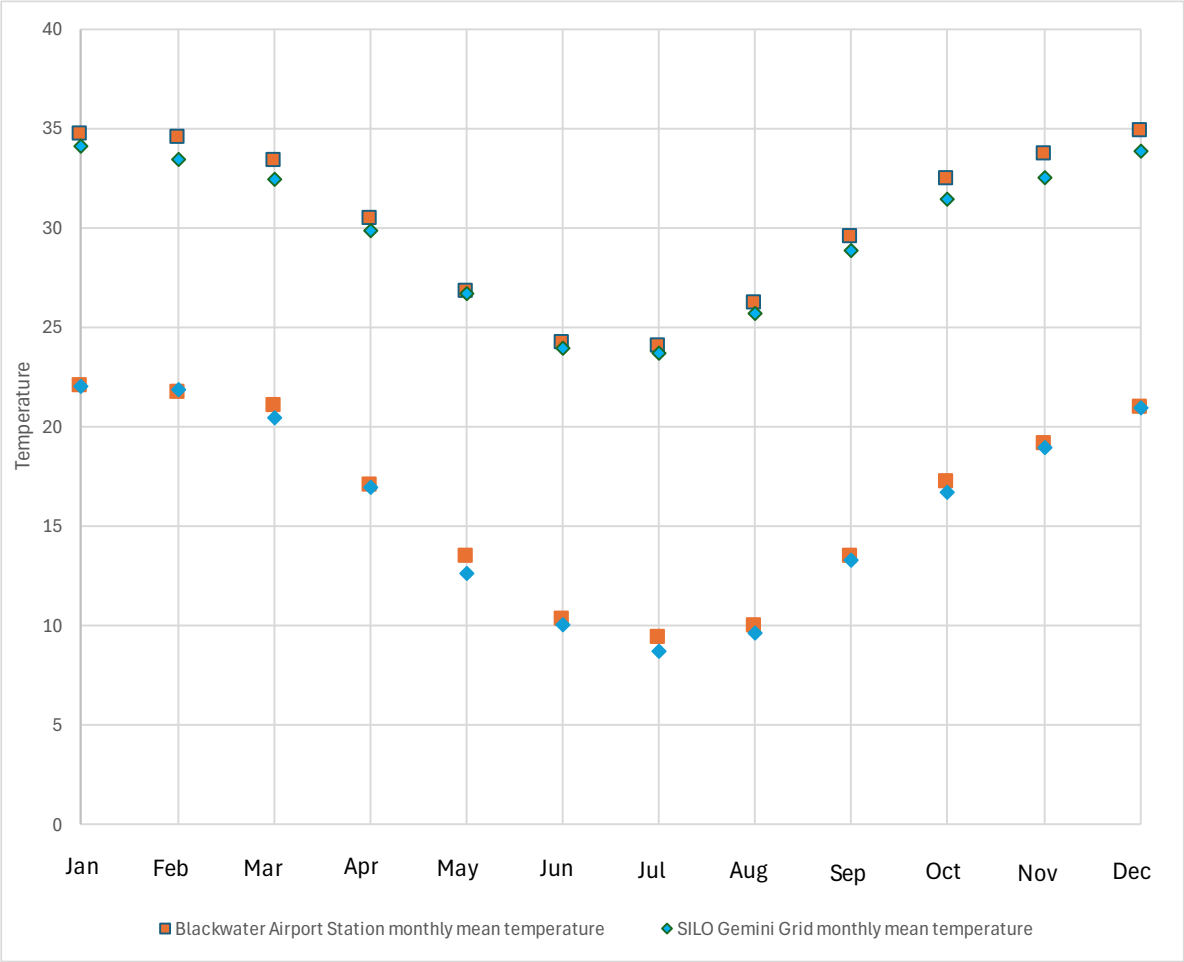

Figure 17: Mean monthly maximum and minimum temperatures in the Project region

3.1.2.4 Climate change

In Australia, climate change is generally expected to result in a shift towards more arid conditions, warmer temperatures, and reduced rainfall. According to the Queensland Government (2019), rainfall in central Queensland is predicted to decrease due to climate change. By 2050, median annual rainfall is projected to decrease by:

- 2% under a lower emissions scenario (with emissions reduced from 'business as usual'); and
- 8% under a high emission, or 'business as usual' scenario.

Long-term climate projections predict that conditions will become warmer, with hotter and more frequent hot days. Rainfall events are predicted to become more intense, and tropical cyclones are predicted to become less frequent but more intense.

3.1.3 Geological setting

The Gemini Project coal deposit is hosted within the Permian Rangal Coal Measures and the Yarrabee Structural Zone. Seven seams or seam groups have been identified at the site, which belong to either the Rangal Coal Measures or the underlying Burngrove Formation (BOYD 2019). In descending stratigraphic order, the seams include the Aries, Castor, Pollux, Orion, Pisces, Virgo and Leo seams. The seams contain several individual plies that have been identified for mining at the site; the main coal seams that are encountered at the site and their typical thickness are described in Table 6 below.

Surface geology at the site predominantly comprises sediments of the Tertiary Duaringa Formation and Quaternary alluvium associated with ephemeral creeks, including Charlevue Creek and Springton Creek. The surface geology of the Project area is shown in Figure 18 and Figure 19 shows the project location in relation to the underlying Bowen Basin solid geology (i.e. the surficial unconsolidated Quaternary and Tertiary units have been removed, revealing the relationship between the underlying Triassic and Permian sediments and the prevalence of regional-scale faults). The two mining areas (Mine A and Mine B) occur where folding has brought the coal seams close to the surface at depths that can be economically mined.

Table 6: Summary of local stratigraphy

Geological Age	Unit	Coal Seams	Description	Typical thickness (m)
Quaternary	Alluvium		Unconsolidated soil, silt clay, sand and gravel associated with current surface drainage systems, e.g. Charlevue Creek and Springton Creek	1.5
Tertiary	Duaringa Formation		Mudstone, sandstone, conglomerate, siltstone	15 - 30
	Basalt		Minor basalt at one location path of Mine A	20
Triassic	Rewan Group		Lithic sandstone, piney lithic sandstone green to volcanilithic brown mudstone and minor conglomerate at the base	0-50
Permian	Rangal Coal Measures	Aries Upper	Feldspathic and Lithic sandstone, carbonaceous mudstone, siltstone, tuff and coal seams. Includes the Aries, Castor and Pollux Coal Seam, which are the target coal seam for mining at the Gemini Project	2.1
		Aries Lower		4
		Castor Upper		1.6
		Castor Lower		2
		Pollux Upper		1.9
		Pollux Lower Upper		2.9
		Pollux Lower Lower		3.5
		Orion		6.1
		Pisces Upper		1.7
		Yarrabee Tuff		0.9
		Pisces Lower		0.7
	Burngrove Formation	Virgo		2.8
		Leo	Mudstone, siltstone, sandstone, coal, tuff	4.4
	Gyranda Formation		Siltstone and shale with minor tuff and volcanilithic sandstone and rare coal	0 to 100+

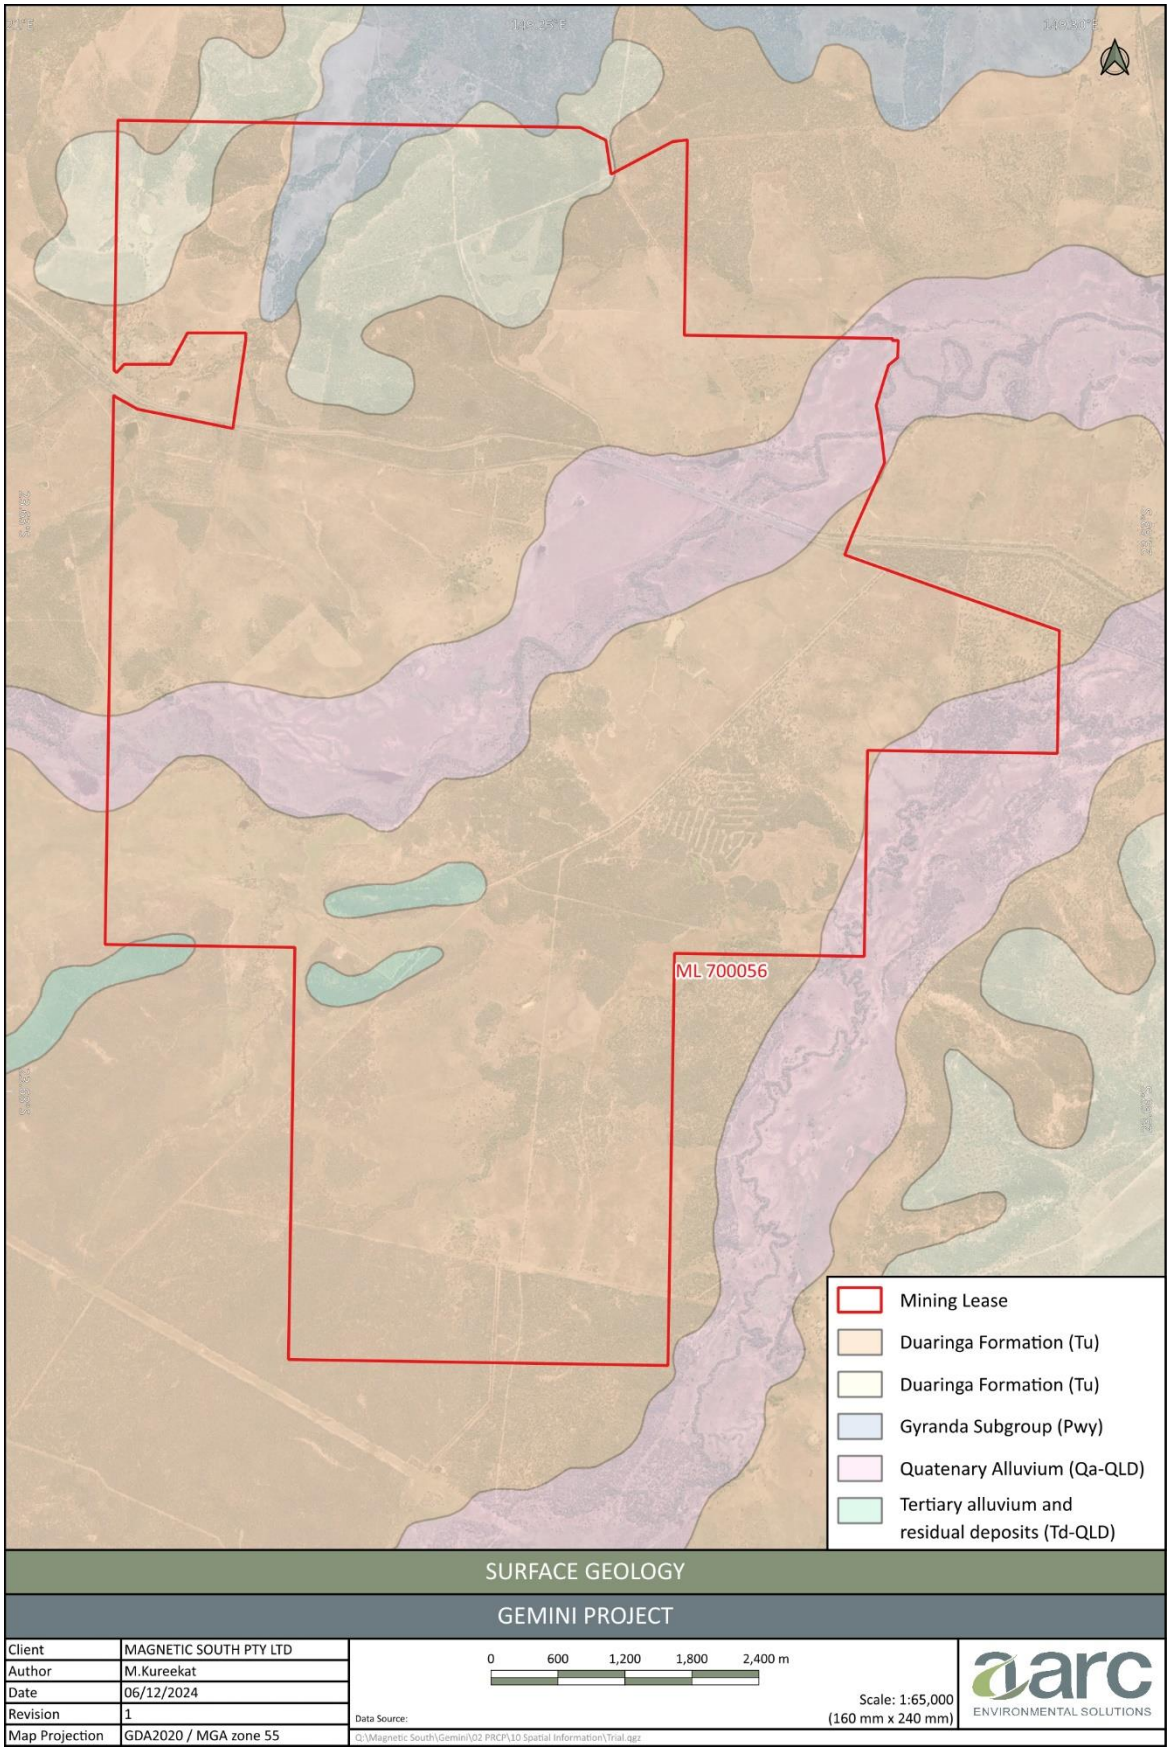

Figure 18: Surface geology of the Project

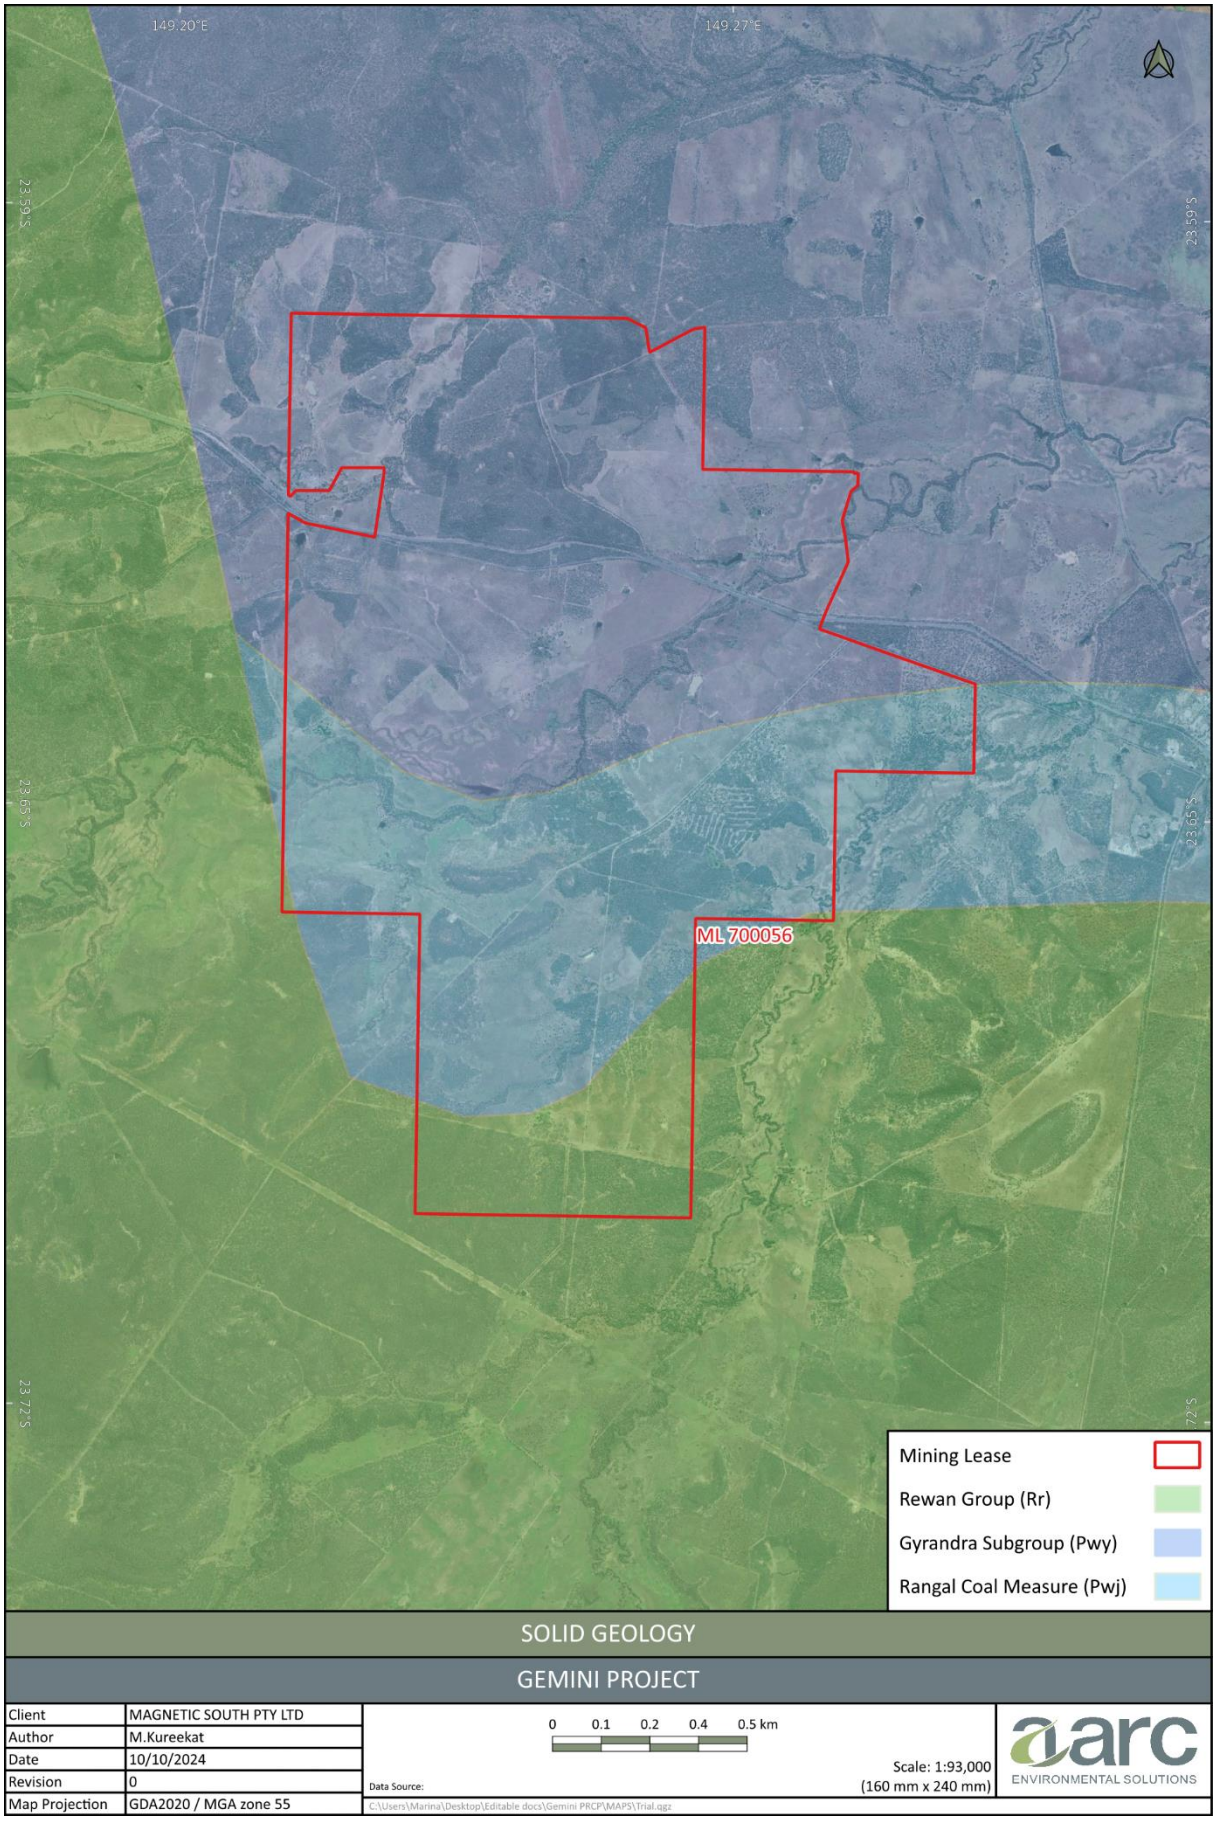

Figure 19: Solid geology of the Project

3.1.4 Topography and surface hydrology

The Project area is described as gently undulating with elevations between 120-150 mAHD. The physiography of the area is characterised by a dissected tableland having a general relief variation of about 80 m. The topography of the Project is representative of the surrounding region. The viewshed, some 15-18 km distant to the southwest and west is to the Blackdown Tableland National Park and Arthurs Bluff State Forest, which rise approximately 450 m above the elevation of the Project site. There is little relief to the north and east, with the land falling gently toward the Mackenzie River valley.

The Project lies within the Mackenzie River sub-catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River Basin. The major water body associated with the Project site is Charlevue Creek. This creek begins within the boundaries of Blackdown Tablelands National Park, flowing to the northeast before joining Springton Creek (Figure 20). Springton Creek flows to the Fitzroy River, eventually reaching the Pacific Ocean approximately 46 km north of Gladstone.

The Project landscape is influenced by the presence of Charlevue Creek, which bisects the ML from west to east, and Springton Creek, which flows alongside the southeast boundary of the ML (Figure 20). The associated floodplains of these two watercourses result in localised lower elevations within the surrounding landscape. A significantly smaller tributary, Stanley Creek crosses the northwest corner of the ML boundary eventually converging with Springton Creek downstream of the ML. Minor associated tributaries, dams and drainage features also exist across the site (Figure 20). The land system is characterised by fluvial plains surrounding these waterways. It is mostly composed of stable flood plains traversed by a branching pattern of drainage floors.

3.1.4.1 Surface water quality

A baseline water quality monitoring program has been implemented for the Project, which includes field monitoring and automated flow gauges that monitor a variety of physical water parameters.

The baseline water quality at Gemini has been compared to the relevant water quality objectives (WQO) outlined in the Environmental Protection (Water and Wetland Biodiversity) Policy 2019 and toxicant trigger values sourced from the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG) (2018). Of note, Gemini is located within the Mackenzie River Sub-basin for the purposes of Schedule 1 of the Environmental Protection (Water and Wetland Biodiversity) Policy 2019. The key WQO are described in Table 7.

Table 7: Mackenzie River Sub-basin Water Quality Objectives

*ANZG (2018) Aquatic ecosystem protection for moderately disturbed system (95% protection)

Field monitoring of surface water quality was first undertaken as part of the Gemini EA application and consisted of two monitoring events at Charlevue Creek and Springton Creek in late February 2018 and mid-April 2019. Water quality monitoring has continued since then, with samples taken every year during the wet season, following a flow event. Water quality field monitoring was last undertaken at Gemini on 8 April 2024.

Automated flow gauging stations were installed at downstream locations within Springton Creek and Charlevue Creek by ALS in December 2020. In addition to flow rates, the gauges also monitor a number of physical parameters, including salinity, turbidity and pH. Water quality monitoring via flow gauges has been continuously undertaken since their establishment. The average water quality results of field and flow gauge monitoring are outlined in Table 8.

Table 8: Baseline mean water quality monitoring results

Site	Method	DO (%)	EC (µS/cm)	TDS (mg/L)
Springton Creek	Field	58.9	162.5	72.9
	Flow Gauge	nil	397.8	nil
Charlevue Creek	Field	76.4	150	72.0
	Flow Gauge	nil	330.2	nil

The surface water quality of these waterways was generally found to be moderate to low, with DO and turbidity not meeting the WQO. Low DO levels were recorded at field and flow gauge monitoring locations within the Springton and Charlevue Creeks. Given the ephemeral nature of these systems, such exceedances are unreliable indicators of long-term system health. During the short periods in which these two creeks are flowing, the DO levels are expected to be higher; however, this cannot be confirmed.

Exceedances of the turbidity WQO were observed across all sites, likely due to the ephemeral nature of the creeks. Of note, flow gauge monitoring reported higher average turbidity than field monitoring by 450 to 700 NTU, depending on the creek. Charlevue Creek has lower turbidity than Springton Creek; however, both exceed the relevant WQO. Increased turbidity can affect the rate of photosynthesis and, therefore, the growth of plants or algae in the creeks. Therefore, high turbidity values indicate poor stream health and reduced biodiversity in aquatic fauna and flora, which remains consistent with the ephemeral nature of the creeks.

In addition to field parameters, surface water samples also underwent laboratory analysis, including measuring dissolved and total metals (Table 9). Comparing dissolved metal concentrations against the WQO, both Springton and Charlevue Creeks recorded the aquatic ecosystem limit exceedances for turbidity, suspended solids and dissolved aluminium, copper and silver. Fluoride was the only metal to not record an exceedance of stock watering limits at both Springton and Charlevue Creeks. These exceedances were observed in monitoring sites from 2021 to 2024.

Table 9: Summary statistics of baseline surface water monitoring data (2019-2024)

Zinc	mg/L	20	41.45	32.5	63.6	92.65	18.92	15	28	50

Note: Parameters without values present were not included in baseline monitoring

Overall, the baseline surface water quality of Springton and Charlevue Creek was generally found to be moderate to low based on field and lab results and flow gauge monitoring. Physical parameters remained within the aquatic ecosystem WQO, except for turbidity and suspended solids, which both recorded exceedances. Dissolved aluminium, copper and silver all recorded exceedances of the aquatic ecosystem WQO; however, all other monitoring water quality parameters for dissolved metals were within the limits. Fluoride was the only total metal that remained within the stock watering limit; exceedances were recorded for all other total metals water quality parameters collected as part of field sampling and flow gauge readings.

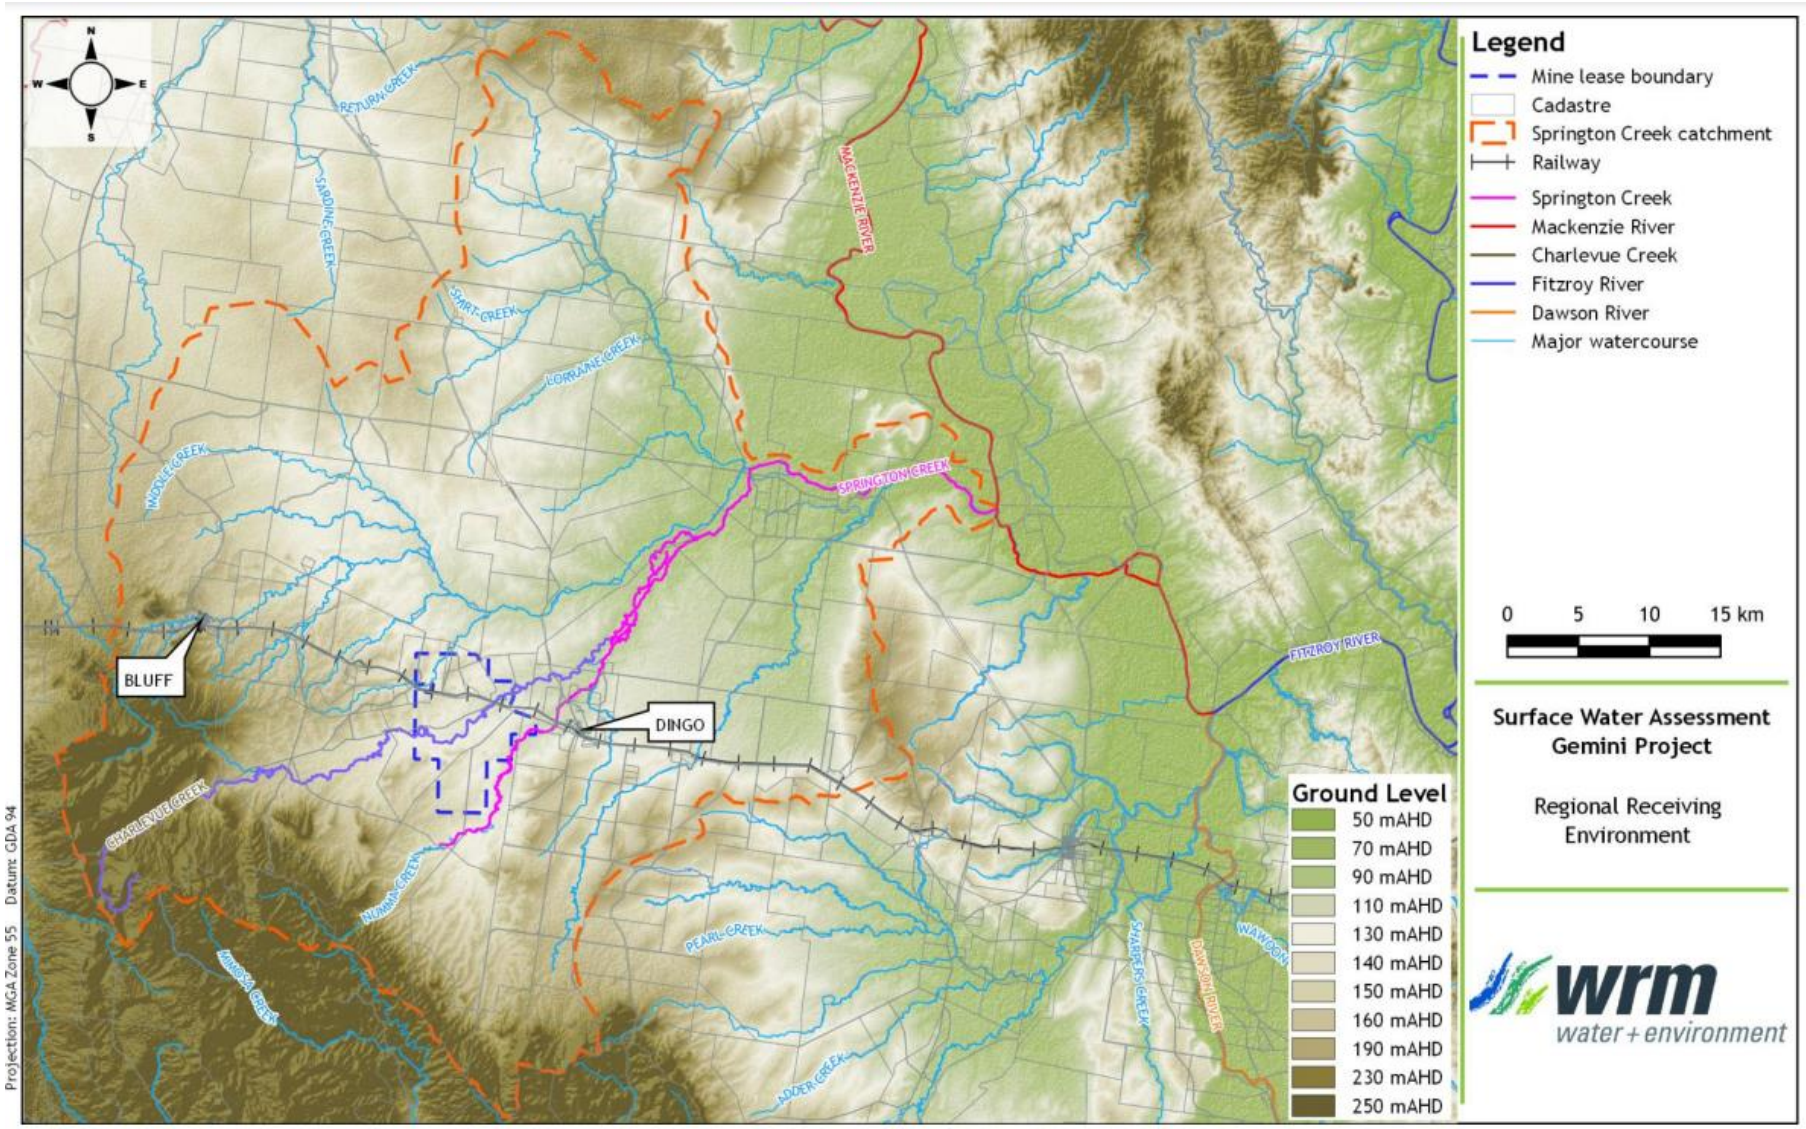

Figure 20: Watercourses and catchments of the Project region

3.1.5 Groundwater

Groundwater of the Project site has been characterised as three main groundwater units, including:

- Quaternary alluvium aquifers
- Tertiary sediments of the Duaringa Formation; and
- Permian Rangal Coal Measures.

3.1.5.1 Quaternary alluvium

Quaternary-age alluvial deposits are associated with the major drainage features of Charlevue and Springton Creek, which occur to the west and east of the proposed mining area, respectively. Alluvium recharge is via direct rainfall recharge and occurs at a low rate. This is consistent with the observation of elevated salinity in the shallow sediments, likely due to the low rate of recharge and high residence times for groundwater.

3.1.5.2 Tertiary sediments

The Tertiary sediments of the Duaringa formation are variably saturated, with the elevation of the base of the Tertiary being a control on the occurrence of water within the sediments. Observation from both exploration records and groundwater modelling suggests the presence of dry bores within the Tertiary, as well as a variation in water level between the topographically elevated base of the Tertiary and the topographically lower base of the Tertiary, suggesting that a continuous water surface does not exist in the Tertiary sediments and that the elevation of the base of Tertiary will be a control on the presence of groundwater within the sediments. The Tertiary sediments exhibit recharge and salinity characteristics similar to those of the Quaternary alluvium.

3.1.5.3 Permian Rangal Coal measures

Groundwater in the Permian sediments occurs preferentially in the coal seams due to the open nature of the cleats, providing a conduit for infiltrating rainfall. Within the Permian coal measures the coal seams are the primary conduits for groundwater flow with no significant trend for upward or downward movement of groundwater between the coal seams.

However, a trend occurs for groundwater movement through the coal seams from the southwest to the northeast, and also from the northwest to the southeast, towards a depression that is centred on the area where Mine B is proposed to be developed. The coal seams are recharged in subcrop areas where the coal seams directly underlay Tertiary and/or Quaternary sediments. The extremely high salinity of groundwater within the coal measures supports an interpretation of a low rate of recharge to these units.

A minor occurrence of Tertiary basalt has been identified from geological drilling to the north of Mine A. The basalt area is approximately 600 m long, 200 m wide and 20 m thick and has been interpreted as a localised basalt paleochannel (JBT 2019) (Appendix E). One groundwater monitoring bore was located within the basalt (bore DW7105W1); the bore was 23 m deep and was found to be dry. The basalt flow is considered dry (as it lies above the regional groundwater level) and of limited extent. It is, therefore, not considered an important groundwater feature within the project area. Extensive geological drilling across the project area has shown no other evidence of basaltic flows or intrusions (JBT 2019) (Appendix E).

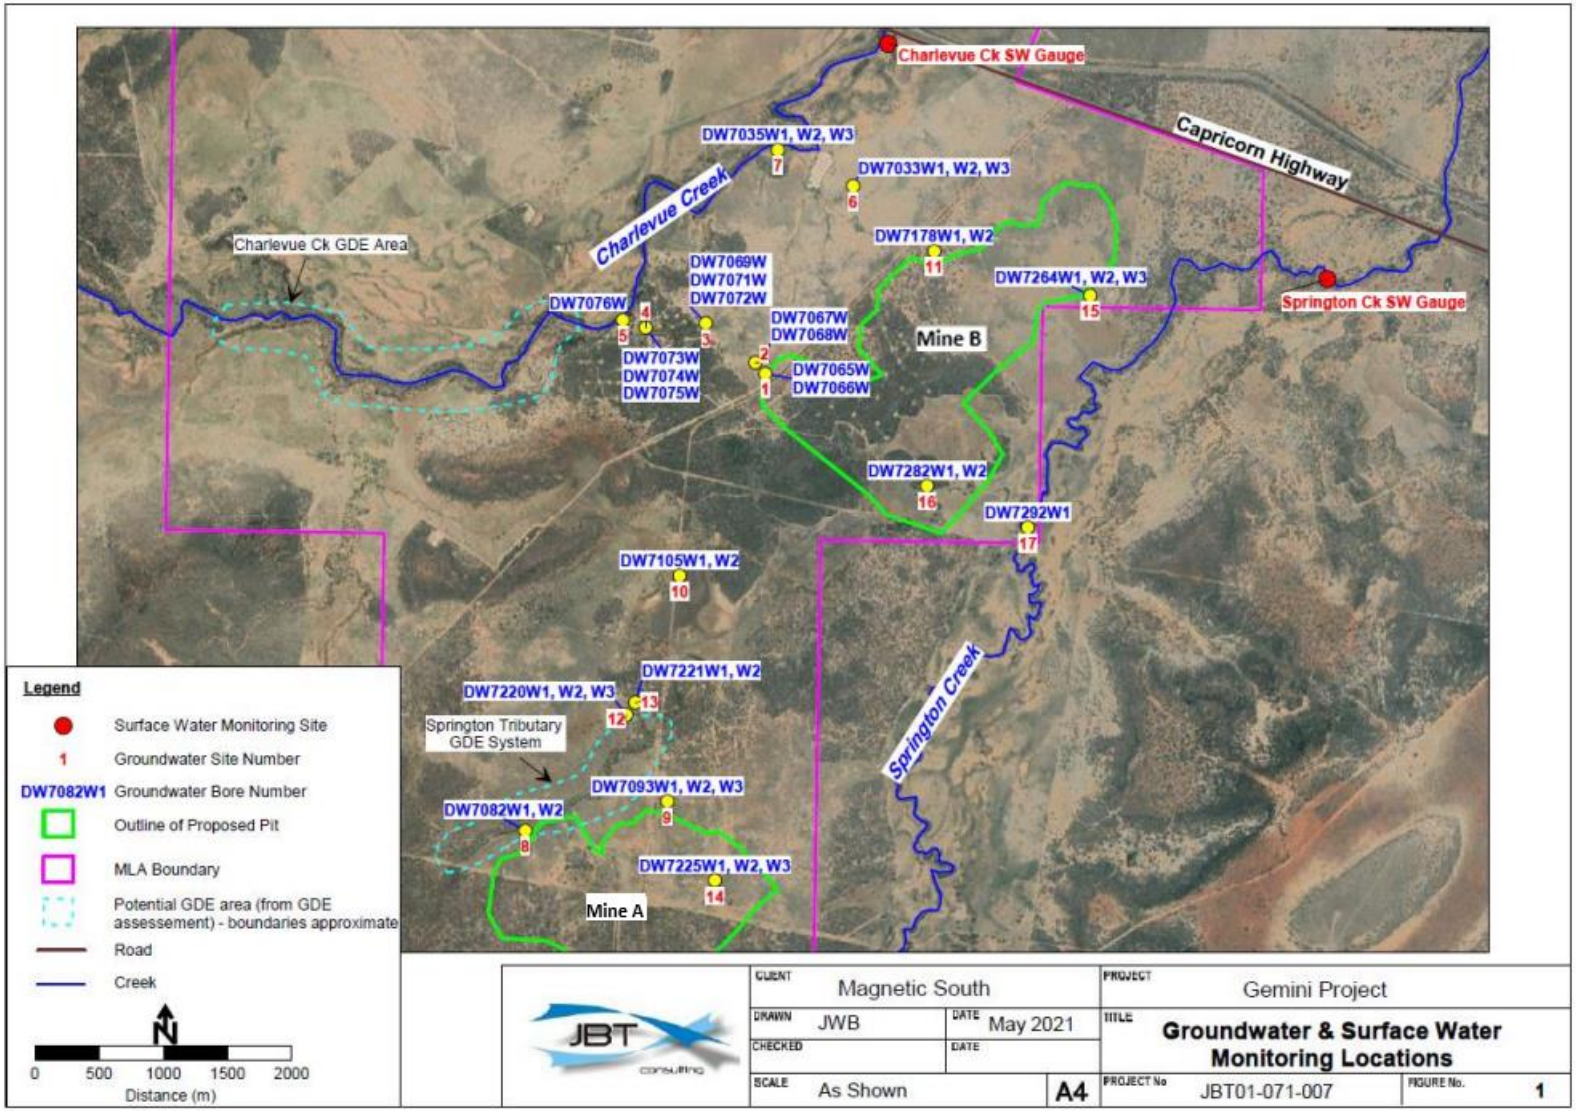

Figure 21: Groundwater and surface water monitoring locations

3.1.5.4 Regional Groundwater Use

Data from the Department of Natural Resources and Mines, Manufacturing, and Regional and Rural Development (DNRMMRRD) Groundwater Database was reviewed for the Project and the surrounding area (within 10 km) as part of the Groundwater Impact Assessment (JBT 2019) (refer to Appendix E). The available groundwater bore data are illustrated in Figure 22 and Figure 23, respectively.

The findings of the database review are summarised as follows:

- There are 48 registered bores within 10km of the Project; the majority were listed as existing, while five bores were listed as abandoned but usable.
- The majority of bores are screened within Tertiary units (26 bores) or Permian coal measures (15 bores).
- Several considerations were identified with respect to assessing baseline EC, namely:
    - six (6) monitoring bores recorded an EC of <1000 µS/cm. These bores consisted of four sites in Tertiary sediments located outside of ML 700056 (Figure 23);
    - fourteen (14) bores that record an EC between 1,000 and 6,000 µS/cm. A limit of 6,000 µS/cm was assessed as this EC equates to 4,000 mg/L, which is the ANZG (2018) livestock drinking limit for beef cattle (assessed to the most likely stock use for the area); and
    - twelve (12) bores that record an EC >6,000 µS/cm (assessed to be of limited or no use for stock watering).

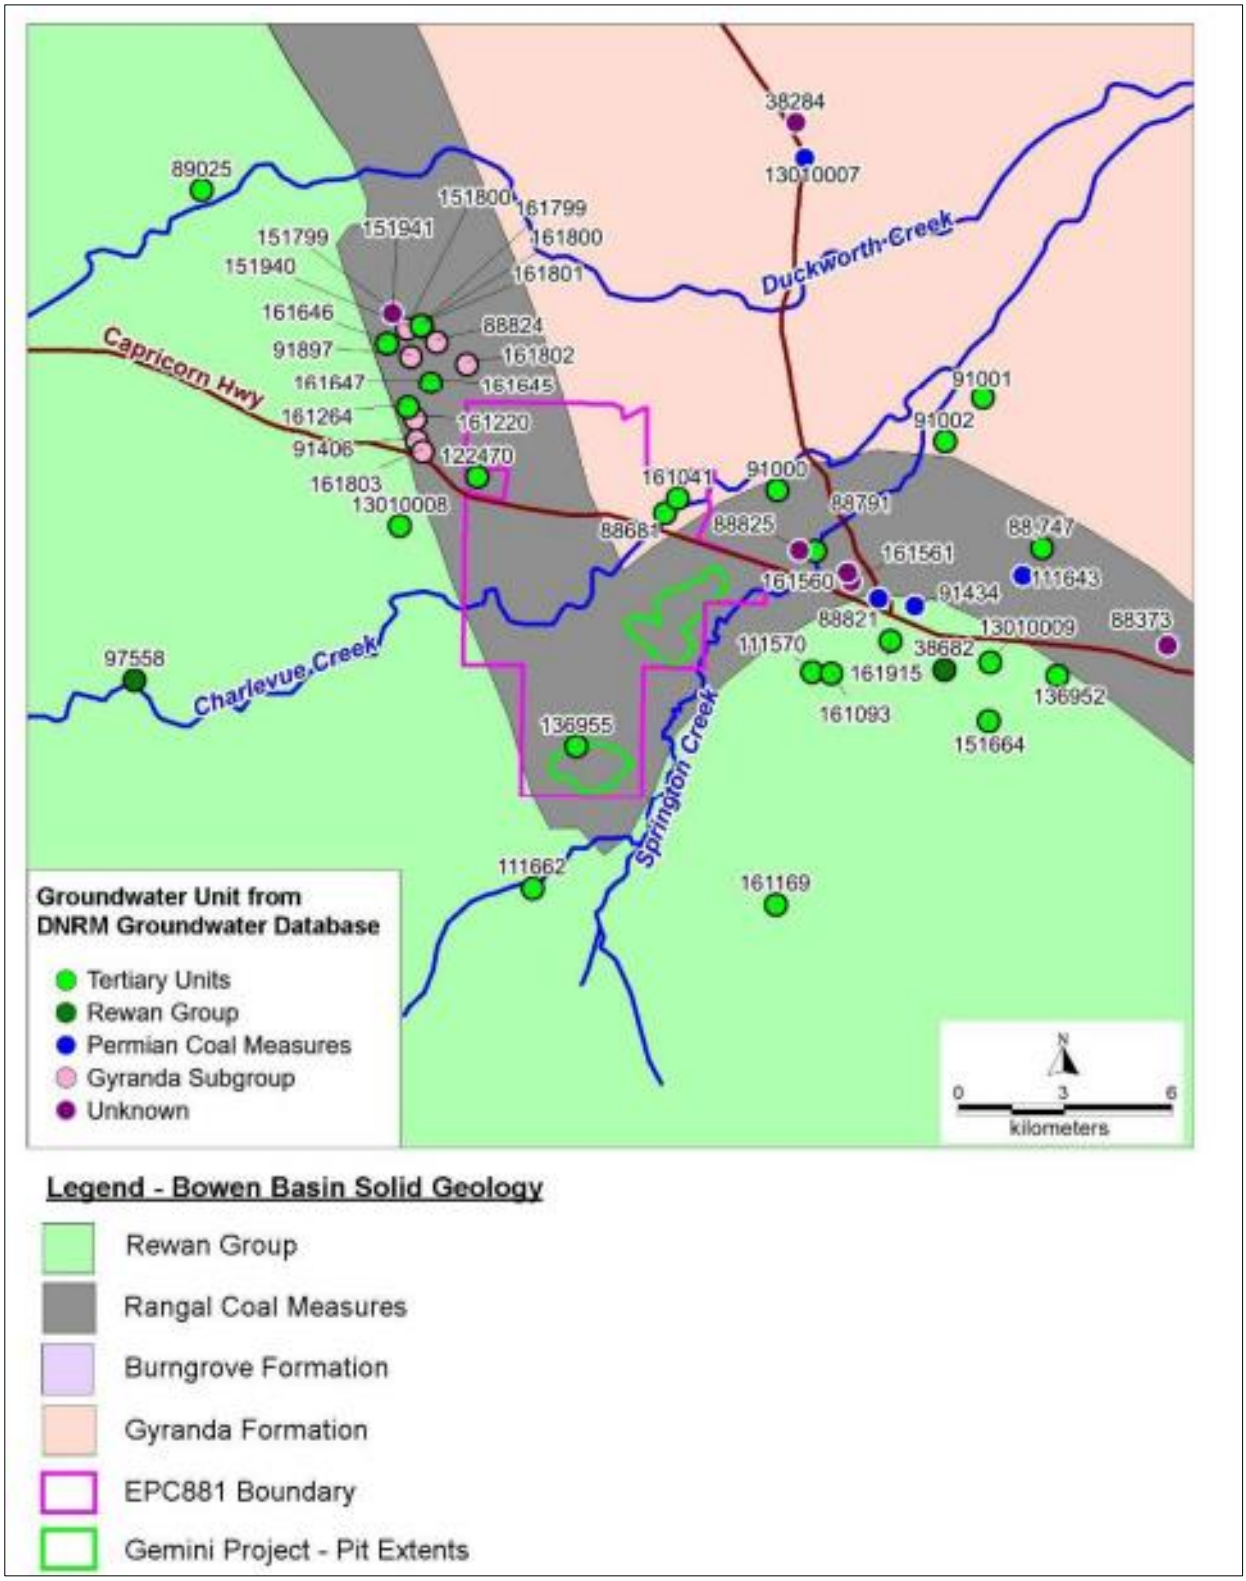

Figure 22: Registered bores by Groundwater unit from DNRM groundwater database

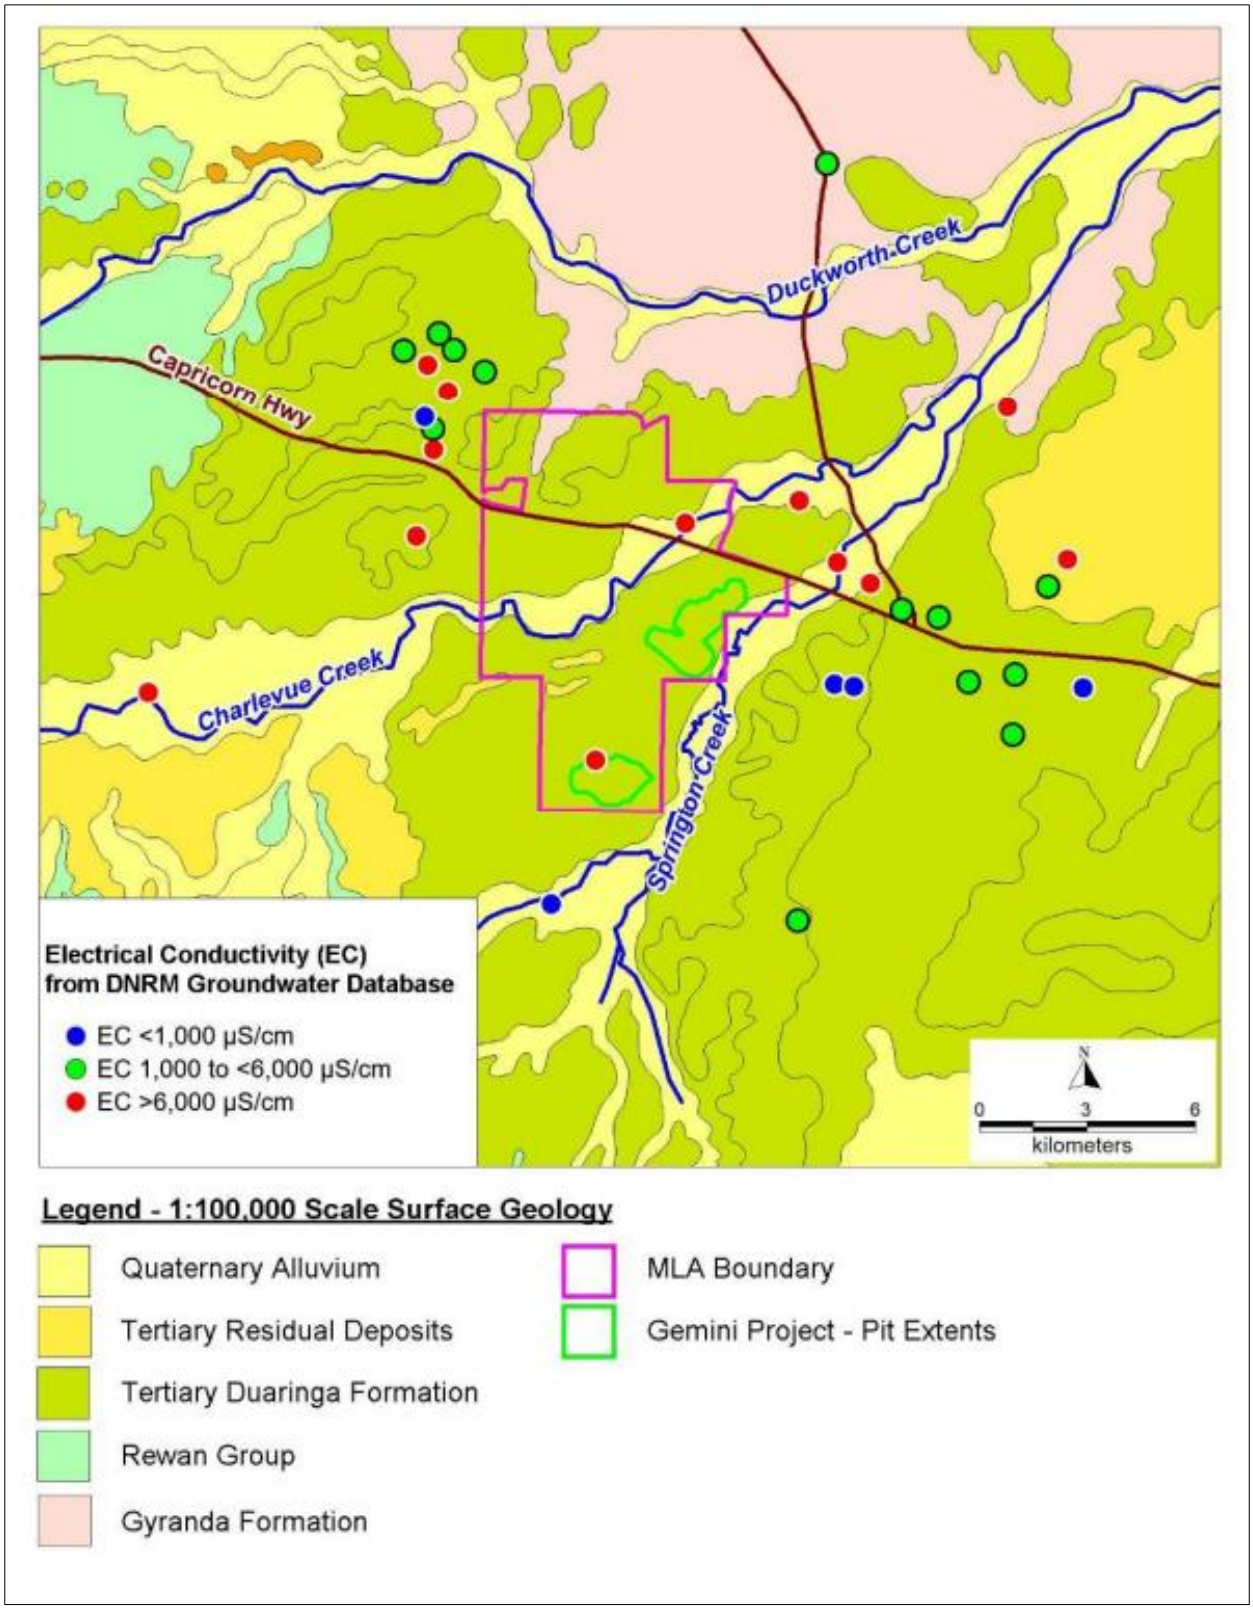

Figure 23: Registered bores by Electrical conductivity (EC) from DNRM Groundwater Database

3.1.5.5 Groundwater Quality

Regional Groundwater Quality

ANZG (2018) outlines the livestock drinking limit on total dissolved solids (salinity) for beef cattle of 4,000 mg/L, which equates to an approximate EC value of 6,000 µS/cm. Bores that recorded a salinity greater than this limit were determined to be of limited or no use for stock watering, with a decline in animal health at progressively higher salinity values.

As outlined in section 3.1.5.4, the majority of bores within or close to the ML recorded EC in excess of 6,000 µS/cm, JBT (2019) noted that the EC of groundwater within the Tertiary sediments was often in excess of 10,000 µS/cm and at some sites in excess of 20,000 µS/cm (highly saline). The majority of Tertiary bores outside the tenement area recorded an EC of <6,000 µS/cm, with four bores in Tertiary sediments to the east or south of the project area recording an EC <1000 µS/cm (mostly fresh).

Local groundwater quality

Continuous groundwater monitoring has been undertaken since December 2018, with the most recent groundwater sampling completed in July 2024. Groundwater quality results are summarised in Table 10 and bore specific data is presented in Appendix I.

Table 10: Summary of groundwater quality results from monitored bores

Groundwater Unit		Field pH	EC (µS/cm)	Sulphate (mg/L)	Boron (mg/L)	Copper (mg/L)	Zinc (mg/L)
ANZG (2018) Livestock drinking water limit		6.5 - 8.5	5,970	1000	5	0.5	20

	Mean	7.35	10,317	104	3	0.1	0.04
	Median	7.77	13,500	137	4	0.07	0.04
Tertiary Sediments	**Range**	5.74 - 12.20	387 - 27,300	17-645	0.2 - 2	<0.001 - 0.01	<0.005 - 3
	Mean	7.61	13,641	212	0.8	<0.001	0.1
	Median	7.65	13,150	166	0.7	<0.001	<0.005
Coal Seams	**Range**	5.59 - 12.50	24 - 28,900	4 - 817	0 - 2	0 - 0.01	0 - 2
	Mean	7.50	14,493	302	0.8	<0.001	0.07
	Median	7.56	14,300	230	0.7	<0.001	0.01

All groundwater units (Quaternary alluvium, Tertiary sediments and Permian coal measures) recorded very high EC with values occurring above the ANZG (2018) livestock drinking limit for beef cattle (5,970 µS/cm). Salinity increases with aquifer depth, and groundwater units within the Project are unlikely to be used for stock watering. Samples were also relatively variable in sulphate concentrations, with the highest levels recorded in the coal seams. Sulphate concentrations in all groundwater units were recorded below the livestock drinking water limit of 1,000 mg/L.

The pH (field testing) of groundwater within the Project area was primarily neutral; however, some sharp increases in pH were observed within the tertiary sediments and coal seams. Given the low mean and

median values for these seams, it is reasonable to conclude that such exceedances are rare and are not representative of the groundwater quality surrounding the Project, which is generally neutral.

Groundwater quality was typically below the ANZG (2018) livestock drinking water limit for boron, copper and zinc.

3.1.5.6 Hydraulic Conductivity of aquifers

Falling head tests were undertaken on 25 bores from the Project bore network to obtain site-specific hydraulic conductivity data from all Project groundwater units. Hydraulic conductivity and air-lift yield data for each monitoring bore is in Table 4-2 of Appendix E (JBT 2019) and has been summarised for each groundwater unit in Table 11.

A total of 17 slug tests were performed on bores screened within the coal seams. The hydraulic conductivity decreased with depth, with the difference evident when comparing coal seam bores screened at a depth of less than 80 meters below ground level (mbgl) to bores screened at a depth greater than 80 mbgl.

Table 11: Hydraulic conductivity and Air-Lift yield data per groundwater unit

Groundwater Unit	No. of Tests	Hydraulic Conductivity (metres per day)			Average Air-lift Yield (L/s)
		Min	Max	Geometric Mean	
Quaternary Alluvium	1	0.097	-	-	-
Tertiary	5	0.027	3.805	0.27	0.548
Permian Coal Seams	17	0.002	5.387	0.13	1.185
Coal Seams <80 mbgl	11	0.012	5.387	0.37	1.578
Coal Seams >80 mbgl	6	0.002	0.245	0.02	0.320
Permian Interburden	2	0.001	0.002	-	-

The relationship between hydraulic conductivity and depth is shown graphically in Figure 24. The data for the coal seam bores are of particular interest. The trend line and the 95% confidence interval applied to the data illustrate the trend for lower hydraulic conductivity with increasing depth.

The Permian coal seams, specifically those less than 80 mbgl, are the primary conduits for groundwater flow at the Project. As identified in Table 11, coal seams located <80 mbgl had the highest hydraulic conductivity maximum and geometric mean, which is further reflected in the average air-lift yield. With pit depths expected to reach approximately 80 mbgl, it is unlikely that groundwater inflows will occur as a result of the deeper coal seams. When comparing the estimated hydraulic conductivity and air-lift yield for the coal seams against the interburden/overburden units, the apparent increases strongly support the understanding that the Permian coal seams are the primary conduits for groundwater flow.

Despite this, the Gemini geology is heavily faulted, which may act to influence groundwater occurrence and movement through the identified groundwater units. Shear zones associated with faulting may act as a store of water and as locally higher hydraulic conductivity zones. As recharge to the groundwater system is assessed to be low, the faults may initially provide relatively high inflow rates to the workings. Still, the total storage within the faults is anticipated to be relatively low, with the initial inflow rates not able to be sustained in the long term. Where the faults completely disrupt the coal seams, especially in cases where the coal seam terminates against lower-hydraulic conductivity interburden, the faults will act to disrupt groundwater flow.

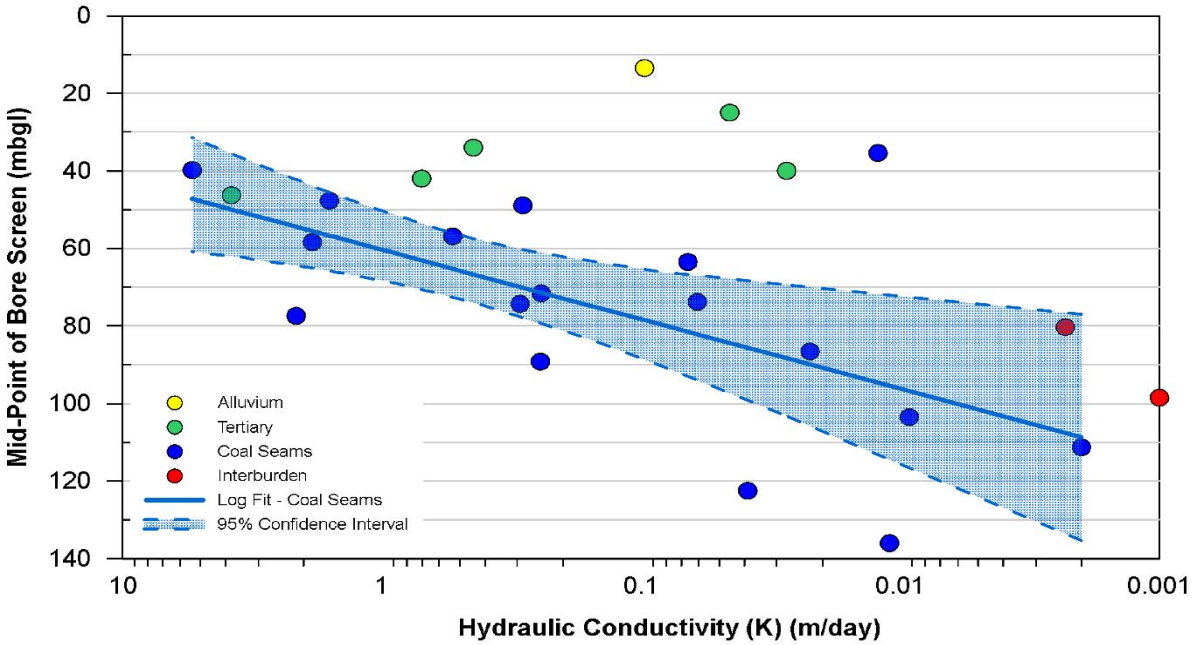

Figure 24: Relationship between hydraulic conductivity and depth

3.1.5.7 Groundwater Level

Groundwater monitoring has continued to be undertaken at Gemini after the original EA application, with the most recent monitoring data collected in November 2024. Groundwater level data at the Gemini Project site has been assessed over a two-year period and can generally be described as follows:

- Alluvium groundwater levels range from 11 m to 14 m below ground level (mbgl) for bores adjacent to the creek channels, with an average standing water level of 13 m below ground level (105 mAHD).
- The water level within the Tertiary sediments ranges from dry (5 bores, ranging in depth from 14 to 23 m) to 16 to 47 mbgl (where water is present). The presence of water within the Tertiary sediments is related to the RL of the base of Tertiary and from review of available data it is assessed that it is probable that the Tertiary sediments are dry above 120 mAHD and likely dry above 110 mAHD, with the average groundwater level sitting at 97 mAHD.
- The water level in the coal measures ranges from 18 to 48 mbgl, with an average water level of 99 mAHD, approximately 31 mbgl.

A graph showing the groundwater levels over the two-year period can be found in Figure 25. Site specific groundwater data can be found in Figure 26 to Figure 31. Groundwater levels across the Tertiary units and Permian Coal Seams, modelled from the existing bore network, are illustrated in Figure 32 and Figure 33.

3.1.5.8 Groundwater environmental values

The Project is located within the 'Mackenzie Groundwaters' region within the broader Fitzroy Basin. Under the Environmental Protection (Water and Wetland Biodiversity) Policy 2019 (EPP(WWB)), the relevant environmental values (EVs) for this region are identified to be:

- Aquatic ecosystems;
- Cultural and spiritual;
- Industrial use;
- Agricultural purposes; and
- Drinking water.

The groundwater that may be impacted by the Project is not known or reported to have any cultural or spiritual values. The groundwater may be suitable for industrial purposes; however, other than coal mining, there are no known industrial users of groundwater. Groundwater in the area is not known to be used as a drinking water supply due to its poor quality and exceedance of WQOs, as summarised in Table 10. Therefore, the values relevant to the ML and the surrounding area include:

- agricultural uses, where groundwater is extracted from surrounding agricultural bores; and
- aquatic ecosystems, where shallow groundwater may support GDEs in some capacity.

Groundwater for agricultural purposes within the Project area is likely to be of limited or no use for stock watering. ANZG (2018) outlines an EC of 6,000 µS/cm as the livestock drinking limit for beef cattle. The majority of bores within or close to the MLA recorded EC in excess of 6,000 µS/cm, as outlined in section 3.1.5.5. There is potential for bores that do not exceed the salinity limit to be used for stock watering; however, the use of groundwater for this purpose is limited.

Aquatic ecosystem values that are potentially associated with groundwater are those that support GDEs. Within the Project area, two potential GDEs were identified by database searches (Figure 21), in association with the two major watercourses, Charlevue Creek and Springton Creek. As outlined in section 3.1.7.4, the potential impact on groundwater by the Project is unlikely to affect these GDEs. Groundwater modelling estimated a maximum drawdown of 5 m; however, it is unlikely to impact the GDEs. The GDE within Charlevue Creek is supported by a perched aquifer that has limited hydraulic connectivity with the regional groundwater table. The Project is situated downstream of Charlevue Creek's GDE, making it unlikely that the Project will reduce the surface flows that replenish the associated perched aquifer. Therefore, it is unlikely that shallow groundwater supports the identified GDEs, making impacts on groundwater from the Project affecting the GDEs unlikely.

3.1.6 Land and Soil

3.1.6.1 Underlying landholders

The properties underlying the Gemini ML include freehold, leasehold and road reserve land parcels owned by Magnetic South or the State of Queensland (Department of Transport and Main Roads). Underlying land ownership is outlined in Table 12 and shown in Figure 34.

A number of publicly gazetted road reserves are located within the ML, including the Capricorn Highway and Cooinda Road. The Blackwater Railway occurs within leasehold land (643 / SP260475) along the northern side of the Capricorn Highway. The Capricorn highway will be used for site access to facilitate the delivery of goods and services, access by mine personnel and other activities. The Blackwater Railway will be used for the transport of coal, with a TLO and rail loop proposed to be constructed on the ML north of the Capricorn highway. Cooinda Road currently runs through the Mine A footprint and will be closed and diverted prior to impact. The new road alignment is not within the scope of the EA (P-EA-100114292), with separate approvals required. As such, it falls outside of the scope of this PRCP.

Table 12: Underlying land ownership

Registered Owner/s	Lot / Plan	Tenure	Property Name
Blue Valley Land Pty Ltd	100 / SP325594	Freehold	Redrock
Magnetic South	1 / RP904099	Freehold	Ellesmere
	2 / RP904099	Freehold	
	1 / HT424	Freehold	Longdale
	2 / HT138	Lands Lease	Sanders
	47 / H406	Freehold	Fairview
	4 / HT165	Freehold	Gumflat
	4 / RP801280	Freehold	Olives
The State of Queensland (Department of Transport and Main Roads)	643 / SP260475	Lands Lease	Rail corridor
	624 / SP260477	Lands Lease	

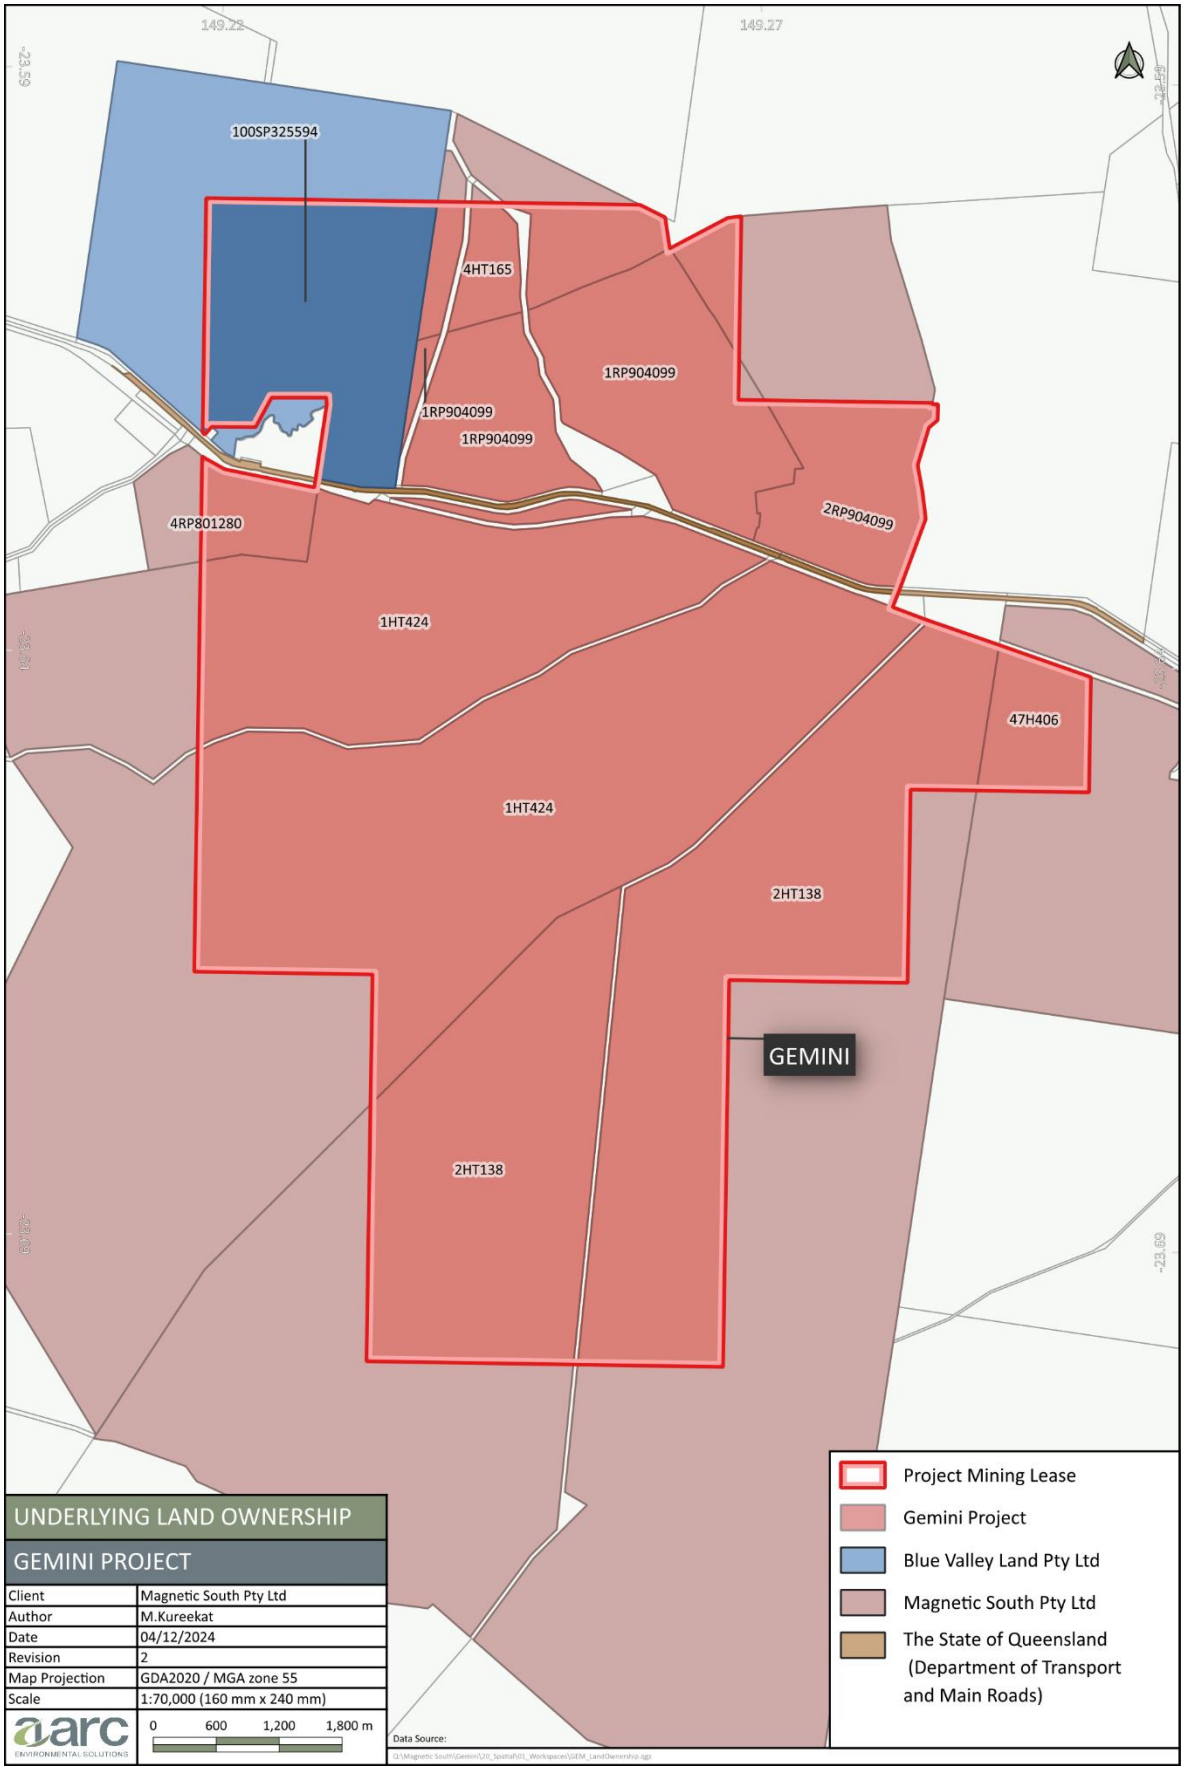

Figure 34: Land ownership

3.1.6.2 Current land use

The Central Highlands Regional Council Planning Scheme (2016) identifies the majority of the Project area as being zoned as rural land use which has a purpose defined as to:

- provide for rural uses and activities; and
- provide for other uses and activities that are compatible with—
  - existing and future rural uses and activities; and
  - the character and environmental features of the zone; and
- maintain the capacity of land for rural uses and activities by protecting and managing significant natural

Other minor land use classifications over the site include residential, reservoir/dam, marsh/wetland, and, primarily in association with the Capricorn Highway, transport and communication, utilities, and services. resources and processes.

The land within the Project boundary is currently used for low-intensity cattle grazing and resource exploration activities. Cattle grazing, being the major land use within the Project, reflects the land suitability assessment, which describes the site as predominantly Class 3 (70%) and a much smaller portion of Class 2 (17%), suitable for grazing with moderate and minor limitations, respectively. Most of the area has been cleared for cattle grazing; however, some patches of remnant vegetation remain, including riparian vegetation along Charlevue Creek. The land in and around the Project is also used for purposes other than cattle grazing, including road transport, stock routes, protected areas, and coal mining.

3.1.6.3 Land Systems

Two land systems are mapped within the Project area and are described as follows.

Dingo Land System

The Dingo land system is characterised by fluvial plains surrounding significant waterways. It is mostly composed of stable flood plains traversed by a branching pattern of drainage floors. The majority of deposits are weathered alluvium, with slopes of coarser or finer textured alluvium (depending on flow patterns). Channels can be up to 30 m wide and 3 m deep, with fringing riparian vegetation. Main drainage floors can then extend 800 m outwards, with deep texture contrast sandy loams over mottled clays, and open spaces of *Eucalyptus tereticornis* (blue gum) and *Eucalyptus crebra* (narrow-leaved ironbark) with sparse shrubs. Large plains surround drainage features (up to 3 km wide) which can contain either deep texture contrast soils with *Eucalyptus populnea* (poplar box) woodlands, or deep layered soils on alluvium with woodlands of blue gum and narrow-leaved ironbark. Slopes within this land unit are usually the result of strongly Gilgai shrink-swell clays, forming depressions of finer soil textures with *Acacia harpophylla* (brigalow) scrub. Geology in this unit is comprised of weathered Quaternary alluvium.

Melbadale Land System

The Melbadale land system is characterised by the shallow dissection of weathered tertiary land surfaces, forming undulating plains dominated by complex depositional mid and lower slopes, with minor lateritic upper slopes in some places. This land system features moderately dense branching drainage patterns, with local relief usually less than 15 m. Depending on the steepness of terrain, upper slopes are often dominated by deep loamy red earths (gentle slopes) with narrow-leaved ironbark, or shallow fine sandy loams (steep terrain) with *Acacia shirleyi* (lancewood) forests. Mid to lower slopes are often associated with deep texture contrast soils of loamy sands overlying mottled sandy clays, with grassy woodlands of open-spaced narrow-leaved ironbark and shrubs. Lower slopes are often associated with deep light to medium clays, with tall forests of narrow-leaved ironbark. Tributaries have variable soil textures depending on slope, though stratified loams and texture contrast soils are common.

The geology in this land system consists of Quaternary to late Tertiary colluvial/alluvium, lateralised tertiary sandstone, conglomerate, and shale.

3.1.6.4 Areas of regional interest

The Project activities are not located within mapped areas of regional interest; however, a strategic cropping land trigger area exists northeast of the Project. The Project does not intersect any areas mapped as priority living areas, priority agricultural areas, strategic cropping land, or strategic environmental areas.

3.1.6.5 Soil types, properties and productivity

A Soil and Land Suitability Assessment was undertaken within the ML by AARC (2019) (Refer to Appendix E). A total of 12 soil management units (SMUs) were identified within the Project. Table 13 provides an overview of each SMU and its extent within the ML. The spatial distribution of the SMUs has been mapped at a scale of 1:70,000, as illustrated in Figure 35.

Methodologies employed throughout this study are detailed in (AARC 2019) (Appendix E) and followed procedures in the *Australian Soil and Land Survey Field Handbook* (NCST 2009) and the *Guidelines for Surveying Soil and Land Resources* (McKenzie et al. 2008). The soil survey was based on a free-survey technique with soil profile and observation sites located to best represent all soil types present in the Project. At the time of the survey, the Project ML boundary was subject to various alterations. Consequently, the study area was based on the EPC 881 boundary, land owner access, and a 5 km buffer around the boundary of the Walton State Forest. No acid sulphate soils have been identified within the Project.

As assessment of the suitability of the below soil types for rehabilitation can be found in section 3.1.6.6.

Table 13: SMUs within the study area

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Anderson	37.8	0.6	Hard-setting soil unit associated with isolated hills. Soil textures grade from loams at the surface to light medium clays with depth, sometimes exhibiting red mottling. Vegetation associated with this unit includes *Eucalyptus crebra*, *Corymbia clarksoniana*, and *Acacia rhodoxylon* with *Erythroxylon australe* in the shrub layer. The Anderson SMU has a very strongly acidic pH throughout the profile, ranging from 4.6 in the topsoil to 4.8 in the lower subsoil. EC and chloride results indicate that salinity is very low at all depths, with EC ranging from 0.064 deciSiemens per metre (dS/m) in the topsoil to 0.02 dS/m in the subsoil layer. Chloride concentrations reflected this result, decreasing with depth from 30 mg/kg to 10 mg/kg, both well below toxic limits.
Barry	156.5	2.5	Hard setting soil associated with rivers, drainage lines and levees. Surface soils in this unit are comprised of clay loams to medium clays, grading into light or medium clays at variable depths. Dominant vegetation includes *Eucalyptus tessellaris*, *Eucalyptus populnea* and *Eucalyptus tereticornis*, with *Bauhinia hookeri, Carissa spinarum* and *Cassia brewsteri* in the shrub layer. The Barry SMU has a slightly acidic pH (6.5), which increases gradually with depth, becoming neutral at 0.2 m (6.8) and increasing to pH 7.2 with depth. EC is very low throughout the profile, ranging from 0.063 dS/m in the topsoil to 0.012 dS/m in the lower subsoil. Chloride concentrations reflect this result, ranging from 20 mg/kg to <10 mg/kg with depth.
Charlevue	232.9	3.8	Hard-setting soil associated with plains and rises. Textures within this unit grade from sandy clay loams or light clays in the surface soil to medium-heavy clays in the subsoil horizons. Dominant vegetation includes *Eucalyptus populnea* and *Eucalyptus crebra,* with *Flindersia dissosperma* (sometimes dominant) and *Carissa spinarum* in the shrub layer. The Charlevue SMU has a variable pH ranging from 5.4 (strongly acid) in the topsoil to 7.9 (moderately alkaline) in the lower subsoil. EC is medium in the surface soil (0.28-0.43 dS/m) and increases to high in the subsoil (0.46 dS/m). Chloride is considered to be high from 0.2 m depth downwards (>600 mg/kg), which can cause toxicity by interfering with plants' osmotic capacity.
Cooinda	34.9	0.6	Hard-setting soil associated with plains. Texture development within this unit is gradual, changing from a sandy clay loam in the topsoil to a sandy light clay at mid-depth and a medium-heavy clay in the deeper subsoil. Dominant vegetation includes *Eucalyptus populnea* and *Flindersia dissosperma* (sometimes dominant), with *Carissa spinarum* in the shrub layer. The pH of the Cooinda SMU ranges from moderately acid (5.6) in the topsoil to neutral (6.8) in the lower subsoil. EC is very low throughout the profile, with topsoil values of 0.015 dS/m, increasing to 0.043 dS/m in the subsoil. Chloride levels reflect EC, increasing from <10 mg/kg to 40 mg/kg with depth.

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Ellesmere	14.6	0.2	Hard-setting soil associated with isolated hills of weathered tertiary surfaces (laterite). Textures within this unit grade from fine sandy loams in the surface soil to medium clays in the subsoil horizons. The dominant vegetation is *Acacia shirleyi*, with *Erythroxylon australe* in the shrub layer. The Ellesmere SMU is a highly acidic soil unit, ranging from 4.6 (very strongly acid) in the topsoil to 5.5 (strongly acid) in the lower subsoil layer. EC is very low throughout the profile, changing from 0.02 dS/m in the topsoil to 0.026 dS/m in the lower subsoil. Chloride concentrations are deficient, consistently presenting at <10 mg/kg.
Geoffrey	4,079.0	66.1	This unit consists of texture-contrast soils with soft surface conditions associated with undulating plains and rises. Textures range from loamy sands to sandy light clays, overlying sandy medium clays with conspicuous orange or red mottling. Extensive washouts and large erosion gullies were observed where these soils were exposed due to insufficient groundcover. In these areas, overland flow removed coarse sandy material, leaving the easily eroded clays exposed to surface runoff. The Geoffrey SMU was often cleared, though when present, dominant vegetation included *Eucalyptus crebra*, *Melaleuca leucadendra*, *Casuarina cunninghamiana* and *Corymbia clarksoniana*, with *Alphitonia excelsa*, *Petalostigma pubescens*, and *Acacia rhodoxylon* in the shrub layer. Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Geoffrey SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0-0.6 m) are moderately acidic, with pH gradually increasing with depth from 5.8 to 6.0. The clay B2 horizon has a pH value over two units higher (8.1) and is classified as 'moderately alkaline'. This is likely due to the increased CEC of the clay in the B2 horizon compared with the sand in the upper horizons.
James	145.2	2.4	Hard-setting red soils are associated with hills and rises. Textures within this unit vary depending on slope, with lesser-developed soils found on crests (sandy clay loams to clay loams) and more developed/deeper soils found on mid-slopes (clay loams to light medium clays). Dominant vegetation includes *Acacia rhodoxylon, Eucalyptus crebra,* and *Corymbia clarksoniana.* The pH in the James SMU is slightly acidic throughout the profile, with minimal variation. It increases gradually with depth from 6.2 in the topsoil to 6.4 in the lower subsoil. EC is very low at all depths, ranging from 0.013 dS/m in the topsoil to 0.015 dS/m in the subsoil. Chloride levels reflect this result, presenting at <10 mg/kg throughout the profile.

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Kosh	927.6	15.0	Hard-setting soil associated with alluvial plains, plains, and low rises. Textures within this unit are gradational, changing from sandy clay loams and light clays in the topsoil to medium heavy clays in the lower subsoil. Commonly, this unit was cleared for grazing, with regrowth consisting of scrub species, including *Vachellia nilotica*, *Carissa spinarum, Capparis lasiantha, Cassia brewsteri*, and *Eucalyptus spp.* shrubs. When present, vegetation included *Eucalyptus tereticornis, Acacia hemiglauca, Acacia salicina, Bauhinia hookeri, Eucalyptus crebra* and *Eucalyptus populnea*. Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Kosh SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0 to 0.6 m) are moderately acid, with pH gradually increasing with depth from 5.8 to 6.0. The low CEC calculated for this unit resulted in extremely low concentrations of exchangeable cations. In the surface soil, calcium and magnesium were relatively equally represented, though concentrations of these cations were extremely limited.
Namoi	177.6	2.9	Hard-setting soil associated with hills and rises. Textures within this unit are gradational, with soils transitioning from a sandy clay loam in the topsoil to a light, medium clay in the subsoil. Dominant vegetation includes *Eucalyptus crebra,* with *Heteropogon contortus* and juvenile *Acacia spp.* The pH in the Namoi SMU is slightly acidic throughout the profile, with minimal variation. It increases gradually with depth from 6.2 in the topsoil to 6.4 in the lower subsoil. EC is very low at all depths, ranging from 0.013 dS/m in the topsoil to 0.015 dS/m in the subsoil. Chloride levels reflect this result, presenting at <10 mg/kg throughout the profile. CEC remains fairly consistent with depth, ranging from 4.3 milliequivalent per 100 grams (meq/100g) (very low) in the topsoil to 5.8 meq/100g (very low) in the subsoil.
Nigel	286.4	4.6	Hard-setting soil associated with isolated high-relief areas of tertiary land surface. Textures within this unit are rudimentary, grading from sands to sandy light clays. Vegetation is variable between sites but includes *Acacia Shirley*, *Acacia rhodoxylon*, *Eucalyptus crebra*, *Melaleuca leucadendron*, *Corymbia clarksoniana*, and *Eucalyptus tessellaris.* The pH within the Nigel SMU is highly variable, changing from 6.3 (slightly acid) in the topsoil to 8.5 (strongly alkaline) in the lower subsoil. EC follows a similar pattern, changing from very low, between 0.0-0.3 m depth to medium in the subsoil. CEC increases with depth from low (6.8 meq/100g) to moderate (17.4 meq/100g), likely due to the increased clay content in the subsoil layers.

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Normanby	48.5	0.8	Deep red earth with soft surface condition, associated with plains, and the flat areas of upper slopes. Textures within this unit are relatively consistent throughout the profile, ranging from loamy sands to sandy light medium clays. Vegetation is mostly cleared, but when present, includes *Eucalyptus crebra* and *Alectryon oleifolius*. The Normanby soil unit has a neutral to slightly acidic pH throughout the soil profile, decreasing with depth from 6.7 to 6.1. EC is very low throughout the profile, ranging from 0.036 dS/m in the topsoil to 0.003 dS/m in the subsoil. Chloride levels reflect this result, presenting at less than 10 mg/kg at all depths. CEC measurements are considered very low, ranging from 2.4 meq/100g to 1.6 meq/100g with depth. The limited nutrient-holding capacity of the Normanby soil unit can be attributed to its low clay content and low organic matter levels.
Wallace	32.0	0.5	Shallow, self-mulching, cracking clay associated with upper slope flats. Textures within this unit grade from medium heavy clays to heavy clays, with the B3/C horizon met at approximately 0.24 m depth. The Wallace SMU is extensively cleared, with the boundary of the unit corresponding to an increase in standing vegetation. The dominant grass species is likely *Aristida latifolia*, with confirmation required during the wet season when an accurate identification can be made. The pH within the Wallace SMU is variable, changing from 6.8 (neutral) in the topsoil to 7.4 (slightly alkaline) in the lower subsoil. EC changes from low in the topsoil to very low in the lower subsoils (0.09 - 0.038). CEC increases with depth from high (39 meq/100g) to very high (44 meq/100g), likely due to the increased clay content in the subsoil layers. High clay content, low sodicity, and desirable nutrient concentrations make this unit one of the best growth mediums in the survey area.

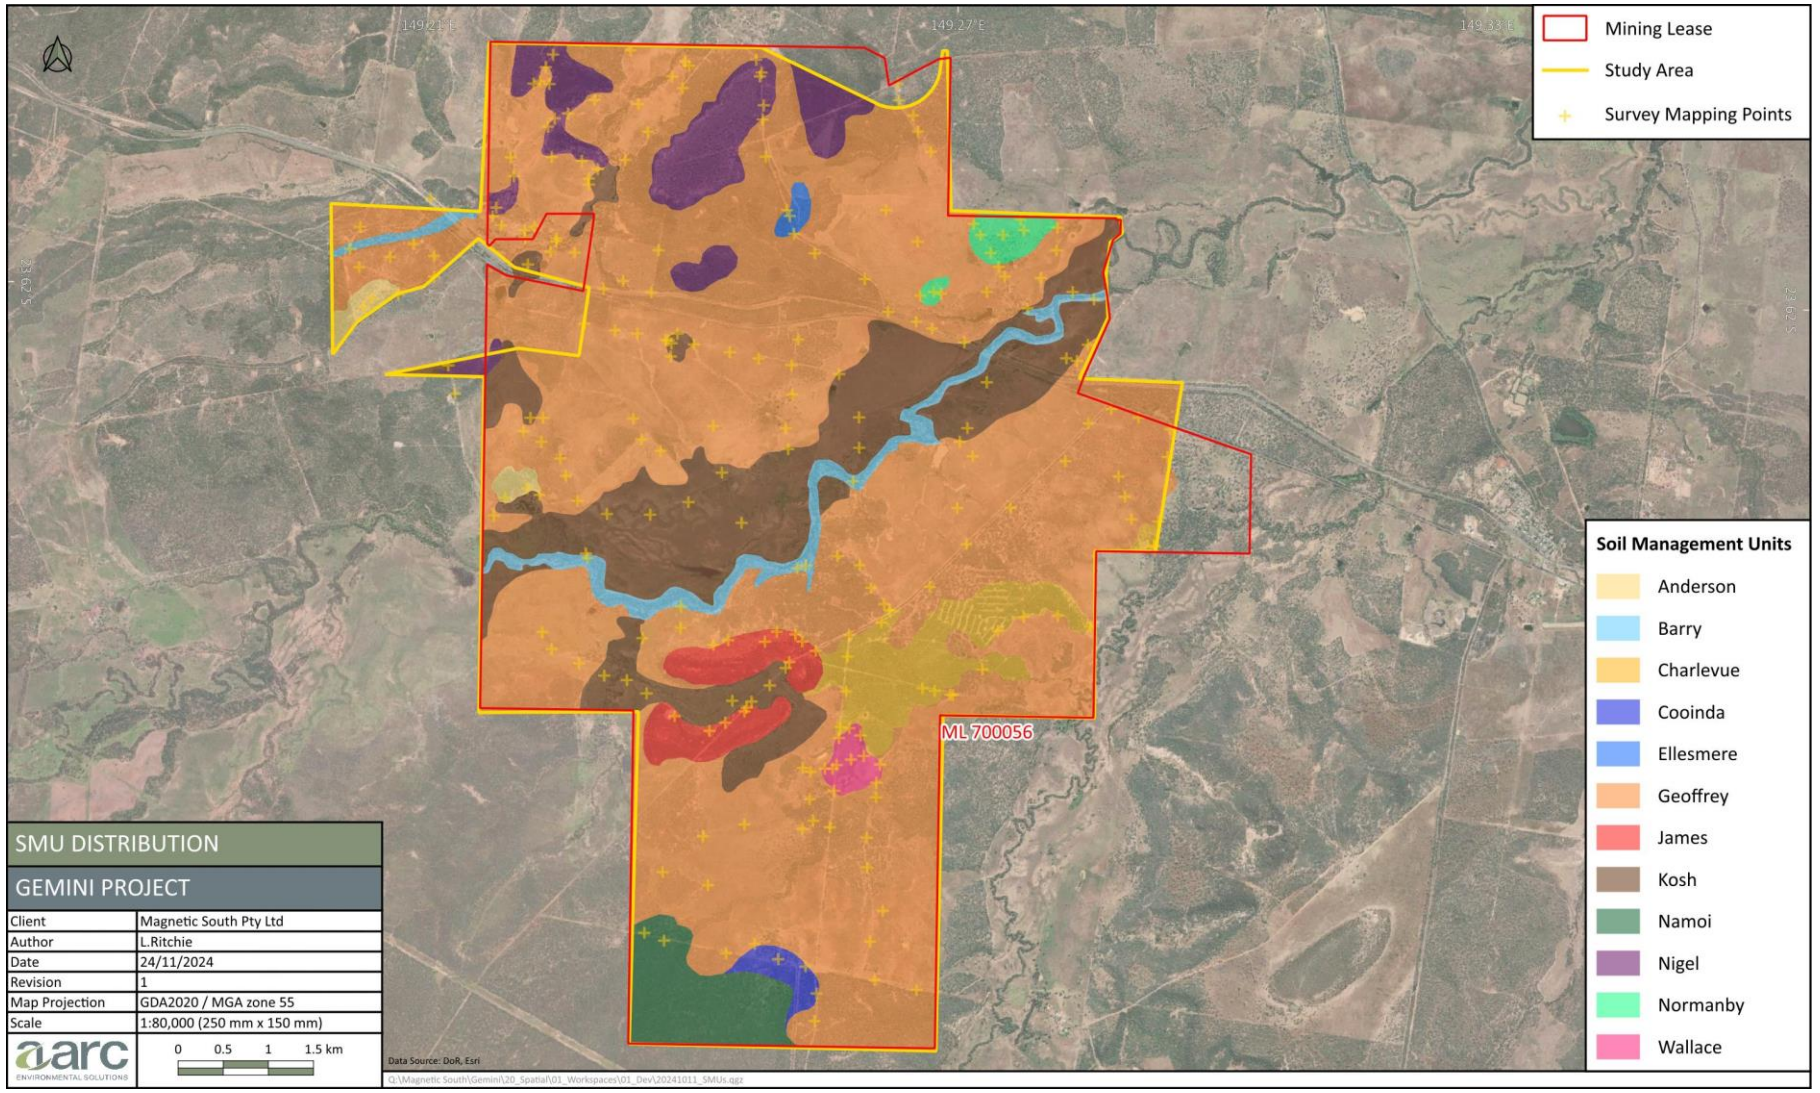

Figure 35: Distribution of SMUs across the Project site

3.1.6.6 Land Suitability

The *Soil and Land Suitability Assessment* (AARC 2019) (Appendix E) considers environmental factors including climate, soils, geology, geomorphology, erosion, topography and the effects of pre-mine land use. The classification indicates the potential of the land to be used for a range of agricultural activities.

The assessment for land suitability (cattle grazing and dryland cropping) was carried out in accordance with the methodologies described in:

- Guidelines for Agricultural Land Evaluation in Queensland (DSITI & DNRM 2015); and
- Chapter 10 (Suitability framework for the inland Fitzroy and southern Burdekin area) of the Regional Land Suitability Frameworks for Queensland (DNRM & DSITI 2013).

An interpretation of the data collected on the physical, chemical and nutritional characteristics of the soil was made to rank the land according to the five-class land suitability system provided in the *Technical Guidelines for Environmental Management and Exploration and Mining in Queensland* (DEM 1995). Although the PRCP follows the *Rehabilitated mined land suitability for beef cattle grazing in the Bowen Basin (2023)* guideline. The five land suitability classes used for assessing the land are defined in Table 14.

Table 14: Agriculture and conservation land class

Agricultural Land Class	Type	Description
Class 1	Agricultural	Suitable land with negligible limitations. This is highly productive land requiring only simple management practices to maintain economic production.
Class 2	Agricultural	Suitable land with minor limitations which either reduce production or require more than the simple management practices of class 1 land to maintain economic production.
Class 3	Agricultural	Suitable land with moderate limitations which either further lower production or require more than those management practices of class 2 land to maintain economic production.
Class 4	Agricultural	Currently unsuitable land. The limitations are so severe that the sustainable use of the land in the proposed manner is precluded. In some circumstances, the limitations may be surmountable with changes to knowledge, economics, or technology.
Class 5	Agricultural	Unsuitable land with extreme limitations that preclude its use.

*Green shading indicates that the land is suitable for agricultural purposes whereas red shading indicates that the land is unsuitable.

The land use of the Project area is more suitable for cattle grazing than dryland cropping based on the average land suitability class across the identified SMUs of the Project. A summary of the land suitability classes for both dryland cropping and cattle grazing for each SMU identified within the study area is provided in Table 15.

Table 15: Land suitability classes for SMUs

SMU	Land Suitability Class (Grazing)	Land Suitability Class (Cropping)
Anderson	4	4
Barry	2	3
Charlevue	4	5
Cooinda	3	5
Ellesmere	3	5
Geoffrey	3	5
James	4	4
Kosh	2	5
Namoi	3	4
Nigel	4	5
Normanby	4	4
Wallace	3	5

*Green shading indicates that the land is suitable for agricultural purposes whereas red shading indicates that the land is unsuitable

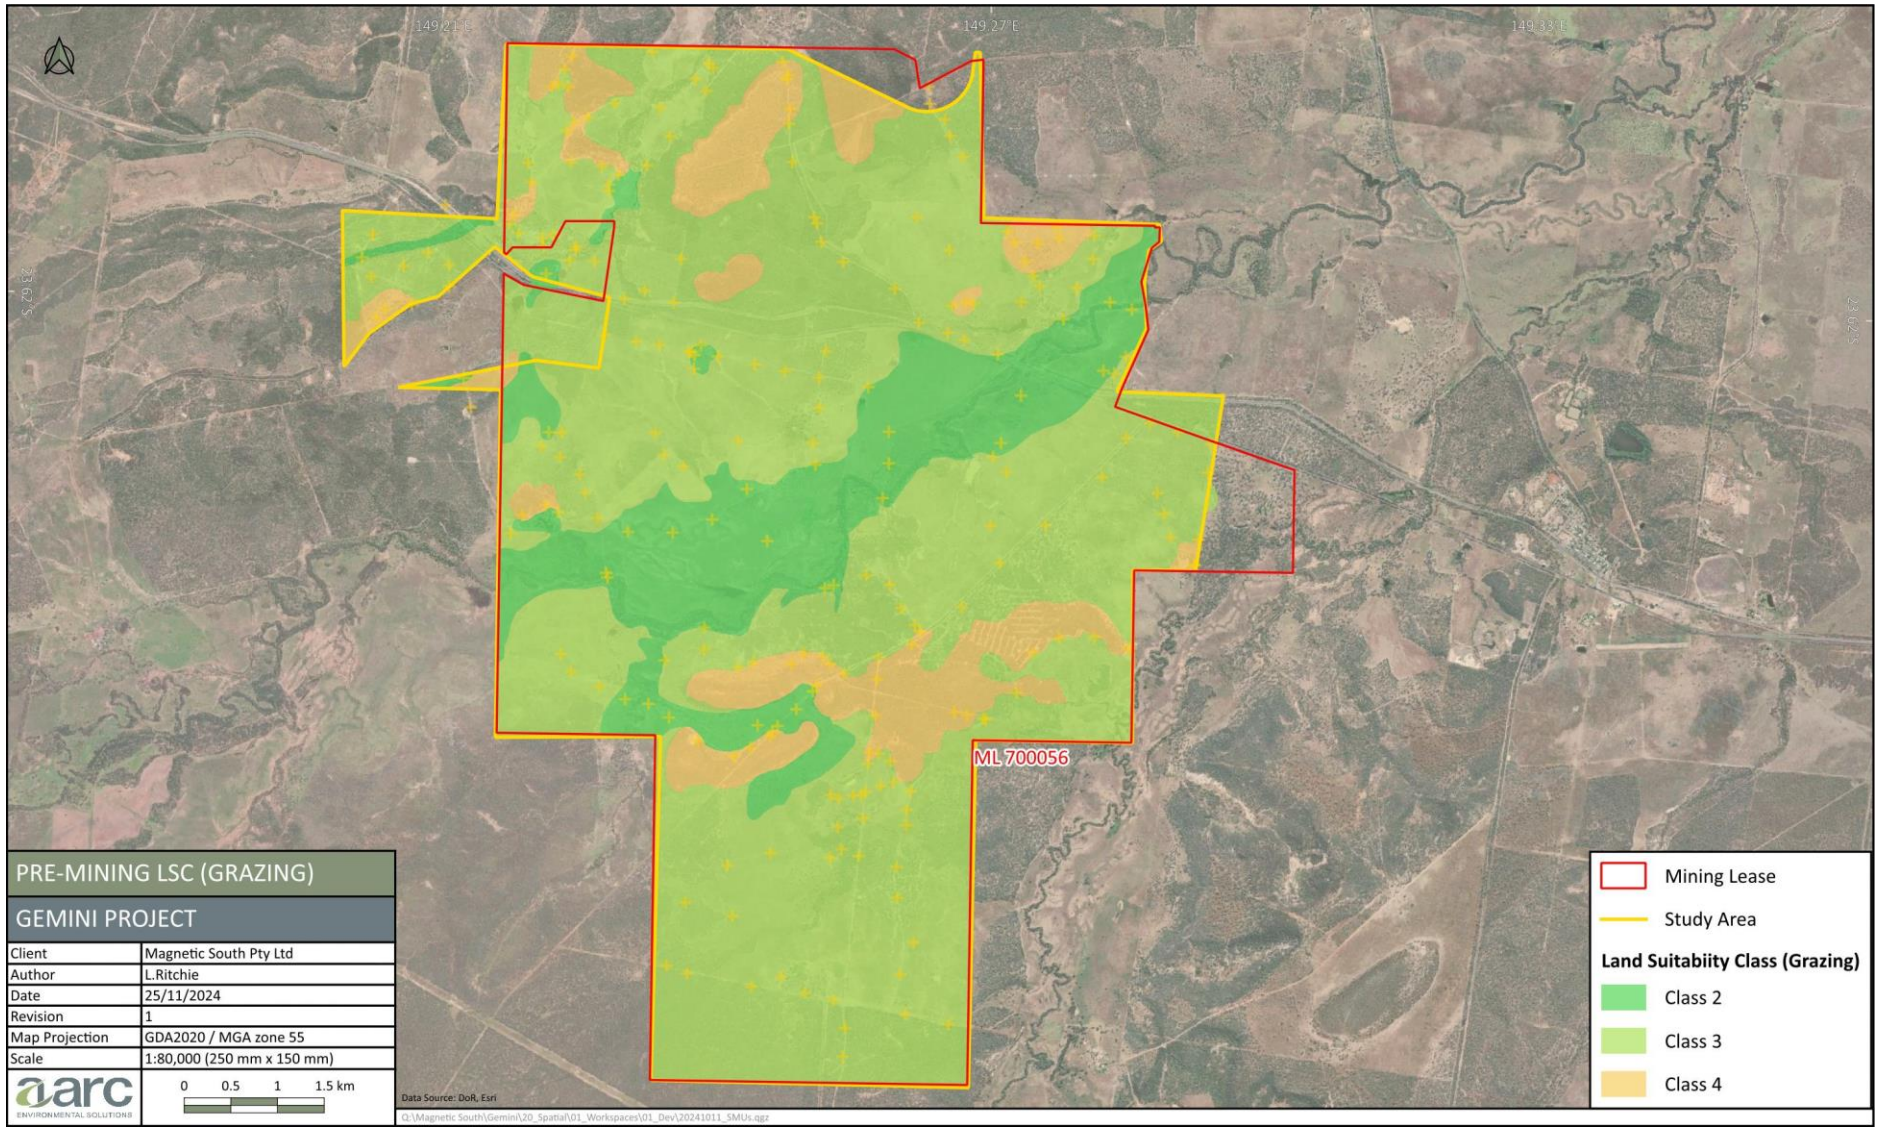

Figure 36: Pre-mining land suitability classes (grazing)

3.1.7 Flora and fauna

3.1.7.1 Terrestrial Flora

The Project area falls within the Brigalow Belt bioregion, which is characterised by Brigalow (*Acacia harpophylla*) woodland but also presents other vegetation such as semi-evergreen vine thickets, dry eucalypt woodlands, and native Bluegrass (*Dichanthium sp*.) grasslands. Due to its size, the Brigalow Belt bioregion covers a broad climatic gradient and a diversity of soils and topography. As a result of agricultural and other land development activities, most of the relatively undisturbed areas are confined to the rugged parts of the landscape.

Surveys of the study area identified one non-remnant vegetation community and ten remnant vegetation communities comprising six different Regional Ecosystems (REs). Table 16 outlines the RE characteristics of each vegetation community, where applicable, provides a short description of the vegetation present and identifies if it will be disturbed during mining activities. The distribution of vegetation communities across the Project site is illustrated in Figure 37.

Table 16: Vegetation community overview

Vegetation Community	Regional Ecosystem	Community Description	VM Act status	Impacted by Mining
VC 1	11.5.2	Narrow-leaved ironbark and Clarkson's bloodwood woodland with a sparse shrub layer on sand plains.	Least concern	Yes
VC 2	11.7.2	Lancewood (*Acacia shirleyi*) and/or Rosewood (*Acacia rhodoxylon)* woodland on lateritic duricrust.	Least concern	Yes
VC 3	11.3.25	Blue gum (*Eucalyptus tereticornis) or E. camaldulensis* with *Bauhinia* spp. and *Casuarina cunninghamiana* fringing woodland on drainage features.	Least concern	Yes
VC 4	11.3.2	Poplar box (*Eucalyptus populnea)* woodland on alluvial plains.	Of concern	Yes
VC 5	11.5.2/ 11.3.25	Mixed polygon where the dominant vegetation community was VC 1 (*Eucalyptus crebra* and *Corymbia clarksoniana* woodland) but along ephemeral creeks and with an important presence of Blue gums.	–	Yes
VC 6	11.3.25/ 11.3.2/ 11.5.2	Mixed polygon as a result of a combination of VC 3 with elements of VC 4 and some elements of VC 1 due to edge effects.	–	Yes
VC 7	11.5.2/ 11.5.9b	Mixed polygon where dominant vegetation was VC 1 with some elements of Narrow-leaved ironbark (*Eucalyptus crebra*), Narrow-leaved white mahogany (*E. tenuipes*), Brown hazelwood (*Lysicarpus angustifolius*) and Clarkson's bloodwood (*Corymbia spp.*) woodland.	–	No
VC 8	11.5.2/ 11.7.2	Mixed polygon where dominant vegetation was VC 1 with some elements of VC 2.	–	No

Vegetation Community	Regional Ecosystem	Community Description	VM Act status	Impacted by Mining
VC 9	11.3.25/ 11.3.2	Mixed polygon with dominant vegetation community of VC 3 and some elements of VC 4.	–	No
VC 10	11.3.2/ 11.3.25/ 11.3.1	Mixed polygon as a result of a combination of VC 4 with some elements of VC 3 and Brigalow (*Acacia harpophylla*) and Black oak (*Casuarina cristata*) open forest on alluvial plains.	–	No
Non-Remnant	NA	Non-remnant vegetation	–	Yes

Consistent with the surrounding country, the ML has predominantly been cleared of remnant vegetation (Figure 37) and is subject to low-intensity cattle grazing. The remaining extent of remnant vegetation consists of patches of Eucalypt woodland within riparian areas and on flat plains. These communities are mapped as riverine wetlands associated with a major watercourse or floodplain. Acacia *sp*. closed woodlands occur on higher ground.

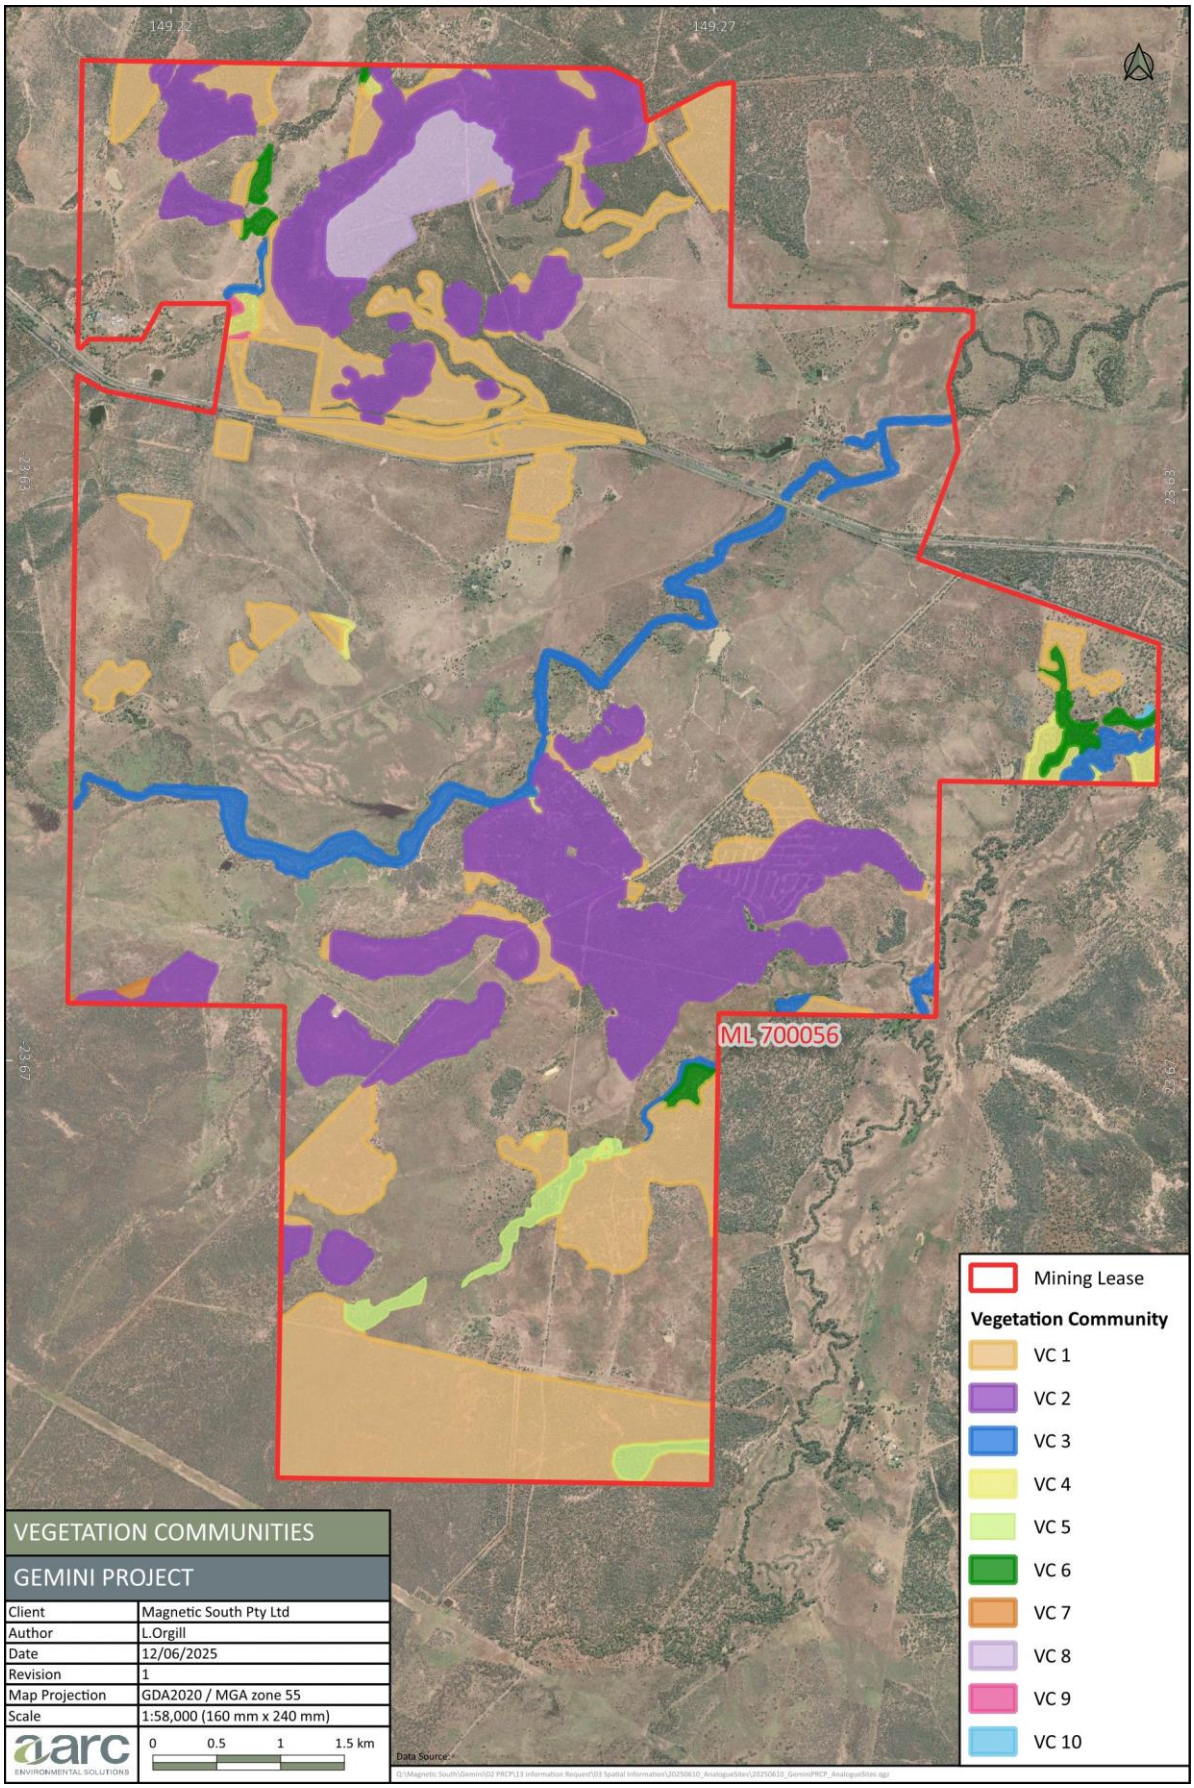

Figure 37: Vegetation communities occurring within the study area

Flora species of conservation significance

The near threatened plant species *Cerbera dumicola* was identified in two rocky areas to the central west of the ML (refer to Figure 38). The project design avoids impacts on these populations.

Weed observation

Five flora species classified as Weeds of National Significance (WoNS) and/or restricted invasive species under the *Biosecurity Act 2014* (Biosecurity Act) (DAF 2023) were identified on the ML. Category 3 restricted invasive species must not be distributed by sale, gift, or release into the environment. These species are identified in Table 17 along with the species' weed status.

Table 17: Weeds of National or State significance

Scientific name	**Common name**	**WoNS Status**	***Biosecurity Act 2014***
Harrisia martinii	Harrisia cactus	n/a	Category 3
Cryptostegia grandiflora	Rubber vine	WoNS	Category 3
Opuntia tomentosa	Velvety tree pear	WoNS	Category 3
Parthenium hysterophorus	Parthenium	WoNS	Category 3
Bryophyllum sp.	Mother of millions	n/a	Category 3
*Vachellia farnesiana**	Mimosa bush	n/a	n/a

*Denotes a species that is considered a noxious weed of management concern.

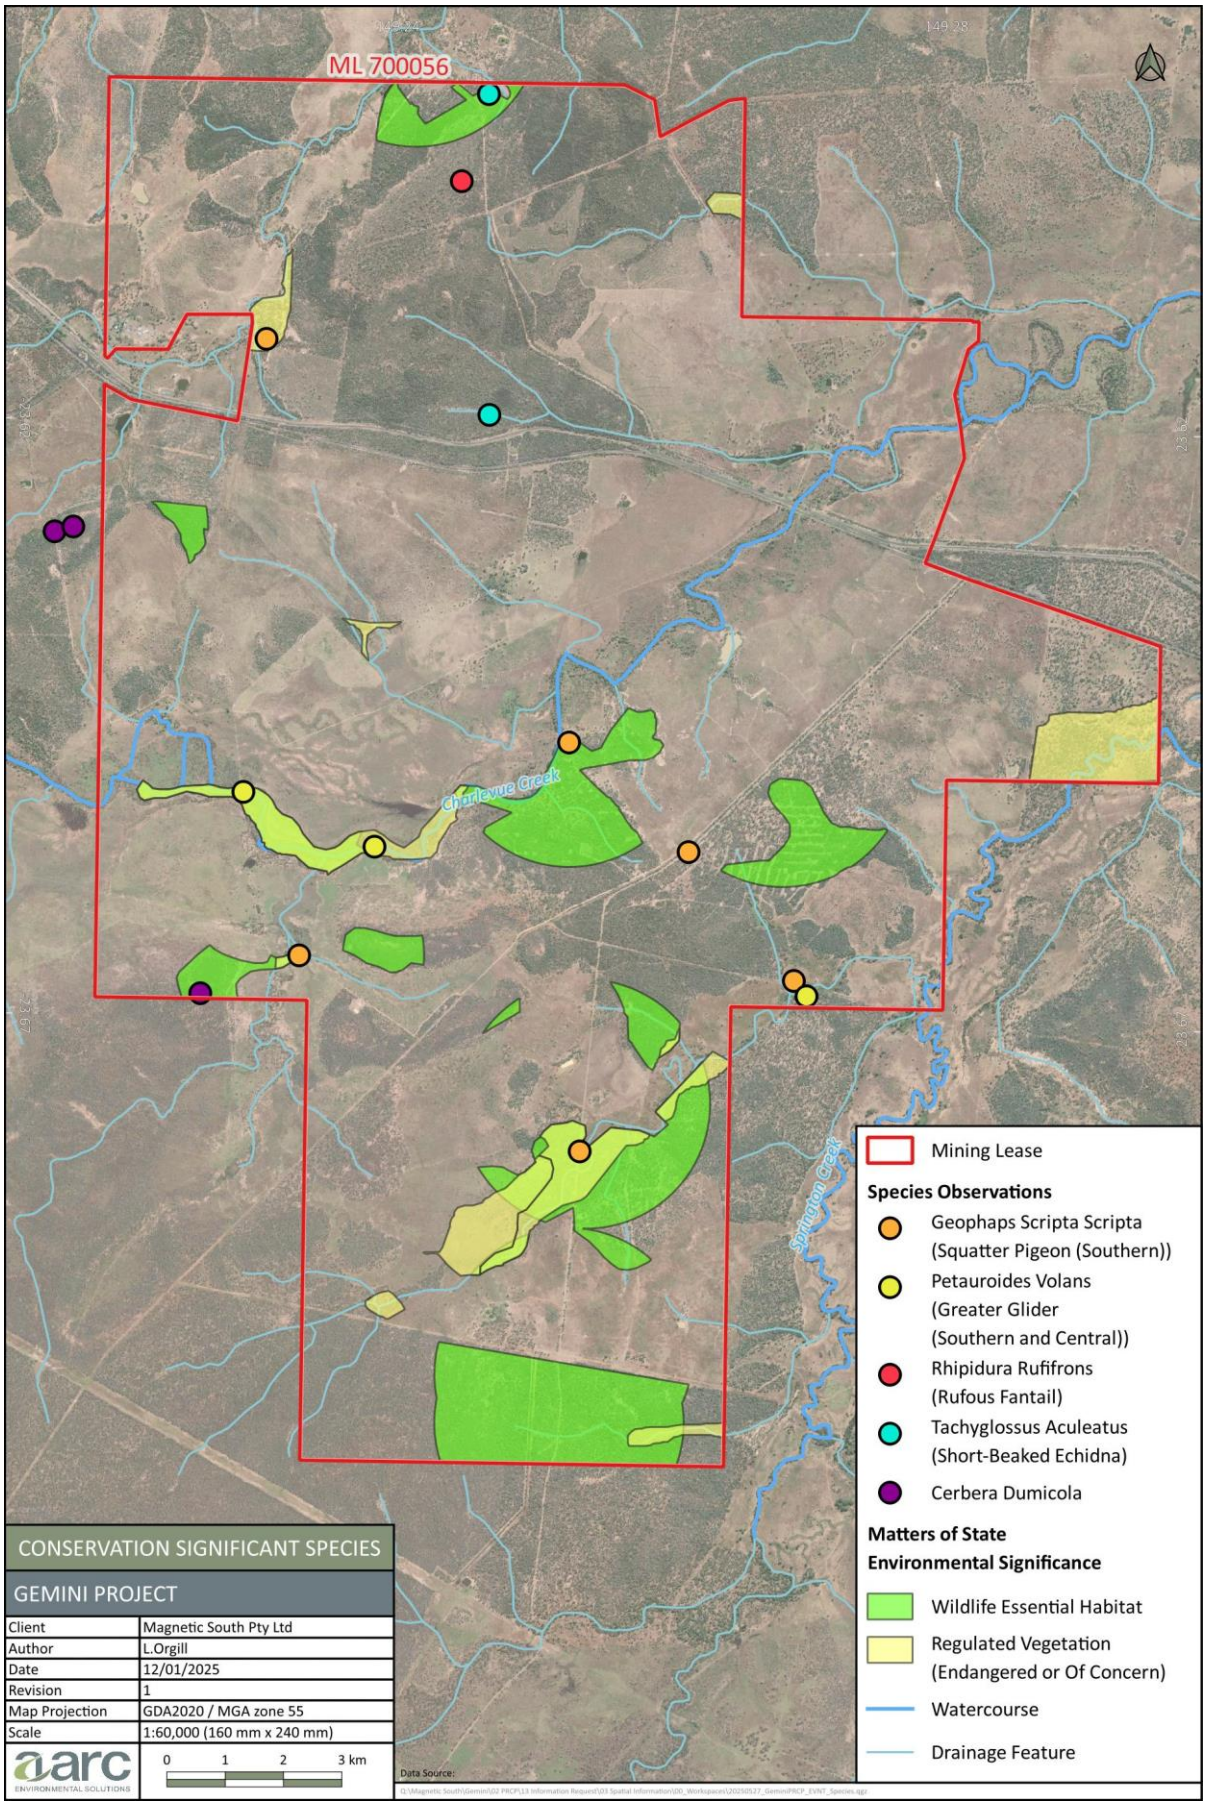

Figure 38: Species of Conservation Significance observed within the study area

3.1.7.2 Terrestrial Fauna

A total of 145 vertebrate species have been positively identified in the Gemini Study area during field surveys. The suite of vertebrate fauna species includes 8 amphibians, 83 birds, 33 mammals, 21 reptiles and 6 introduced fauna species. One migratory and marine species and one marine species were recorded during field surveys.

Field surveys across the study area detected the presence of five fauna species of conservation significance:

- the southern Squatter pigeon (*Geophaps scripta scripta*) and Greater glider (*Petauroides volans*), both of which are listed as Vulnerable under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) and the Queensland *Nature Conservation Act 1992* (NC Act);
- the Rufous fantail (*Rhipidura rufifrons*), which is listed as a migratory and marine species under the EPBC Act, and the Rainbow bee-eater (*Merops ornatus*), which is a listed marine species under the EPBC Act; and
- the Short-beaked echidna (*Tachyglossus aculeatus*), which is not an EVNT species but is listed under the NC Act as Special Least Concern.

Figure 38 demonstrates where these species of conservation significance were located within the study area at the time of detection.

All fauna species are regionally abundant, having been recorded outside of the study area on numerous occasions. Ample equivalent or improved habitat is available for these species in the surrounding area. The Project proposes no significant impact on the species.

Several protected areas occur near the Project, most notably Taunton National Park, which was established to protect a population of Bridled nail-tail wallabies (*Onychogalea frenata*). The Bridled nail-tail wallabies are found in open grassy eucalypt woodland dominated by poplar box (*Eucalyptus populnea*), dense acacia forest dominated by brigalow (*Acacia harpophylla*), transitional vegetation intermediate between the woodland and forest areas of very dense brigalow regrowth (Lundie-Jenkins and Lowry 2005). The Bridled nail-tail wallaby is considered endangered under the EPBC and NC Act. The species was not recorded on the Project site during ecological surveys.

3.1.7.3 Aquatic Ecology

The waterways of the study area are ephemeral, experiencing periodic flows. Charlevue Creek and Springton Creek are the major Water Act ‘determined watercourses’; all other waterways crossing the Project are ‘determined drainage features’. Extensive clearing for agricultural purposes has been undertaken across much of the study area, including the removal of riparian vegetation. The removal of riparian vegetation and direct stock access to the waterways has resulted in bank instability, erosion and the occurrence of weeds.

The Aquatic Ecology Assessment identified the presence of seven fish species within the study area, six of which are classified as least concern under the NC Act, and one species which is listed as introduced under the Biosecurity Act. A complete list of fish detected at each site is provided in the Aquatic Ecology Assessment (AARC 2020a; Appendix E). All fish species recorded in the study area are considered to be common or widespread species in the Mackenzie River Sub-basin.

No threatened aquatic fauna or flora species were detected within the study area during the baseline studies. This is consistent with the highly ephemeral nature of watercourses and the disturbed conditions resulting from past clearing and agricultural land use.

3.1.7.4 Groundwater Dependant Ecosystems

Where wetlands exhibit a degree of dependence on groundwater for survival, drawdown from the mine can result in a reduced ecosystem condition, changes to vegetation composition or dieback.

A Groundwater Dependent Ecosystem (GDE) assessment was undertaken across the Study area (3D Environmental 2020). Data from this assessment and the groundwater data obtained during several

groundwater studies performed by JBT Consulting (2019 and 2020) were used to assess the GDEs and the associated impact of drawdown.

The GDEs identified within the study area are riverine-type wetlands, including riparian vegetation on watercourses and floodplains.

The potential impacts of the Project on the GDEs identified within the study have been assessed within the GDE study (3D Environmental 2020; Appendix E) and are summarised below:

- **Direct clearing:** The GDE located within the tributary of Springton Creek falls within the footprint of the mine and, therefore, is subject to unavoidable vegetation clearing.
- **Groundwater drawdown**: Groundwater modelling estimated that the Project has the potential to cause a maximum drawdown of 5 m (steady-state post-mining drawdown) at some locations below the Charlevue and Springton Creeks (JBT 2019), on the Tertiary and alluvial sediments (regional groundwater table). This drawdown will not impact the riparian habitat identified as GDE within Charlevue Creek based on the limited hydraulic connectivity between the regional groundwater table and the perched aquifer that supports the GDE (3D Environmental 2020). Further, considering that the Project is situated downstream of Charlevue Creek's GDE and there will be no loss of catchment area, it is unlikely the Project will reduce the surface flows that replenish the associated perched aquifer (3D Environmental 2020).

The Groundwater Impact Assessment (Appendix E) concludes that impacts to groundwater have a low risk of impacting groundwater levels beneath the two potential GDEs due to the limited hydraulic connectivity with the regional groundwater table and the perched aquifer that supports the GDEs. In compliance with the EA, ongoing groundwater monitoring will be conducted throughout the Project's life. Additionally, there is no evidence of drawdown impacting the GDEs from modelled groundwater drawdown. While it is unlikely that drawdown will impact the GDEs as they are underlain by perched aquifers, any impacts from the Project will be evident through groundwater monitoring, further described in section 3.7.3.

3.1.7.5 Matters of State Environmental Significance

The offsets framework requires that environmental offsets be delivered where an activity will likely result in a significant residual impact on a prescribed environmental matter. The *Queensland Environmental Offset Policy Significant Residual Impact Guideline* (EHP 2014) was used to determine whether Project impacts are considered to be significant. This guideline outlines the criteria for identifying when an impact on a prescribed environmental matter (i.e., MSES) may be significant. The significant impact criteria provide a trigger for consideration of offsets (EHP 2014).

As part of the ecological assessments (AARC 2020a; AARC 2020d), significant impact assessments were conducted for all prescribed environmental matters identified in the study area. A summary of the results from the assessment is provided in Table 18, and the full assessments can be found in Appendix E (AARC 2020a, AARC 2020d).

Magnetic South is committed to delivering environmental offset requirements for matters with a significant residual impact resulting from the Project. Offsets will be delivered as either a financial settlement or proponent-driven offset (i.e., a land-based offset or *Direct Benefit Management Plan*) or a combination of both.

Table 18: Summary of Project MSES and Likelihood of Significant Residual Impact

Protected Matter	NC Act Status	VM Act Status	Likelihood of Occurrence Within Study Area	Likelihood of Significant Impact
Of concern RE 11.3.2	n/a	OC	Present	Yes

Protected Matter		NC Act Status	VM Act Status	Likelihood of Occurrence Within Study Area	Likelihood of Significant Impact
REs located within the defined distance from the defining banks of a VM Act watercourse		n/a	n/a	Present	Yes
Connectivity area		n/a	n/a	Present	Yes
Wildlife Habitat and Essential Habitat	Southern squatter pigeon	V	n/a	Present	No
	Greater glider	V	n/a	Present	No
	Short-beaked echidna	SLC	n/a	Present	No
Waterways providing for Fish Passage		n/a	n/a	Present	No
HES Wetlands		n/a	n/a	Not present	No

Notes:
n/a not applicable
OC of concern
NT near threatened
V vulnerable
SLC special least concern

3.1.8 Voids in floodplains

To assess the long-term impacts of the final void pit lake a GOLDSIM model (separate to the OPSIM model used for the operational modelling) was used. The historical rainfall and evaporation sequences were repeated 5 times to create a long-term climate record for use in the model. The potential effects of climate change were assessed using climate-change adjusted SILO climate data developed as part of the Consistent Climate Scenarios (CCS) project by the Queensland Government's Department of Environment and Science (DES).

Pre-mining conditions of PMF conditions of the mine are shown in Figure 39. The proposed final void catchments include the pits' plan areas, and immediate upslope catchments. Key details of the final voids are as follows:

- Mine B final void will be approximately 72 m deep, with a floor level of 40 mAHD and an overflow level of approximately 112 mAHD.
- Mine A final void will be approximately 70 m deep, with a floor level of 58 mAHD and an overflow level of approximately 128 mAHD.

The final void will be located and designed such that it is not inundated by flooding in the probable maximum flood (refer Figure 40) (refer section 3.5.7.7).

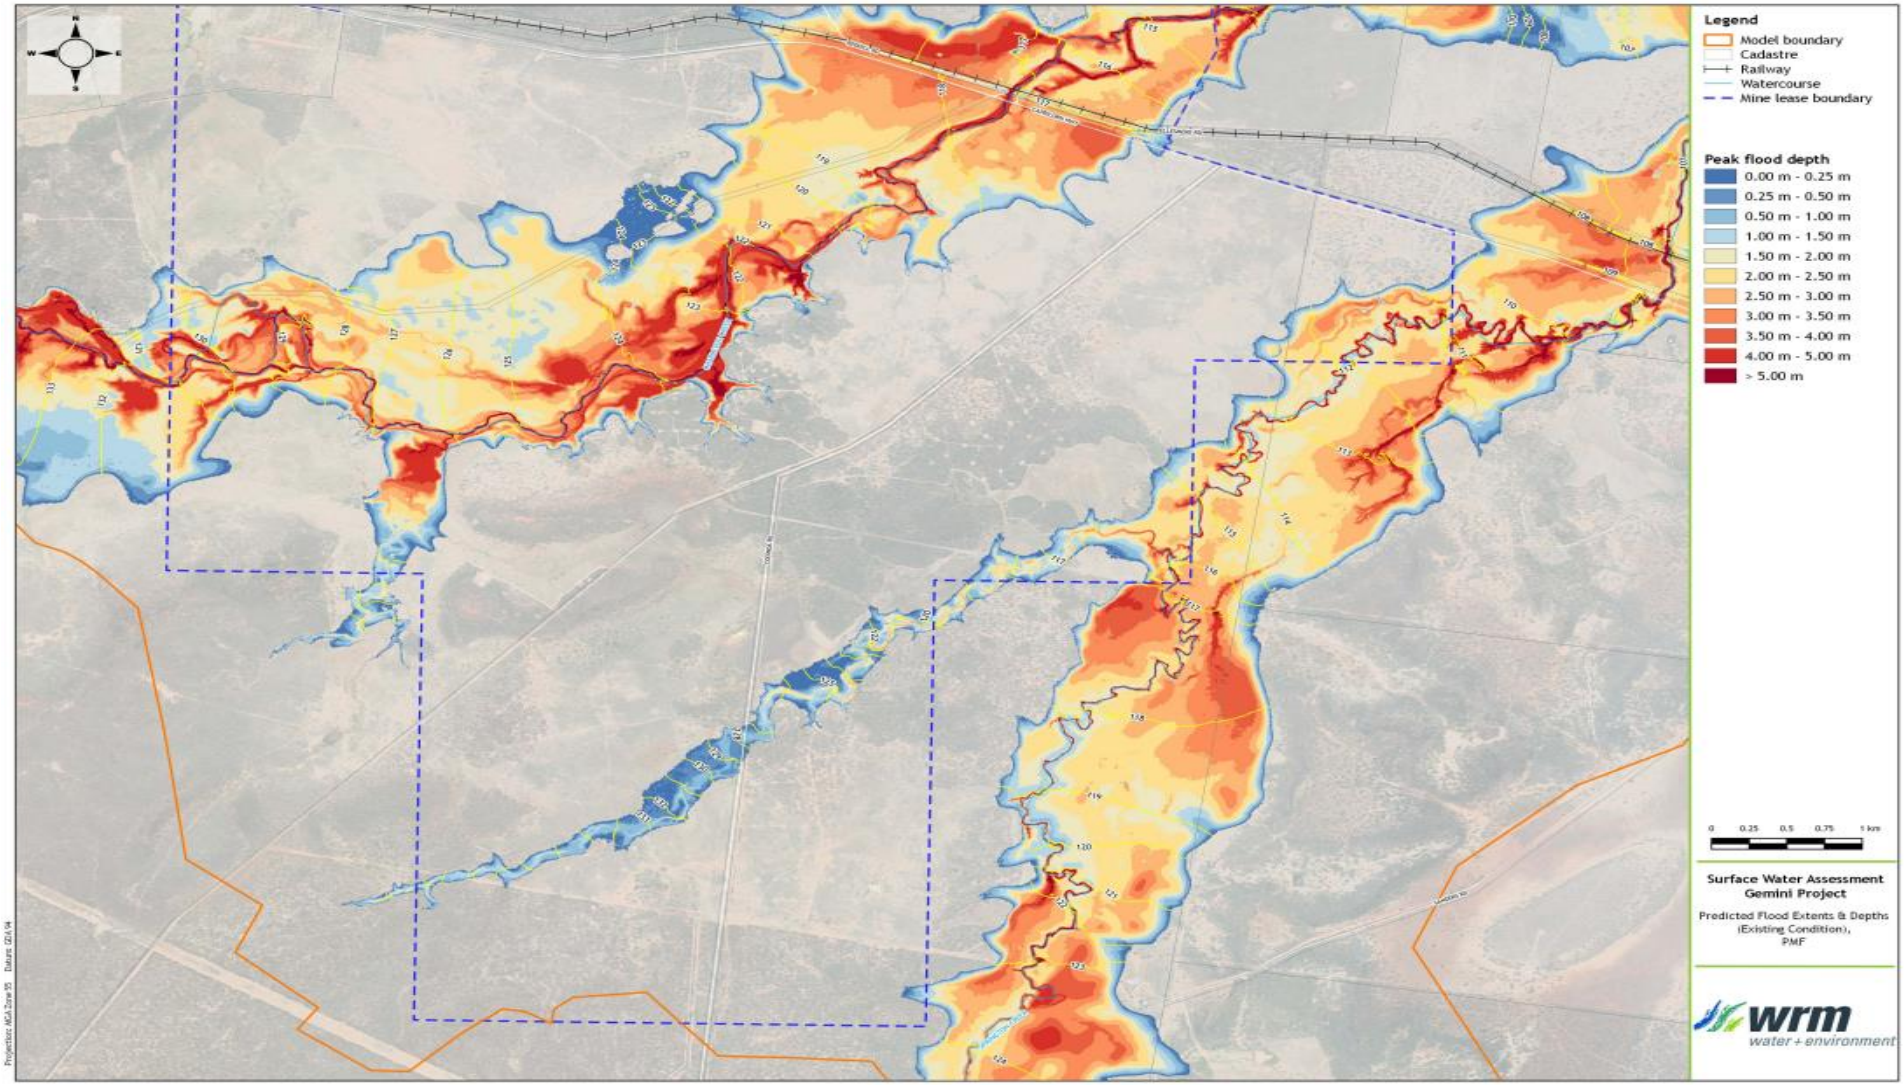

Figure 39: Predicted flood extent and depth (Pre-mining Condition) PMF

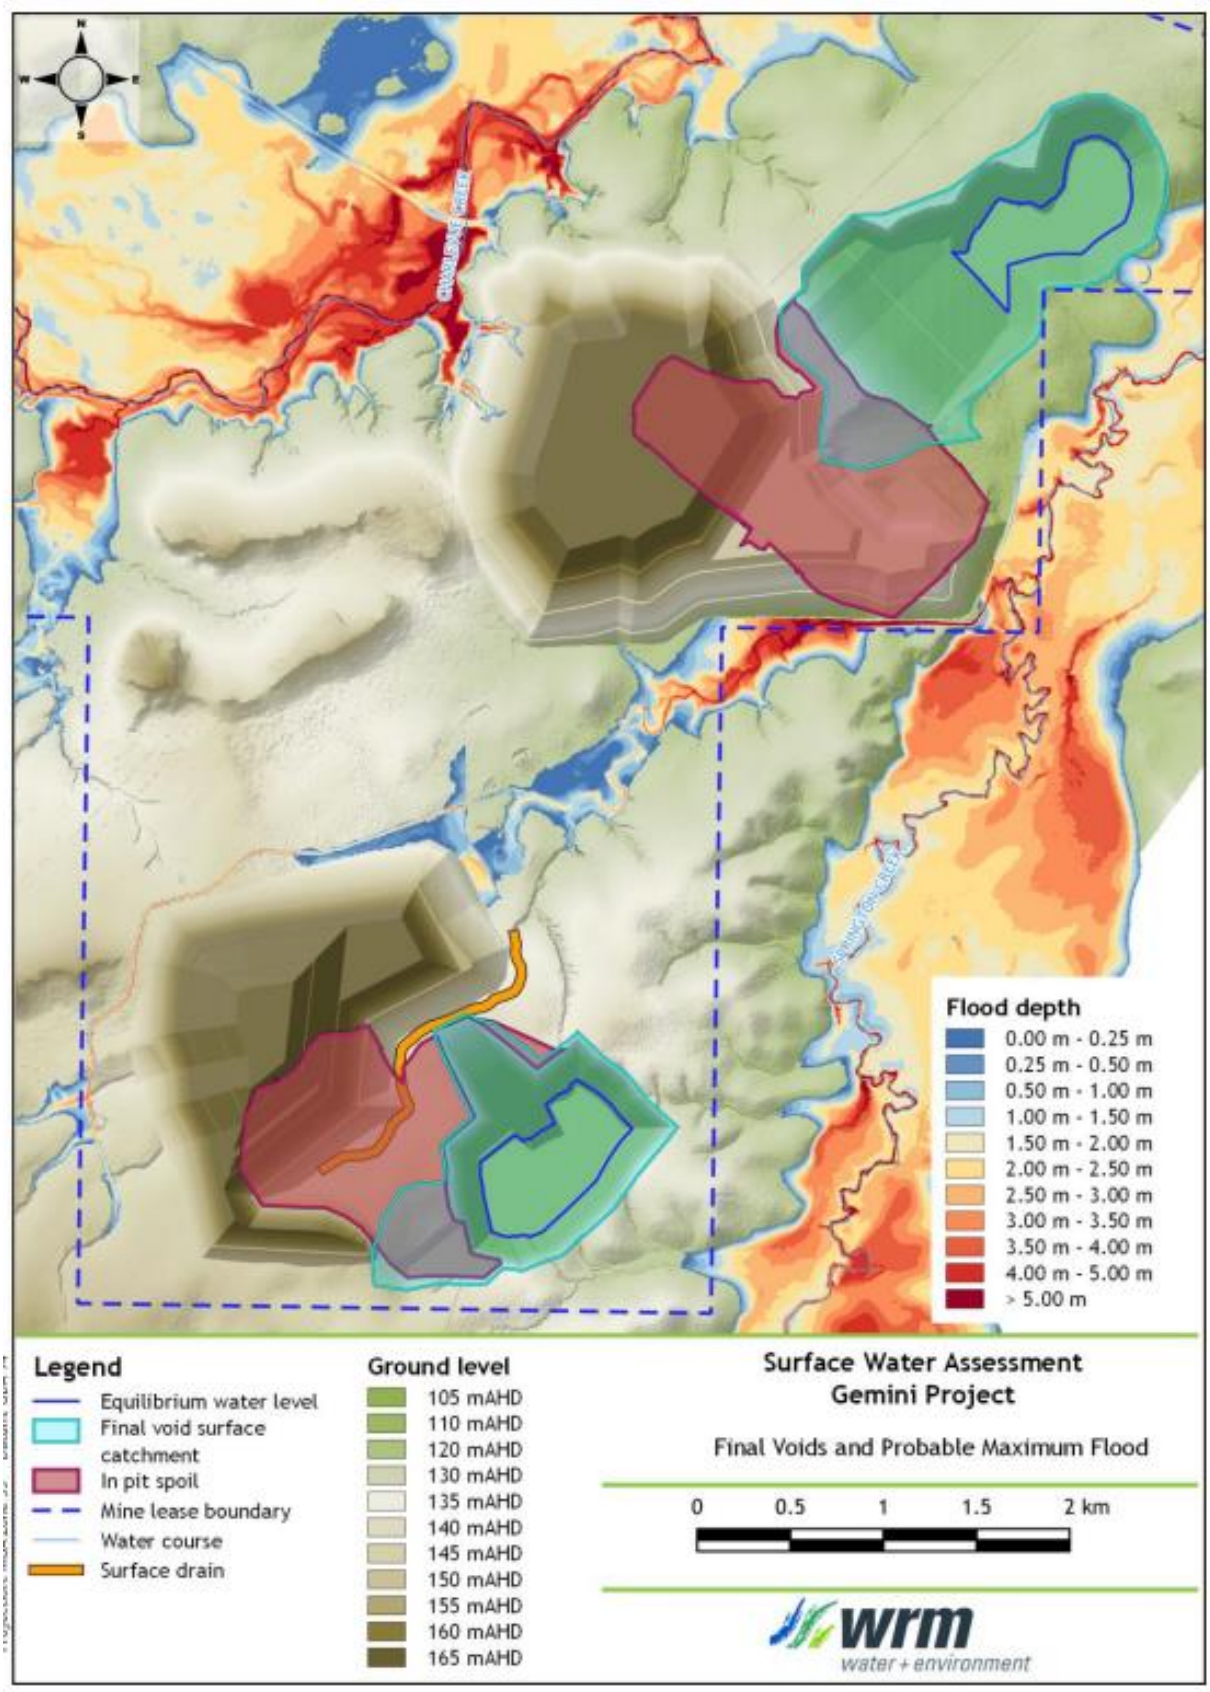

Figure 40: Post closure flood levels in Probable Maximum Flood

3.2 Community consultation

3.2.1 Previous stakeholder and community engagement activities

Magnetic South has undertaken consultation and discussions with underlying landholders, neighbours, native title groups (the Gaangalu Nation People), local council representatives and state government representatives. Consultation has been in the form of public notifications, formal meetings and informal discussions with potentially affected individuals to identify and address specific concerns relating to the Project development and closure.

Magnetic South acknowledges that they are a member of a larger community and consistently uphold their community responsibilities. In accordance with section 126C(1)(c)(iii) of the EP Act, and the PRCP Guideline, Magnetic South maintains a community consultation register (Table 19).

Magnetic South remains focused on ensuring a two-way conversation with stakeholders and the wider community and will actively seek feedback on the Project's impacts and benefits. Key messages and outcomes recorded in the register will be communicated internally to guide future decision making and rehabilitation.

Of note, previous stakeholder and community consultation did not include the Queensland Parks and Wildlife Services, or the managers of Taunton National Park (Scientific). As part of the EA application, it was assessed that the Project would not directly or indirectly impact Taunton National Park. The majority of mining impacts are located south of the Capricorn Highway, with vegetation linking mining operations to Taunton National Park fragmented by both the Capricorn Highway and the Blackwater Rail Network. The vegetation areas impacted by the rail loop north of the highway are fragmented by dedicated road reserves, and as such, there is limited connectivity value in relation to the Taunton National Park.

It was on this basis that the Queensland Parks and Wildlife Services, or the managers of Taunton National Park, were not consulted in the development of the land outcomes for the Gemini Coal Mine. Since the EA application was approved, further discussions with the rangers of Taunton National Park have occurred, with consultation in relation to the status of the Project and the use of noise and air quality monitoring equipment as part of Magnetic South's environmental obligations. However, given the transitional nature of the Gemini Coal Mine PRCP, further consultation with Taunton National Park in relation to the proposed PMLUs at the Project has not been undertaken.

3.2.2 Community consultation

Ongoing stakeholder and community engagement activities have been undertaken during different phases of the Project. Some specific examples of how community consultation has informed the PRC Plan (PMLUs) are as follows:

- The continuation of grazing interests was a key outcome of the consultation with the Central Highlands Regional Council during the presentation hosted by the proponent in 2019. Grazing has been adopted as the primary rehabilitation objective for land impacted by mining;
- While multiple rehabilitation options have been considered, low intensity grazing was chosen as the preferred PMLU for waste rock emplacement on the basis of pre-mining land suitability, landholder/stakeholder preferences, the existing land use and EVs of the surrounding landscape; and
- Unless water storage facilities are identified by the post-mining landholder as of value to their future use of the land, and an agreement is entered into, all water storages will be drained and de-silted, and re-profiled to ensure the area is free-draining and blends in with the surrounding landscape.

3.2.3 Stakeholder engagement plan

A Strategic Communication Framework (SCF) was developed in 2019 (Appendix D) to involve the public in the statutory approval regime, project planning and development. The SCF aims to establish and maintain the connection between Magnetic South (MS) and the community, identify and resolve issues regarding Project development and community concerns at early stages, inform the community about the Project (e.g. Project studies and planning), and satisfy regulatory consultation requirements.

The methods for stakeholder engagement in the SCF generally include:

- identification of stakeholders;
- identification of issues and concerns from stakeholders;
- selection and planned application of engagement tactics that are deemed effective in communicating meaningfully with the stakeholders;
- effective channelling of findings, feedback, issues, ideas, and opportunities to the Project team; and
- performing cyclic reviews of communications and adequacy.

The consultation program undertaken by Magnetic South and AARC consisted of three rounds of implementation:

1) advising intent and scoping selected issues;

2) testing the proposition; and

3) finalisation of expected communications and consultation.

The ongoing stakeholder engagement will be conducted in accordance with methods defined in the SCF. The ongoing stakeholder engagement will:

- provide opportunities for the relevant stakeholders to leave comments and feedback on the Project development and the PRC Plan;
- ensure transparency and inclusion are being incorporated into the Project operation and rehabilitation;
- provide a compliant mechanism to allow affected communities and stakeholders to register complaints, queries or comments and enabling these complaints to be addressed in a timely manner; and
- ensure PMLUs are consistent with community expectations.

A list of tools has been developed to assist in the engagement process, define how community will be engaged and determine how feedback/comments will be considered, such as Stakeholder Assessment Notes, a Stakeholder Contact Planner, and a Stakeholder Assessment Prompter. A public consultation report will be provided. The feedback and comments will contribute to consolidation of the proposition to the stakeholder community. Issues raised during engagement activities will be analysed with a risk assessment, key issues will be categorised and organised in issues tree. The SCF has been provided in full as Appendix D.

Magnetic South has developed a consultation register (Table 19) in accordance with requirements in section 126C(1)(c)(iii) of the EP Act. All the records of the ongoing engagement activities will be logged into the register during the life of the Project. An extract of the key consultation records relevant to the PRC Plan has been provided in Table 19. The properties in relation to affected landholders are outlined in Table 12, and the community members involved in such discussions were the registered landholders at the time of consultation.

Details of the PRC Plan and scheduling were provided to the community as part of the EA application, which included detailed land outcome descriptions and indicative scheduling of progressive rehabilitation. Community consultation was received on the details of the PRC Plan throughout the public notification period, but specifically in September 2021, when affected landholders and the Traditional Owner Group were engaged.

In addition to the SCF, a Cultural Heritage Management Plan (CHMP) also defines how the ongoing engagement and consultation with the Traditional Owner Group will be conducted. The objectives of the CHMP are to minimise the potential impacts of the Project's activities on the cultural heritage of the site through a knowledge of the site's cultural heritage and an effective monitoring and reporting framework for the management of cultural heritage and responsibilities within the Project in compliance with all Aboriginal cultural heritage management requirements under legislation, guidelines, and existing consents. Furthermore, annual consultation meetings were arranged during the EA application process to engage the Traditional Owner Group in assisting Magnetic South with post-mining rehabilitation, as evidenced during the discussions in July, October and December of 2020, provided in Table 19.

Table 19: Summary of community consultation register

Dates	Category	Community member	Consultation Type	Information provided to the community	Issues raised/discussed by the community	Decisions / outcomes of engagement	Commitments made by the applicant
March 2019	Government agency	Department of Natural Resources, Mines and Energy (DNRME)	Presentation	• Plans of land acquisition from landowners • Exploration plans • Environmental approvals and timelines	• Project background and infrastructure • Resource exploration (e.g., resource estimates and classification, drill hole locations, costs) • Environment and water context	Information shared and discussed with the agency, advice received.	- Regional interests of grazing has been identified; - Ongoing engagement of stakeholders and consideration of advice received.
May 2019	Government agency	Department of Environment and Science (DES)	Pre-lodgement Presentation for EA application	• N/A	• Project background and infrastructure • Resource exploration (e.g. costs) • Environmental Assessment reports progress and key findings, including closure studies and PMLUs for Area B and A • EP Act and EPBC approvals process	Information shared and discussed with the agency, comments received. Discussion points were adopted into the EA application.	- Regional interests of grazing has been identified; - Ongoing engagement of stakeholders and consideration of advice received.
October 2019	Affected landholders and interested parties	The landowners of affected properties and interested parties (a complete list of attendees was not captured).	Newspaper / website notification of ML and EA application submission	• EA and ML application information. This information is now publicly available.	• Timing and instructions for objections/submission.	Objections / submissions received.	- Information on the Project was shared with landholders; - Responses to landholders

November 2019	Government agency	Council Meeting	Meeting	• Gemini Project Presentation to Central Highlands Regional Council (CHRC) – Presentation Information • Detailed project description and approval process	• Gemini Project Presentation to Central Highlands Regional Council (CHRC) - Meeting 01 o Introduce Magnetic South PL & Gemini Project o Specific Magnetic South Comments Project is self-funded o Final rehabilitation and continuing grazing interests o Roads - temporary closures o Water supply, Sunwater pipeline & Dingo township o Infrastructure sharing - with council and private utilities companies (e.g. power, water, etc.) o Product Haulage - overhead conveyor to TLO o Sourcing labour - local preferences • Requirement to have a consent and compensation agreement with CHRC as owner of roads, land to allow inclusion of the roads in the surface area of the mining lease. • Proposing temporary closure of two roads, replacement connection from Sanders Rd	Information shared and discussed with the agency, and comments received	- Regional interests of grazing has been identified and implemented in the closure planning of the Project; - Ongoing engagement of stakeholders and consideration of advice received.

June 2020	Affected landholders	The landowners of affected properties	Objection/Submission and responses	• Information on the Project was shared with landholders	• Landholder concern: Further testing to be carried out bi-annually regarding progressive rehabilitation. • HG response: A Rehabilitation Management Plan is being developed for the Project, including monitoring of receiving waters, soils and erosion.	Objections / submissions received. Further rehabilitation detail was included to address community concerns	- A Rehabilitation Management Plan was detailed in EA application (incl. land outcomes and rehabilitation) - More expansive rehabilitation processes were adopted in the Rehabilitation Management Plan. Groundwater testing was expanded to quarterly testing.

Dates	Category	Community member	Consultation Type	Information provided to the community	Issues raised/discussed by the community	Decisions / outcomes of engagement	Commitments made by the applicant
25 July 2020 10 October 2020 12 December 2020	Indigenous Group	Gaangalu Nation People	Meetings	• Provision of all Project information	The operations within the native title claim area and how the parties will maintain and protect Aboriginal cultural heritage Consensus has been made, which was to sign a cultural heritage agreement to address how cultural heritage clearances are undertaken, and the management and avoidance of Aboriginal cultural heritage within the Project area Arrange annual consultation meeting to engage GNP in assisting Magnetic South during the life of the Project including the closure and rehabilitation phases.	Execution of a cultural heritage agreement	- To ensure that the GNP undertake cultural heritage clearances as required by the agreement and to make certain payments to the GNP as compensation. - Magnetic South and the GNP will be parties to the cultural heritage agreement which provides a process for the parties to follow regarding identification, preservation and avoidance of any cultural heritage found within the Project area.

Dates	Category	Community member	Consultation Type	Information provided to the community	Issues raised/discussed by the community	Decisions / outcomes of engagement	Commitments made by the applicant
January 2021	Affected landholders	The landowners of affected properties	Public notification letter regarding the EA changing application	• Description of the change in the EA application process • Resources on where the community could receive further updates	• Magnetic South notified affected landholders regarding the change application for EA application. Changes include: o Relocation of the camp and associated infrastructure to the south of the Capricorn Highway, on Lot 4 on RP801280 and Lot 1 on HT424, to be accessed via the main mine access road. o Removal of the Train Load Out Facility (TLO) access road from the Redrock Park Property to an alternate location further to the east.	NA	- Information on the Project was shared with landholders.

Dates	Category	Community member	Consultation Type	Information provided to the community	Issues raised/discussed by the community	Decisions / outcomes of engagement	Commitments made by the applicant
September 2021	Affected landholders	The landowners of affected properties	Submissions	• Finalised EA application considering the change application and subsequent RFI.	• Discussion of final void PMLUs. • Responses provided to the landholder regarding: o The relatively small extent of the final voids compared to the total disturbance area. o The major PMLU will be grazing. o The analysis of alternative PMLU for the final voids, and the reason why fauna habitat was selected as the most feasible option.	Objections / submissions received from landowners of affected properties. Submissions were resolved through the development of a Rehabilitation Management Plan. Objections were addressed as part of a formal Land Court process. Landholders were predominantly in favour of the closure options presented.	- Responses to landholders and a Rehabilitation Management Plan was developed with final void options considered. - EA was granted in considerations of objections raised as part of the Land Court process. - All PMLU/NUMA issues were resolved by the completion of the Land Court process.
September 2024	Government agency	Department of Environment, Science and Innovation (DESI)	Meeting	•	• Discussion with DESI concerning the proposed EA amendment and changes to the Gemini mine sequence	Concerns raised addressed in EA amendment application and in the development of the PRCP. EA amendment application submitted and approved.	- Information on the Project was shared with DESI for preliminary consideration.

Dates	Category	Community member	Consultation Type	Information provided to the community	Issues raised/discussed by the community	Decisions / outcomes of engagement	Commitments made by the applicant
May 2025	Government agency	Department of Environment, Science, Tourism and Innovation (DETSI)	Meeting	• Gemini PRCP v1.0	• Discussion of the proposed land outcomes for the residual voids • Rehabilitation of the Charlevue Ck crossing	Consensus reached that residual voids were better characterised as NUMAs More stringent rehabilitation requirements for the surrounding Charlevue Ck crossing area.	Vegetation along Charlevue Ck within the crossing boundary will be rehabilitated as a riparian corridor, rather than grazing, as approved within the LOD.

3.3 Post-mining land use

This section of the PRCP describes and discusses the PMLUs proposed for the Project in accordance with section 126C(1)(d) of the EP Act. PMLUs align with the pre-approved outcomes defined in the relevant land outcome document (LOD).

3.3.1 Land outcome documents

As per the definitions provided under section 750 of the EP Act, the LOD for the Project is "an environmental authority for a resource activity on the land". The EA is therefore considered to satisfy the definition of a land outcome document (LOD) for the Project.

3.3.2 Pre-mining and existing land use

The Queensland Land Use Mapping (DES 2020) classifies the majority of the Project area as a 'Grazing Native Vegetation' land use (Figure 41), which is defined as (ABARES 2016):

> *Land uses based on grazing domestic stock on native vegetation where there has been limited or no deliberate attempt at pasture modification.*

Other land use classifications over minor areas of the site include residential and farm infrastructure, reservoir/dam, marsh/wetland, and other minor uses, primarily in association with the Capricorn Highway, and transport and communication utilities (Figure 41).

The dominant land uses in the surrounding region are grazing of native vegetation, improved pasture, cropping and mining, with associated minor land uses including road transport, stock routes, and protected areas. The Project area is subject to low-intensity cattle grazing, consistent with the surrounding country and has predominantly been cleared of remnant vegetation (Figure 37).

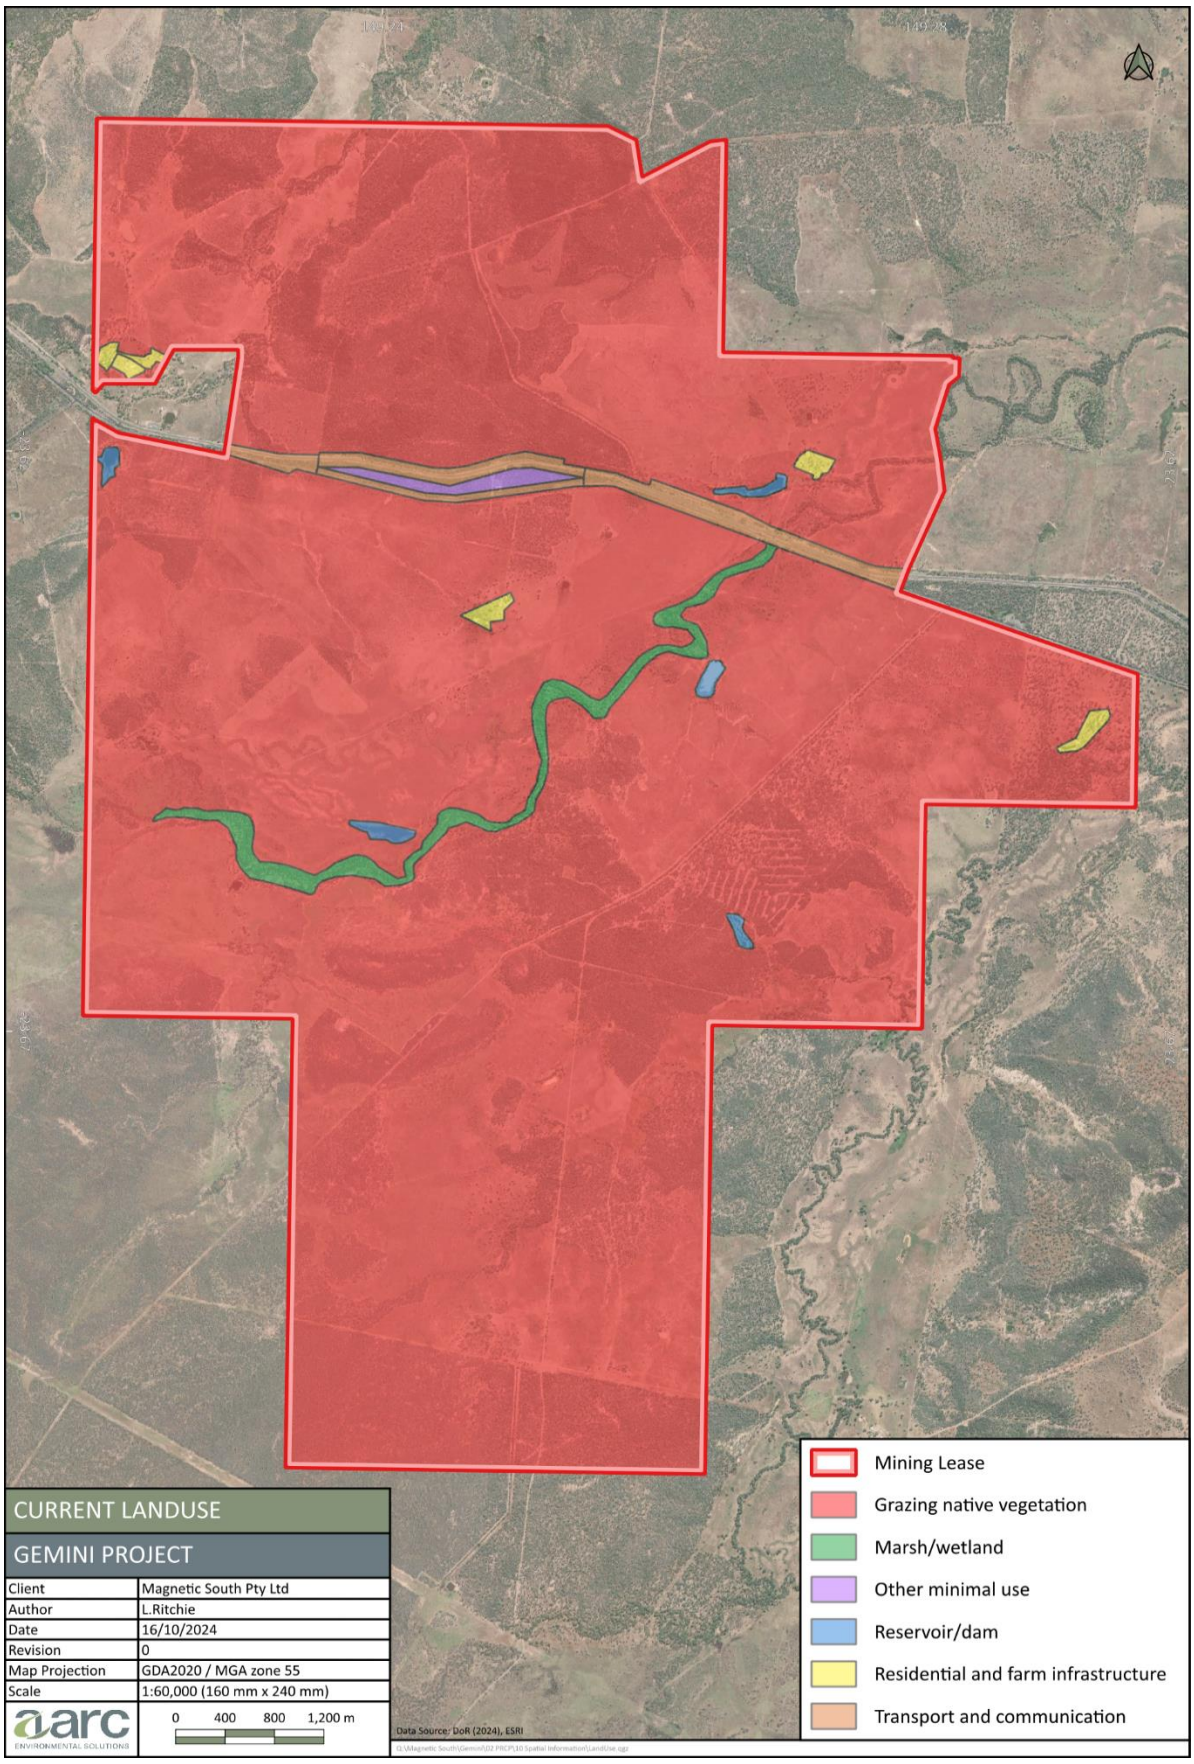

Figure 41: Current Land Use of the Project

3.3.3 Proposed post-mining land uses

3.3.3.1 Prescribed post mining land use

This section describes the proposed PMLUs for the Gemini Project, which are currently authorised under the Gemini EA (P-EA-100114292), the LOD for the PRC Plan. The PMLUs were developed with consideration for the existing local and regional land use, the Central Highlands Regional Council Planning Scheme (2016), the local ecological values and the site characteristics.

Other key factors considered in the determination of the PMLUs for the Project included:

- the pre-mining land use of low-intensity cattle grazing;
- stakeholder consultation during the approvals process;
- planning considerations, as defined in the relevant Council Planning Schemes;
- environmental considerations, specifically the need to prevent release of contaminants to the receiving surface waters or groundwater;
- environmental values and physical considerations as they relate to the safe and stable nature of the final landform and the development of self-sustaining ecosystems required for successful rehabilitation; and
- economic considerations relating to the cost of recreating the final land uses and the likelihood of achieving rehabilitation success.

The proposed PMLUs aim to reinstate the existing land use of low-intensity grazing (‘Grazing’) by returning the land to similar vegetation type and land class suitability to that existing prior to mine disturbance and delivering a beneficial environmental outcome by restoring, as far as practicable, existing native vegetation communities on diversion drains. Where a grazing land use is unsuitable, alternative PMLUs have been nominated and authorised. The alternative PMLUs intend to restore novel fauna habitat values, consistent with the local ecosystem values, through the restoration of ‘Native ecosystem supporting fauna habitat’ and ‘Riparian corridor’ supporting aquatic flora and fauna and ecosystem connectivity.

The authorised closure domains for the Gemini Project are described in Table H1 of the Project EA and are presented below in Table 20. The location and extent of each PMLU is illustrated in Figure 42.

Table 20: Rehabilitation domains and post mining land use

Rehabilitation Area	Post-mining Land Use	Post mining land description	Approximate Footprint Area (ha)	Approximate Proportion of Total Disturbance (%)
RA1: Waste rock emplacement (>3° slope)	Grazing	Low intensity cattle grazing	530.9	27.0
RA2: Waste rock emplacement (<3° slope)	Grazing	Low intensity cattle grazing	207.3	10.5
RA3: Residual void high walls	Native ecosystem supporting fauna habitat	Native ecosystem comprising vegetation on the upper shallow slope areas and cliff habitat on the steeper high walls Both sustaining fauna habitat (avifauna, ground dwelling fauna including small mammals and reptiles)	132.8	6.7
RA4: Residual void low walls	Grazing	Low intensity cattle grazing on class 4* or better pasture grasslands	186.8	9.5
RA5: Rehabilitated dams	Grazing	Low intensity cattle grazing on class 3* or better pasture grasslands	35.8	1.8
RA6: Retained dams	Retained infrastructure	Retained infrastructure at request of the underlying landholder	34.0	1.7
RA7: Diversion drains	Native ecosystem	Native ecosystem targeting RE11.5.2 with pasture understorey	14.3	0.7
RA8: Mine Infrastructure areas	Grazing	Low intensity cattle grazing on class 4* or better pasture grasslands	734.6	37.3
RA9: Retained infrastructure	Retained infrastructure	Retained infrastructure at request of underlying landholder	13.8	0.7
RA10: Riparian corridor	Riparian corridor	Pre-mining riparian vegetation targeting RE11.3.25	1.4	0.1

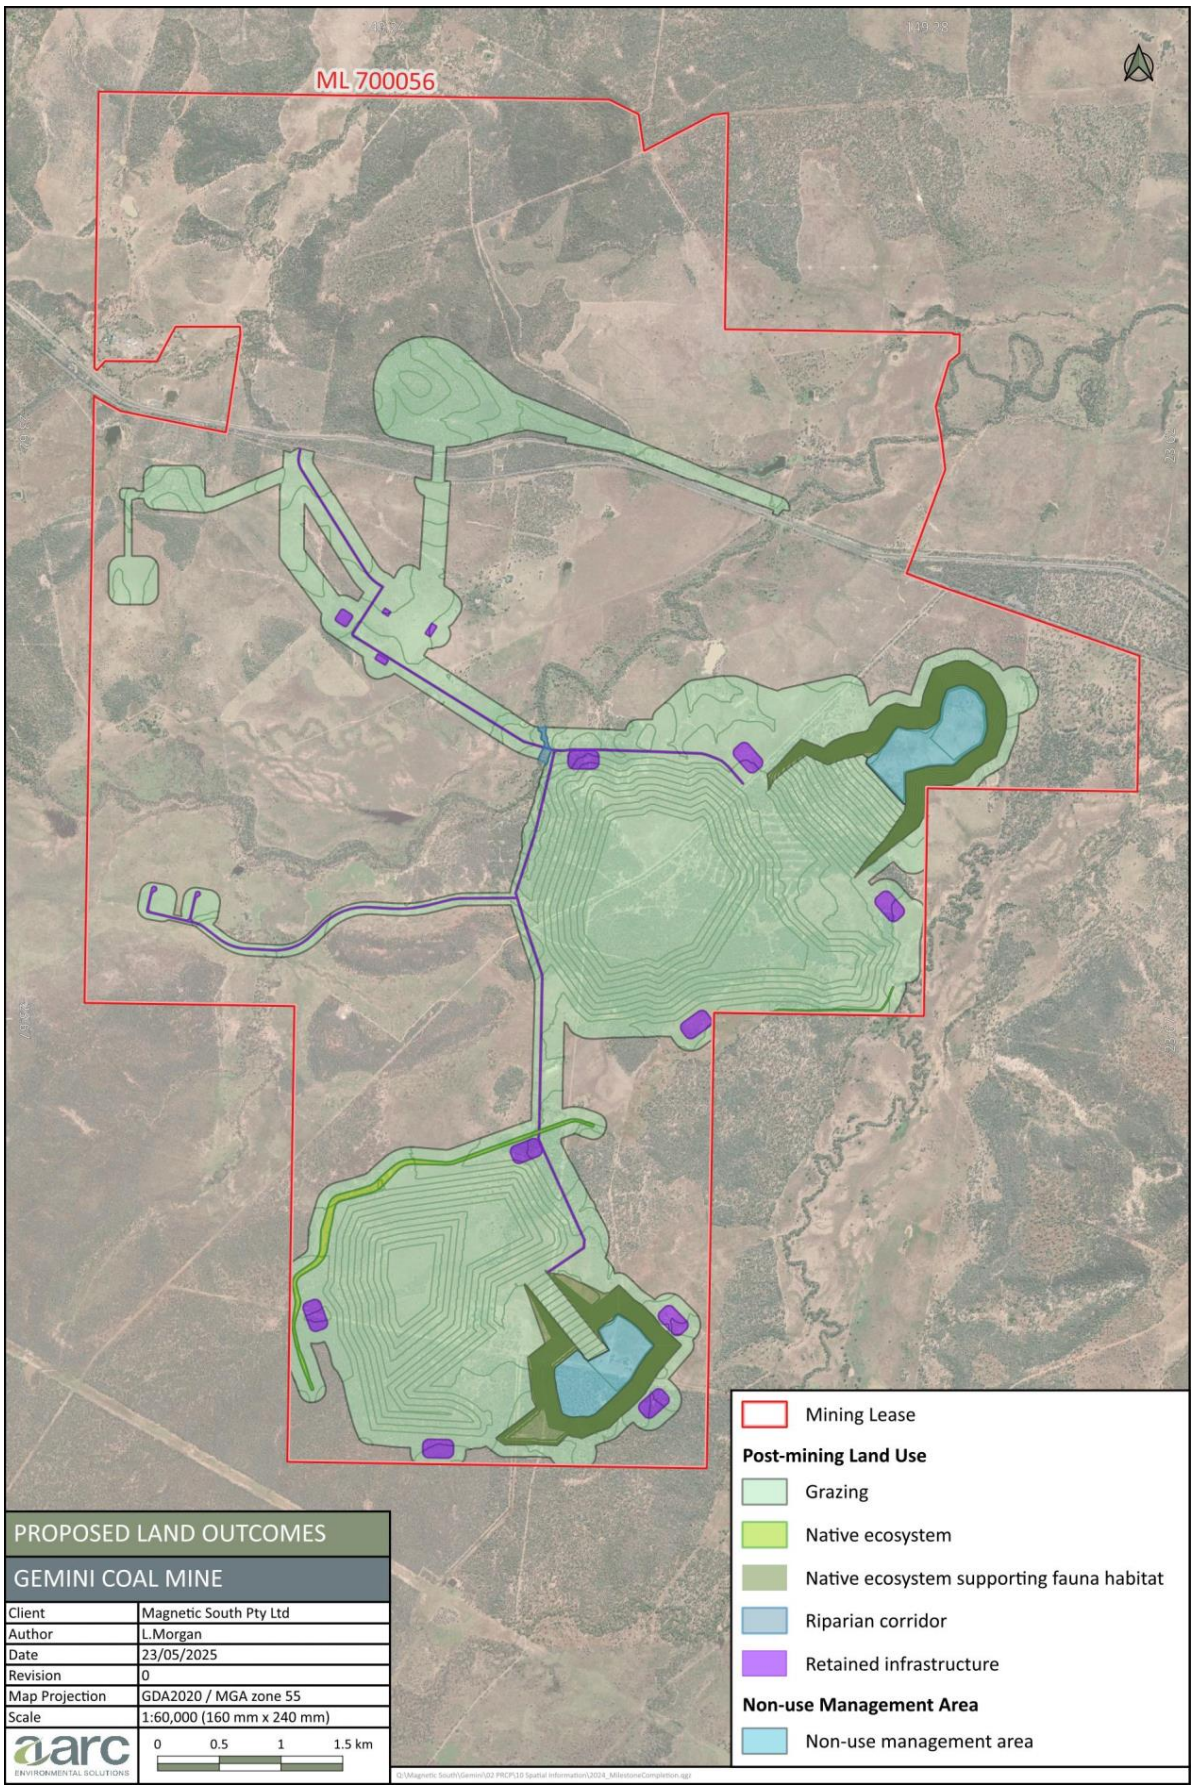

Figure 42: Post mining-land use

Justification for grazing PMLU

Low intensity grazing was chosen as the preferred PMLU for waste rock emplacement, void low walls and mine infrastructure areas on the basis of the pre-mining land suitability (refer to section 3.1.6.6), landholder/stakeholder preferences (refer to section 3.2), the existing land use of grazing (refer to section 3.1.6.3) and the environmental values of the surrounding landscape. With appropriate management of the higher sodicity topsoils identified, it is anticipated that rehabilitated landforms will be capable of sustaining improved and native pastures equivalent to a land suitability (LSC) class 4. Rehabilitated dams are also proposed to be rehabilitated to a grazing PMLU post-mine. The Soil and Land Suitability Assessment, prepared as part of the EA application, suggests these dams will achieve an LSC 3.

Justification for native ecosystem supporting fauna habitat PMLU

The high walls associated with pit lakes can provide suitable refuge and brooding habitat for several mobile fauna species (particularly birds and bats). Native vegetation proposed to rehabilitate the high-wall slopes will provide additional refuge for ground-dwelling fauna, including small mammals and reptiles. Similarly, grass tussocks provide nature refuges for a number of mammals and reptile species found on the Project site during the fauna survey, including the Delicate Mouse, Short Beaked Echidna, Rakalie Bynoes Gecko, Elegant Snake-Eyed Skink, Prickly Knob-tailed Gecko, Eastern Stone Gecko and Box-patterned Gecko (Appendix E AARC 2020d). The use of high-wall vegetation by goats, cattle, small mammals and reptiles has been observed in open cut mines of Queensland (pers comms. C. Cote March 2020).

The residual high wall offers the potential to provide a steeper slope habitat that can be used by native nesting birds. For example, a resident Peregrine Falcon pair has been recorded successfully breeding in nests created in the high walls of an open cut mining pit in the Northern Territory (Potts and Donato 2008). Additional individual Peregrine Falcons were observed utilising the various open pit high walls for roosting. Birds documented to nest on inland, flat land or slopes may utilise the high-wall pit slopes as nesting habitat (O'Donnell and Debus 2012). Anecdotally, birds of prey have been reported to utilise the high wall as refuges in an open cut coal mine located in central Queensland (pers comms. J. Fittler March 2020); the Wedgetail Eagle, a species that has been recorded on the Project site, is one example of such a species of bird of prey.

Insectivorous bats have been documented feeding on insects in the airspace above pit lakes in both Western Australia and central New South Wales (Griffiths et al. 2014a; Griffiths et al. 2014b). A number of insectivorous bats have been identified on the Project site by ANABAT surveys, including the Chocolate Wattled Bat, Eastern Bent-winged Bat, Eastern Cave Bat, Gould's Wattled Bat, Inland Forest Bat, Little Pied Bat, Northern Free-tailed Bat, Troughton's Sheathtail Bat, White-striped Free-tailed Bat and the Yellow-bellied Sheath-tailed Bat (AARC 2020b).

To facilitate the rehabilitation of residual void high walls to native ecosystem supporting fauna habitat, the residual high walls will be regraded to 18° or lower, where located within unconsolidated sediments and saturated tertiary. For the remaining Permian geology, an overall angle of 55° will be achieved by 50 m high batters at 65° incorporating 15 m wide intermediate benches. Perimeter safety bunds and fencing adjacent to final high wall crests will be constructed at the end of mine life. Hydromulch will be applied to the high wall surfaces. Areas of flat bench and 18° slopes will be revegetated to a novel native ecosystem by targeting species composition elements of *Corymbia citriodora* woodland on coarse-grained sedimentary rocks (RE 11.10.3).

A novel native ecosystem is required for this PMLU due to the landform design constraints and material characteristics of the growth media and subsoil materials. Given the rehabilitation design of the final high walls, it is unlikely that any surrounding regional ecosystems comprised of coarse-grained sedimentary rocks (landzone 10), which are located primarily within the Blackdown Tableland National Park, will be representative of the native ecosystem likely to be achieved. This limitation was considered as part of the EA application where the terminology of "native vegetation" was used in reference to the residual void high walls. Based on the modern rehabilitation framework described in contemporary literature (Spain et al. 2025), this classification of "native vegetation" is best described as a novel native ecosystem.

RE 11.10.3 was nominated for the rehabilitation of the high walls as the vegetation composition is consistent with surrounding REs within the Gemini ML, specifically RE 11.7.2. As such, the growth of these species has been observed on the same topsoil and subsoil material, suggesting that these species can successfully

establish on the high walls and benches of the residual voids. Furthermore, targeting these species provides greater certainty that viable seed can be sourced during rehabilitation and closure of the site. However, due to the risk of erosive failure on the high walls, a groundcover of 80% will be required (Appendix L), which is considered the upper bounds of RE 11.10.3 per the Regional Ecosystem Technical Description (2018) published by the Queensland Government. As such, the high walls and benches are likely to require a novel groundcover and canopy structure compared to areas of RE 11.10.3 surrounding the site to protect against erosive failure and ensure that the residual voids remain stable.

Justification for retained infrastructure PMLU

Some mine infrastructure areas will be retained post-mining at the request of the landholder, with signed agreements to be provided as part of the rehabilitation milestones associated with the PMLU. Infrastructure to be retained includes a number of sediment and raw water dams, retained for stock watering purposes, and access tracks to be used by landholders to assist with their cattle grazing activities post-mining.

A watercourse crossing over Charlevue Creek is required to be constructed to connect the mine infrastructure area to the east of the creek and mining operations to the west of the creek. The watercourse crossing will be retained post-mining as it provides direct and safe access to the properties from the Capricorn Highway.

Justification for native ecosystem PMLU

Native ecosystem has been nominated as the preferred PMLU for the two diversion drains present on site to remain consistent with the pre-mining landscape. Based on ground-truthed vegetation mapping, the diverted streams predominantly sustain eucalypt woodlands on sandy plains (RE 11.5.2), with some areas of mixed eucalypt woodland on fringing drainage lines (RE 11.3.25). Both drainage features are unnamed, second-order streams that are ephemeral in nature. Due to the both streams experiencing extended dry periods, neither segment being diverted would support a dominant riparian ecosystem pre-mining activities. Furthermore, the understory of the remnant vegetation surrounding the diverted streams area is heavily grazed by cattle and is not a pristine representation of either RE 11.5.2 or 11.3.25. Therefore, both diversion drains will be rehabilitated to a native ecosystem PMLU, and will target species composition elements of RE 11.5.2 with a pasture understory, consistent with pre-mining conditions.

Justification for riparian corridor PMLU

Charlevue Creek is a known riparian biodiversity corridor, and as such, it will be rehabilitated to its native ecosystem, consistent with the pre-mining land use. The haul road and watercourse crossing will be a width of approximately 80 m; however, the authorised disturbance footprint is an approximate width of 250 m. Therefore, the watercourse crossing will be significantly narrower than the 250 m corridor, leaving large areas of remnant vegetation undisturbed. All riparian vegetation surrounding Charlevue Creek within the authorised footprint will be identified as a riparian corridor on the basis that only the watercourse crossing will be retained, and any unimpacted vegetation will remain undisturbed post-mining.

As part of the construction of the watercourse crossing, some areas of riparian vegetation adjacent to the watercourse crossing will be impacted. The expected impact will consist of vegetation clearing; however, the works will not include topsoil stripping or result in a change to watercourse morphology. Cleared areas will be rehabilitated to a natural native ecosystem, targeting 11.3.25, consistent with the pre-mining land use. It is expected that this will represent a small section of the riparian corridor, with the majority of the existing regional ecosystem to be unimpacted by mining.

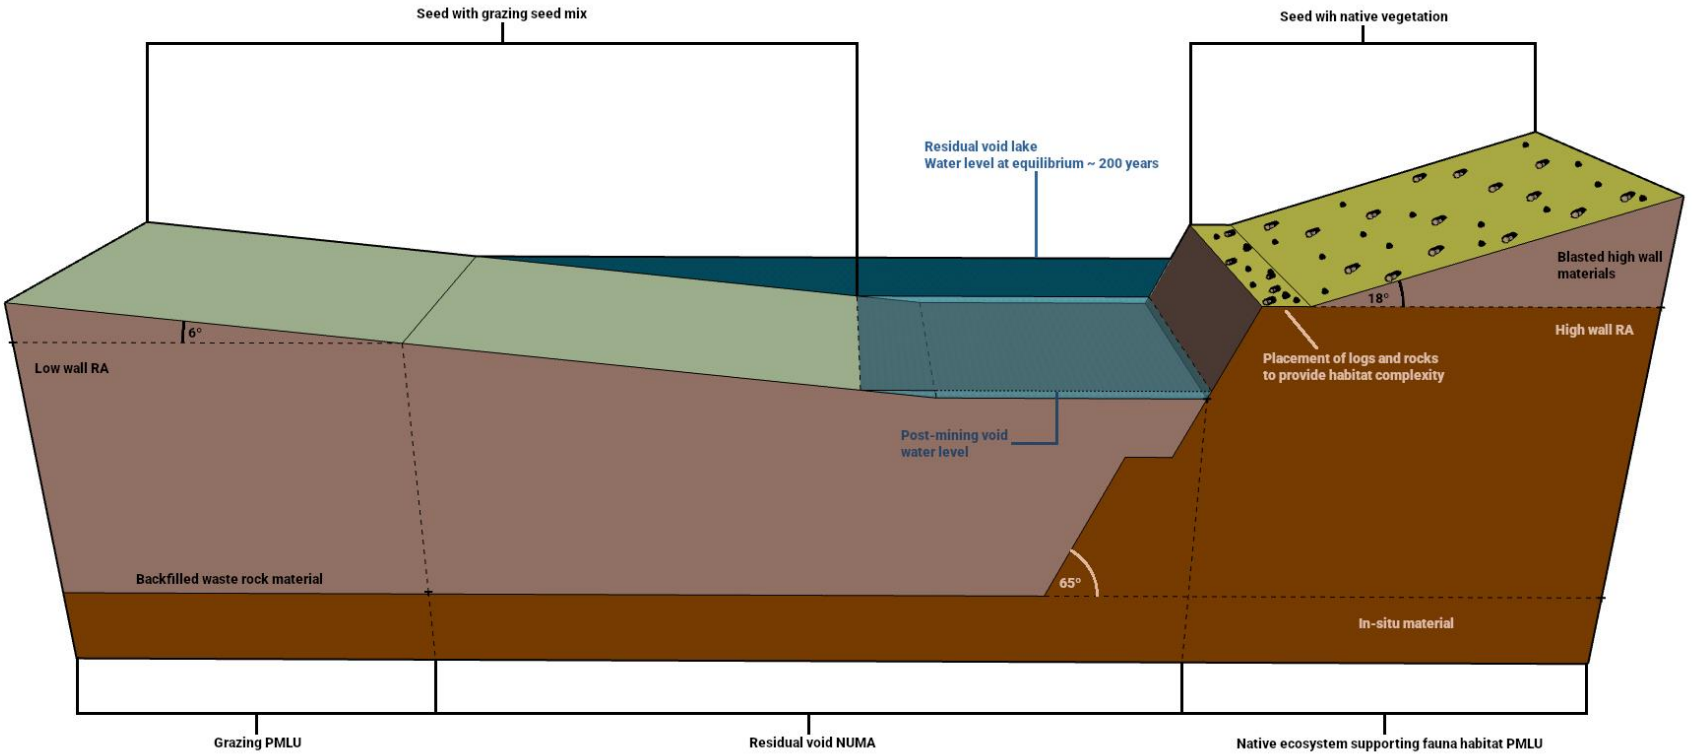

Figure 43: Conceptual 3D sketch of residual void final landform design

3.3.3.2 Post mining land suitability

The post mining cattle grazing Land Suitability Class (LSC) proposed to be achieved for each mine domain is shown in Figure 44. This was determined based on the *Land Suitability Assessment Technique* (DME 1995), with consideration of the pre-mining LSC for the Project site (refer to Figure 36) and physical characteristics of the post mining landscape, such as topography, recreated soil profiles and the underlying substrate (e.g. mine waste).

Water storages that are not to be retained for use by the landholder will be regraded to natural surface levels and returned to a grazing land use. It is anticipated that areas returned to a post mining land use of cattle grazing can be returned to LSC 3.

It was determined that where dams and mine infrastructure areas are to be rehabilitated to a state of grazing, they would have a post-mining LSC of 3. It is anticipated that all other areas returned to a post-mining land use of cattle grazing can be returned to LSC 4, based on the pre-mining LSC of the SMUs impacted, as outlined in the SLSA prepared for the EA application (Appendix E). These classifications have been established by the conservative approach adopted for waste rock dump areas to ensure successful rehabilitation. Pre-mining LSC for waste rock dumps primarily intersect with Class 3; however, portions of Class 4 have been identified within these areas. Consequently, these areas have been proposed to achieve Class 4 on the basis that some topsoil may be unable to sustain Class 3 long-term.

The calculated area (in hectares) for each pre and post mining LSC within the project disturbance area is provided in Table 21.

Table 21: Pre and post mining cattle grazing LSC areas

	Area (ha)					
	Class 2	**Class 3**	**Class 4**	**Class 5**	**Class 3/5**	**Total**
Pre-mining	63.2	1644.0	246.3	0	0	1953.5
Post-mining	0	631.5	1027.1	224.4	70.5	1953.5
Change from pre to post	-63.2	-1012.5	+780.8	+224.4	+70.5	0

An examination of the land suitability limitations for cattle grazing indicated that the majority of the Project area (4,338 ha) is suitable for cattle grazing with moderate limitations (Class 3), whilst 1,080.5 ha of the study area is deemed suitable for cattle grazing with minor limitations (Class 2). The remaining area (750.84 ha) was comprised of Class 4 land. No Class 1 or Class 5 land was identified within the Project area.

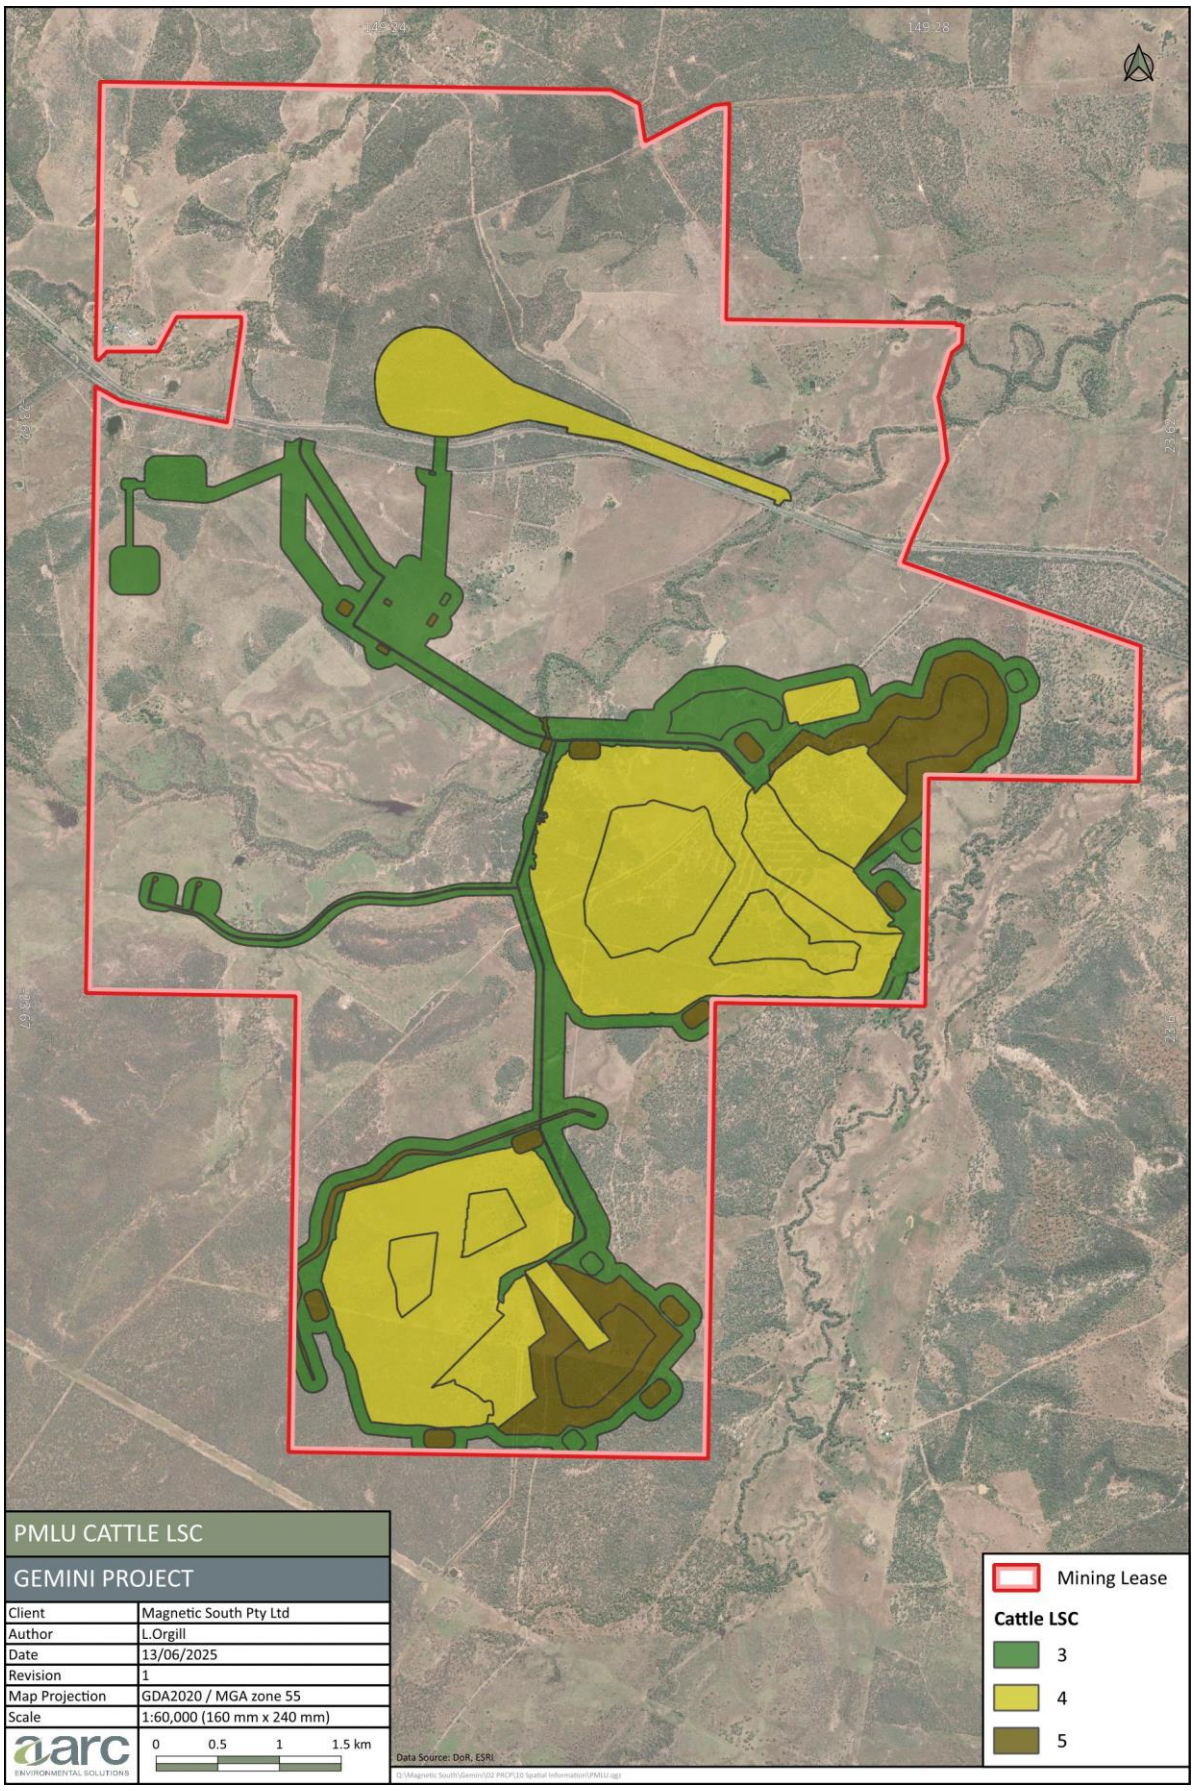

Figure 44: Proposed post mining land use (PMLU) LSC for cattle grazing

3.3.4 Final void evaluation

3.3.4.1 Alternate residual void options considered

Mine planning assessed a number of options to manage and reduce final landform residual risk including backfilling the pits to a modified pre-mining topography, backfill to approximately 80 m below the pre-mining topography and no backfilling of pits. All options required the rehandle of waste rock material, the reduction of remnant high wall angles, the reshaping of waste rock emplacements, and normal rehabilitation techniques related to topsoiling, surface preparation and revegetation. Options were evaluated on the relative basis of cost, overall project value and relative reduction in environmental risk.

Option 1: The modified pre-mining topography option was based on backfilling voids to a level slightly higher than the original topography to allow for settlement over time. Once a sufficient period has been allowed for settlement, the area would be shaped and drained to manage erosion and then topsoiled and revegetated. Advantages of this option include negation of the need to stabilise high wall slopes or make safe the final void itself. The primary disadvantages with this option are:

- the significant cost of rehandling extremely large volumes of waste rock at the end of mine production;
- the significant limitation on being able to undertake progressive rehabilitation given the need to rehandle a majority of waste rock material at the end of mine life; and the ongoing settlement of the final landform surface potentially resulting in long term stability issues.
- The modified pre-mining topography option resulted in the net present value (NPV) of the project being so low that the Project could not proceed. In consideration of the margins of error within the financial model assumptions, the risk of a negative return was far too high for development. This option was therefore not considered further.

Option 2: The option of not backfilling the final void provides the greatest economic value to the Project by reducing the costs required to rehandle waste materials. However, it will decrease land availability for grazing activities post-mining and will significantly increase the salinity of the pit lake (Appendix E, JBT 2019). As such, the environmental impacts of not backfilling the final voids were considered significant and the option was not considered further.

Option 3: The preferred (and approved) option is to backfill the residual voids to 80 m below ground level (bgl), based on the findings of the *Groundwater Impact Assessment* (JBT 2019). This study indicated that, with controls to limit surface water draining to the pits, saline inflows would be significantly reduced if the pit was backfilled to 80 mbgl. To achieve the final landform design, the base of the pit will be integrated with the in-pit waste emplacement by reshaping backfill to a maximum slope gradient of 6°, to be utilised for a grazing post-mining land use.

High wall slope management requirements would be reduced, and additional areas would be available for grazing. Only minor restrictions on progressive rehabilitation would arise. Although salinity will still increase over time, the pit lake water quality is modelled to remain suitable for aquatic ecosystem development for up to 100 years post-mining.

The residual voids will comprise three ‘rehabilitation areas’ having differing landform characteristics and, as a result, differing PMLUs. These areas are described as:

- Regraded, topsoiled and revegetated low wall slopes draining to the pit lakes and able to support a grazing PMLU.
- Two water bodies with a surface level modelled to gradually increase to an equilibrium level of between 70-80 mAHD; acting as a groundwater sink and having a gradually increasing salinity. A key rehabilitation objective for this rehabilitation area is to reduce the rate of predicted water salinity present in the void primarily to allow the ecology of the residual void waterbody sufficient time to adapt to salinity changes. Backfilling the voids to 42 mAHD for Mine B and 65 mAHD for Mine A reduces saline groundwater inflows and surface water drainage, resulting in a significant reduction in the rate of salinity development within the pit water body.

- Salinity is predicted to remain below 5,000 mg/L in the first 100 years following mining and will remain below 10,000 mg/L for the first 200 years. It should be noted that modelling inherently overestimates the rate of salinity increase in residual void water bodies by assuming that the source of mobile salts in overburden is infinite (Appendix E, AARC 2020c)
- There is little currently available data on the long-term behaviour of water bodies resident in Bowen Basin coal mine overburdens, particularly the rate of approaching a long-term equilibrium salinity level. The backfilling option adopted is intended to seal the poorer quality remnant coal seam aquifers and limit salt inputs to the pit lake from groundwater.
- Residual void high walls will be regraded to 18° or lower, where located within unconsolidated sediments and saturated tertiary to achieve a factor of safety (FOS) of 1.5, or an appropriate site-specific FOS as advised by an Appropriately Qualified Person (AQP). For the remaining Permian geology, an overall angle of 55° will be achieved by 50 m high batters at 65° incorporating 15 m wide intermediate benches. Perimeter safety bunds and fencing adjacent to final high wall crests are designed and constructed to prevent human or animal injury and exclude cattle and prevent erosion. Safety bunds adjacent to final high wall crest are designed and constructed in compliance with industry best practice and safety bunds for high walls are certified as long-term stable.

Figure 45 and Figure 46 provides cross-sections depicting the proposed backfilling of waste rock within Mine A and Mine B.

Options 1-3 were the only scenarios evaluated in developing the PRCP. There are no other economically viable options for the Project that would improve the water quality outcome for the residual void. Therefore, Option 3 is the preferred scenario as it will deliver the best possible environmental outcome for the residual void that is economically feasible.

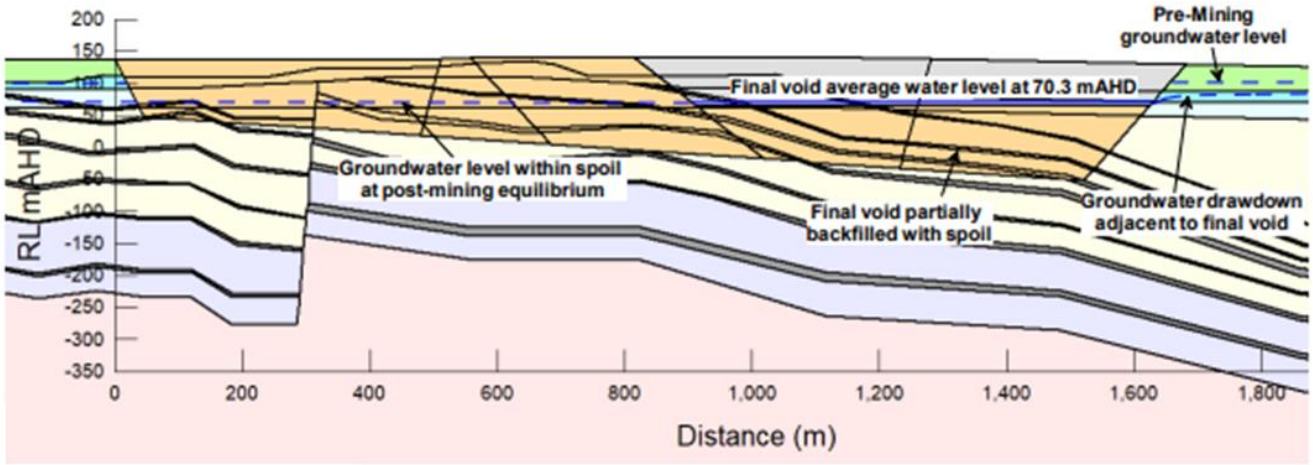

Figure 45: Conceptual layout of end of mining (Mine A) groundwater level

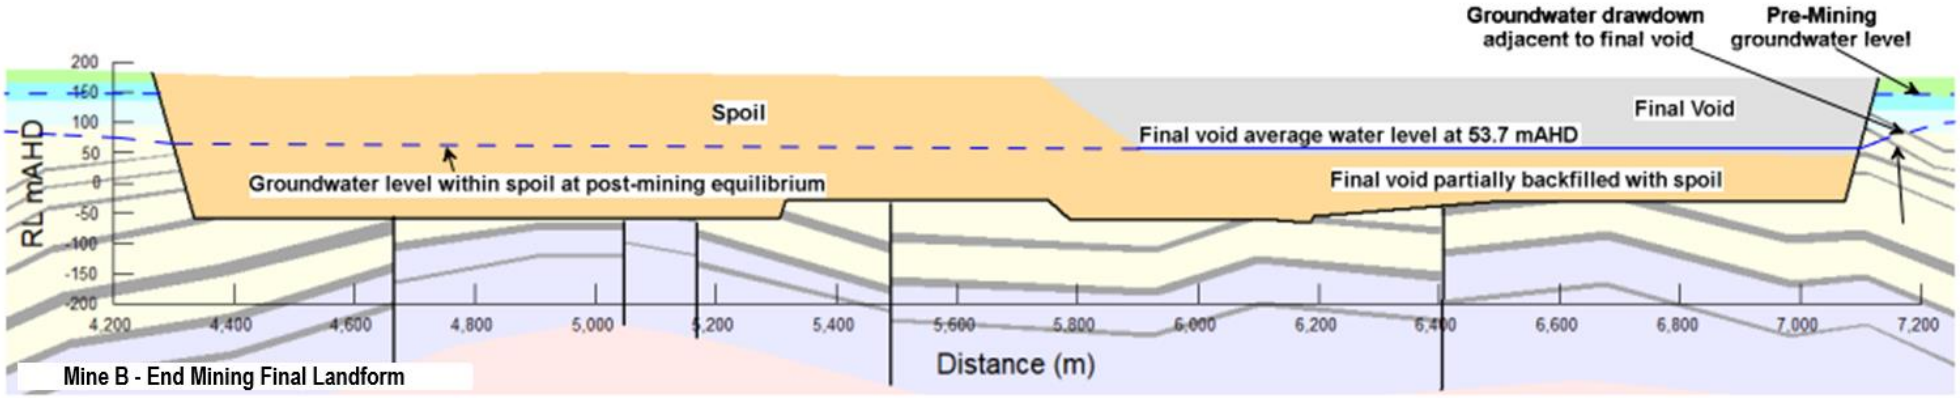

Figure 46: Conceptual layout of end of mining (Mine B) groundwater level

3.4 Non-use management areas

3.4.1 Land outcome documents

As outlined in section 3.3.1, the Gemini Coal Mine EA is considered the LOD for the purposes of the PRCP. Currently, the EA prescribes that the final void waterbody will achieve a fauna habitat PMLU post-mining. The land outcome associated with this PMLU is not clearly defined in the EA itself; however, it is described in the supporting information documents supplied as part of the EA application for the Gemini Coal Mine.

The EA application outlines three options assessed to manage and reduce the final landform residual risk of the residual void pits. The preferred option proposes to backfill residual voids with spoil to approximately 80 mbgl. The *Groundwater Impact Assessment* (JBT 2019) indicates that under a partial backfill scenario, the modelled groundwater inflow rate is zero. The final landform will be achieved by integration of the base of the pit with the in-pit waste emplacement; with reshaping of backfill to a maximum slope gradient of 6°. Backfilling the voids reduces saline groundwater inflows and surface water drainage, resulting in a significant reduction in the rate of salinity development within the pit water body. This option is intended to seal the poorer quality remnant coal seam aquifers and limit salt inputs to the pit lake from groundwater.

As outlined in the EA application supporting information, two residual voids will remain post-mining and are anticipated to accumulate water over time to an equilibrium level. The pit lakes, in conjunction with the surrounding high walls, were proposed to support a PMLU of fauna habitat. The air/waterbody interface was proposed to support a range of waterborne and flying insects, as well as avifauna and various bat and microbat species. Furthermore, the waterbody itself was proposed to support a range of freshwater aquatic plants and invertebrates in shallower edge areas and over time transition to brackish water species as water quality changes.

However, when considering the proposed backfill option described above, it is not possible for the residual voids to sustain the proposed PMLU due to the modelled salinity over time. While modelling suggests that the TDS of the final voids will remain below 5,000 mg/L over 100 years, these values are expected to progressively increase to 30,000 mg/L after 500 years. Based on contemporary research concerning the long-term viability of aquatic ecosystems in post-mining landscapes ([include ref to QMRC Paper]), the current modelled salinity suggests that the residual voids will be unable to sustain the nominated fauna habitat PMLU in the long-term.

A NUMA is defined in section 122 of the EP Act as an area of land the subject of a PRC plan that cannot be rehabilitated to a stable condition after all relevant activities for the PRC plan carried out on the land have ended. Stable condition is further defined by section 111A of the EP Act as, among other descriptions, land that can sustain a post-mining land use. With these considerations in mind, based on the land outcome described in the EA application, the residual void lakes will be unable to reach a stable condition and therefore are proposed to be defined as non-use management areas as part of the Gemini Coal Mine PRCP. This outcome minimises the risk of environmental harm while ensuring that the land outcome remains consistent with what was proposed as part of the EA application for the Gemini Coal Mine.

3.4.2 Proposed non-use management areas

Proposed NUMAs are presented in Table 22 along with approximate footprint area and proportion of disturbance.

Table 22: Non-use management areas

Improvement Area	Non-use management area	Non-use management area description	Approximate Footprint Area (ha)	Approximate Proportion of Total Disturbance (%)
IA1: Residual void lakes	Non-Use Management Area (NUMA)	Void lake to remain as water body, providing some fauna habitat value initially, before salinity increases in the long-term	76.3	3.9

Justification for non-use management areas

Residual void lakes in the project site are proposed to be backfilled to a minimum of 80 mbgl to limit groundwater inflow and the potential for pit water to recharge any of the surrounding aquifers. The partial backfill offers the best environmental outcome while remaining economically viable. This option will reduce the saline inflows into the final void lakes from the groundwater sources and create groundwater sink behaviour at both voids.

Based on a partial backfill scenario, salinity modelling was undertaken as part of the EA application. Salinity modelling excluded water balance inputs from groundwater inflow into the final voids, leaving salinity to be driven by surface water runoff from natural, rehabilitation and pit areas. Modelling based on these assumptions predicted that salinity would remain below 5,000 mg/L for the first 100 years following mining and would remain below 10,000 mg/L for the first 200 years; however, void lake salinity is expected to exceed a TDS of 30,000 mg/L after approximately 500 years. Based on this salinity modelling, the fauna habitat PMLU approved in the EA application is unsuitable for the residual void final landform design; therefore, the residual voids have been approved as NUMAs.

After backfilling, before salinity exceeds the suitable threshold, the residual voids may have some limited ecological value and support limited habitat function for a range of waterborne and flying insects, as well as avifauna and various bats and microbat species. However, as salinity increases, the capacity of the residual voids to support fauna habitat diversity will decline. Therefore, a NUMA outcome is more appropriate for these areas as salinity modelling suggests that the residual void conditions cannot support long-term habitat diversity.

One of the final rehabilitation milestones will include the installation of perimeter safety bunds and fencing adjacent to final high wall crests, designed to exclude cattle use and prevent erosion. This will ensure the project site is in a stable condition at surrender and prevent access by fauna and humans. Areas will remain accessible to avifauna and bats after installation.

3.5 Rehabilitation management methodology

3.5.1 Rehabilitation objectives

In Queensland, mine rehabilitation is required under the EP Act. Amendments to the EP Act in late 2018 implemented key elements of the State Government's Mined Land Rehabilitation Policy (Queensland Government 2018) which intends to ensure that, for land disturbed by mining activities:

- the land is safe and structurally stable;
- there is no environmental harm being caused by anything on or in the land; and
- the land can sustain a post-mining land use (section 111A of the EP Act).

3.5.2 Rehabilitation areas and improvement areas

To allow the development of a PRCP schedule that satisfies the requirements of the PRCP Guideline, discrete rehabilitation areas (RAs) and improvement areas (IAs) have been defined for the Project. An RA is defined in the EP Regulation as an area of land subject to a PMLU to which a rehabilitation milestone for the post-mining use relates. The EP Regulation defines an IA as, for a NUMA, an area of land in the NUMA to which a management milestone for the NUMA relates. RAs or IAs have been nominated for areas of disturbance within the Project, with consideration for the disturbance type and the proposed PMLU, and are shown in Table 23 and Figure 47.

Table 23: Rehabilitation areas and post-mining land use

Rehabilitation Area reference	Rehabilitation Area	Description	Post-mining Land Use
RA1	Waste rock emplacement (>3°)	Overburden placed in pit and out of pit, including dry rejects disposed of in waste rock dumps at a slope greater than 3°.	Grazing
RA2	Waste rock emplacement (<3°)	Overburden placed in pit and out of pit, including dry rejects disposed of in waste rock dumps at a slope equal to or less than 3°.	Grazing
RA3	Residual void high walls	Reshaped high wall slopes with native ecosystem supporting native fauna habitat	Native ecosystem supporting fauna habitat
RA4	Residual void low walls	Gradual slope for cattle grazing; regraded, topsoiled and revegetated	Grazing
RA5	Rehabilitated dams	Temporary levee Permanent drainage structures Raw water dams Sediment dams Mine water dams	Grazing
RA6	Retained dams	Retained dams at request of underlying holders	Retained infrastructure
RA7	Diversion drains	Diversion drains regraded to natural landform	Native ecosystem
RA8	Mine infrastructure areas	MIA (except water management infrastructure footprint) Roads	Grazing
RA9	Retained infrastructure	Retained infrastructure at request of underlying landholder	Retained infrastructure
RA10	Riparian corridor	Pre-mining riparian vegetation targeting RE 11.3.25	Riparian corridor
IA1	Residual void lakes	Void lake to remain as water body, providing some fauna habitat value initially, before salinity increases in the long-term.	NUMA

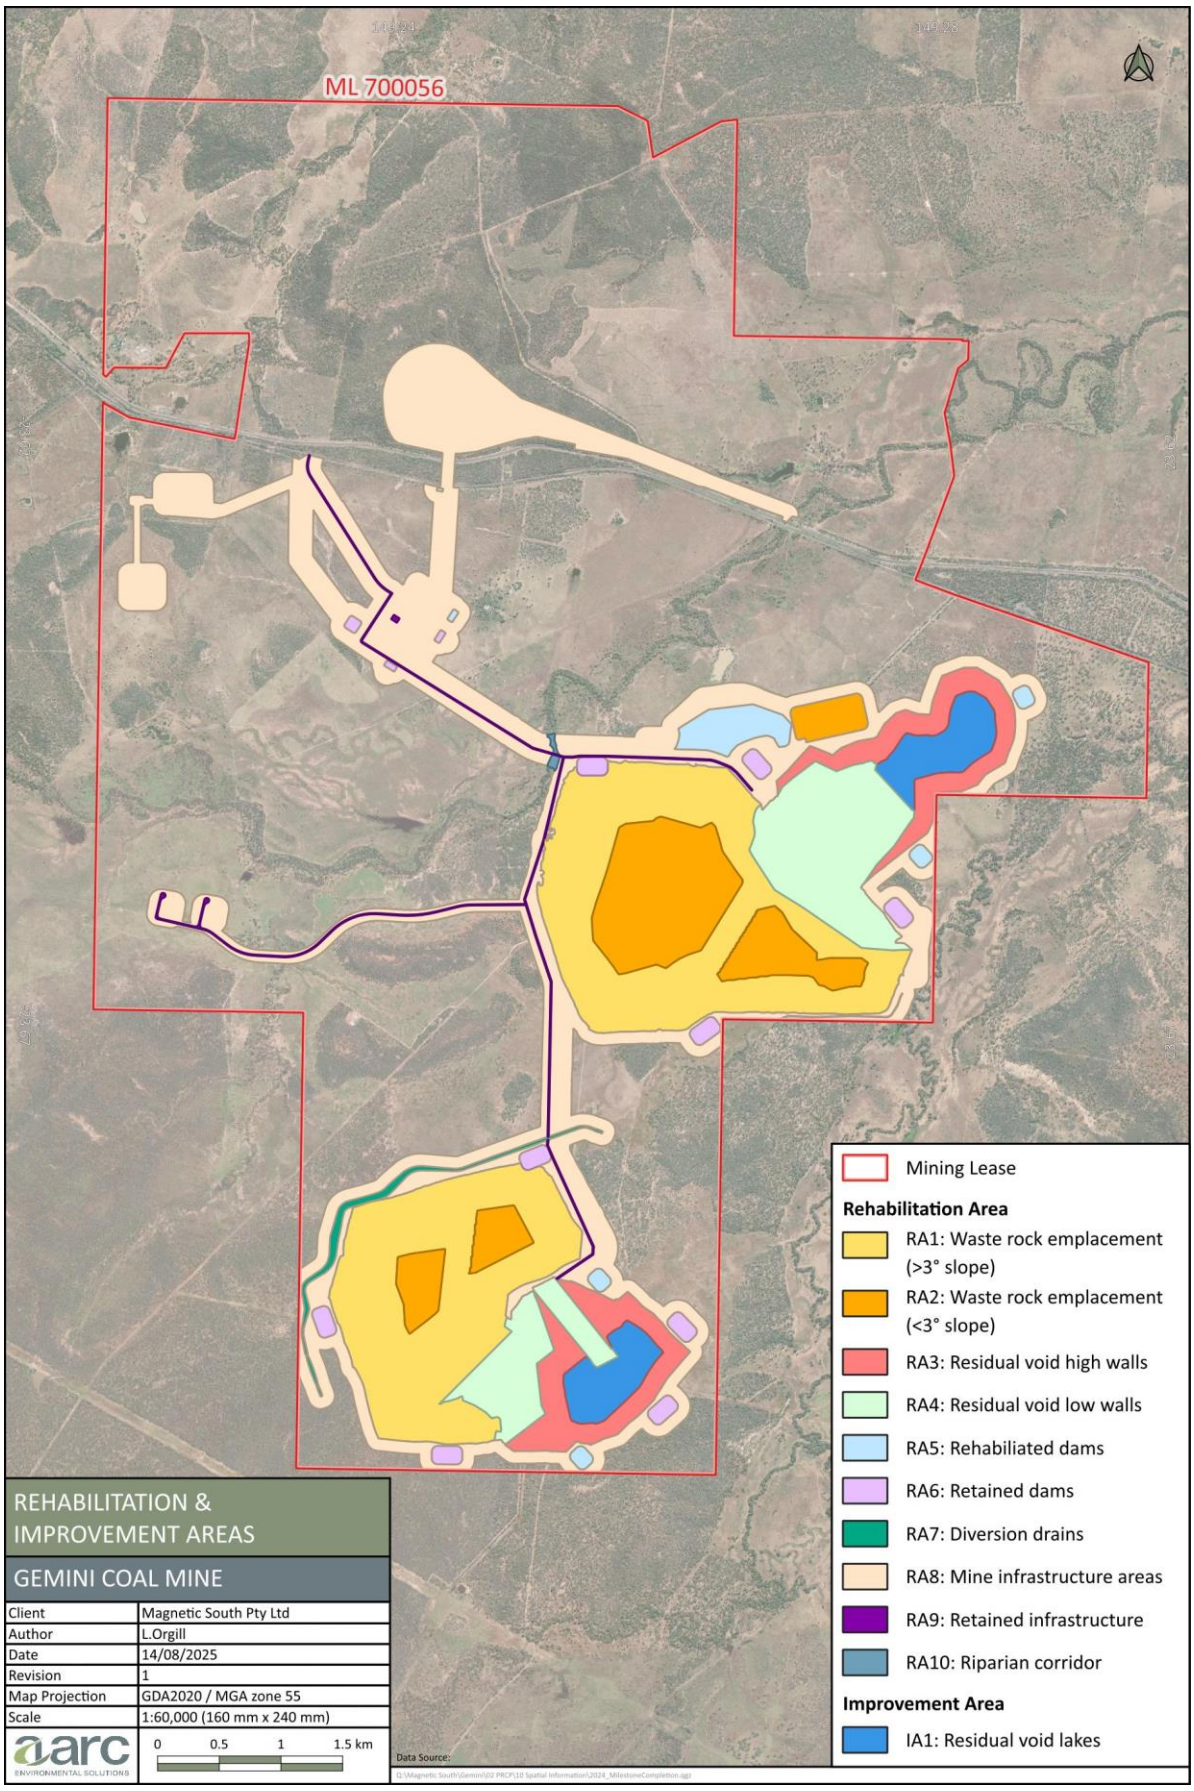

Figure 47: Rehabilitation and Improvement Areas

3.5.3 Rehabilitation milestones

Rehabilitation milestones are defined as each significant event or step necessary to rehabilitate an area of land to a stable condition (section 112, EP Act). Key to assessing the success of rehabilitation is the definition of milestone criteria. Milestone criteria must be consistent with the SMART (specific, measurable, achievable, realistic and timely) principles. They should:

- be outcome-based (linked to the end land use);
- be flexible to adapt to changing circumstances;
- be able to evolve as the mine life progresses;
- include metrics suitable to demonstrate that rehabilitation is trending positively;
- undergo periodic review; and
- include a measurement approach that details how the criterion will have been met (CoA 2016, ANZMEC and MCA 2000).

A set of milestone criteria has been identified for the Project to provide a clear definition of milestone completion and successful rehabilitation for each rehabilitation area (Table 24). The milestone criteria demonstrate the completion of progressive rehabilitation steps and events (refer Table 26). The completion criteria for each PMLU will be used as the milestone criteria for the final milestone in the proposed schedule, which shows achievement of the PMLU to a stable condition at surrender.

Table 24: Milestones and their applicability to rehabilitation areas

Milestone	Description	RA1 Waste rock emplacement (>3°)	RA2 Waste rock emplacement (<3°)	RA3 Residual void high wall	RA4 Residual void low wall	RA5 Rehabilitated dams	RA6 Retained dams	RA7 Diversion drains	RA8 Mine infrastructure areas	RA9 Retained infrastructure	RA10 Riparian corridor

3.5.4 Management milestones

The nominated management milestones for NUMAs in the final landform are outlined in Table 25. All management milestones are applicable to IA1, as it is the only IA in the Project.

Table 25: Management milestones and their applicability to improvement areas

Management Milestone	Description
MM1	Achievement of final landform design
MM2	Achievement of surface and safety requirements
MM3	Achievement of sufficient improvement

3.5.5 Milestone criteria

Key to assessing the success of rehabilitation and improvement is the definition of milestone criteria. Milestone criteria are preferably specific, measurable, achievable, realistic and timely. They should:

- be outcome-based (linked to the end land use);
- be flexible to adapt to changing circumstances;
- be able to evolve as the mine life progresses;
- include metrics suitable to demonstrate that rehabilitation is trending positively;
- undergo periodic review; and
- include a measurement approach that details how the criterion will have been met (CoA 2016; ANZMEC and MCA 2000).

A set of milestone criteria has been identified for the Project to provide a clear definition of milestone completion and successful rehabilitation for each rehabilitation area or sufficient improvement of each improvement area. The milestone criteria demonstrate the completion of progressive rehabilitation or improvement steps and events.

Milestone criteria relevant to each RA and IA are provided in Table 26 and Table 37. It should be noted that not all rehabilitation milestones are applicable to all RAs; the applicability of rehabilitation milestones to the various RAs is also indicated in Table 26.

Table 26: Rehabilitation milestone criteria

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
RM1: Infrastructure decommissioning and removal	RA8	1. With the exception of any infrastructure to remain as part of the post-mining land use (PMLU) or where infrastructure is agreed to be retained by the landholder as evidence by a signed landholder agreement, the following are completed: a) all non-required services disconnected and removed; b) all concrete, bitumen and gravel road material removed; c) all pipelines drained and removed; d) all fencing that is not part of the PMLU removed; e) all remaining infrastructure demolished and/or removed unless agreed to be retained by the landholder; f) all machinery and equipment removed; g) all surface water drainage infrastructure that is not retained in the final landform removed; and h) all rubbish removed.	Milestone criteria demonstrate that no infrastructure remains in the final landform.
RM2: Remediation of contaminated land	RA8, RA9	1. Contaminated Land Investigation Document completed in accordance with the Environmental Protection Act 1994, including a site investigation report, and, where required, a Validation Report and/or a draft Site Management Plan. 2. Contaminated and hazardous material either remediated in-situ or removed/transported to facility lawfully able to accept the material. 3. Suitably Qualified person (SQP) certifies that that no contamination unsuitable for the PMLU remains or is occurring.	Criteria ensures that all contaminated land and hazardous material is identified, and managed such that there is no impact to the post mine land use.
RM3: Landform development of waste emplacement (RA1, RA2 & RA4)	RA1, RA2, RA4	1. All bulk landform earthworks (excluding topsoil cover) completed. 2. Slopes of waste rock emplacements and void low walls conform to a maximum slope of 6°.	To establish a stable condition for land, the final site design specifications must be met to demonstrate final landform stability.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		3. The final landform is assessed to be geotechnically stable by an AQP[1], modelled to achieve a factor of safety of ≥ 1.5. 4. Final landform surveyed and certified by an AQP[1], as constructed per design specifications. 5. No reactive material is present on the land surface.	Certification must be provided by a geotechnical engineer that the final landform is geotechnically stable post reshaping / re-profiling the landform, meaning that there is low risk of mass failure.
RM4: Landform development of diversion drains (RA7)	RA7	1. The clean water diversions are constructed in accordance with relevant design specifications prepared by an AQP[1]. 2. AQP[1] certifies that the constructed landform is geotechnically stable.	To establish a stable condition for land, the final site design specifications must be met to demonstrate final landform stability. Certification must be provided by a geotechnical engineer that the final landform is geotechnically stable post reshaping / re-profiling the landform, meaning that there is low risk of mass failure.
RM5: Landform development of infrastructure areas (RA8) and rehabilitated dams (RA5)	RA5, RA8	1. All bulk earthworks completed to reshape landform to final design. 2. AQP[1] certifies that the constructed landform achieves design criteria for geotechnical stability with a FOS ≥ 1.5.	To establish a stable condition for land, the final site design specifications must be met to demonstrate final landform stability. Certification must be provided by a geotechnical engineer that the final landform is geotechnically stable post reshaping / re-profiling the landform, meaning that there is low risk of mass failure.
RM6: Landform development of residual void high wall (RA3)	RA3	1. The final void high walls located within the unconsolidated sediments and saturated tertiary will be constructed at an angle of 18°. 2. The final void high walls located within the Permian geology will be constructed with an overall angle of 55° by constructing 50 m high batters at a maximum angle of 65°, incorporating 15m wide intermediate benches between batters. 3. AQP[1] certifies that as constructed landform achieves design criteria for geotechnical stability with a FOS ≥ 1.5.	To establish a stable condition for land, the final site design specifications must be met to demonstrate final landform stability. Certification must be provided by a geotechnical engineer that the final landform is geotechnically

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		4. Safety bunds adjacent to final high wall crest are designed and constructed in compliance with industry best practice and are certified as long-term stable.	stable post reshaping / re-profiling the landform, meaning that there is low risk of mass failure.
RM7: Surface preparation	RA1, RA2, RA4, RA5, RA7, RA8	1. All earthworks completed with placement of topsoil. 2. All surface drainage features installed. 3. Topsoil placed over all reshaped surfaces to a depth of 0.3 m and deep ripping to be undertaken along the contour of slopes. 4. An assessment of placed growth media health and suitability completed by an AQP[1] to confirm soil is suitable for target revegetation outcomes. 5. Soil testing requires the following requirements: a) Soil pH >4.5 to <8; b) EC < 1.0 dS/m; and c) Exchangeable Sodium Percentage (ESP%) <6% (at 0-10cm depth). 6. Where required, ameliorants such as gypsum are added to improve soil quality characteristics at the rates recommended by an AQP[1].	Soil testing should be completed by an appropriately qualified person to ensure soil is suitable for target vegetation establishment and specify any requirements for potential amelioration prior to seeding. Ameliorants may be required to improve cohesion with the subsoil / topsoil and given local variability in soil quality it is considered appropriate for recommendations to be made following testing of the material to be used in rehabilitation prior to use. Ripping to encourage water infiltration and grass root development to a depth that is sufficient for adequately stabilising surface soils.
RM8: Surface preparation and revegetation of residual void high wall (RA3)	RA3	1. Hydromulch placed over the upper high wall (18° slope) and exposed benches. Before application, an assessment of placed growth media health and suitability is completed by an AQP[1] to confirm hydromulch is suitable for target revegetation outcomes. 2. Where required, ameliorants such as gypsum are added to improve hydromulch quality characteristics at the rates recommended by an AQP[1]. 3. Seed mix incorporated into hydromulch and applied to upper high wall and exposed benches in accordance with a selection of seed mix provided in Attachment 2 (Table 28). a) Revegetation completed for tree/shrub seed mix at a minimum total rate of 4 kg/ha and a minimum of 6 native species; and	Hydromulching enables the revegetation of steep slopes due to the additional binder agents with the slurry. In addition to binders, soil ameliorants and fertiliser can be included as part of the hydromulch composition to improve vegetation growth. Ameliorants may be required to improve cohesion with the subsoil / topsoil and given local variability in soil quality it is considered appropriate for recommendations to be made following testing of the material to be used in rehabilitation prior to use. Records to demonstrate that seeding has been undertaken in accordance with the rehabilitation objectives set out in the PRCP.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		b) Revegetation completed for a ground cover seed mix at a minimum total rate of 12 kg/ha and a minimum of 4 native species. 4. Seeding undertaken prior to forecasted rainfall during the wet season. 5. Details to be documented to indicate completion of the milestone: a) GIS files of areas where seeding and/or planting has occurred; b) date the seed mix was applied, or planting of tube stock was carried out; c) if seeding, the seed mix and rate of seeding applied; and d) if planting, the number of tube stock planted.	
RM9: Revegetation for grazing	RA1, RA2, RA4, RA5, RA8	1. Seeding of all topsoiled surfaces completed in accordance with a selection of seed mix provided in Attachment 1 at a minimum total rate of 12 kg/ha (Table 27) 2. The seed mix sown should comprise a minimum of 25% (by weight) native pasture species and include a minimum of 3 x 3P native species from Attachment 1 (Table 27). 3. Seeding undertaken prior to forecasted rainfall during the wet season. 4. Details to be documented to indicate completion of the milestone: a) GIS files of areas where seeding and/or planting has occurred; b) date the seed mix was applied, or planting of tube stock was carried out; c) if seeding, the seed mix and rate of seeding applied; and d) if planting, the number of tube stock planted. 5. Where required, fertiliser, mulch and ameliorants, such as gypsum, are added to improve growth media quality characteristics at the rates recommended by an AQP[1].	The purpose of this milestone is to establish sufficient seed quantity and composition to achieve a stable, sustainable landform for a grazing PMLI with suitable pasture species. Records to demonstrate that seeding has been undertaken in accordance with the rehabilitation objectives set out in the PRCP.
RM10: Revegetation for native ecosystem	RA7, RA10	1. **RA7:** Seeding of all topsoiled surfaces completed in accordance with a selection of seed mix provided in Attachment 3 (Table 29).	Records to demonstrate that seeding has been undertaken in accordance with the rehabilitation objectives set out in the PRCP.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		a) Revegetation completed for tree/shrub seed mix at a minimum total rate of 3 kg/ha and a minimum of 4 native species; and b) Revegetation completed for a ground cover seed mix at a minimum total rate of 16 kg/ha and a minimum of 3 native species. 2. **RA10:** Seeding of all topsoiled surfaces completed in accordance with a selection of seed mix provided in Attachment 4 (Table 30). a) Revegetation completed for tree/shrub seed mix at a minimum total rate of 3 kg/ha and a minimum of 6 native species; and b) The groundcover seed mix sown should comprise a minimum of 25% (by weight) native pasture species and include a minimum of 3 x 3P native species from Attachment 4 (Table 30). 3. Seeding undertaken prior to forecasted rainfall during the wet season. 4. Details to be documented to indicate completion of the milestone: a) GIS files of areas where seeding and/or planting has occurred; b) date the seed mix was applied, or planting of tube stock was carried out; c) if seeding, the seed mix and rate of seeding applied; and d) if planting, the number of tube stock planted. 5. Where required, fertiliser, mulch and ameliorants, such as gypsum, are added to improve growth media quality characteristics at the rates recommended by an AQP[1].	
RM11: Achievement of surface requirements (grazing)	RA1, RA2, RA4, RA5, RA8	**1. RA2, RA5, RA8:** Rehabilitation polygons have a median fractional vegetation cover greater than the first quartile of reference polygons[2] for at least 85% of all sample times, as determined using the satellite-derived fractional vegetation cover method.[2 3 4] **2. RA1, RA4:** Total percentage of vegetative groundcover to be >70%. 3. Minimum of 3 target species established (Attachment 1,Table 27).	The purpose of this milestone is to demonstrate that the RA is trending towards the final milestone, allowing for early intervention with reparation activities as required. Monitoring against the criteria nominated for this milestone should be consistent with monitoring undertaken as part of the Project's annual rehabilitation monitoring, with datasets already

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		4. Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. **5.** No areas of "Moderate" or "Severe" erosion as defined in Attachment 5 (Table 31)	collected to be used for tracking progress against milestone criteria
RM12: Achievement of surface requirements (native ecosystem supporting fauna habitat)	RA3	1. A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2. QBEIS index scores achieve the following milestones based on a novel RE 11.10.3 native ecosystem: a) ≥80% established and persistent native groundcover species from Attachment 2 (Table 28) on 18° slopes and intermediate benches. b) >5% native canopy cover on 18° slopes and intermediate benches. c) Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3. No areas of "Moderate" or "Severe" erosion as defined in Attachment 5 (Table 31).	The purpose of this milestone is to demonstrate that the RA is trending towards the final milestone, allowing for early intervention with reparation activities as required. Monitoring against the criteria nominated for this milestone is consistent with monitoring undertaken as part of the Project's annual rehabilitation monitoring, with datasets already collected to be used for tracking progress against milestone criteria
RM13: Achievement of surface requirements (native ecosystem)	RA7	1. A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2. QBEIS index scores achieve the following milestones based on a hybrid RE 11.5.2 native ecosystem: a) ≥60% established and persistent groundcover species from Attachment 3 (Table 29) within the pasture understory. b) >10% native canopy cover from species listed in Attachment 3 (Table 29). c) Evidence of flora recruitment from rehabilitation monitoring data. d) Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring.	The purpose of this milestone is to demonstrate that the RA is trending towards the final milestone, allowing for early intervention with reparation activities as required. Monitoring against the criteria nominated for this milestone is consistent with monitoring undertaken as part of the Project's annual rehabilitation monitoring, with datasets already collected to be used for tracking progress against milestone criteria

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		3. Assessment by an AQP[1] confirms that creek beds and banks are trending toward a geomorphologically stable condition, and recommendations for management and mitigation actions have been implemented. 4. Incorporate natural features (including geomorphological and vegetation) present at the location of the diversion.	
RM14: Achievement of surface requirements (riparian corridor)	RA10	1. A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2. QBEIS index scores achieve the following milestones based on a natural RE 11.3.25 native ecosystem: a) ≥60% effective groundcover (including organic litter) with ≥30% live groundcover from species listed in Attachment 4 (30). b) >15% native canopy cover from species listed in Attachment 4 (30). c) Evidence of flora recruitment from rehabilitation monitoring data. d) Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3. No areas of "Moderate" or "Severe" erosion as defined in Attachment 5 (Table 31).	The purpose of this milestone is to demonstrate that the RA is trending towards the final milestone, allowing for early intervention with reparation activities as required. Monitoring against the criteria nominated for this milestone is consistent with monitoring undertaken as part of the Project's annual rehabilitation monitoring, with datasets already collected to be used for tracking progress against milestone criteria
RM15: Achievement of stable PMLU – Grazing	RA1, RA2, RA4, RA5, RA8	1. Sediment and erosion control structures removed after disturbed areas stabilised. 2. No evidence of erosion classified as 'moderate' or 'severe' as defined by Attachment 5 (Table 31). 3. Drainage follows intended and appropriate drainage paths. 4. Land suitability assessment by an AQP[1] certifies that land has achieved a post mine land suitability class of 3 or better. 5. A species presence that is consistent with those used in the recommended rehabilitation seed mix in Attachment 1 (Table 27).	Land suitability assessment to demonstrate that land suitability is similar to the pre-mining landscape. It is considered that the confirmation and certification by an AQP[1] that the landform is safe, stable, non-pollution and sustainable; and that there is a low risk of environmental harm with no significant increases in risk expected over time. The certification of this assessment is underpinned by the life-of mine monitoring through the period of rehabilitation assessment.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		6. Recommended species selected for revegetation which includes 3P grasses as recommended by Grazing Land Management information provided by NQ Dry Tropics[6] or the Fitzroy Basin Association[7] and are suitable to achieve the approved PMLU. 7. Assessed as geotechnically stable by an AQP[1] indicating landform stability for a gradient slope of 6°. 8. Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring.	This approach requires that potential impacts are assessed in consideration of: • specific site-based factors; • actual monitoring data from the life-of mine, including from applicable upstream and downstream locations from the rehabilitated landforms; • long-term monitoring trend analysis; and • a broad-catchment overview with high local resolution. Monitoring of stream sediment parameters is to be undertaken in accordance with the requirements of the Project Receiving Environment Monitoring Program.
RM16: Achievement of Stable PMLU – Native ecosystem	RA7	1. A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2. QBEIS index scores achieve the following milestones based on a hybrid RE 11.5.2 native ecosystem: a) ≥70% established and persistent groundcover species from Attachment 3 (Table 29) within the pasture understory. b) >30% native canopy cover from species listed in Attachment 3 (Table 29). c) ≥60% of native tree/shrub species listed in the rehabilitation seed mix (Attachment 3, Table 29) are established and persistent. d) Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3. Geotechnical assessment by an AQP[1] confirms that long-term geotechnical stability has been achieved for each relevant landform.	The purpose of this milestone is to demonstrate rehabilitation achieves the objectives of the stable native ecosystem PMLU of providing habitat connectivity, bank stability (stable) and a self-sustaining ecosystem. Erosion classification will assist in the determination that the landform is stable. Assessment by an AQP[1] to demonstrate that the PMLU is safe, stable, sustainable and non-polluting.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		4. An AQP[1] has certified that diversions being retained in the landform continue to achieve the incorporation of natural features (including geomorphic and vegetation) present at the location of the diversion. 5. Maintain equilibrium and functionality in all substrate conditions at the location of the diversion. A hazard and safety assessment completed by AQP[1] demonstrates hazards in RAs are consistent with the type and severity of hazards typical of neighbouring equivalent land use. Remaining hazards are considered to be low risk with no significant increase in risk expected over time.	
RM17: Achievement of Stable PMLU – Riparian corridor	RA10	1. A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2. QBEIS index scores achieve the following milestones based on a natural RE 11.3.25 native ecosystem: a) ≥60% effective groundcover (including organic litter) with ≥30% live groundcover from species listed in Attachment 4 (30). b) >30% native canopy cover from species listed in Attachment 4 (30). c) ≥60% of native tree/shrub species listed in the rehabilitation seed mix (Attachment 3, Table 29) are established and persistent. d) Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3. No areas of "Moderate" or "Severe" erosion as defined in Attachment 5 (Table 31).	The purpose of this milestone is to demonstrate rehabilitation achieves the objectives of the stable native ecosystem PMLU of providing habitat connectivity, bank stability (stable) and a self-sustaining ecosystem. Erosion classification will assist in the determination that the landform is stable. Assessment by an AQP[1] to demonstrate that the PMLU is safe, stable, sustainable and non-polluting.
RM18: Achievement of Stable PMLU – Native ecosystem supporting fauna habitat	RA3	1. A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2. QBEIS index scores achieve the following milestones based on a novel RE 11.10.3 native ecosystem: a) ≥80% established and persistent native groundcover species from (Attachment 2, Table 28) on 18° slopes and intermediate benches.	Assessment by an AQP[1] to demonstrate that the PMLU is safe, stable, sustainable and non-polluting.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		b) >50% native canopy cover on 18° slopes and intermediate benches. c) Evidence of flora recruitment from rehabilitation monitoring data. d) Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. Weed[5] management recommendations to be provided in annual reports. 3. Fauna survey report provides evidence of >5 native species inhabiting or utilising high wall ecosystems annually including macroinvertebrates, aquatic vertebrates, avian species, bats, and other mammals. 4. No areas of "Moderate" or "Severe" erosion as defined in Attachment 5 (Table 31). 5. Perimeter safety bunds and fencing adjacent to final high wall crests are designed and constructed to exclude cattle use and prevent erosion. 6. Safety bunds adjacent to final high wall crest are designed and constructed in compliance with industry best practice and safety bunds for high walls are certified as long-term stable. 7. Geotechnical assessment by an AQP[1] confirms that long-term geotechnical stability has been achieved for each relevant landform. 8. Report prepared by an AQP[1] confirms the native ecosystem PMLU has been achieved with consistency to surrounding landscape.	
RM19: Achievement of Stable PMLU – retained dams	RA6	1. Transfer of ownership agreements in place for all dams to be retained. 2. AQP[1] certifies that all contaminated sediment has been removed from all dams that are not backfilled. 3. Dams to remain for landholder use are safe for stock access. 4. All retained water storages achieve geotechnical and erosional safety and stability as assessed and approved by an AQP[1]. 5. No areas of "Moderate" or "Severe" erosion as defined in Attachment 5 (Table 31).	Assessment by an AQP[1] to demonstrate that the retained dams are safe, stable, sustainable and non-polluting. It provides a justification that the transfer of infrastructure to the underlying landholder will not result in environmental impacts post-closure.

Rehabilitation Milestone	Applicable Rehabilitation Areas	Criteria	Justification for criteria
		6. Retained water storage water quality for quality characteristics to be below the trigger values for livestock drinking water defined in Environmental Protection (Water) Policy 2009 Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin, September 2011[8], or the most recent version. 7. Final landform survey confirms no built structures remain other than those that form part of a landholder agreement.	
RM20: Achievement of Stable PMLU– retained infrastructure	RA9	1. Transfer of ownership agreements in place for all infrastructure to be retained. 2. All retained structures and landforms to be assessed and approved as safe and stable by an AQP[1]. 3. Final landform survey confirms no built structures remain other than those that form part of a landholder agreement.	Assessment by an AQP[1] to demonstrate that the retained infrastructure is safe, stable, sustainable and non-polluting. It provides a justification that the transfer of infrastructure to the underlying landholder will not result in environmental impacts post-closure.
RM21: Surface water and groundwater demonstrate non-polluting landform	RA1, RA2, RA3, RA4, RA5, RA6, RA7, RA8, RA9, RA10	1. Surface water quality results monitored monthly during flow at, but not limited to, downstream locations specific in Attachment 10 (Table 36), must not exceed the limits in Attachment 6 (Table 32), for a minimum of 3 consecutive years. 2. If the surface water quality in the downstream receiving environment exceeds criteria (1), the applicable upstream site must be compared to the downstream site result; and quality measured at a downstream site must be equal to or less than the quality measured at the applicable upstream site, taking into consideration the additional distance travelled in the environment. 3. Groundwater level is monitored quarterly, and all results comply with Level Trigger Thresholds outlined in Attachment 9 (Table 35) at the monitoring locations specified in Attachment 7 (Table 33) for 10 consecutive years. 4. For a minimum of 3 consecutive sampling years, groundwater quality must be monitored quarterly at bored specified in Attachment 7 (Table 33) for all quality characteristics listed in Attachment 8 (Table 34). 5. Groundwater quality results must not exceed the limits in Attachment 8 (Table 34), for 3 consecutive results.	Assessment by an AQP[1] to demonstrate that the PMLU is safe, stable, sustainable and non-polluting.

[1] Appropriately Qualified Person (AQP) means a person who has professional qualifications, training, skills or experience relevant to the nominated subject matter and can give authoritative assessment, advice and analysis on performance relating to the subject matter using the relevant protocols, standards, methods or literature

[2] Reference polygons for fractional vegetation cover are required to be of Land Class Suitability 3 or 4, or better. A minimum of two additional reference sites will be nominated by 2026, and upon assessment must represent a land suitability class of either 3 or 4, or better.

Table 27: Attachment 1 – Grazing PMLU seed mix

Scientific name	Common name	Nominal application rate (kg/ha)
Bothriochloa bladhii	Forest bluegrass	3
*Bothriochloa ewartiana**	Desert bluegrass	3
Chamaecrista rotundifolia	Roundleaf cassia	1
Chloris gayana	Rhodes grass	2
*Dichanthium sericeum**	Queensland bluegrass	3
Echinochloa esculenta	Japanese millet	5
*Enteropogon acicularis**	Curly windmill grass	3
*Panicum decompositum**	Native millet	3
Stylosanthes hamata cvv. Verano or Amiga	Caribbean stylo	1
Stylosanthes Seabrana cvv. caatinga	Caatinga stylo	1
Themeda triandra	Kangaroo grass	3

*Denotes a 3P pasture species.

Table 28: Attachment 2 - Native ecosystem supporting fauna habitat PMLU seed mix

Scientific name	Common name
Canopy/Tree	
Acacia shirleyi	Lancewood
Corymbia citriodora	Lemon-scented gum
Acacia rhodoxylon	Rosewood Wattle
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus exserta	Queensland peppermint
Shrub	
Acacia complanata	Long-pod wattle
Acacia crassa	Curracabah
Alphitonia excelsa	Soap tree
Petalostigma pubescens	Quinine bush
Flinersia dissoperma	Scrub leopardwood
Pittosporum spinescens	Wallaby apple
Groundcover	
Aristida calycina	Dark wiregrass

Scientific name	Common name
Cleistochloa subjuncea	Soft grass
Scleria sphacelata	Razor grass
Entolasia stricta	Wiry panic
Eragrostis lacunaria	Purple lovegrass
Thyridolepis xerophila	
Panicum larcomianum	Larcom's panic grass

Table 29: Attachment 3 - Native ecosystem PMLU seed mix

Scientific name	Common name
Canopy/Tree	
Corymbia citriodora	Lemon-scented gum
Corymbia clarksonia	Grey bloodwood
Acacia rhodoxylon	Rosewood Wattle
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus moluccana	Grey box
Shrub	
Acacia complanata	Long-pod wattle
Acacia crassa	Curracabah
Alphitonia excelsa	Soap tree
Petalostigma pubescens	Quinine bush
Flinersia dissoperma	Scrub leopardwood
Pittosporum spinescens	Wallaby apple
Ground	
Aristida calycina	Dark wiregrass
Cymbopogon refractus	Barbed wire grass
Entolasia stricta	Wiry panic
Eragrostis sororia	Lovegrass
Enneapogon lindleyanus	Lindley nineawn
Perotis rara	Comet grass
Panicum effusum	Hairy panic

Table 30: Attachment 4 - Riparian corridor PMLU seed mix

Scientific name	Common name
Canopy/Tree	
Corymbia clarksoniana	Grey bloodwood
Corymbia tessellaris	Moreton Bay ash
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus tereticornis	River blue gum
Eucalyptus camaldulensis	River red gum
Shrub	
Alphitonia excelsa	Soap tree
Acacia salicina	Willow wattle
Acalypha eremorum	Native acalypha
Petalostigma pubescens	Quinine bush
Bauhinia carronii	Queensland ebony
Terminalia oblongata	Yellow wood
Melaleuca trichostachya	Narrow-leaved honey myrtle
Ground	
Arundinella nepalensis	Reedgrass
Aristida personata	Purple wiregrass
Dichantium sericeum	Queensland bluegrass
Heteropogon contortus	Black speargrass
Lomandra longifolia	Spiny-head mat-rush
Themeda triandra	Kangaroo grass
Paspalidium jubiflorum	Warrego summer grass

Table 31: Attachment 5 – Erosion classification framework

Erosion classification	Minor	Moderate	Severe
Sheet erosion	Shallow soil deposits downslope	Partial exposure of roots; moderate soil deposits downslope, etc	Loss of surface horizon; root exposure; moderate substantial soil deposits downslope
Rill erosion	<0.3m deep<15 rills/transect*	<0.3m deep 15-30 rills/transect*	<0.3m deep>30 rills/transect*
Gully erosion	Absent	>0.3m deep Gullies are linear, continuous, and restricted to primary or minor drainage lines	>0.6m deep Gullies are continuous or discontinuous, and either tend to branch away from primary drainage lines and on to foot slopes, or have multiple branches within drainage lines
Tunnel erosion	Absent	Absent	Present
Mass movement	Absent	Absent	Present

Table 37: Management milestones criteria

Management milestone	Applicable improvement area	Criteria	Justification for criteria
MM1 – Achievement of final landform design	IA1	1. The residual void has been backfilled to the following levels: a) ≥65 mAHD for Mine A; and b) ≥42 mAHD for Mine B. 2. Updated predictive modelling undertaken by an AQP[1] based on final residual void lake landform which confirms that the void will remain as a groundwater sink.	To establish a stable condition for land, the final site design specifications must be met to demonstrate final landform stability. Certification must be provided by a geotechnical engineer that the final landform is geotechnically stable post reshaping / re-profiling the landform, meaning that there is low risk of mass failure.
MM2 – Achievement of surface and safety requirements	IA1	1. AQP[1] certifies that final void lake landform, including low and high walls, are geotechnically stable and achieved FOS ≥1.5. 2. Adequate bunding in place, confirming to be geotechnically stable by an AQP[1]. 3. Perimeter fencing and signage erected to prevent access to fauna and humans.	Assessment by an AQP[1] to demonstrate that the PMLU is safe, stable, sustainable and non-polluting. Area must be inaccessible to fauna and people to ensure landform is stable.
MM3 – Achievement of sufficient improvement	IA1	1. Voids assessed to be geotechnically stable by a AQP[1], achieving: a) a modelled FOS of ≥1.5 for the in-situ pit walls before maximum in-pit water level is reached b) a modelled FOS ≥1.5 for the in-situ pit walls after maximum in-pit water level is reached; and c) a FOS ≥1.5 spoil pit walls above the maximum in-pit water level. 2. Certification from an AQP[1] that water level and quality in the residual void will not cause environmental harm to the surrounding environment, and the void acts as a groundwater sink to the receiving groundwater environment.	Certification must be provided by a geotechnical engineer that the final landform is geotechnically stable post reshaping / re-profiling the landform, meaning that there is low risk of mass failure

3.5.6 Rehabilitation timeframes

The rehabilitation milestones must be achieved as soon as practicable after land becomes available for rehabilitation. Land is considered to become available for rehabilitation at the completion of mining, except where land is required for future activities, for future rehabilitation, or is identified as being retained infrastructure post-closure.

Rehabilitation milestone timeframes have been developed with consideration for the size of the rehabilitation area, the activities applicable to the milestone and interim rehabilitation activities that are scheduled to occur or anticipated to be required prior to the area becoming available for rehabilitation (Table 38).

Milestones that involve revegetation activities, including monitoring of revegetation, make provision for unfavourable growing seasons and unforeseen extreme events such as droughts or storms that could negatively impact vegetation establishment. As a result, milestone timeframes are extended to ensure achievement.

Table 38: Typical timeframes for RMs associated with each RA

Rehabilitation Milestones (RM)	Summary rehabilitation methodology	Associated risks	Risk level assigned	Typical time frame (years)	Justification for assigned timeframe
Infrastructure Decommissioning and Removal (RM1)	• Infrastructure decommissioning and disposal	• Initial/ongoing gully/sheet erosion • Significant slope failure	Moderate	2	Some mine infrastructure (e.g. haul road) will be required to facilitate rehabilitation activities and will therefore not become available for rehabilitation for several years post closure. Decommissioning activities are considered low risk, therefore decommissioning is expected to take less than 2 years.
Mine water dam and Mine infrastructure areas -> Remediation of Contaminated Land (RM2)	• Remediation or removal of contaminated material (where applicable) • Determination of contaminated land status by appropriately qualified person	• Contaminated land	Low	1	A contaminated land assessment will be undertaken by an appropriately qualified person. If contaminated land is identified, remediation works will be undertaken promptly. Given the low risk classification associated with this activity, the timeframe assigned is 1 year.
Land available for rehab -> Landform development (RM3, RM4, RM5, RM6)	• Void lake high walls and low walls to meet specification requirements including slope gradient, lengths • Geotechnical stability of the rehabilitated landform to achieve FOS ≥ 1.5.	• Void lake high walls and low walls failing to meet the specifications required for the PMLU; and • Significant slope failure • Initial/ongoing gully/sheet erosion	Moderate	2	As land becomes available, all bulk earthworks are to be completed according to rehabilitation design specifications and assessed as geotechnically stable by a suitably qualified person. Given the variability in the size of areas becoming available at the same time and changing climatic conditions that may affect scheduled earthworks, typical timeframe assigned is two years.

Rehabilitation Milestones (RM)	Summary rehabilitation methodology	Associated risks	Risk level assigned	Typical time frame (years)	Justification for assigned timeframe
Landform development (RM3, RM4, RM5) -> Surface preparation (RM7)	• Ripping of soil profile/subsoil • Soil health and suitability assessment • As required, application of ameliorants to subsoil and topsoil	• Erodible topsoils and subsoils not able to be rectified with amelioration. • Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas • Insufficient quality of topsoil resources onsite available to undertake rehabilitation activities	Moderate	2	Topsoil testing and classification before placement is the key process in this timeframe to minimise risk. As a low-level risk, a typical timeframe of 2 year has been assigned
Landform development (RM6) -> Surface preparation and revegetation (RM8)	• Application of hydromulch • As required, application of ameliorants • Seeding of target key species completed at specified sowing rates (refer section 3.5.4)	• Hydromulch fails to allow seeds to revegetate • Subsoil material is unable to support long-term vegetation growth • Insufficient quantity of hydromulch to be sourced for application	Moderate	7	Hydromulch testing and classification before placement is the key process in this timeframe to minimise risk. The seeding of key target species has been assigned a low-level risk. Rates of seeding are and seeding species in section 3.5.7.4 A typical time frame of 7 years has been assigned.
Surface preparation (RM7) -> Grazing revegetation (RM9)	• Seeding of target key species completed at specified sowing rates (refer section 3.5.4)	• Failure to meet seeding rate of key target species. • Natural hazards (fire, drought, heavy rainfall) following planting resulting in poor seed establishment and loss of topsoil	Low	2	The seeding of key target species has been assigned a low-level risk. Rates of seeding are and seeding species in section 3.5.7.4 A typical time frame of 2 years has been assigned.

Rehabilitation Milestones (RM)	Summary rehabilitation methodology	Associated risks	Risk level assigned	Typical time frame (years)	Justification for assigned timeframe
Surface preparation (RM7) -> Native ecosystem revegetation (RM10)	• Seeding of target key species completed at specified sowing rates (refer section 3.5.4)	• Failure to meet seeding rate of key target species. • Natural hazards (fire, drought, heavy rainfall) following planting resulting in poor seed establishment and loss of topsoil	Low	5	The seeding of key target species has been assigned a low-level risk. Rates of seeding are and seeding species in section 3.5.7.4 A typical time frame of 5 years has been assigned to allow for growth of trees and shrubs.
Revegetation (RM9) -> Achievement of surface requirements (RM11)	• Revegetated areas to be assessed against ground cover and stability related completion criteria (refer section 3.5.4)	• Erodible topsoils and subsoil • Ongoing rill, gully or sheet erosion • Excessive rainfall, droughts or fire events that may directly affect groundcover establishment; and • Pests and weeds	Moderate	5	The achievement of target revegetation criteria is dependent on good climatic conditions, which result in optimal growing seasons and good soils to enhance plant growth. The four years assigned for this timeframe considers the time necessary for establishment of mature, self-sustaining vegetation (i.e., multiple seasons of successful recruitment). Consideration of allowances for poor growing seasons due to extreme events such as droughts or storms that may negatively impact the germination of seeds, cause erosion, or drive maintenance actions to be taken in previously revegetated areas.

Rehabilitation Milestones (RM)	Summary rehabilitation methodology	Associated risks	Risk level assigned	Typical time frame (years)	Justification for assigned timeframe
Native ecosystem & Native ecosystem supporting fauna habitat revegetation (RM8, RM10) -> Achievement of surface requirements (RM12, RM13, RM14)	• Revegetated areas to be assessed against ground cover and stability related completion criteria (refer section 3.5.4)	• Erodible topsoils and subsoil • Ongoing rill, gully or sheet erosion • Excessive rainfall, droughts or fire events that may directly affect groundcover establishment; and • Pests and weeds	Moderate	15	The achievement of target revegetation criteria is dependent on good climatic conditions, which result in optimal growing seasons and good soils to enhance plant growth. The fifteen years assigned for this timeframe considers the time necessary for establishment of mature, self-sustaining vegetation (i.e., multiple seasons of successful recruitment). Consideration of allowances for poor growing seasons due to extreme events such as droughts or storms that may negatively impact the germination of seeds, cause erosion, or drive maintenance actions to be taken in previously revegetated areas.
Achievement of surface requirement (RM11) -> Achievement of stable PMLU (RM15)	• Vegetation monitoring & maintenance as required	• Erodible topsoils and subsoils • Ongoing rill, gully or sheet erosion • Drainage of final landform not meeting the water quality objectives • Excessive rainfall, droughts or fire events that may directly affect groundcover establishment • Drainage of final landform not meeting the water quality objectives; and • Pests and weeds.	Moderate	5	Achievement of a target PMLU requires it to be stable, safe, non-polluting and sustainable. The five years assigned for this timeframe considers the time necessary for establishment of mature, self-sustaining vegetation (i.e. multiple seasons of successful recruitment) and the timing needed to achieve the surface water quality objectives. Allowance is also given for natural hazard events such as fires or severe storms that may drive additional maintenance works or even revegetation.

Rehabilitation Milestones (RM)	Summary rehabilitation methodology	Associated risks	Risk level assigned	Typical time frame (years)	Justification for assigned timeframe
Achievement of surface requirements (RM12, RM13, RM14) -> Achievement of stable PMLU (RM16, RM17, RM18)	• Vegetation monitoring & maintenance as required	• Erodible topsoils and subsoils • Ongoing rill, gully or sheet erosion • Drainage of final landform not meeting the water quality objectives • Excessive rainfall, droughts or fire events that may directly affect groundcover establishment • Drainage of final landform not meeting the water quality objectives; and • Pests and weeds.	Moderate	5	Achievement of a target PMLU requires it to be stable, safe, non-polluting and sustainable. The five years assigned for this timeframe considers the time necessary for establishment of mature, self-sustaining vegetation (i.e. multiple seasons of successful recruitment) and the timing needed to achieve the surface water quality objectives. Allowance is also given for natural hazard events such as fires or severe storms that may drive additional maintenance works or even revegetation.
Achievement of stable PMLU (RM19)	• Dams to remain safe, stable and accessible to livestock with appropriate water quality values based on stockwatering guidelines	• Water quality is not able to support stockwatering • Erodible topsoils and subsoils • Ongoing rill, gully or sheet erosion	Low	1	Retention of these dams has been confirmed by the underlying landholder. There is no indication that sediment dams will be unable to meet the relevant water quality objectives, or will experience high rates of erosion.

Rehabilitation Milestones (RM)	Summary rehabilitation methodology	Associated risks	Risk level assigned	Typical time frame (years)	Justification for assigned timeframe
Achievement of stable PMLU (RM20)	• Infrastructure to remain in good, working order and is able to facilitate the intended land use	• Infrastructure dilapidation due to mine usage	Low	1	Retention of the infrastructure has been confirmed by the underlying landholder and it is expected that infrastructure will be in good, working order.
Surface water and groundwater demonstrate non-polluting landform (RM21)	• Groundwater and surface water values remain in compliance with the Gemini EA and no rehabilitated landforms are contributing to exceedances on site.	• Water quality is unable to meet the relevant objectives described in the EA	High	End of Mining	Is it difficult to isolate sources of contaminants within surface water and groundwater systems during mine operations. As such, this milestone is expected to be relevant at the end of mining, once the site has been successfully rehabilitated and no contaminants are being produced by the site. There is a high risk that if rehabilitation works are unsuccessful due to water impacts, rehabilitation works may need to be removed and re-established to preserve environmental values.

3.5.7 General rehabilitation practice

The rehabilitation practices to be used for the Gemini project have been developed from increasing knowledge gained from experience at other local mines in the Blackwater area, including:

- early rehabilitation successes and failures;
- weather, subsoils, soils, local flora and fauna and revegetation species;
- final landform design, stability and erosion risks; and
- site preparation and seeding practices.

While rehabilitation objectives and completion criteria for the Project are detailed at sections 3.5.1 and 3.5.4, the following overarching rehabilitation principles are will be adopted:

- Ensuring that reshaped areas proposed for rehabilitation meet the required landform design principles, that prepared areas meet the rehabilitation design specification for the area, and that local site drainage has been considered and surrounding areas graded to mitigate any rainfall runoff from adjacent areas to run-on to prepared rehabilitation areas.
- Soil testing will be carried out progressively to ensure topdressing materials, amelioration and final surface preparation methods support vegetative growth.
- Revegetation species selection, seeding and/or planting methods, and fertiliser applications target rapid vegetative ground cover effective at mitigating soil erosion, during the period of initial revegetation when areas are most at risk.
- Ongoing monitoring and maintenance will occur as needed to assess rehabilitated area performance against completion criteria and inform future rehabilitation practices; and to identify rehabilitation methodology adjustments such that RAs are proceeding along a trajectory towards the designated PMLU.

The following sub-sections outline the range of information considered necessary to inform the development of rehabilitation methods for the Gemini Project. The information addresses the content requirements of Guideline – Progressive rehabilitation and closure plans V3.01 (Department of Environment and Science).

3.5.7.1 Waste characterisation

Geochemical waste characterisation studies were carried out for the Gemini Project by RGS in 2019 (Appendix E) and RGS 2020 (Appendix E) with the aim of understanding any potential geochemical risks during operations and post closure. The assessments provide a geochemical characterisation of samples representative of the mining wastes (overburden and interburden materials) and coal reject materials.

Both static and kinetic testing methods were utilised to indicate the presence and degree of risk from the oxidation of reactive sulphides, and the potential for acid generation and leaching of soluble metals/metalloids and salts. The assessments also included characterisation of chemical parameters related to sodicity and material stability. Measurement of the geochemical/weathering behaviour of waste samples over time were assessed via kinetic leach column (KLC) test. The KLC tests comprised composite mining samples representing the main lithological rock types likely to be generated at the proposed open pit as well as some carbonaceous material and uneconomic coal. The KLC tests were completed over a period of six months from July 2017 to January 2018, under a monthly watering and leaching cycle.

Waste rock geochemistry

A total of 70 waste samples were collected from three drill holes within the Project area; representative of the main overburden, interburden and potential coal reject materials likely to be encountered during development of the Project. Samples were collected from the surface down through the stratigraphic profile (including economic and uneconomic coal seams) to the base of the open pit.

The pH (1:5) of samples were assessed using the 1:5 soil:water suspension method, which is considered the de facto standard pH measurement. Across all sample types, pH ranged from 5.0 to 9.7 with a median value of 9.2. The samples with the lowest pH values (pH 5.0 to 5.5) represent clay and soil materials.

EC(1:5) ranges from 270 to 1,440 µS/cm with a median of 646 µS/cm, and is considered to be moderate. The weathered material tends to have a higher EC value than the fresh material.

Total sulphur content ranges from less than 0.01-0.60 %S (median 0.06 %S). Compared to the median crustal abundance of sulphur (0.07%) (INAP 2009), the median value of the mining waste materials is relatively low. The sulphur content of carbonaceous siltstone and coal are both higher than natural background values and both lithologies show greater variation in sulphur content than the weathered material, sandstone and siltstone.

The results of the multi-element analysis were assessed against the geochemical abundance index in accordance with relevant guidelines and practices (Bowen 1979; INAP 2009). The geochemical abundance index results indicate that, compared to median crustal abundance, only one of the 10 selected samples was enriched and then only with respect to cobalt.

Sample analysis indicated that the CEC of the materials varies between 4.2-18 meq/100g with a mean value of 10 meq/100g. The resulting effective CEC rating for the materials is from very low to moderate.

The ESP of the 10 selected samples ranged from low (4.5%) to very high (31.5%) with a median of 19.3%, indicating that some of the sample materials are likely to be sodic.

The findings of the geochemical assessment of waste rock samples (RGS 2019) can be summarised as follows:

- all of the mining waste samples tested are NAF, have excess ANC and typically have low sulphur content. The sulphur content of coal and carbonaceous siltstone can be elevated compared to typical background concentrations, but is mainly present in a non-sulfidic form, which does not contribute to acid generation. Overall, these materials have a low risk of acid generation and a high factor of safety with respect to potential for AMD;
- initial and ongoing surface runoff and seepage from mining waste materials is expected to be moderately alkaline and have a moderate level of salinity;
- KLC test results indicate that mining waste materials are unlikely to generate acid conditions and more likely to generate pH neutral to alkaline conditions;
- metal/metalloid enrichment in mining wastes, compared to median crustal abundance in unmineralised soils, is limited to cobalt in a single carbonaceous siltstone sample;
- most metals/metalloids are sparingly soluble at the neutral to alkaline pH of leachate expected from bulk mining waste materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk mining waste materials are therefore expected to be low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities;
- mining waste materials should be amenable to revegetation as part of rehabilitation activities, although, gypsum and fertiliser will be used as necessary for sodic materials to limit dispersion and erosion and to provide a reasonable growth medium for revegetation and rehabilitation; and
- mining materials are likely to be susceptible to dispersion and erosion, ongoing testing programs will be implemented to validate material properties during operations. Final landform slope angles have been designed at a maximum grade of 6°. Dispersive or saline waste rock types, typically weathered waste rock) will not be placed on the outer slopes of waste rock emplacements.

Coal rejects geochemistry

A total of 80 coal reject samples from coal quality washability tests were provided from 14 different drill holes, comprising 52 coarse reject and 28 fine reject samples.

The pH(1:5) of the 22 composite coal reject samples from the Project ranged from 5.1 to 8.3 with a median value of 7.4 indicating that coal reject materials are typically in the pH neutral range. There does not appear to be any significant correlation between pH and reject type or coal seam.

EC(1:5) ranges from 398 to 1,062 µS/cm (median 774 µS/cm), with no apparent correlation between EC and reject type or coal seam. Based on the median pH and EC values, the coal reject samples tested are generally regarded as having 'high' soil pH and 'medium' salinity values with respect to the criteria for mining waste materials as defined by the Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland (DME 1995).

The total sulphur content (measure as total sulphur concentration - %S) of the samples ranges from 0.23-4.20 %S with a median value of 1.03 %S. This compares to a median crustal abundance value of 0.07 %S in unmineralised soils (Bowen 1979; INAP 2009). Materials with a total sulphur content less than or equal to 0.1 %S have negligible capacity to generate acidity. The reject samples used in the KLC tests retained at least about 95.6% of their inherent total sulphur content after three months of exposure to idealised oxidising conditions. This reflects a relatively slow rate of sulphide oxidation (and potential acid generation) for these materials.

The results of the multi-element analysis were assessed against the geochemical abundance index (GAI) in accordance with relevant guidelines and practices (Bowen 1979; INAP 2009). The geochemical abundance index results indicate that of the metals/metalloids measured, none are significantly enriched compared to median crustal abundance. The main findings of the coal reject geochemical assessment (Appendix E, RGS 2020) are:

- the coal reject samples represent materials with a variety of geochemical characteristics. As a bulk material, coal reject is expected to be NAF with excess acid neutralising capacity (ANC). Overall, most coal reject materials have a relatively low risk of acid generation and an increased factor of safety with respect to potential for AMD;
- initial and ongoing surface runoff and seepage from coal reject materials is expected to be pH neutral and have a moderate level of salinity. The salinity of leachate from higher sulphur coal reject materials could increase over time if exposed to atmospheric conditions, due to the release of sulphate through sulphide oxidation;
- comparison with guideline values and median crustal abundance in unmineralised soils indicates that the coal reject materials are not significantly enriched with metals/metalloids; and
- most metals/metalloids are sparingly soluble at the current pH of the leachate from coal reject materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk coal reject materials are expected to be relatively low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities. To minimise risk, rejects materials will be contained within waste rock emplacements, well away from the outer surface of the final rehabilitated landform.

3.5.7.2 Soil and cover material

Cover materials

Coal reject materials present a range of geochemical properties; however, the bulked reject stream is expected to be NAF with excess acid neutralising capacity (ANC). Conservatively, all reject material will be placed as a dry material inside the NAF waste dumps to prevent water infiltration into the reject materials.

Topsoil

Site clearing within the proposed footprint for the infrastructure and mining footprints will generate topsoil suitable for rehabilitation work. Soil studies conducted in the Project area (Appendix E, AARC 2019) conclude that most topsoils are suitable for use as plant growth medium for rehabilitation, while some subsoils were found to be limited for rehabilitation value due to increased potential for erosion and dispersion. The main limiting factor identified was the soil profile pH for the Nigel SMU, which ranges from 4.5 to 5. The SMU has

been identified within the mining disturbance footprint affecting the topsoil rehabilitation value. A practical topsoil management plan will be adopted for the management of soil resources, including a program of ongoing soil testing.

Soils with weak structures, such as sands, loamy sands or massive structure soil may pose an erosion risk as a result of activities with the potential impact to result in soil erosion or sediment generation, including:

- land clearing, construction activities and maintenance of haul and access routes.
- movement of equipment; and
- surface water run-off from waste rock material, coal, and topsoil stockpiles.

These soils may be treated with gypsum to overcome dispersive properties.

Soil placement and surface preparation

Given available knowledge, the approach to surface preparation and topsoil placement will involve assessment by an AQP to advise on site-specific requirements such as:

- Identification of the topsoil resource to be utilised for a given rehabilitation area, and the carrying out composite soil sampling and agronomic laboratory analyses.
- Determination and procurement of type and quantity of ameliorants that would be beneficial for the topsoil resource (if needed).
- Topsoil is to be placed by scraper or truck at the top of the profiled slope and pushed by dozer or grader to achieve desired thickness.
- Gypsum and or other ameliorants considered necessary to promote revegetation will be spread on the soil surface prior to deep ripping.
- The dump surface will then be deep ripped (dozer or grader) to below the depth of the topsoil, to encourage infiltration of water for plant growth.
- Seeding and hay mulching of topsoil will occur as soon as possible to encourage plant growth and prevent soil loss erosion.

Topsoil inventory

Topsoil stripping depths and volumes are presented in Table 39. All topsoil material required for rehabilitation is anticipated to be sourced from the Project area. Rehabilitation topsoil requirements are summarised in Table 40.

Table 39: Estimated topsoil resources available for rehabilitation

Soil Management Unit	SMU area (m^2)	Surface Area to be Disturbed (m^2)	Topsoil Stripping Depth (m)	Estimated Volume of Recoverable Topsoil (m^3)	Maximum Topsoil Stripping Depth (m)	Maximum Volume of Recoverable Topsoil (m^3)

RA8 - Mine Infrastructure areas	2,203,740
Total volume of topsoil required for rehabilitation*	**5,484,390**

*Topsoil requirement based on the placement of topsoil to a depth of 0.3 m

Topsoil management

Vegetation and topsoil will be removed from the footprint area and will either be used directly in rehabilitation areas or stockpiled for use in the rehabilitation of the site. Suitable topsoil is generally stripped by either scrapers or excavators/trucks and either transported to areas prepared for rehabilitation or stockpiled for later use.

Topsoil will be temporarily stockpiled on or near waste rock dumps, in the proximity to placement location. Long term storage of topsoil stockpiles is located on natural surface within proximity to the mine infrastructure area.

Stockpiled soil will require careful management to protect its agronomic qualities and to optimise its value as a plant growth medium. Stockpiles will generally have a maximum height of 2 m to allow oxygen to diffuse through the topsoil stockpile, maintaining seed viability and microorganisms. Where topsoil stockpiles are to remain in place for an extended period due to operational requirements, stockpiles will be seeded with species targeted in the grazing PMLU seed mix (Table 27), as required to increase soil organic matter levels, encourage water infiltration, maintain soil structure, microbial activity and prevent erosion.

Before topsoil is used in rehabilitation, chemical analysis of soil is to be undertaken by an AQP to determine its quality and viability as a growth medium and amelioration requirements will form basis of treatment prior to use.

3.5.7.3 Landform design

The final landform design and the sequencing of landform development (and hence the resultant rehabilitation milestone schedule) are influenced by the nature of the mining practices proposed. The final landform has been designed with consideration for the pre-mining landscape, stakeholder consultation, proposed PMLUs and post-mining stability.

The proposed final landform for the Project is shown in Figure 48.

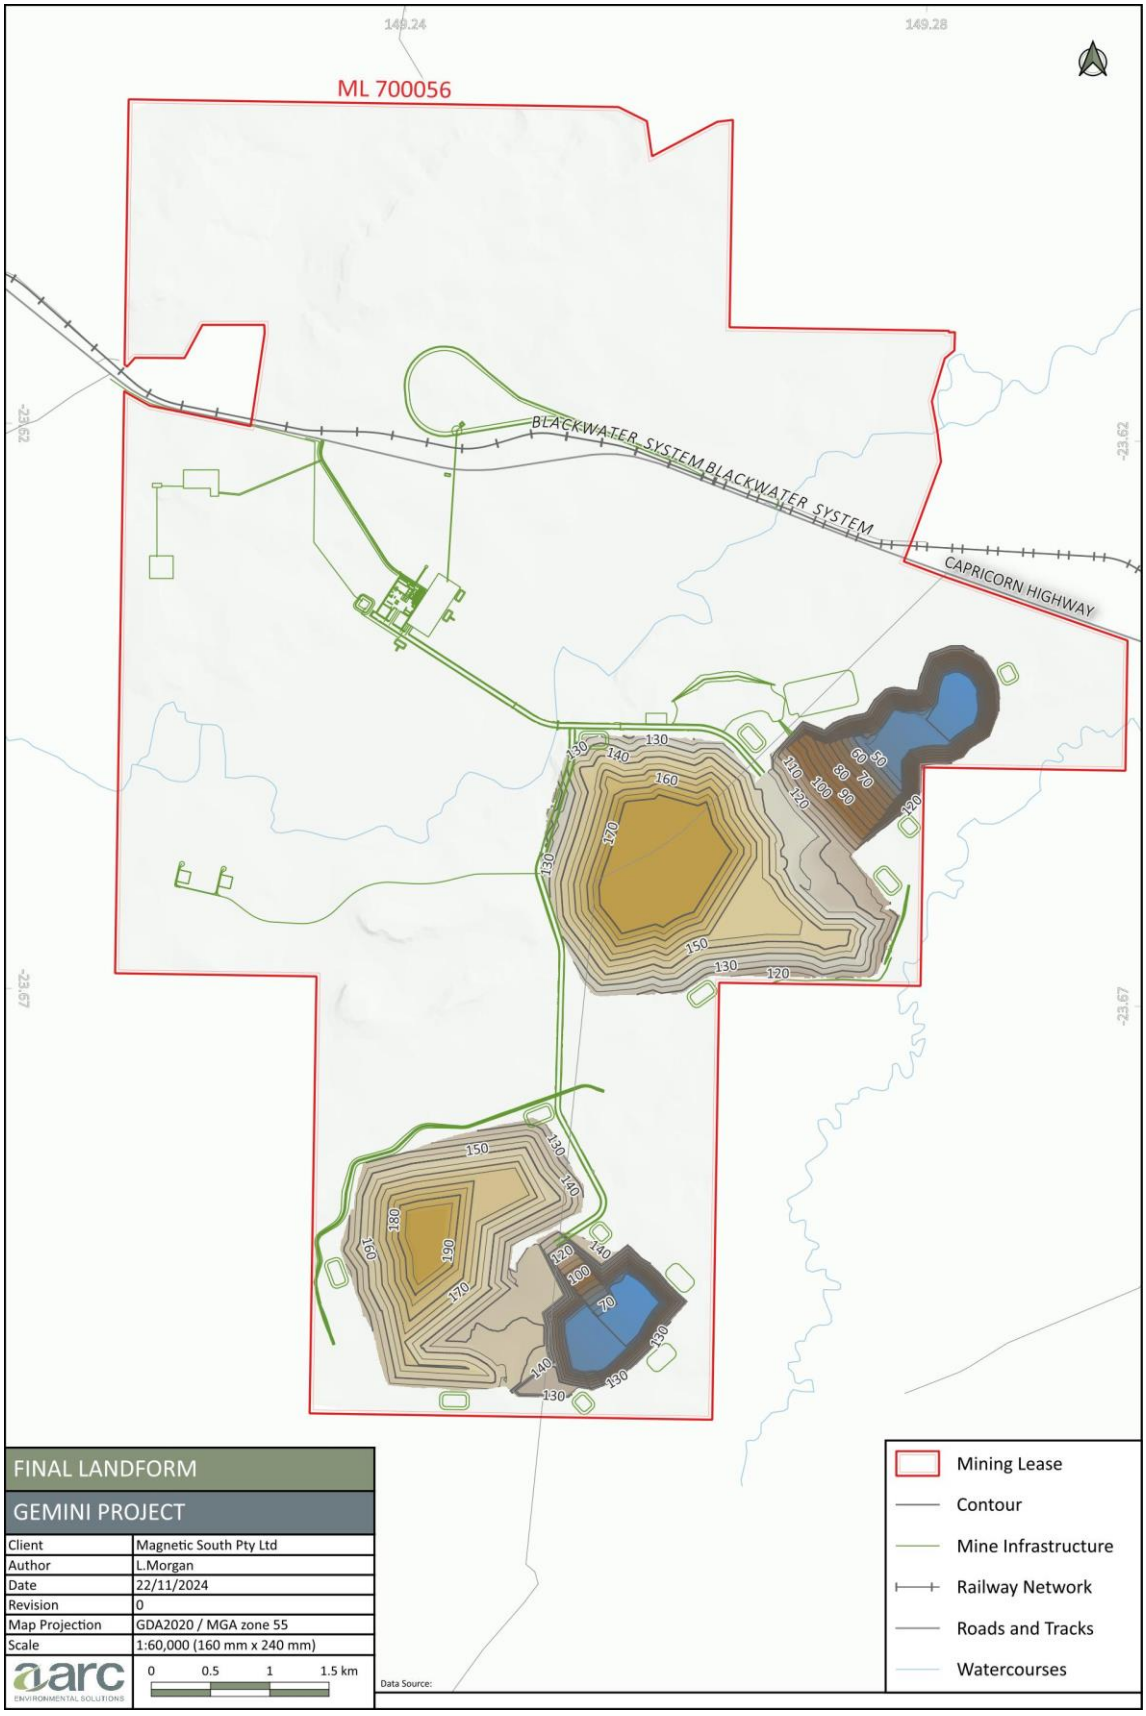

Figure 48: Final landform design

Waste emplacement landforms

Waste rock will be placed in mined-out pits after coal extraction and in external waste rock emplacements. With the exception of the temporary waste rock pile, waste rock dumps have been designed as permanent landforms, ensuring long-term stability post mining.

Excluding the final void high wall and pit lake, the design specification adopted for permanent waste rock dumps is as follows:

- Maximum elevation of 194 mAHD and 175 mAHD for Mine A and B, respectively;
- Maximum batter slope angle of 6°;
- Maximum uninterrupted batter slope length of 230m; and
- Separated by flat berms of 10-15 m width, designed not to concentrate runoff.

Where possible, concentration of water will be minimised in the rehabilitated landform, preventing erosion on slopes.

These areas of in-pit and ex-pit waste rock will be revegetated to achieve a pasture grassland community, supporting the designated PMLU of grazing. Establishment of vegetation will naturally provide increased water infiltration and reduce runoff velocities, assisting with stability.

Previous studies conducted in central Queensland have investigated the groundcover required to minimise erosion on slopes. Erosion risk on rehabilitated landforms is greatest during the establishment phase, especially on steeper gradients. The greatest erosional risk is typically observed when >50% of the surface is exposed to rainfall and overland flow. In a study conducted on three open cut coal mines in central Queensland, Carroll, Merton and Burger (2000) found that erosion rates declined rapidly on slopes when vegetation cover was >50%, with erosion rates reduced to negligible levels by Year 6, even on steeper slopes. A literature review of erosion research conducted in the Fitzroy Basin region of Queensland (Carroll et al. 2010) also concluded that foliage surface cover of 40–60% reduces erosion to <0.5 t/ha/yr, regardless of slope. Similarly, Loch et al. (2000) found that approximately 50% foliage groundcover was sufficient to limit erosion rates to >0.5 t/ha/yr on <15% slopes, for slopes up to 70 m long.

To validate the literature described above and assess the long-term stability of the final landform, erosion modelling was undertaken for Gemini in-pit and ex-pit final landforms using the Water Erosion Prediction Project (WEPP) model. WEPP modelling considers four key data points: climate information, soil profile, land use management and slope design. Climate parameters were modelled from the area using CLIGEN 5.3, with input data sourced from SILO (daily rainfall, maximum and minimum temperature, solar radiation and maximum relative humidity) and BOM (pluviograph data). Twelve soil profiles were included for modelling derived from the Gemini Soil and Land Suitability Assessment (Appendix E, AARC 2019), namely:

- Anderson
- Barry
- Charlevue
- Cooinda
- Ellesmere
- Geoffrey
- James
- Kosh
- Namoi
- Nigel
- Normanby
- Wallace

In creating the land use management parameters for WEPP modelling, cover classes were established at 5% intervals ranging from 0% to 100%. Vegetation cover was fixed at these percentages throughout the WEPP simulations, such that consistent cover was maintained across the 100-year simulation period without growth or decay. Slope design specifications were based on a maximum slope angle of 6° over a length of 228 m, which is the longest slope proposed as part of the final landform design.

In total, 252 100-year WEPP iterations were run, covering the range of soil samples and land use management profiles identified above. To determine the maximum potential erosivity of the slope, the average annual soil loss, expressed in tonnes per hectare per year (t/ha/yr), for each iteration was calculated and assessed against

a target and maximum erosion rate. A target (or 'tolerable') erosion rate of 5 t/ha was adopted for assessing land suitability and erosivity risk (Landloch 2013; Howard and Loch 2019). Additionally, a maximum tolerable erosion rate of 10 t/ha was adopted, as the rate was considered acceptable for mining rehabilitation purposes (Lu 2001). The results of this analysis can be found in Figure 49.

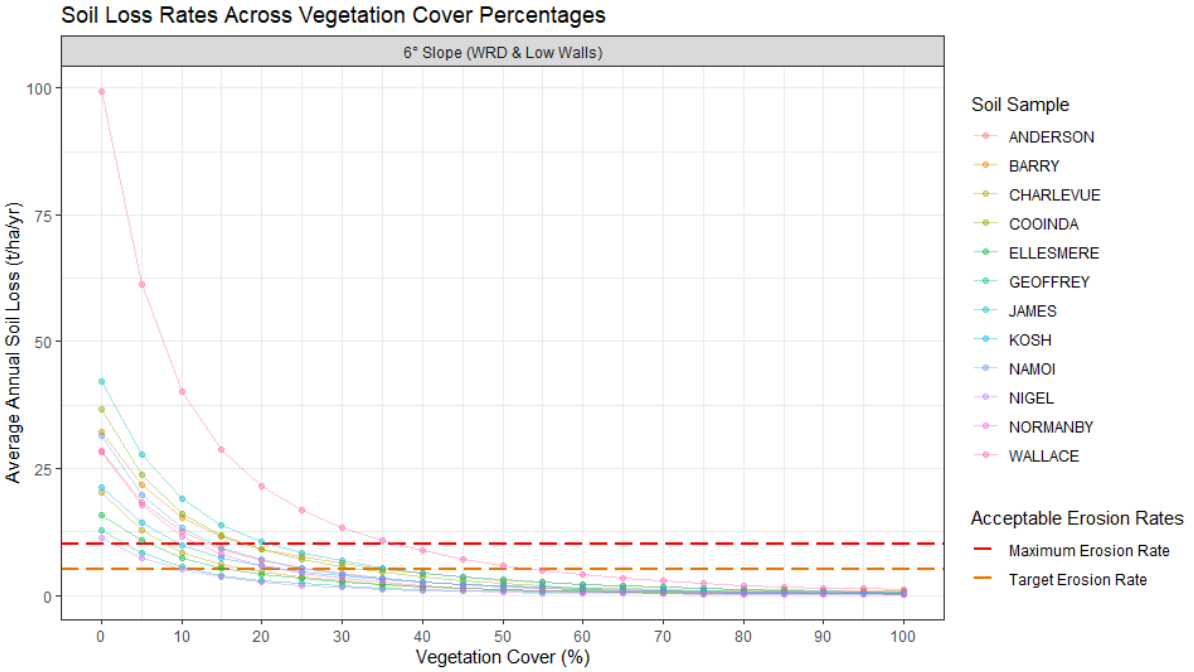

Figure 49: Average annual soil loss rates (t/ha/yr)

The average base erosion (i.e. no vegetation cover) modelled for the slope is 31.7 t/h/yr, with a maximum base erosion rate of 99.4 t/ha/yr, based on the properties of the Wallace SMU. At 25% vegetation cover, all SMUs, excluding Wallace, achieved the maximum tolerable erosion rate, with the Wallace SMU meeting the maximum erosion rate at 40% cover.

Similarly, all SMUs, excluding Wallace, achieved the target tolerable erosion rate at 40% cover, with the Wallace SMU meeting the target erosion rate at 55% cover (Table 41).

Table 41: Summary of required vegetation cover on slopes

Erosion Rate Thresholds	**Vegetation Cover (%)**	
	Wallace SMU	**All other SMUs**
Maximum tolerable erosion rate (10 t/ha/yr)	40	25
Target tolerable erosion rate (5 t/ha/yr)	55	40

Given these results, the final landform design is expected to remain stable and non-erosive irrespective of topsoil properties, where greater than 55% vegetation cover is maintained. However, vegetation cover can decrease to 40% while maintaining structural integrity on the slope when considering a maximum tolerable erosion rate of 10 t/ha/yr.

It is acknowledged that the data used to inform the erosion modelling above is based on pre-mining soil and climate information as well as design slopes not yet constructed. It is expected that as mining activities commence and improved site-specific information is obtained that the quality and accuracy of the model will improve. The Project proposed to engage with an AQP to provide updated erosion modelling based on updated information and conditions appropriate for the Project and the local region prior to rehabilitation activities commencing. A detailed erosion stability assessment is provided in Appendix J.

Final void landforms

The pit lakes will not support a beneficial post-mining land use and will be designated as NUMAs. The surrounding high walls will be rehabilitated to sustain a native ecosystem supporting fauna habitat. Two pit lakes with a total footprint area of approximately 81 ha will be formed as part of the final Project landform. Both voids will be partially backfilled with water rock to ensure adequate coverage of the deeper coal seams and elevate the void floor above the level of significant groundwater inflows.

A pit lake will form within each void, reaching a steady state level where water losses through evaporation are equal to water inputs from rainfall, runoff and groundwater inflows. While water levels in the voids will vary over time, dependent on the prevailing climatic conditions, the results of modelling indicate that an equilibrium level of approximately 70 mAHD in Mine A and 53 m AHD in Mine B will be reached after 200 years. The steady state water level of both voids is predicted to remain well below the base of the Tertiary aquifers acting as groundwater sinks, thereby negating any risk of contamination.

The void low wall will be rehabilitated to a gradual slope of less than 6° to the base of the backfilled void, ensuring safe access and supporting a PMLU of cattle grazing. The low wall RA area will be fenced off at the long-term equilibrium water level of the pit lake to ensure the final pit void is inaccessible to fauna and humans. However, the slope will be reseeded using a grazing seed mix (Table 27) to the post-mining water level of the void to reduce the risk of erosion before fencing is installed.

For the low void walls to support the proposed PMLU of grazing, the final landform's stability needs to withstand cattle activity in the area. Measures to ensure the PMLU is sustainable include the application of hydromulch material and the achievement of ≥80% groundcover species to minimise the effects of erosion. Additionally, fencing the low wall at the long-term equilibrium water level of the pit lake will restrict cattle access to residual voids, reducing the risk of bank erosion and establishing a stable condition at surrender.

Pit high walls will be throw blasted and/or shaped to achieve a stable slope of 18° in the unconsolidated weathered zone, above the pit long-term equilibrium water level of the void. For the remaining Permian geology, an overall angle of 55° will be achieved by 50 m high batters at 65° incorporating 15 m wide intermediate benches. Erosion modelling has demonstrated that these slopes are expected to remain stable if a vegetation cover of 80% is achieved (Appendix J). However, the assessment considered high wall erodibility on the basis of topsoil application rather than the proposed hydromulch applied to throw blasted materials. Consequently, the vegetation cover may be an overestimation. A conceptual 3D sketch of the residual void final landform is provided in Figure 43.

Cartledge Mining and Geotechnics (Appendix E, Cartledge2021) assessed the proposed final void design to be geotechnically stable, achieving a Factor of Safety of 1.5.

The physical void characteristics are summarised in Table 42.

Table 42: Final Void Physical Characteristics

Mining area	Approx. Pit Lake Area (ha)	Low Wall Slope	High Wall Slope
Mine A	37	<6°	Final void high walls slopes are 18° or lower, where located within unconsolidated sediments and saturated tertiary.
Mine B	43		An overall angle of 55° by constructing 50 m high batters at 65°, incorporating 15 m wide intermediate benches.

Permanent clean water drains

The permanent diversion of an unnamed tributary of Springton Creek will be constructed in two parts to divert clean water around the final landform dumps and voids. The diversions will be constructed during operations, providing for long-term monitoring and maintenance during the operational mine life.

The proposed landform design aims to achieve permanent stable landforms. The preliminary concept designs of the two drains are provided in Figure 50 and Figure 51 while general arrangement of site drainage and mans is provided in Figure 52. The final designs will be decided as per best practice by an AQP prior to constructions to achieve:

- Mine A drain:
    - design 1 in 50 AEP depths are up to 1.3 m, and peak velocities range between 1.0 m/s and 2.0 m/s.
- Mine B drain:
    - design 1 in 50 AEP depths are up to 3.7 m, and peak velocities range up to 2.5 m/s;

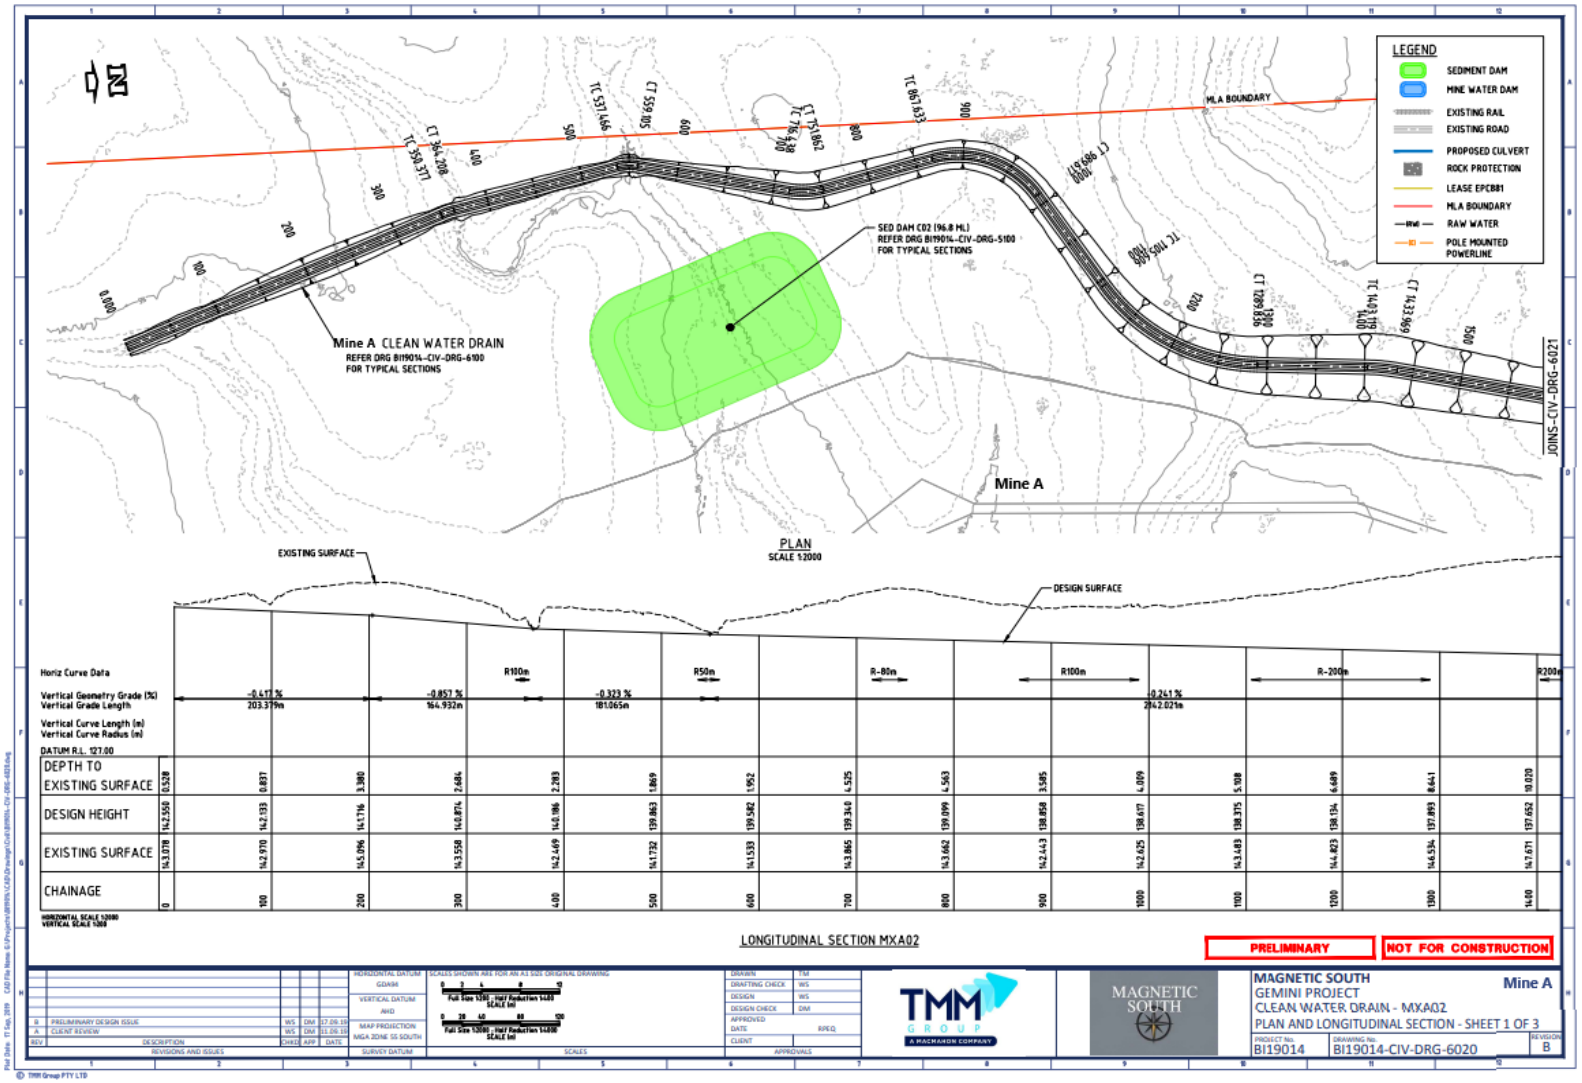

Figure 50: Mine A clean water diversion

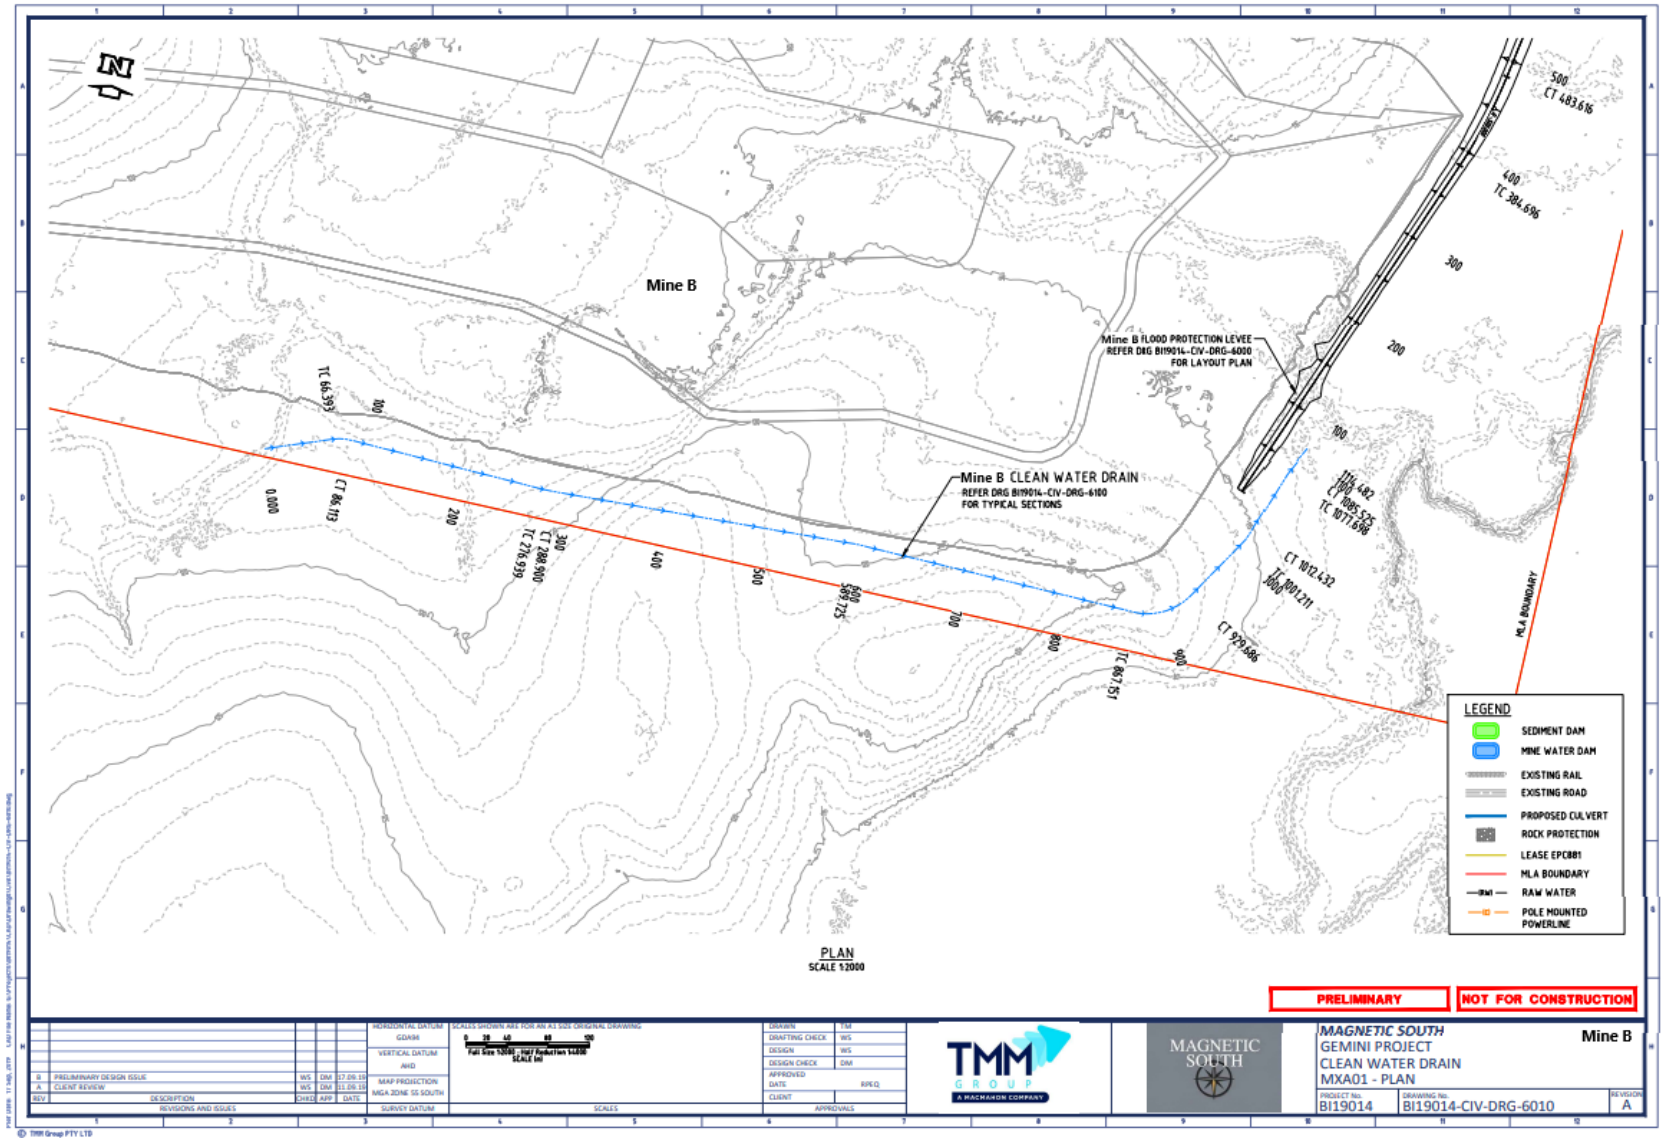

Figure 51: Mine B clean water diversion

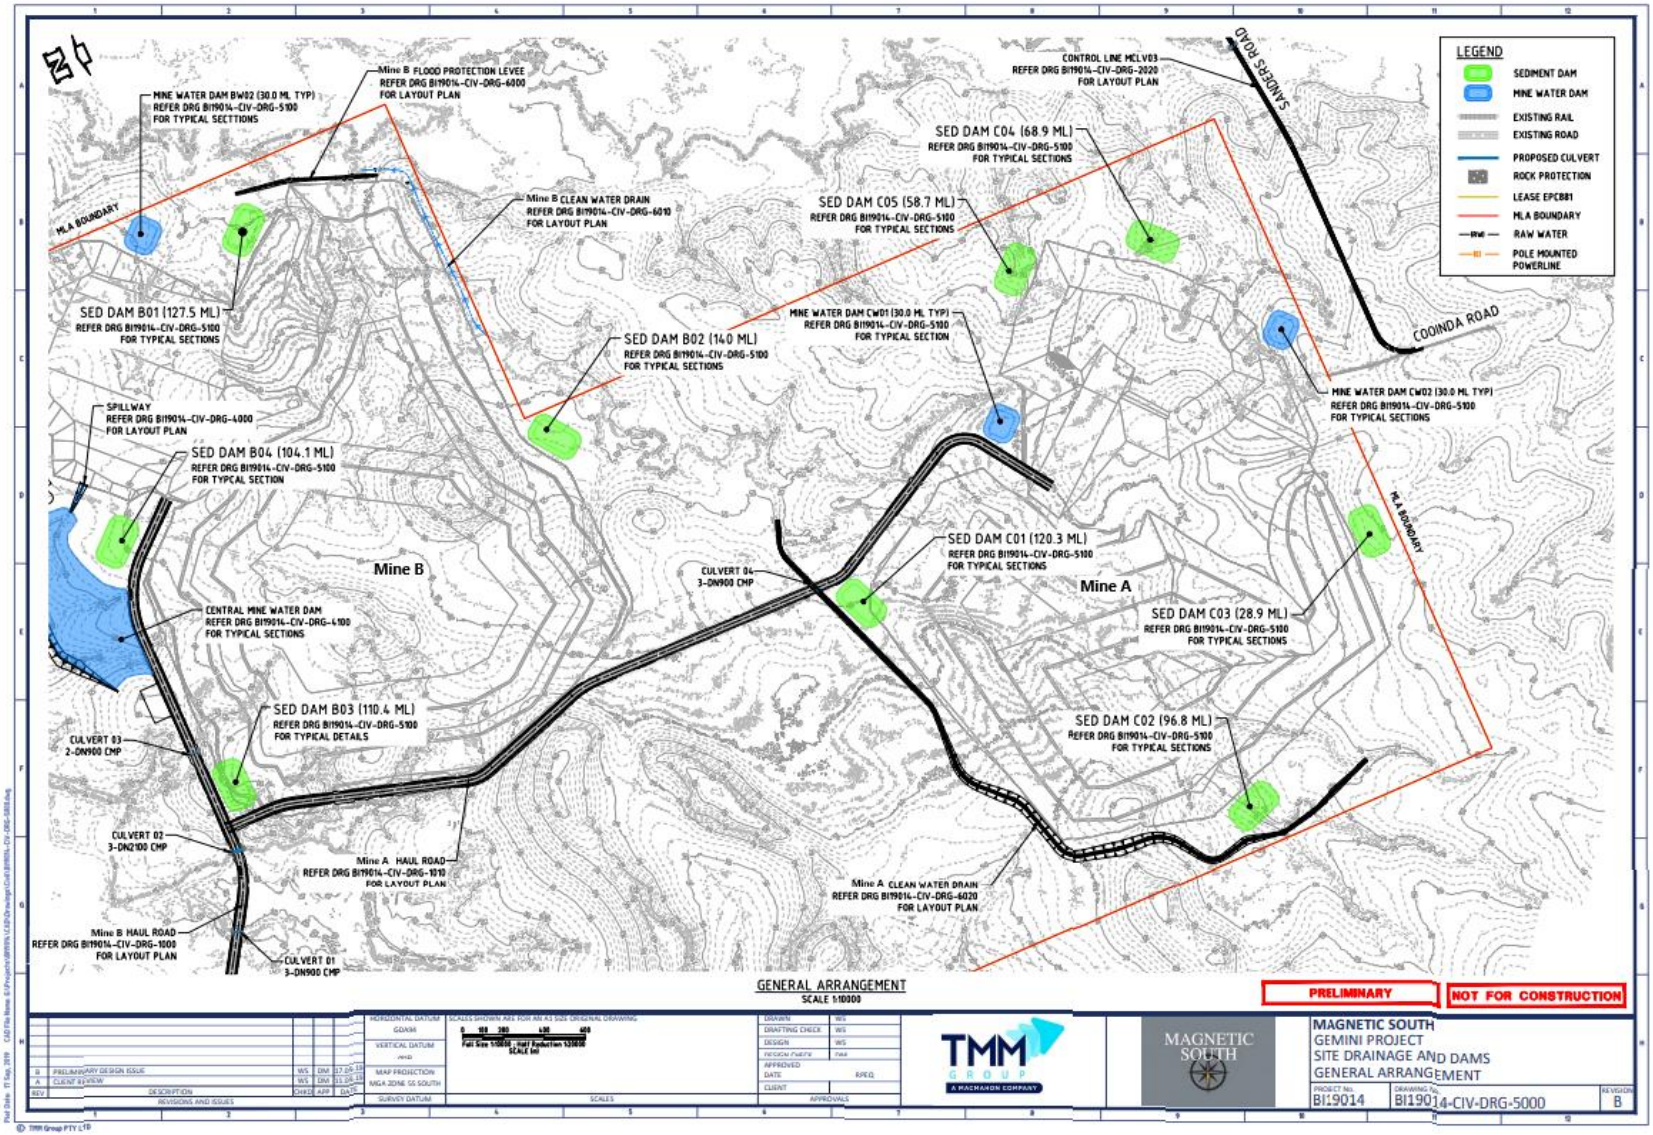

Figure 52: Site drainage and dams – General arrangement

3.5.7.4 Revegetation

The primary objective of the revegetation plan is to reinstate self-sustaining vegetation communities suitable for the target PMLU (refer section 3.3.2).

Revegetation activities will be scheduled to occur after landform reshaping, topsoiling and surface preparation works.

Growth media and ameliorants

Topsoils at the Project are generally suitable for supporting plant growth. However, some topsoils were identified as likely susceptible to dispersion and erosion and would require amelioration through the addition of gypsum and other ameliorants. A program of ongoing agronomic soil testing will occur during operations to inform the specific soil ameliorants for all topsoil used in rehabilitation.

The high-wall final landform design features a maximum slope design of 18°, for which traditional growth media application methods are not practical. As such, hydro mulching will be utilised as the growth media, as the resulting slurry can be easily applied via spray trucks or aerial spraying if required. The hydromulch will consist of subsoil ameliorants (where required), soil wetting agent, seed, fibre, binder, fertiliser and water in doses as advised by AQP. It is expected that the hydromulch will act as a binding agent to allow for seed germination and establishment on steep slopes while providing the necessary ameliorants to the underlying material to encourage vegetation growth and supporting the PMLU.

Grazing PMLU

Grazing areas will be evenly seeded with pasture grass species at the rates indicated in Table 43. The suite of pasture grasses includes native and introduced species known to occur in the Project area, several of which are considered palatable, perennial and productive (i.e. 3P grasses).

The recommended grazing seed mix is indicative of the species suited to the Project area, the rehabilitation landforms and the PMLU. The suite of pasture species used in grazing revegetation areas may be subject to change due to seasonal availability and/or knowledge gained from previous rehabilitation performance. All species listed suit the central highlands climate and site-specific environmental conditions and, in most cases, have previously been recorded during baseline studies at the Project site.

The pasture species recommended within the species list are considered desirable native grasses for beef cattle grazing as per Clay et al. (2024) and a number of the nominated species are classified as 3P (palatable, perennial and productive) pasture grasses.

Table 43: Grazing PMLU seed mix

Scientific name	Common name	Recommended nominal application rate (kg/ha)
Bothriochloa bladhii	Forest bluegrass	3
*Bothriochloa ewartiana**	Desert bluegrass	3
Chamaecrista rotundifolia	Roundleaf cassia	1
Chloris gayana	Rhodes grass	2
*Dichanthium sericeum**	Queensland bluegrass	3
Echinochloa esculenta	Japanese millet	5
*Enteropogon acicularis**	Curly windmill grass	3
*Panicum decompositum**	Native millet	3
Stylosanthes hamata cvv. Verano or Amiga	Caribbean stylo	1
Stylosanthes Seabrana cvv. caatinga	Caatinga stylo	1
Themeda triandra	Kangaroo grass	3

*Denotes a 3P pasture species.

Seed application

To maximise revegetation success, seeds will generally be spread during spring before the wet season rainfall begins. Excluding areas to be hydromulched, seeds will be sown using direct seeding with a tractor mounted spreader. Hay mulch will be applied immediately following the placement of seed providing benefits such as:

- improved conditions for germination;
- protection from predation;
- erosion prevention; and
- improvement of surface soil properties.

Tubestock planting of tree species may occur in place of seeding in particular areas where it makes strategic sense. High wall rehabilitation areas will likely utilise hydromulching for the spread of seed and growth medium due to the steeper rehabilitation slopes. Species mixes will target surface stability and fauna habitat.

Native ecosystem supporting fauna habitat PMLU

The native ecosystem supporting fauna habitat PMLU is designated for the final void high wall areas. The suite of native flora species recommended for seeding in the native ecosystem supporting fauna habitat PMLU areas is provided in Table 44. This species list is representative of the species composition recorded in VC2 - Lancewood (*Acacia shirleyi*) and/or Rosewood (*Acacia rhodoxylon)* woodland on lateritic duricrust (refer to section 3.1.7.1). The proposed seeding mix is therefore consistent with naturally occurring vegetation (RE 11.10.3) on the Project site and is considered best suited to the upper slopes of the high wall final landform.

Whilst the species presented in this list are recommended for seeding of the high wall upper slopes and benches in RA3, the final seeding list will depend on the availability of seed stock at the time of revegetation.

Where dieback occurs, the impacted area will be revegetated with appropriate species from the native vegetation species list. The species list is provisional, and subject to change based on species suitability and availability and as new information becomes available from rehabilitation monitoring and research.

Table 44: Native ecosystem supporting fauna habitat PMLU seed mix

Scientific name	Common name
Canopy/Tree	
Acacia shirleyi	Lancewood
Corymbia clarksonia	Grey bloodwood
Acacia rhodoxylon	Rosewood Wattle
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus exserta	Queensland peppermint
Shrub	
Acacia complanata	Long-pod wattle
Acacia crassa	Curracabah
Alphitonia excelsa	Soap tree
Petalostigma pubescens	Quinine bush
Flinersia dissoperma	Scrub leopardwood
Pittosporum spinescens	Wallaby apple
Groundcover	
Aristida calycina	Dark wiregrass
Cleistochloa subjuncea	Soft grass
Scleria sphacelata	Razor grass
Entolasia stricta	Wiry panic
Eragrostis lacunaria	Purple lovegrass
Thyridolepis xerophila	
Panicum larcomianum	Larcom's panic grass

Native ecosystem PMLU

The native ecosystem PMLU is to be applied along the permanent clean water diversions and around rehabilitated water management infrastructure. Rehabilitation areas, including the banks of the reconstructed channel, will be evenly revegetated with pasture grasses and native tree and shrub species, selected from the list of species recommended in Table 45. The dominant species from baseline vegetation communities (RE 11.5.2) were identified and included as part of the recommended seed mix for RA7. The suite of pasture grasses includes native grasses known to occur on the Project site and considered palatable, perennial and productive.

These seed mixes are indicative only and are subject to change due to seasonal availability and/or experience from previous rehabilitation performance. All species listed are suited to the central highlands climate and site-specific environmental conditions.

Table 45: Native ecosystem PMLU species list

Scientific name	Common name
Canopy/Tree	
Corymbia citriodora	Lemon-scented gum
Corymbia clarksonia	Grey bloodwood
Acacia rhodoxylon	Rosewood Wattle
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus moluccana	Grey box
Shrub	
Acacia complanata	Long-pod wattle
Acacia crassa	Curracabah
Alphitonia excelsa	Soap tree
Petalostigma pubescens	Quinine bush
Flinersia dissoperma	Scrub leopardwood
Pittosporum spinescens	Wallaby apple
Ground	
Aristida calycina	Dark wiregrass
Cymbopogon refractus	Barbed wire grass
Entolasia stricta	Wiry panic
Eragrostis sororia	Lovegrass
Enneapogon lindleyanus	Lindley nineawn
Perotis rara	Comet grass
Panicum effusum	Hairy panic

3.5.7.5 Hydrogeology

Groundwater modelling by JBT (Appendix E, 2019) predicts that a permanent cone of depression will develop directing groundwater flow towards the final voids. The assessment concludes the risk of water quality impacts of the project (via outflow to the groundwater system) to be low.

However, it was assessed that the Project could impact groundwater quality if the water within the final void were able to exit the void via unconsolidated sediments (i.e. the base of Tertiary) and flow via the groundwater system towards sensitive environmental receptors such as Springton Creek. For this reason, an assessment of the potential for water within the final voids to exit the void via the base of Tertiary sediments has been undertaken as follows:

- Contours for the base of Tertiary sediments was obtained for the area of Mine A and Mine B from the site geological model.
- The final void water level was obtained for each of the final voids from the surface water assessment report WRM (Appendix E, 2020) and was assessed for:
    - the maximum final void water level for the Base Case; and
    - the maximum final void water level for the High Inflow Case.

The data for each mining area was assessed to establish whether any pathways existed for water to exit the final void via the base of Tertiary sediments, for the maximum Base Case and maximum High Inflow Case final void water levels.

Based on the assessment described above it was concluded that there is no outlet via the base of Tertiary for water within the final void of either the Mine A or Mine B, for either the maximum Base Case water level or the maximum High Inflow Case water level. It is therefore concluded that there is a low risk of the Project impacting on groundwater quality.

The modelled drawdown extent at the end of mining is shown in Figure 53 and at post-mining equilibrium (i.e., steady-state post-mining drawdown) in Figure 54.

At the end of mining, the 5 m drawdown extent is approximately 2 km from Mine B and 1.8 km from Mine A, on the western side of the mining areas. On the eastern side, the 5 m extent is approximately 2 km from both Mine B and Mine A. The 5 m extent of drawdown is approximately 1 km from Mine A at the southern end of the mining area, and approximately 2 km from Mine B at the northern end. The 2 m drawdown contour extends approximately 1 km further than the 5 m drawdown extent.

The 2 m drawdown is located at a vertical depth of approximately 50 to 60 m below the base a potential GDE. However, due to the depth of the drawdown and the GDE being supported by a perched aquifer, the modelled drawdown poses a very low risk of impacting groundwater levels beneath the potential GDE. While the risk is considered low, any damage to the GDE will be evident through compliance monitoring bores (Figure 55).

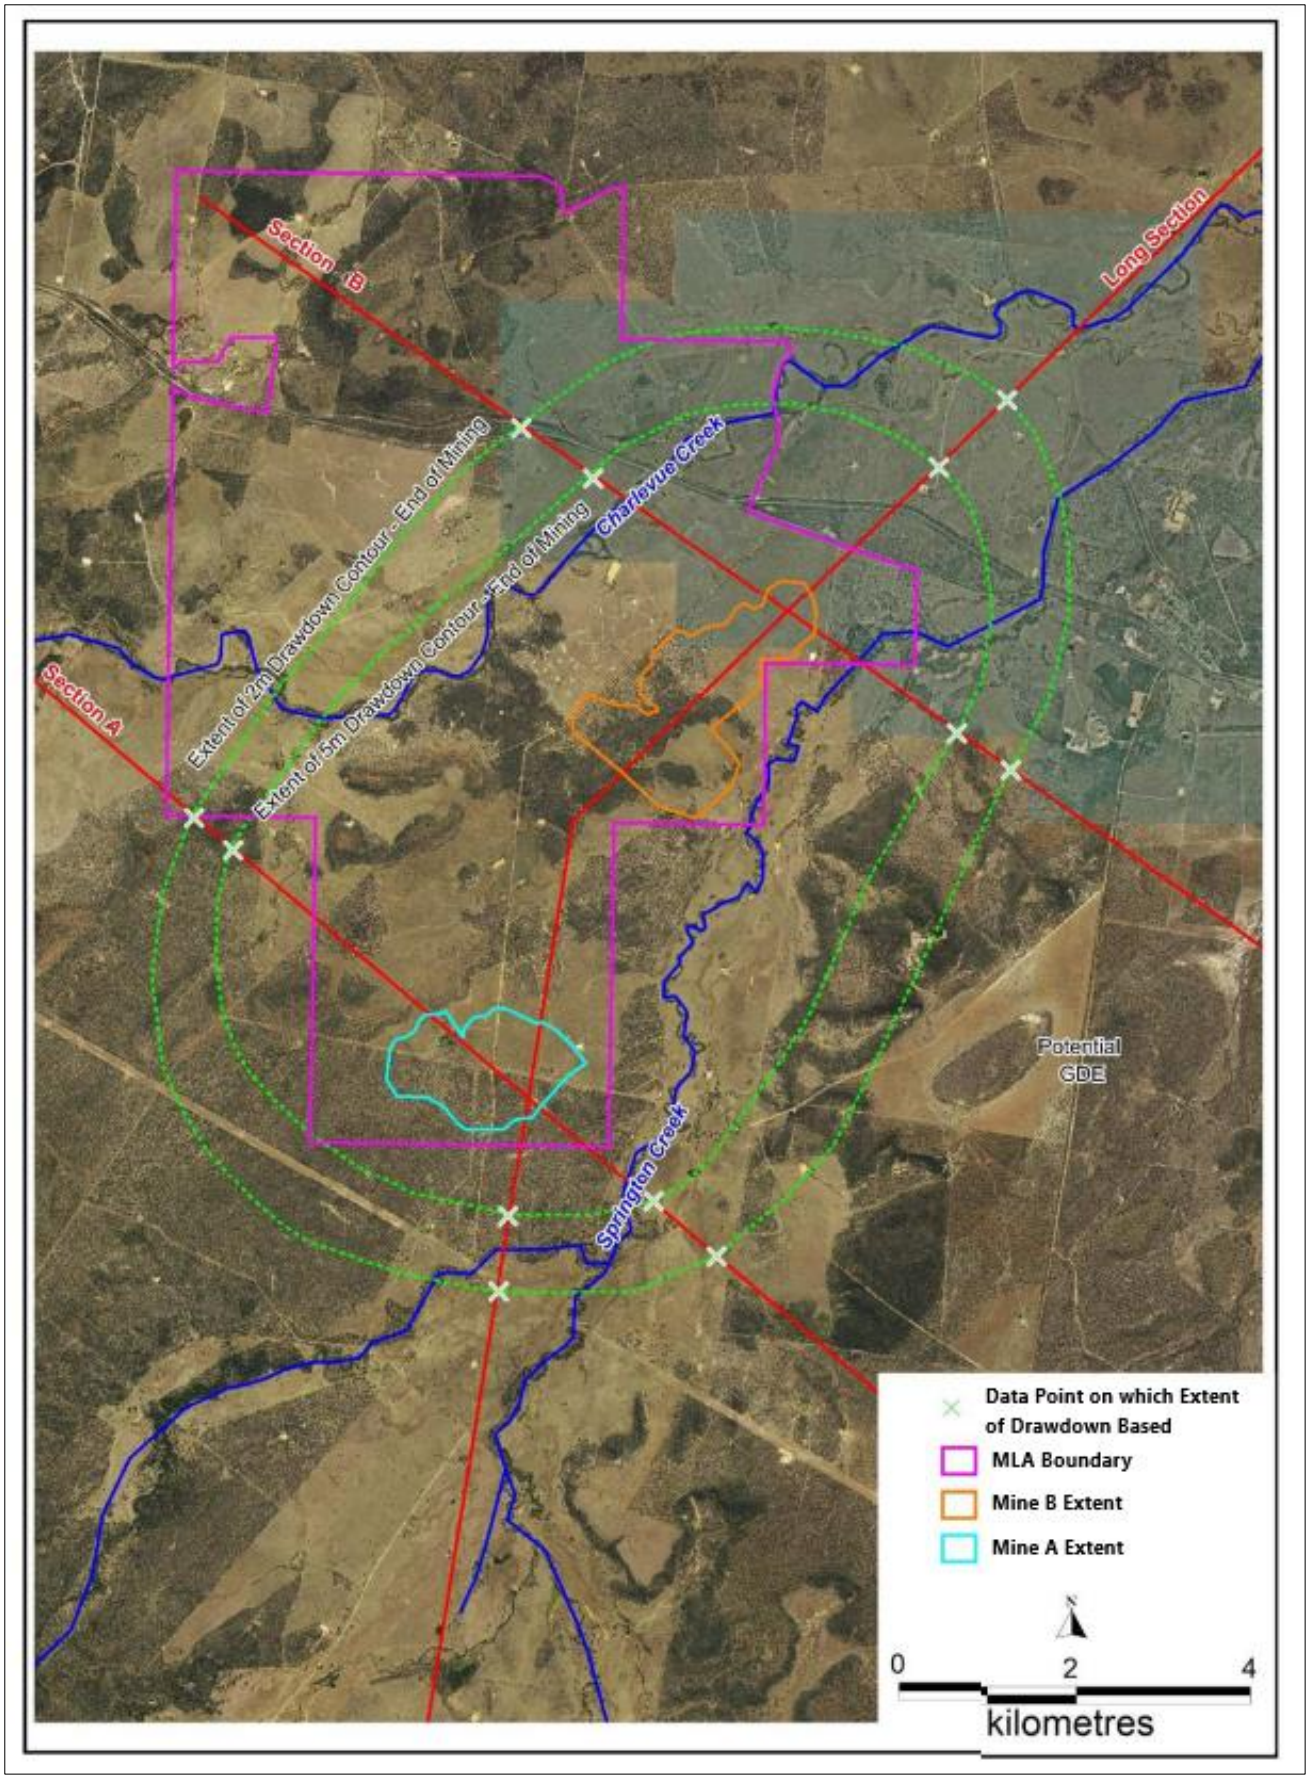

Figure 53: Drawdown at end of mining

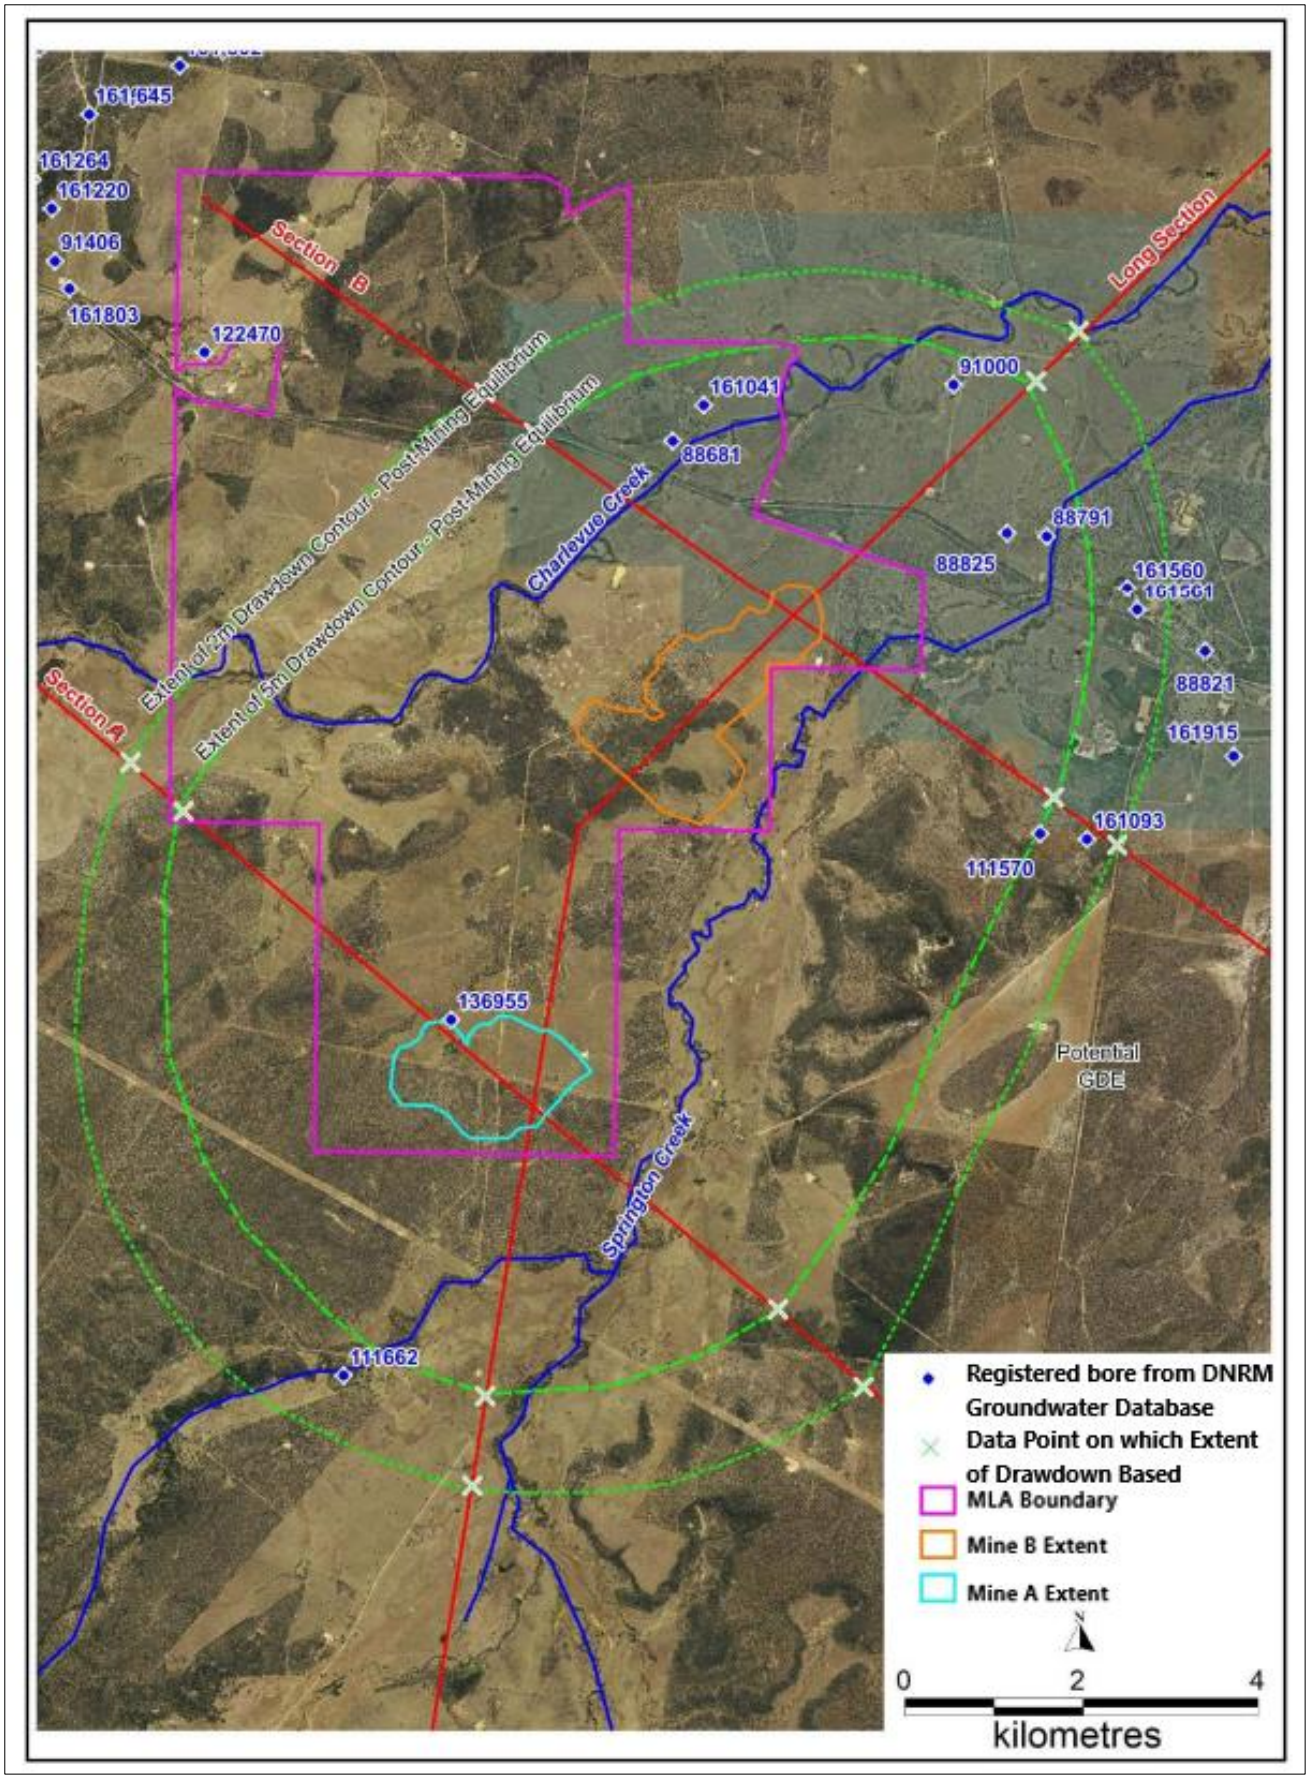

Figure 54: Drawdown Post-mining equilibrium

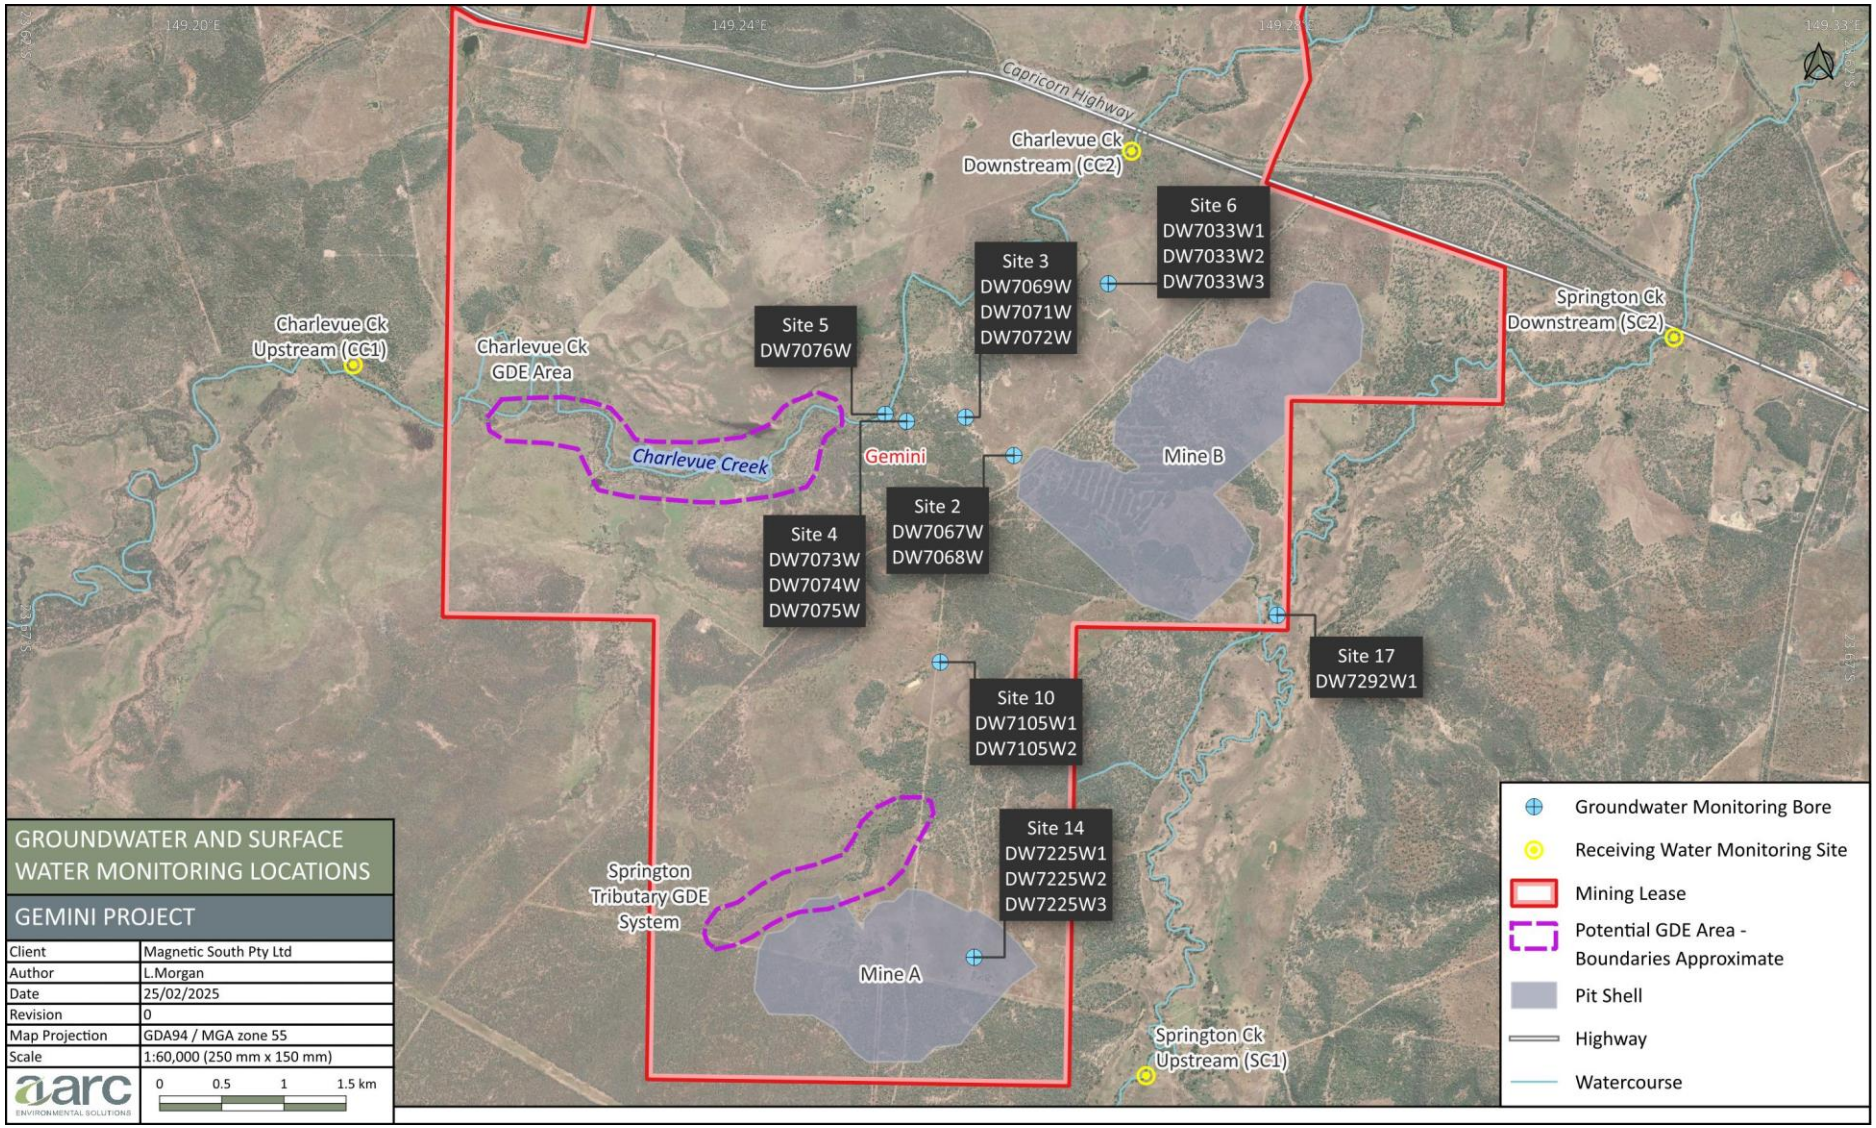

Figure 55: Groundwater and surface water monitoring locations

3.5.7.6 Flooding

Flood modelling (Appendix E, WRM 2020) was undertaken as part of the Gemini EA application and was updated to ARR 2019 for the Gemini PRCP (Appendix M) to assess the flood risks associated with the Gemini Project final landform. The XP-RAFTS flood model was used to estimate design discharges for the 50%, 10%, 2%, 1% and 0.1% AEP as well as the probable maximum flood (PMF) design discharge using an ensemble of design temporal patterns. In the absence of gauged streamflow data, the resulting peak discharges were validated against the Rational Method and Regional Flood Frequency Estimation (RFFE) estimates.

The XP-RAFTS modelling was then adopted as inflows to the TUFLOW hydraulic model to estimate flood extents and depths along the channel and floodplain of Charlevue Creek and Springton Creek for the nominated design events (Figure 56).

The final voids will be located and designed such that it is not inundated by flooding in the 0.1% AEP flood event. A flood protection bund to the east of the Mine B final void is required to ensure that the void is not inundated by flooding during a probable maximum flood event.

There are four locations where (based on the flood model results) floodwaters could potentially come into contact with the overburden dumps:

1) The north-eastern end of Mine A; due to flow backing up to the west of the haul road crossing of the engineered drainage feature. Modelled flow velocities in this area are less than 0.4 m/s in the 0.1% AEP design flood and would, therefore, not cause the migration of sediment from the final landform.

2) The western side of Mine B; due to water backing up a minor tributary of Charlevue Creek. Flow velocities in this area are expected to be less than 0.2 m/s, and therefore the likelihood of migration of sediment from these dumps is minimal.

3) The eastern side of Mine B; due to flow on the left (western) floodplain of Springton Creek. Flow velocities against the final landform are modelled to be less than 1.2 m/s in the 0.1% AEP flood, and therefore the likelihood of erosion of the dump toe is minimal.

4) The southern side of Mine B; due to water overflowing from the unnamed tributary of Springton Creek upstream of the inlet to the engineered drainage feature. During operations, this section of the dump would be protected by a temporary levee, which would be incorporated into the final landform profile on closure. In events up to the 0.1% AEP design flood, modelled flow velocities are less than 1 m/s along most of the length of the proposed levee. Such flows would be non-erosive – and especially given the relatively short flow durations in this small catchment, the risk of sediment migration in floodwaters would be minimal. During the detailed design of the engineered drainage feature, provisions will be made to ensure that flows will be non-erosive along the final landform post-closure.

A flood protection bund approximately 600 m long and 1 m high will be installed along the eastern edge of Mine B to prevent inundation and will be rehabilitated in accordance with MM2 of IA1 (see Table 37). A graphical representation of the post-closure predicted flood extent and flood velocity are provided in Figure 57 and Figure 58, respectively.

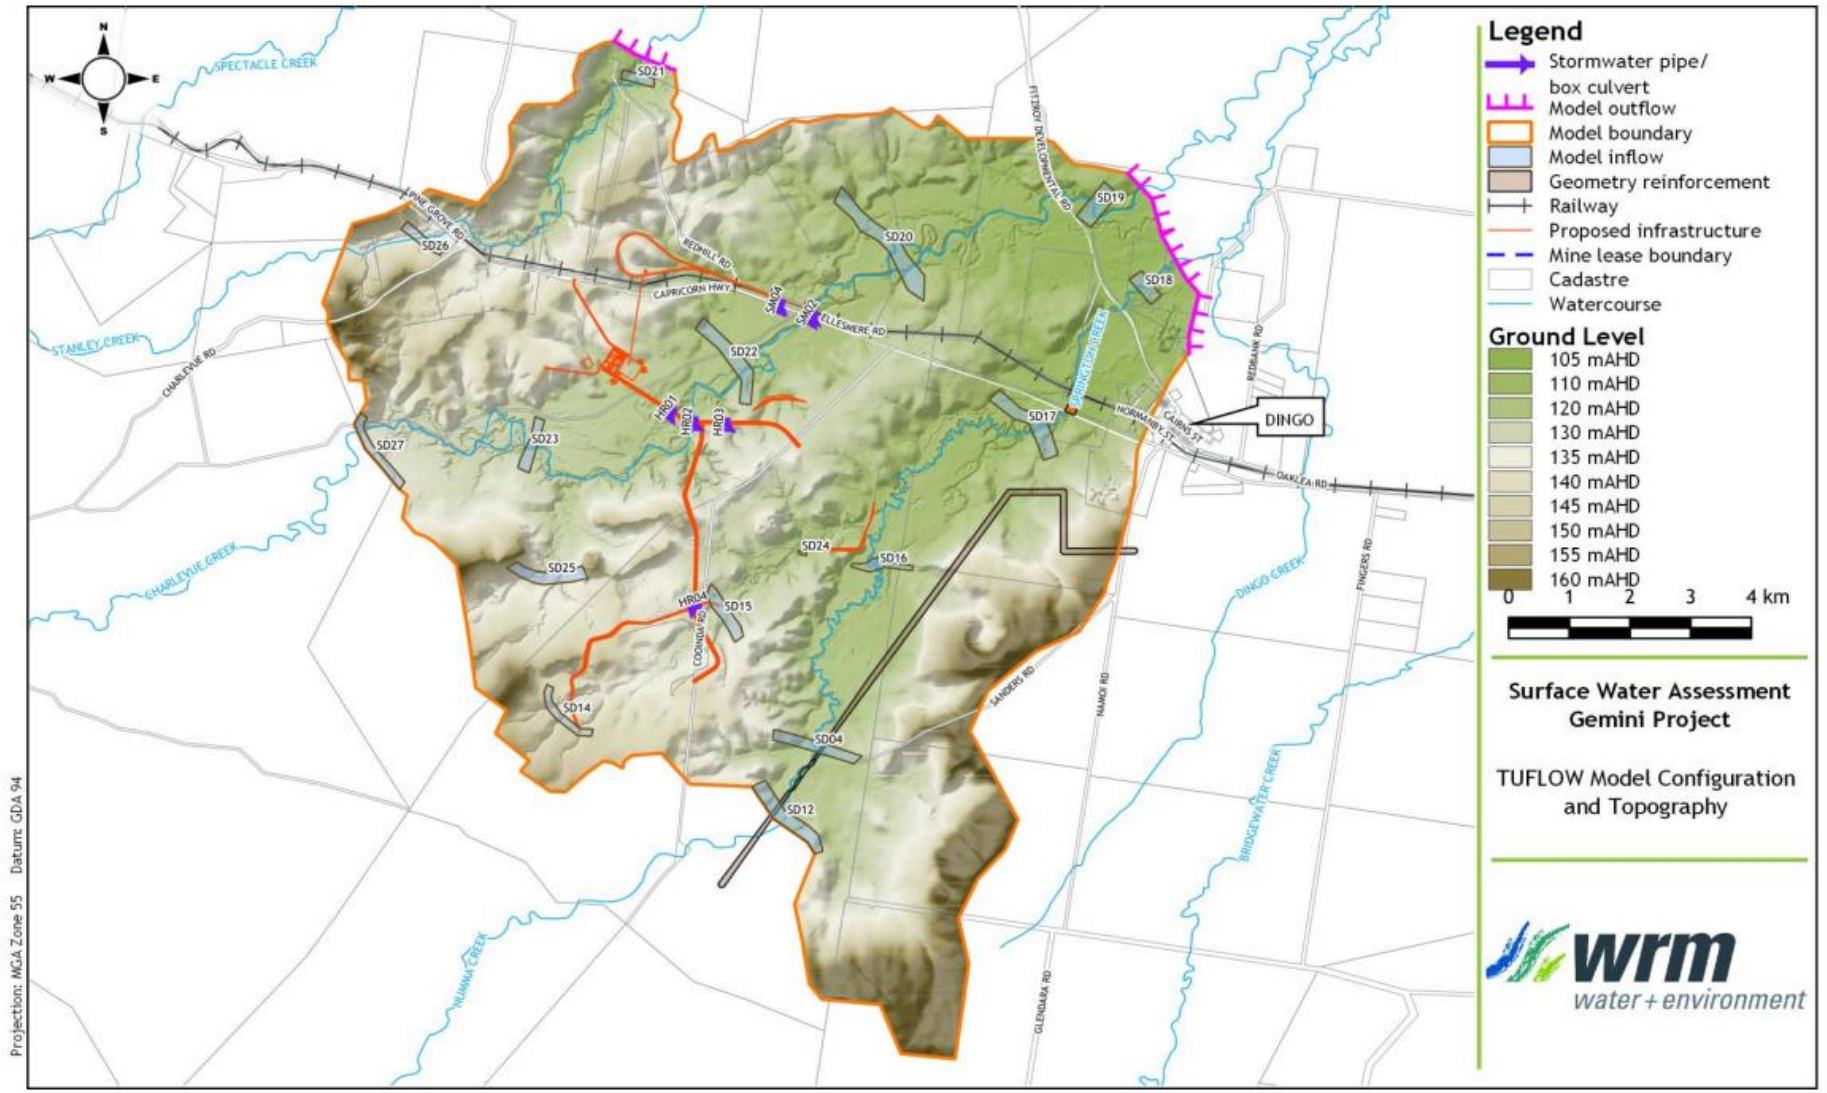

Figure 56: TUFLOW model configuration

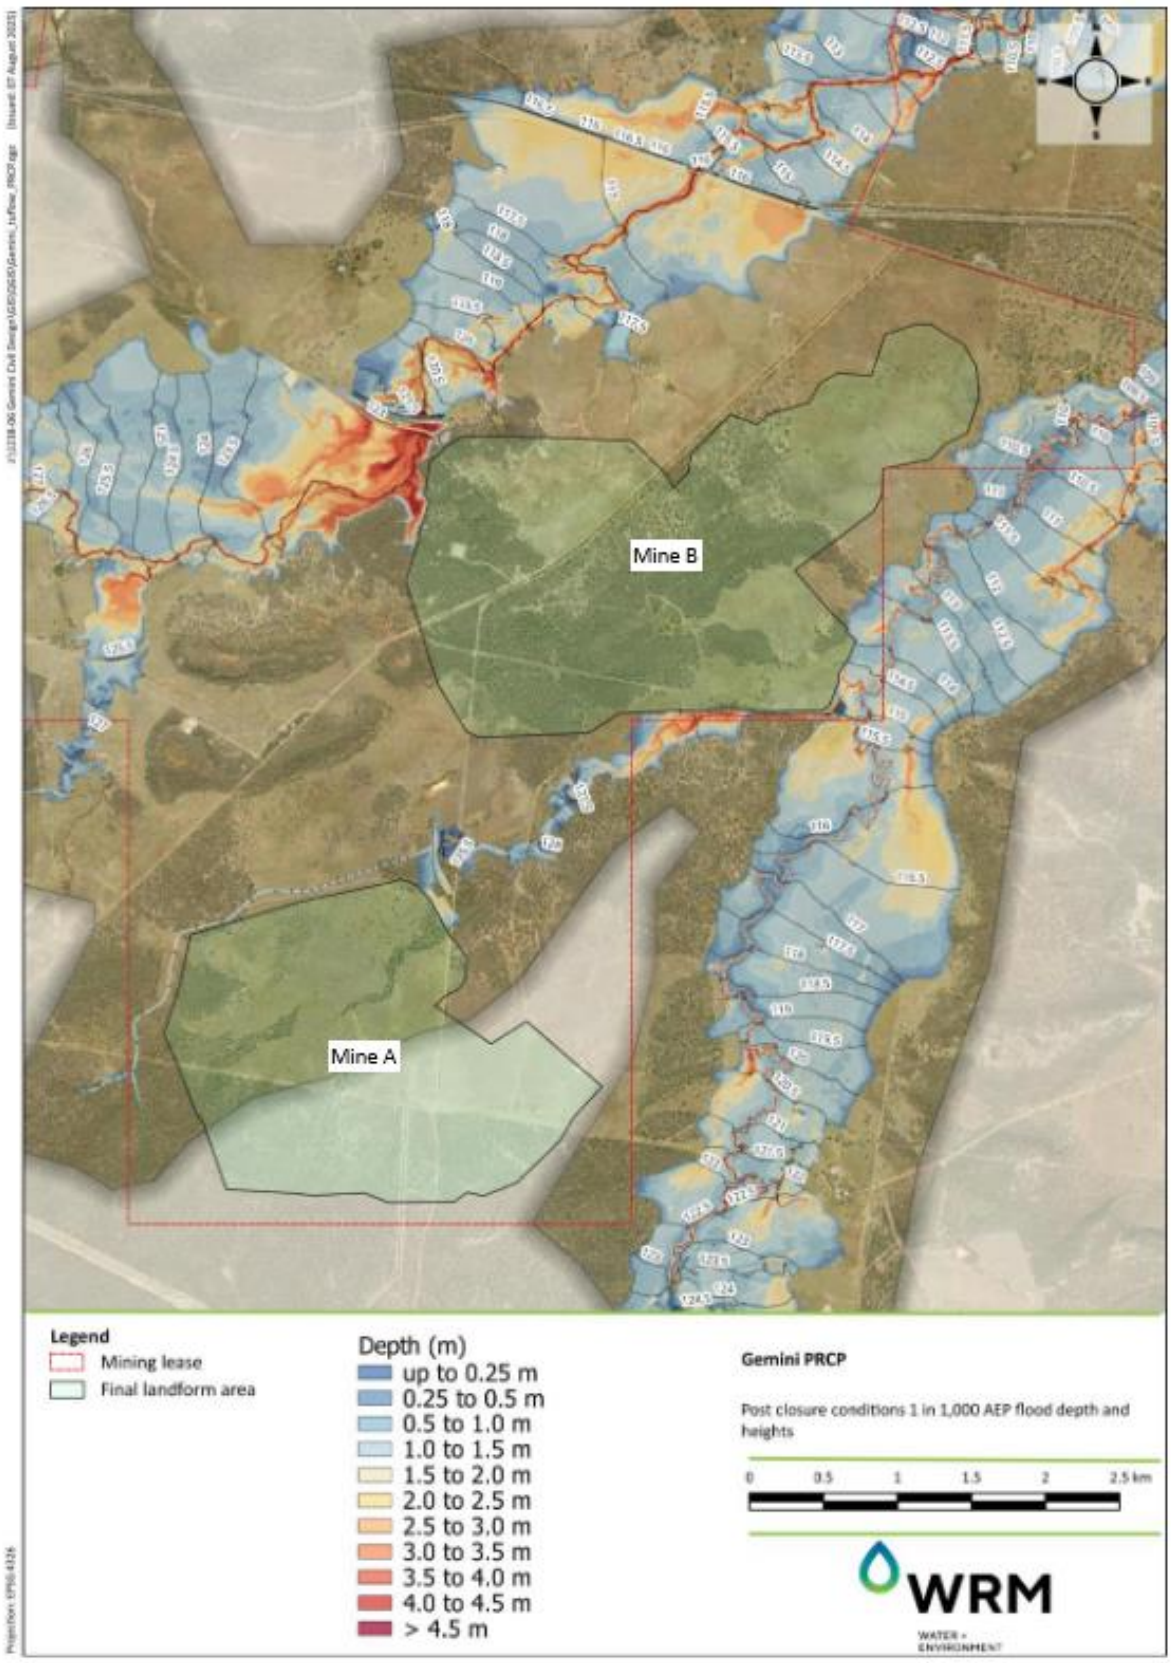

Figure 57: Post closure predicted flood extents and depths (0.1% AEP)

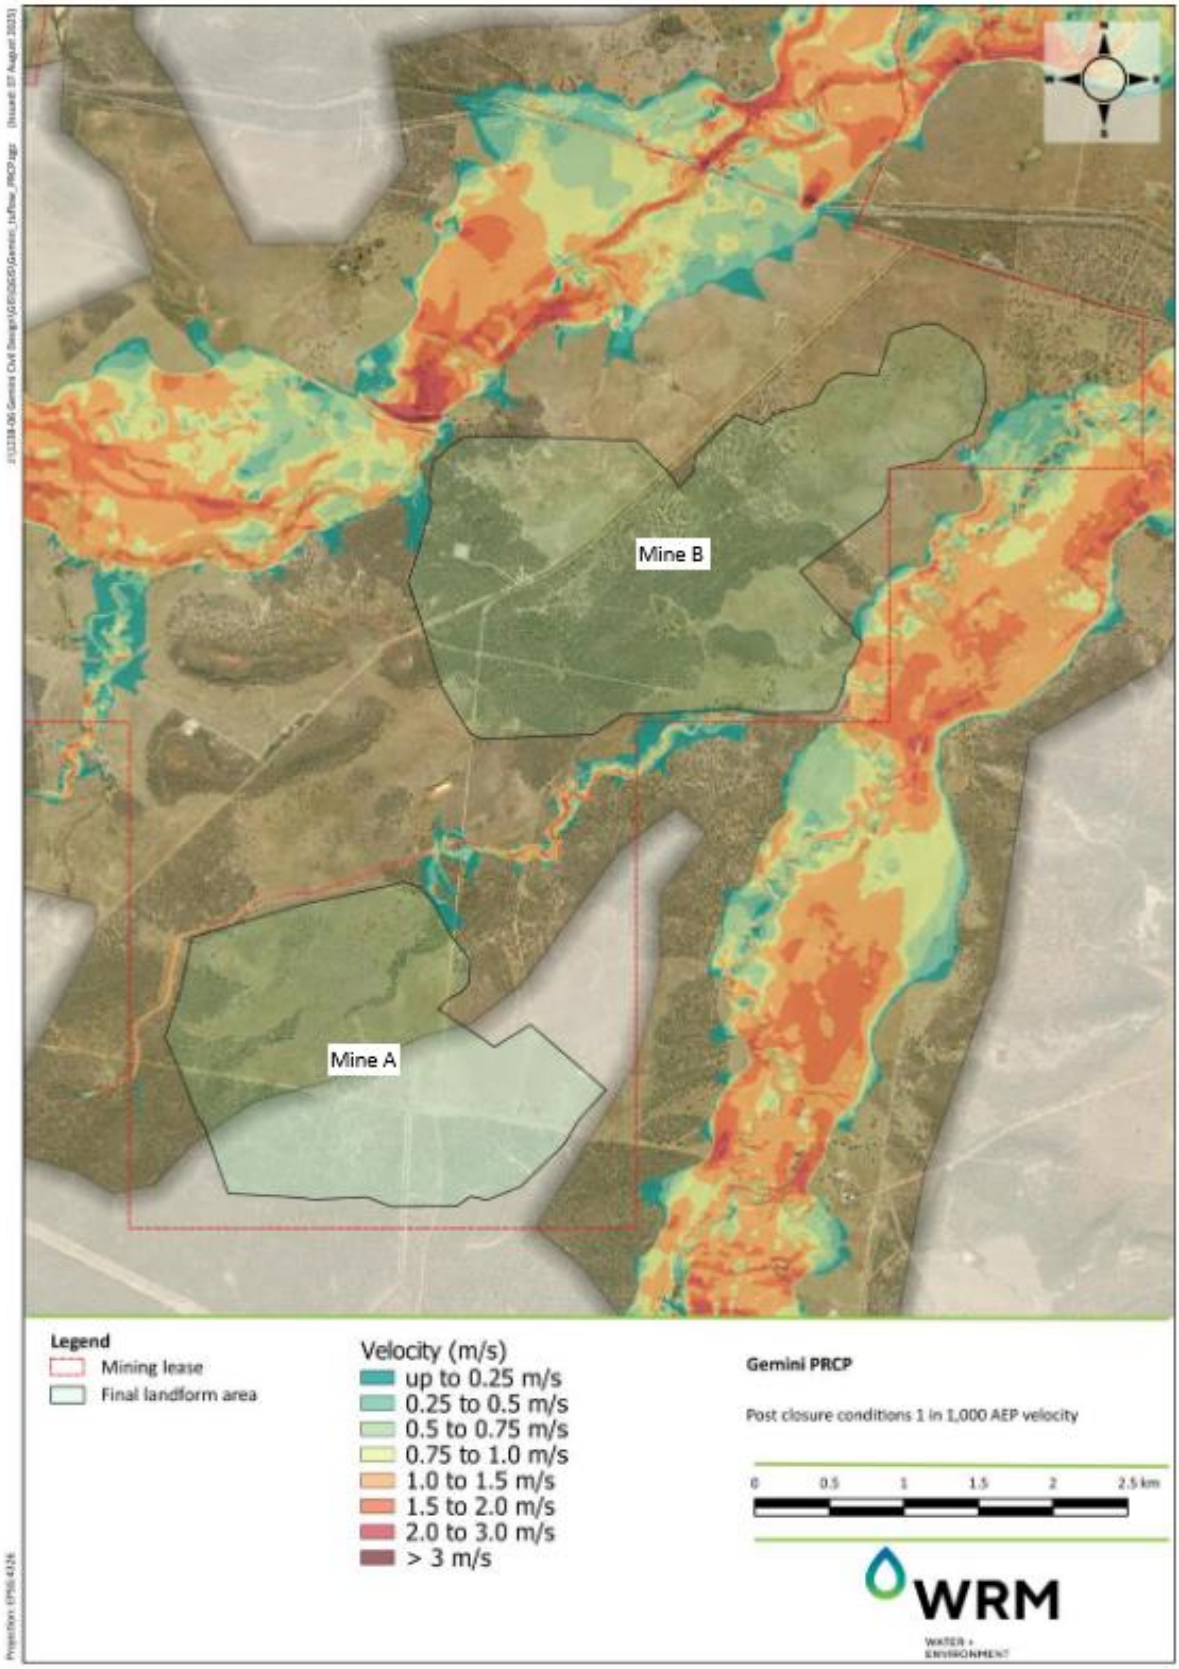

Figure 58: Post closure predicted flood velocity 0.1% AEP

3.5.7.7 Final void study

A GOLDSIM model (separate to the OPSIM model used for the operational modelling) was used to assess the likely long-term behaviour of the final void pit lakes. The historical rainfall and evaporation sequences were repeated 5 times to create a long-term climate record for use in the model. The potential effects of climate change were assessed using climate-change-adjusted SILO climate data developed as part of the Consistent Climate Scenarios (CCS) project by the Queensland Government.

Key water inputs for the final void balance include rainfall on pit lake water surfaces, runoff from pit faces and rehabilitated upstream catchment areas, and groundwater interception. Depending on the configuration of the waste rock dump, rainfall may also infiltrate through in pit waste rock. Groundwater investigations by JBT (Appendix E, JBT 2019) Consulting indicate that due to partial backfilling of the voids, groundwater inflows to the final voids are expected to be negligible.

Sources of salt include salts dissolved in groundwater and catchment runoff. In the absence of any seepage or surface outflows to the environment, there is generally no removal of salt from the system, and thus, salts are expected to accumulate over time. The Gemini Project voids are to be partially backfilled to prevent the interchange of water between the coal seams and the lakes – resulting in lower water levels and salinities than would otherwise be the case. These lower salinities are considered suitable for the establishment of native habitat conditions for the void.

Final voids were modelled to remain as a groundwater sink and do not present a risk of overtopping. The maximum modelled water level for Mine B is 57.6 mAHD, which is approximately 54 m below the void overflow level/natural surface elevation (112 mAHD). Similarly, the maximum modelled water level for Mine A is around 73.5 mAHD, which is 54.4 m below the void surface overflow level/natural surface elevation of approximately 128 mAHD. Modelled water levels in the voids are presented in Table 46.

Table 46: Final void pit lake modelled levels

Water Level	Mine A (mAHD)	Mine B (mAHD)
Long term equilibrium water levels	70.3	52.9
Maximum long-term water levels	73.5	57.6
Minimum long-term water levels	66.0	47.4
Overflow level at natural surface	128.0	112.0

Modelling of long-term water levels in the final void under existing (SILO) climate change scenarios indicates that equilibrium water level is lower than the existing climate scenario (refer Figure 59 and Figure 60).

Figure 61 and Figure 62 show the results of the salt balance. Salt accumulates within both voids over time. Under the existing climate conditions scenario, the void lake salinity exceeds a TDS of 30,000 mg/L after approximately 500 years of simulation. During the first 200 years, apart from short periods when inflows are very low, and salt concentrations temporarily increase rapidly due to evaporation, lake salinities are predicted to be less than 10,000 mg/L.

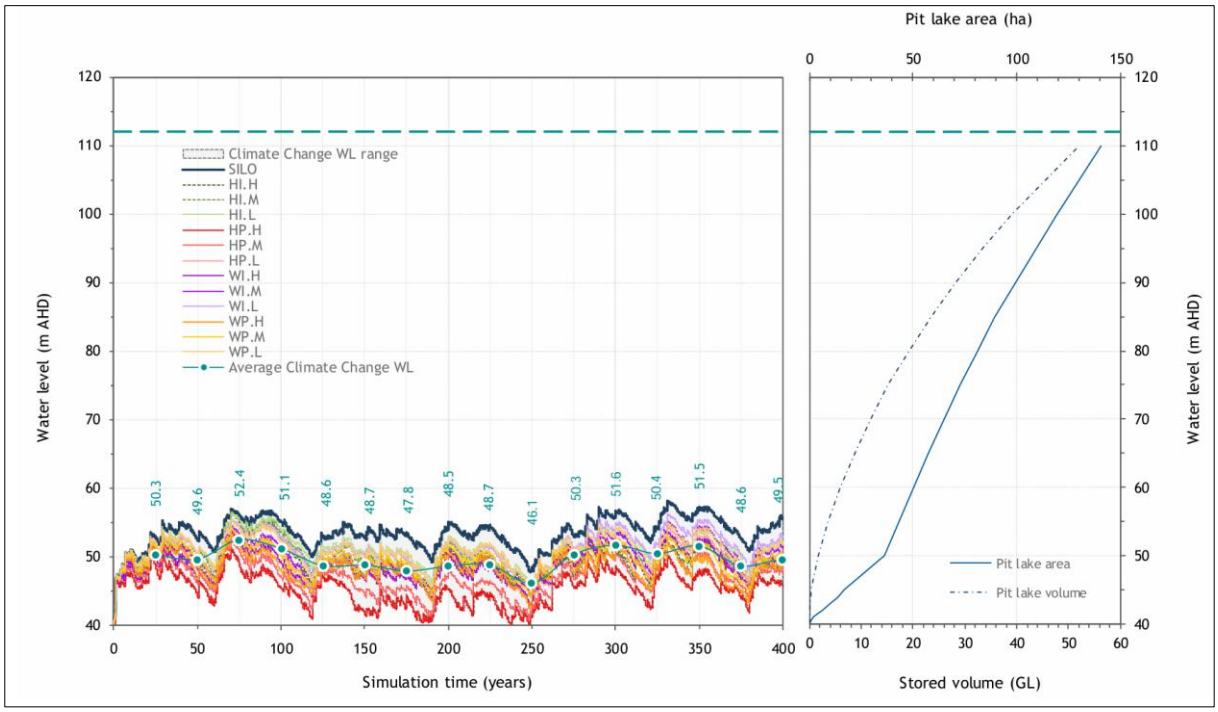

Figure 60: B Void post mining water level

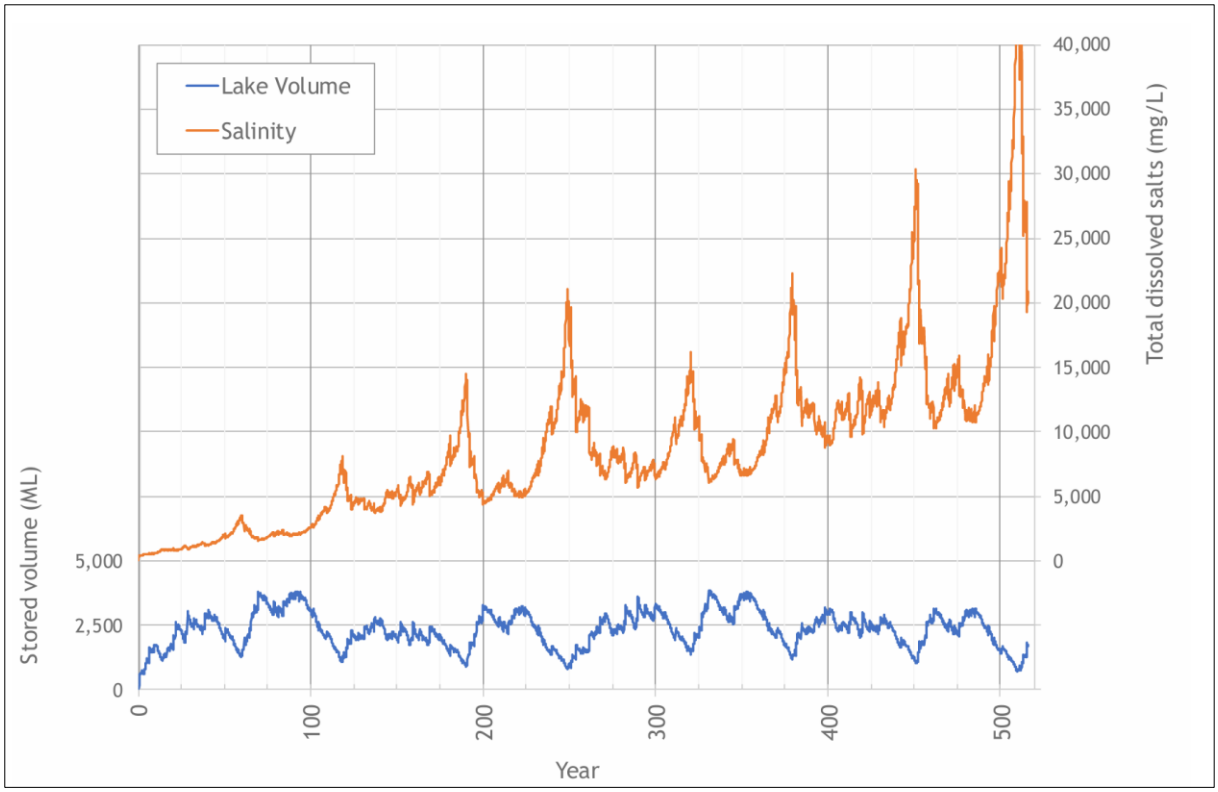

Figure 61: A Void post mining salinity

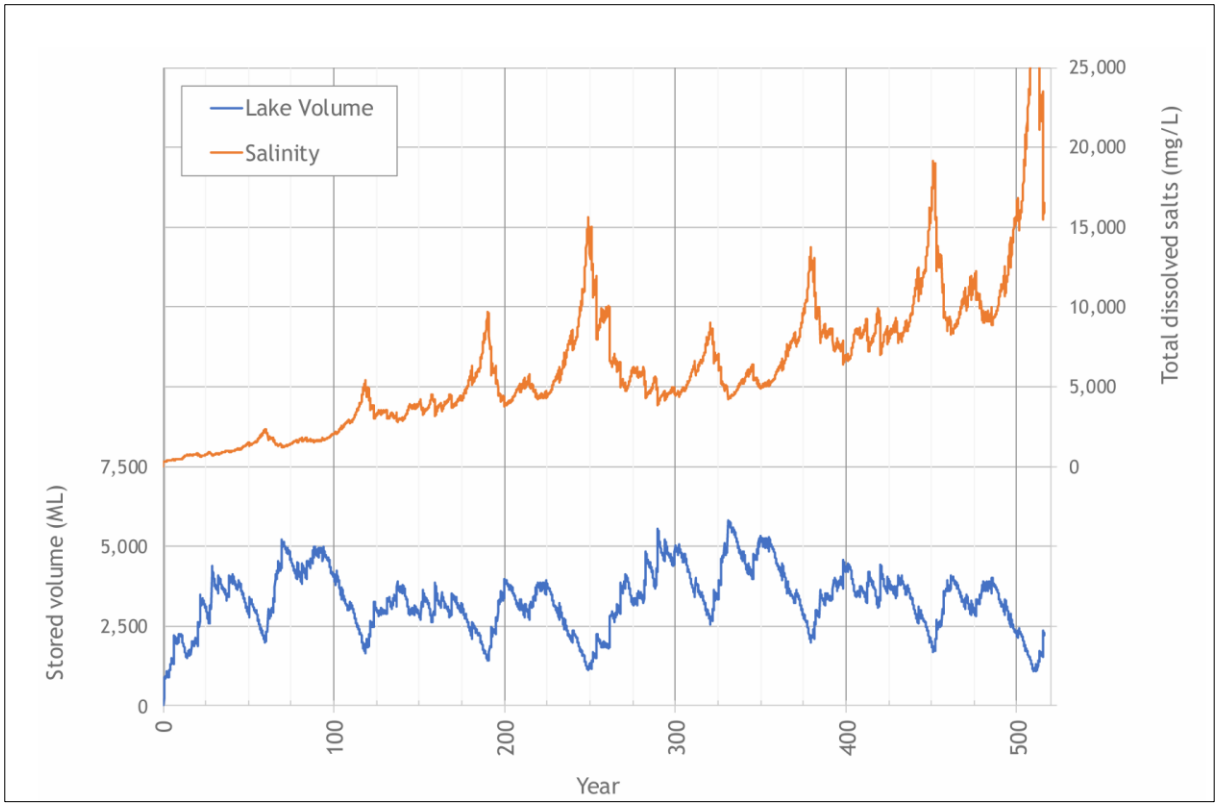

Figure 62: B Void post mining salinity

3.5.7.8 Water management

Operational water management

Operational water management will be undertaken in accordance with a Site Water Management Plan. The plan will include a Site Water Management System (SWMS) developed for the Project by WRM Water and Environment Pty Ltd (Appendix E, WRM).

The SWMS for the Gemini Project is based on the following key principles:

- divert clean catchment water around mining works to the extent practicable;
- use/recycle lesser quality water in preference to higher quality water;
- use potentially contaminated water in preference to imported raw water or uncontaminated water;
- release water from site only in accordance with the conditions of the EA, such that the released water will not significantly impact on the values of the receiving waters or downstream properties;
- manage water storages and transfers within the site in order to:
    - maximise onsite storage to meet reasonably anticipated periods of wet and dry weather; and
    - minimise disruption to mining operations.

The proposed strategy for managing surface water at the Project is based on the separation of water from different sources based on anticipated water quality. The SWMS separates water into two segregated management systems:

- **Mine affected water (MAW) system:** manages runoff and seepage from the mine pits, CHPP, coal stockpiles, and MIA. This is a closed system designed to prevent releases of MAW to the environment.
- **Sediment water system:** runoff from overburden dumps will be managed under an *Erosion and Sediment Control Plan* (ESCP) which is to be implemented throughout the Project, such that sediment generated and transported by runoff will be settled in a sediment dam. As overburden runoff quality is expected to be relatively benign (refer Appendix E, RGS 2020) the sediment dams will potentially discharge directly into the environment (after the settlement of suspended sediment), and as such, will not affect the mine water balance. However, the water balance assessment has assumed sediment dams will be pumped back to the CHPP for reuse.

Clean water flows from undisturbed areas are generally diverted around the areas of disturbance. A raw water supply pipeline is proposed to supply all site water requirements prior to dam construction, and supplement site water supplies throughout the life of the Project. Raw water will be delivered to a dedicated raw water dam (located adjacent to the MIA), which will also intercept clean water from its local upstream catchment.

Water management infrastructure proposed for the Project is shown in Figure 63 and includes:

- a temporary flood protection levee to protect Mine B from potential flood waters;
- a permanent flood protection bund to protect the Mine B residual void from potential flood waters during a PMF flood scenario;
- permanent clean water drains to divert runoff from undisturbed catchments around areas disturbed by mining activities;
- sediment water drains to divert water from waste rock emplacements and areas yet to be rehabilitated;
- sediment water dams to store water from waste rock emplacements and allow settlement of sediment loads before discharging treated water or recycling back to the CHPP;
- mine water drains to divert water from MIA, CHPP and coal stockpile areas into the MAW system; and

- mine water dams to store water pumped out of the pits, and collect water from the MIA, CHPP and coal stockpile areas.

All water storage dams, structures and facilities will be designed, constructed and managed in accordance with the 'Manual for assessing consequence categories and hydraulic performance of structures' (DES 2016a). The Project's water management system is designed such that any unplanned overflows from mine water dams would overtop into the pit preventing any uncontrolled releases from the MAW system to receiving waters.

Closure water management

All water storage dams will be rehabilitated to the grazing PMLU, except those structures that are to be retained for agricultural purposes as agreed with the landholder. Where dams are to be retained, water quality will be monitored against the criteria for livestock drinking water defined in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG 2018) to ensure suitability until ownership of the dam has been transferred.

The final landform design of all waste rock dumps aims to avoid concentration of water runoff. Flat benches will be maintained in waste rock slopes to reduce runoff velocities. Constructed drains and drop structures are not proposed for the final landform design. Sediment control dams and drains will remain in place to capture sediment, until rehabilitation monitoring verifies the stability of rehabilitated slopes on all dumps.

A flood levee and a flood protection bund are required for operations. The levee to the south of Mine B will be temporary, required only until the final overburden profile is achieved. The levee constructed to protect the operational pit would not be required post-mining and will be incorporated into the rehabilitated dump as it progresses during operations. The flood protection bund required on the eastern edge of the Mine B residual void will be required during operations and closure to ensure the void is not inundated by flooding during a PMF event. The bund would span a length of approximately 600 m up to a height of approximately 1 m.

The permanent diversion of an unnamed tributary of Springton Creek will be constructed in two locations to divert clean water around the final landform dumps and voids. The diversions will be constructed during operations, providing for long-term monitoring of stability and rehabilitation success during the operational mine life. The final designs will be decided as per best practice by an AQP prior to constructions to achieve:

- For Mine A drain:
    - design 1 in 50 AEP depths are up to 1.3 m, and peak velocities range between 1.0 m/s and 2.0 m/s
- For Mine B drain:
    - design 1 in 50 AEP depths are up to 3.7 m, and peak velocities range up to 2.5 m/s;

Preliminary watercourse diversion designs were provided as part of the Gemini EA application and were generally designed in accordance with the design principles set out in the guideline; *Works that interfere with water in a watercourse for a resource activity – watercourse diversions authorised under the Water Act 2000* [OSW/2019/4599] (DNRME 2019). Of note, neither of the diverted tributaries are defined as watercourses under the *Water Act 2000* (Water Act) and, therefore, are not required to be assessed against this guideline. The watercourse diversion design presented in the Gemini PRCP, and outlined in Figure 50 and Figure 51, were approved by the Department and included within Figure A1 of the Gemini EA.

The purpose of the PRCP is to plan the progressive rehabilitation of the land to a stable condition and provide for the condition to which the EA holder must rehabilitate the land before the EA may be surrendered. To this extent, the re-assessment of a watercourse diversion against design principles outlined in a guideline intended to assist with the approval to divert a watercourse, when such a diversion is already approved under the EP Act, reasonably falls outside of the scope of the PRCP.

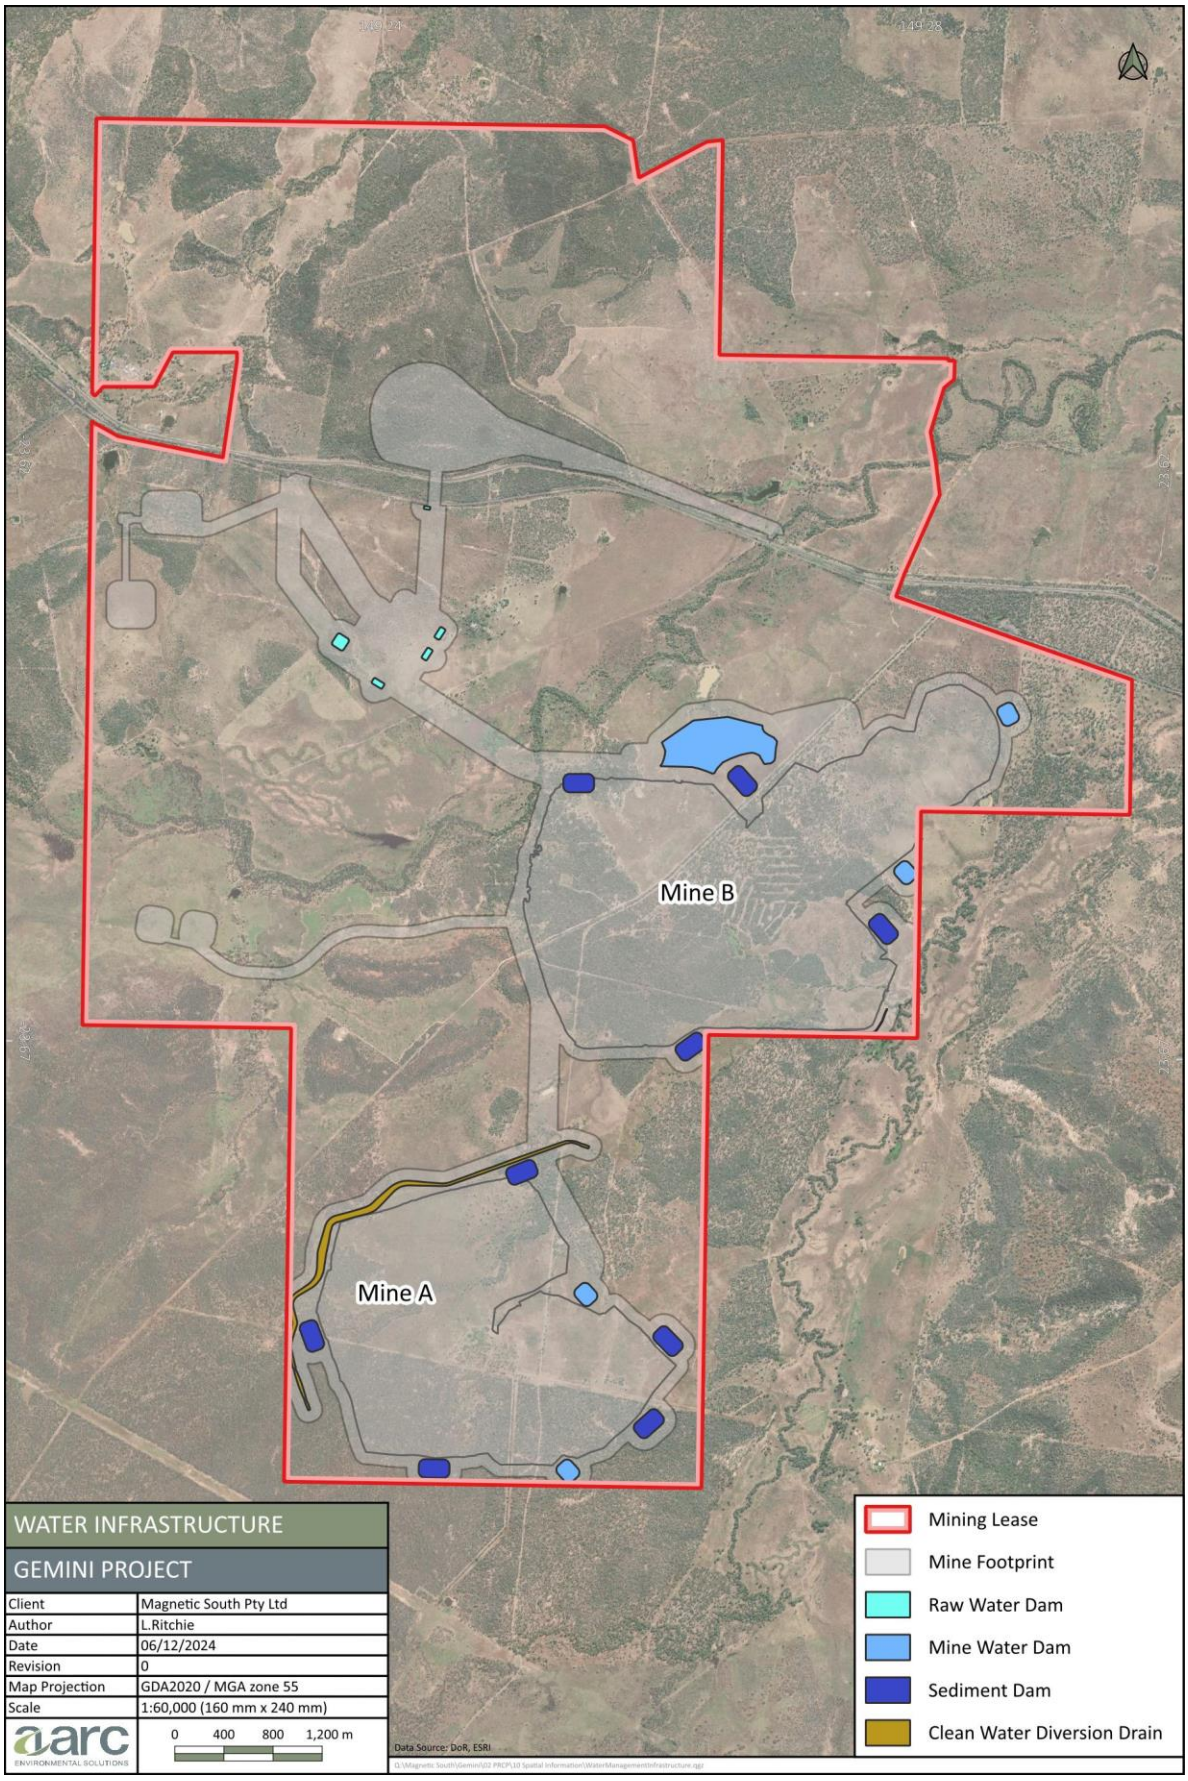

Figure 63: Water management infrastructure

3.6 Risk assessment

3.6.1 Risk assessment requirements

Section 126C(1)(f) of the EP Act requires the PRCP to identify the risks, for each PMLU, of a stable condition not being achieved and how the applicant intends to manage or minimise the risk.

The corresponding management of environmental risk was informed by both expert opinion and the Project specific technical studies detailed within this EA application.

A risk assessment has been carried out in accordance with the following standards:

- *AS/NZS ISO 31000:2018 Risk management - Guidelines*; and
- *HB203:2012 Managing environment-related risk*.

This risk assessment has informed the scope of the planning part of this PRCP, as well as the development of comprehensive rehabilitation success criteria. Where higher risks were identified for the Project, the scope of the PRCP was expanded to provide confidence in the rehabilitation methods to achieve the objectives and milestones proposed.

3.6.1.1 Built infrastructure

At the end of the Project life, all remaining infrastructure will be decommissioned and removed, with the exception of infrastructure that is subject to a future landholder retention agreement.

The CHPP, rail loop and the majority of associated buildings and equipment will be dismantled and removed upon the cessation of mining operations and rehabilitated to pasture. Roads, carparks, and hardstands will be removed, reprofiled, topsoiled and seeded.

The following components are located within the MIA footprint and will need to be decommissioned and removed, unless they are otherwise subject to a landholder retention agreement at closure:

- mine offices, bathhouse, crib rooms, warehouses and storage areas, workshops and potable water storage;
- fuel storage and refuelling facilities;
- sewage, effluent and liquid waste storage;
- tyre bay and laydown area;
- Go-line, wash bay, and other associated amenities;
- Sediment dams and water storage areas;
- ROM coal stockpile and associated infrastructure, including coal haulage loading area;
- raw water, clean water and mine water dams (discussed in section 3.5.7.8).
- substation and electricity distribution infrastructure;
- diesel backup generator;
- sewage treatment plant; and
- other associated minor ancillary infrastructure.

For any roads or additional infrastructure to be retained, a written agreement will be entered into with the underlying landowner that transfers liability for the structure and its use to the landowner.

3.6.2 Risk assessment process

Any risk assessment needs to be undertaken in consideration of the scope, context and criteria relevant to the assessment. For this risk assessment, the following scope and purpose was discussed and agreed to:

> *"The purpose of this risk assessment is to identify and analyse any risks arising because of the Project that may impact on environmental aspects, including socioeconomic aspects; at the local, regional and state levels and across the construction, operational and closure stages of the Project."*

For this risk assessment, risk scenarios (or 'threats') were identified and considered for each rehabilitation area associated with the Project. The causes attributable to each risk scenario were documented as well as the potential impacts. Existing controls were noted, defined as those reasonably expected to be in place for a Project of this nature and having appropriate and contemporary management systems. Each risk scenario was then assessed with respect to health, safety, the environment and compliance against the risk assessment schema outlined in section 3.6.3.

3.6.3 Risk assessment scheme

Risks specific to the rehabilitation of the Gemini Project were classified using the risk classification schema, which is described below. The risk assessment schema used is comparable to those used widely within the mining industry and comprises the following components:

- a control effectiveness ranking (Table 47) used for assessing the operational controls expected to be in place for a project of this type;
- a likelihood classification descriptor (Table 48) and;
- a consequence classification descriptors table (Table 49) intended to guide a consistent assessment of consequences.

Following a consensus determination of likelihood and consequence, the risk level was determined using the matrix shown in Table 50. For any risks classified as 'significant' or above, mitigation and management measures were identified and documented. Mitigation and management measures were also documented for lower-level risk components.

Table 47: Control effectiveness ranking

Control Rank	Description	Guidance
C1	Substantially effective/adequate design	Controls considered adequate and operating effectively on almost all occasions
C2	Mostly effective/adequate design	Controls considered adequate and operating effectively on most occasions
C3	Inadequate design/partially effective	Controls considered inadequate or only operating to partial effectiveness on most occasions
C4	No controls/ineffective	There are no controls, or the existing controls are operating ineffectively on all occasions

Table 48: Likelihood of Exposure to the hazard

Likelihood	Description	Probability	Frequency
Highly Likely	The event is expected to occur in most circumstances	> 25%	The event and consequence is expected to occur at least twice per year
Likely	The event will probably occur in most circumstances	10%–25%	The event and consequence is expected to occur once to twice per year
Possible	The event could occur at some time	1%–10%	The event and consequence is expected to occur at least once in 1 to 10 years
Unlikely	Not expected but the event may occur at some time in the future	0.1%–1%	The event and consequence is expected to occur at least once in 10 to 100 years
Rare	The event may occur only in exceptional circumstances	< 0.1%	The event and consequence is expected to occur less than once in every 100 years

Table 49: Severity and consequence classification

Severity level	Consequence				
	Very Low	Low	Moderate	High	Very High
Human Health and Safety	No treatment of first aid	Reversible impairment requiring medical treatment (medical treatment injury)	Significant reversible impairment to one or more persons (lost time injury, disabling injury)	Single fatality, significant irreversible impairment to a person	Multiple fatalities, significant irreversible impairment to multiple persons
Natural Environment	Negligible/minor effects on biological or physical environment	Moderate, short-term effects but not affecting ecosystem functions	Serious medium-term environmental effects	Very serious, long-term environmental impairment of ecosystem functions	Very severe, long-term environmental impairment of ecosystem functions
Community/ Cultural Heritage	Minor medium-term social impacts on local population. Mostly repairable	Ongoing social issues. Permanent damage to items of cultural significance	Ongoing serious social issues. Significant damage to structures/items of cultural significance	Ongoing severe social issues. Significant damage to structures/items of cultural significance	N/A

Table 50: Risk level classification matrix

Likelihood	Consequence				
	Very low	**Low**	**Moderate**	**High**	**Very High**
Almost Certain	Class II	Class III	Class IV	Class IV	Class IV
Likely	Class II	Class III	Class III	Class IV	Class IV
Possible	Class I	Class II	Class III	Class IV	Class IV
Unlikely	Class I	Class I	Class II	Class III	Class IV
Rare	Class I	Class I	Class II	Class III	Class III

3.6.4 Risk assessment outcomes and management

In total, 84 risk scenarios or hazards have been identified across the ten Rehabilitation areas and one Improvement area. These have been assessed against the risk assessment framework. Of the 84 risk scenarios assessed, 14 were classified as 'moderate', 43 were classed as 'low' and the remainder as 'very low'.

The risk assessment outcomes for each rehabilitation area are detailed in Table 51 below. The detailed risk assessment outcomes are included in Appendix F.

Table 51: Summary of risk assessment outcomes by rehabilitation or improvement area

Rehabilitation/Improvement area	Risk Classification					
	Very low	**Low**	**Moderate**	**High**	**Very High**	**Total**
In-pit and out-of-pit waste emplacements, including dry rejects disposal areas	3	8	0	0	0	11
Temporary waste emplacements	5	6	0	0	0	11
Residual void lakes	2	2	4	0	0	8
Residual void high walls	0	3	7	0	0	10
Residual void low walls	2	8	0	0	0	10
Water management infrastructure Rehabilitated dams	6	2	0	0	0	8
Retained dams	4	1	0	0	0	5
Diversion drains	1	4	3	0	0	8
Mine infrastructure areas	3	6	0	0	0	9
Retained infrastructure	1	3	0	0	0	4
Total	**27**	**43**	**14**	**0**	**0**	**84**

The risk scenarios identified as 'moderate' risk were associated with the residual void lake, residual void high walls and diversion drains. Erosional and geotechnical stability risks were identified with respect to the residual void lake and high walls as well as the retained drainage diversion.

- Residual void lake –
    - Class III (Moderate) risk classification: applied to four (4) risk scenarios in association with the erosional and geotechnical stability of the high walls at or below the lake water level
- Residual void high walls –
    - Class III (Moderate) risk classification: applied to seven (7) risk scenarios in association with the erosional and geotechnical stability of high walls
- Diversion drains –
    - Class III (Moderate) risk classification: applied to three (3) risk scenarios relating to the geotechnical and erosional stability of the diversion drains.

Any identified Class III risks were then reassessed to identify if additional controls could be introduced to lower the risk ranking. For the most part, Class III risks could be re-ranked to Class II through ongoing monitoring and maintenance of rehabilitation areas. Class III risks relating to the high wall and residual void high wall sections remain as Class III risks due to physical rehabilitation limitations.

3.7 Monitoring and maintenance

Rehabilitation monitoring for the Project aims to assess the rehabilitation objectives and agreed completion criteria. Monitoring data will be used to track the progress of revegetated areas and determine requirements for intervention, such as weed control or supplementary planting. Additionally, rehabilitation monitoring will specifically aim to:

- evaluate coverage and application of topsoil prior to seeding;
- monitor drains and assess water quality to determine whether substantial silting of inverts and/or any localised failure of drain embankments has occurred;
- evaluate topsoiled areas following rainfall events (particularly on slopes) to assess whether significant rill development or loss of topsoil has occurred;
- evaluate the behaviour of placed topsoil over time (erosion or dispersion, compaction, salting or hard setting);
- assess the germination success in revegetated areas (including recording of diversity and abundance);
- monitor revegetation success over time (e.g., survival rate, plant growth, species diversity, weed content, fauna usage);
- evaluate potential threats to rehabilitated areas (e.g., weed invasion, pest species, dispersive soils or potentially acid forming (PAF) low-capacity materials, erosion); and
- record key rehabilitation information (e.g., photographic records, surveys, file notations).

Rehabilitation will be monitored on an annual basis, with the survey period occurring post-wet season, as monitoring at this time allows for more accurate identification of the species present and a clearer understanding of species richness on-site. Where sufficient data is acquired that demonstrates that rehabilitation is clearly on a trajectory to achieve milestone criteria, the frequency of monitoring may be reviewed.

Rehabilitation transects will generally be monitored for a minimum of five years or longer until the rehabilitation area has achieved the final milestone criteria. The results will then be used to continually inform and assess the effectiveness of rehabilitation strategies and methodologies and enable movement towards progressive certification. Where new monitoring techniques and technologies are identified, these will be adopted as appropriate.

To monitor the success of progressive rehabilitation, permanently marked transects will be established. The following methods will be employed at each monitoring site:

- permanent vegetation monitoring transects (monitoring of tree and shrub canopy cover, ground cover and species richness);
- photographic monitoring;
- erosion monitoring; and
- topsoil characterisation (upon commencement of monitoring and every 5 years thereafter).

The rehabilitation monitoring program aims to achieve data collection at sufficient spatial and temporal resolution to ensure statistically valid results.

3.7.1 Monitoring methodology

A transect-based approach consistent with the Queensland Biodiversity and Ecology Information System (QBEIS) methods outlined in the *Methodology for Survey and Mapping of Regional Ecosystems and Vegetation Communities in Queensland* (Neldner et al. 2025) will be utilised for rehabilitation monitoring. This approach aims to provide a measure of the capacity of a terrestrial ecosystem to maintain biodiversity values at a local or property scale and allows a comparative assessment of pre- and post-mining ecosystems.

QBEIS monitoring assesses a suite of parameters at different landscape positions on each site, namely on flats, slopes and troughs. Repeated edaphic (soil properties) and biological measurements are taken over time for various parameters that indicate changes in ecosystem function as rehabilitation proceeds. In general, the method involves monitoring two groups of sites:

- **analogue / reference sites:** selected to best reflect the pre-mining land use (i.e., cleared pasture for cattle grazing) as recommended by an AQP and will aim to obtain relevant and realistic rehabilitation criteria as close as the matching PMLU. Analogue sites will be chosen as close as possible to the rehabilitated area so that the same climatic and environmental conditions exist at both sites to the extent possible; and
- **rehabilitated sites:** monitored for rehabilitation performance, successful or otherwise.

Multiple analogue/reference sites will be established on and around the Project that best represent the pre-mining ecosystems. For the Project, reference sites will represent the pre-mining condition relevant to the nominated PMLU and reference transects will be established before the commencement of rehabilitation monitoring at the Project. In general, reference sites will be representative of low-intensity grazing areas comprising improved pastures. Native ecosystems will not have reference sites and will be scored against the modified QBEIS scores described in section 3.7.1.1.

Structured, periodic monitoring of reference sites will provide an understanding of the pre-mining landscape, assisting in the future planning and refinement of rehabilitation strategies relevant to site specific, as well as providing data for the determination of completion criteria when assessing rehabilitation success.

The frequency and timing of monitoring of reference sites will coincide with the monitoring of rehabilitation areas. Monitoring will occur annually, with the survey period occurring post-wet season, to align with rehabilitation monitoring to allow for comparison of conditions between rehabilitation and reference sites. Each transect is to be located in an area that is accessible to ensure sampling repeatability over the life of the monitoring program. Results from reference sites will be compared to monitoring results obtained from rehabilitated site transects.

Rehabilitation transect sites will also be established within rehabilitated landforms post-mining. The following parameters will be monitored annually, at each site (where appropriate):

- aspect and slope;
- tree density and shrub density (measured as trees/ha or shrubs/ha) in areas compromising a native ecosystem PMLU component;
- herb/grass density (grasses/ha);
- groundcover (%);
- species composition;
- chemical and physical indicators of soil;
- erosion indicators (depth of rills or erosion lines, surface crusting, slopes); and
- photographic records of the site.

In addition to rehabilitation transect monitoring, other related site environmental monitoring will continue throughout and following the life of the mine (e.g. surface water monitoring). These data sets will also work to further inform future assessments of rehabilitation success.

Per current standards, rehabilitation monitoring will ultimately aim to demonstrate that domain-specific completion criteria have been continuously met for a period of three years or greater.

The rehabilitation monitoring methodologies proposed to be adopted for the Project are detailed below.

3.7.1.1 Sampling locations

Rehabilitation monitoring locations will be determined prior to the commencement of rehabilitation activities. Sites will be selected randomly within the rehabilitation area, with the orientation of the transect based on the physical parameters of the landform, to ensure all observations are statistically independent. GPS coordinates for monitoring locations will be collected, and physical markers will be installed to identify the transect start and end points.

Grazing reference sites

Grazing reference sites have been chosen based on aerial imagery and mapping of rehabilitation areas to be representative of areas of low-intensity grazing (Figure 47). The reference sites will provide an indicator for revegetation success of the grazing PMLU.

The EA specifies that grazing sites should be located within the Project area on land that best represents the pre-mining land use under the same climatic and environmental conditions.

Two grazing analogue sites were selected immediately to the north and south of the Capricorn Highway on established paddock areas that will remain undisturbed from mining activities. These locations are visually represented in Figure 64. Locating analogue sites within the mining lease boundary allows for an appropriate comparison between rehabilitation areas and reference sites under similar conditions, ensuring access for monitoring.

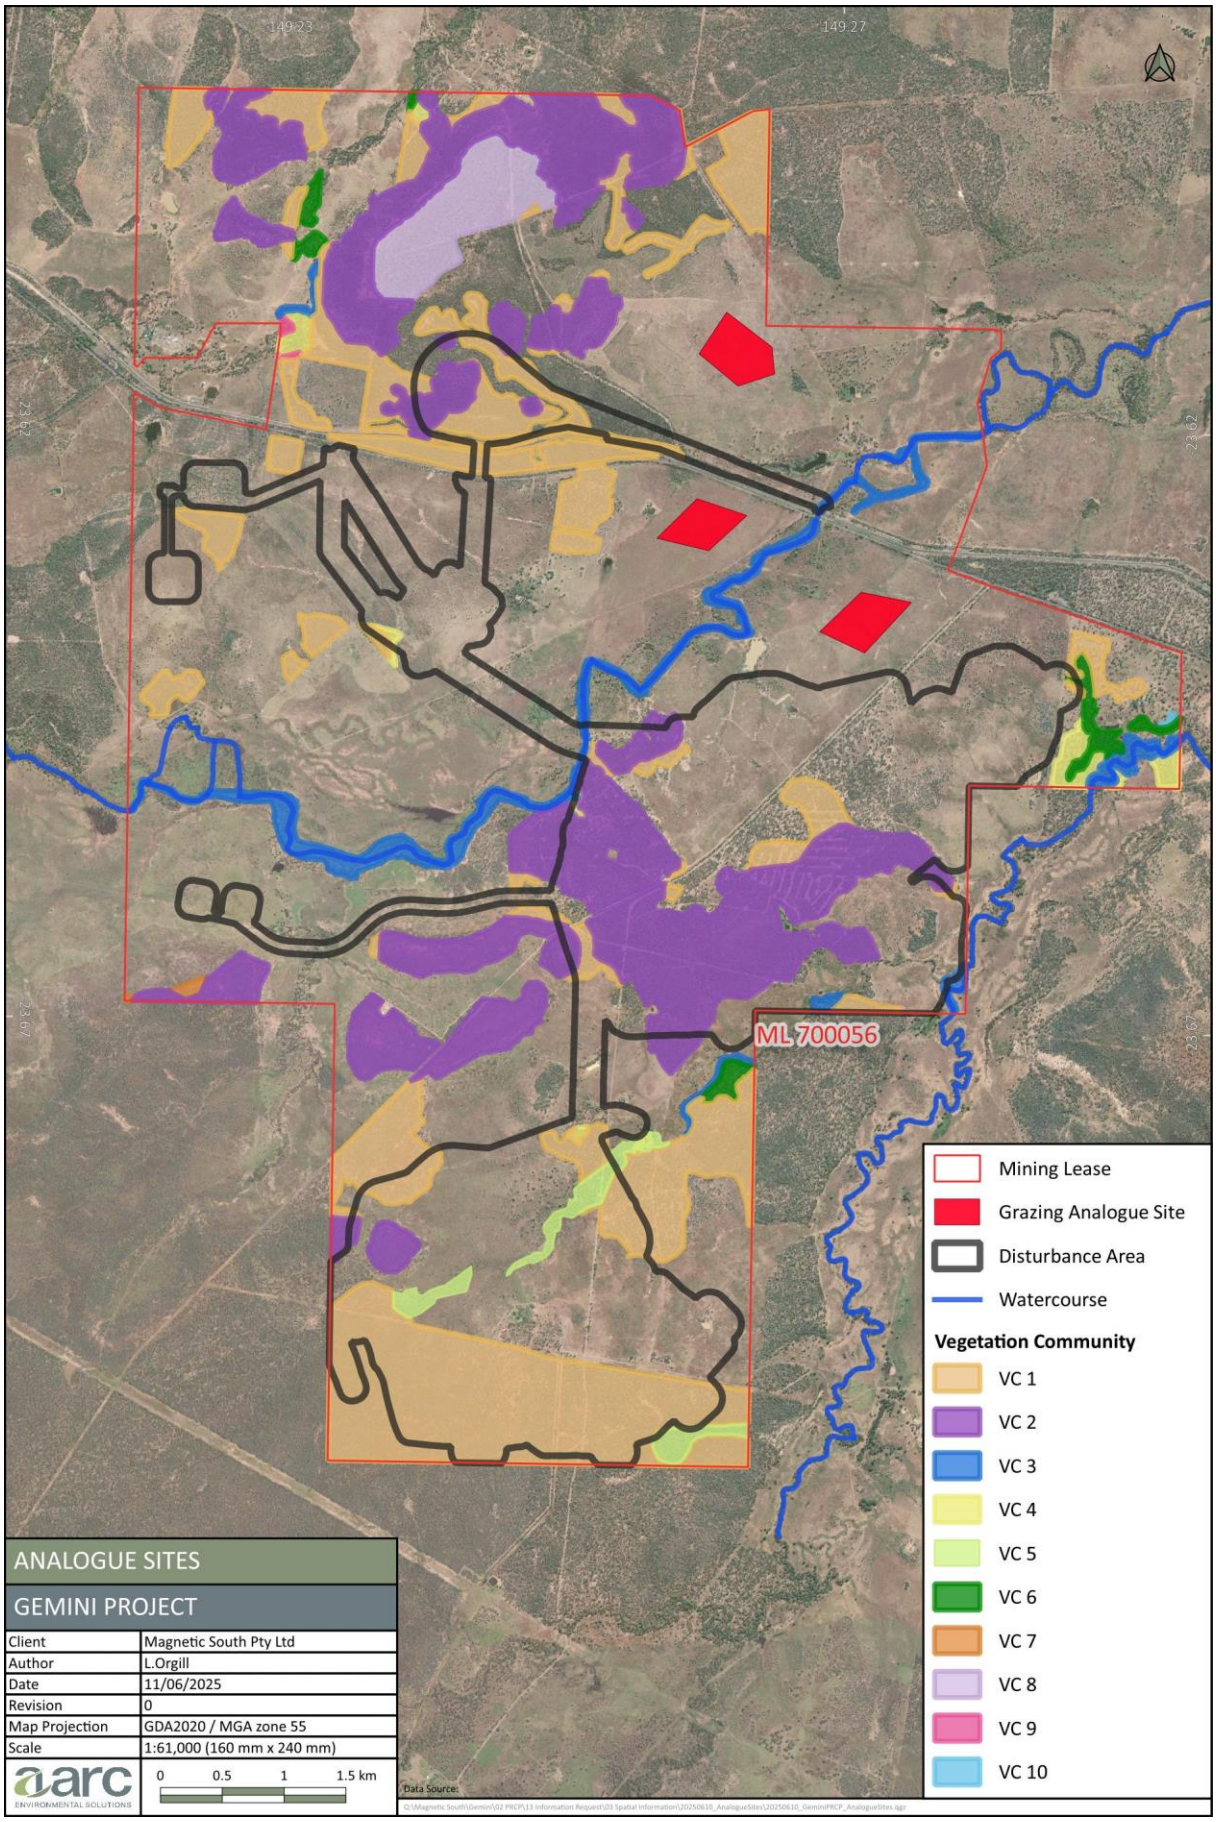

Figure 64: Grazing analogue sites

Native ecosystem reference sites

The native ecosystems targeted for the clear water diversions and the residual void high walls are hybrid and novel regional ecosystems, respectively. These ecosystems are termed no-analogue ecosystems on the basis that they lack any comparable natural native ecosystem that can be used as a reference sites (Spain et al 2025). While reference sites can be informative for the assessment of rehabilitation success, no reference sites for the target areas have been identified as representative of the land outcomes described in section 3.3.

As such, regional ecosystem analogues have been selected based on the Regional Ecosystem Technical Descriptions, which are compiled using survey data from the Queensland Herbarium QBEIS database. Quantitative site data from relatively undisturbed sites are extracted from QBEIS and summarised to provide information specific to each vegetation community. These values have been interpreted in relation to the existing site condition described in the Terrestrial Ecology Assessment (Appendix E) for the Project to form a set of representative QBEIS scores to be achieved by native ecosystem PMLUs. The QBEIS scores are outlined in section 3.5.5.

3.7.1.2 Vegetation monitoring

A transect-based approach (consistent with the QBEIS methodology) will be utilised for vegetation monitoring. This approach aims to provide a measure of the capacity of a terrestrial ecosystem to maintain biodiversity values at a local or property scale and allows a comparative assessment of pre- and post-mining ecosystems.

Vegetation monitoring involves the collection of quantitative data such as ground cover, species richness, canopy cover and height, woody stem density, recruitment basal area and weeds within each plot within the monitoring site.

At each monitoring site, a 50 m tape is extended and the coordinates of each end are recorded to establish a permanent 50 m transect. A star picket is installed at each end of the transect to consistently and precisely identify the transect location during each monitoring period. The transect area extends 5 m on either side of the 50 m tape, creating a plot size of 50 m x 10 m, or 500 m^2.

In each quadrat, the percentage cover of rock, logs bare ground, organic litter, cryptogam, water, manure and each plant species present is recorded. Species are classified into one of the following six groups for reporting purposes:

- native pasture species;
- exotic pasture species;
- trees;
- shrubs;
- forbs;
- noxious weeds.

The survey methodologies outlined below have been adapted from the Queensland Herbarium survey technique (Neldner et al. 2019) and the *Method for the Establishment and Survey of Reference Sites for BioCondition* (Eyre et al. 2017).

Results from this survey will be used to compare plant communities between analogue and rehabilitated sites, including the metrics for species diversity and ground cover.

Where available, permanent monitoring transects should be established in rehabilitation and unmined (analogue or reference) areas. The permanent location of these monitoring transects will be decided during the first sample periods, with coordinates to be included in the *Rehabilitation Management Plan* before the next annual monitoring occurs.

Examples of field sheets to be used to collect rehabilitation survey data are provided in Appendix G.

Monitoring of vegetation will preferably be undertaken after the wet season to ensure the presence of ephemeral herbaceous plants and to assist with identification of species that require the presence of flowers/fruiting material for accurate identification.

Monitoring of vegetation should be undertaken annually in the first 5 years following seeding to focus on the establishment of vegetation and to direct early reparation efforts. Monitoring then will be undertaken every two years for 10 years or upon achievement of completion criteria.

3.7.1.3 Ground cover

Ground cover monitoring involves the collection of quantitative data on average ground cover (percent) where the percentage of all types of ground cover within ten 1 m x 1 m quadrats is determined. Similar to the transect above, the quadrat shall be placed every 5 m on alternating sides of the transect, commencing at 0 m on the right and the final quadrat at 45 m. In each quadrat the total percentage ground foliage cover of each plant species and the percentage cover of bare soil, logs, rock, cryptogam, water, manure and organic litter is recorded.

Ground foliage cover incorporates native perennial grass cover, native annual grass cover, native forbs and other species, native shrubs (< 1m height), non-native grass, non-native forbs and shrubs, litter, rock, bare ground and cryptogams. An example of datasheet for the collection of data is provided in Appendix G and to ensure consistency a guide to estimating the percentage ground cover is also included Figure 65.

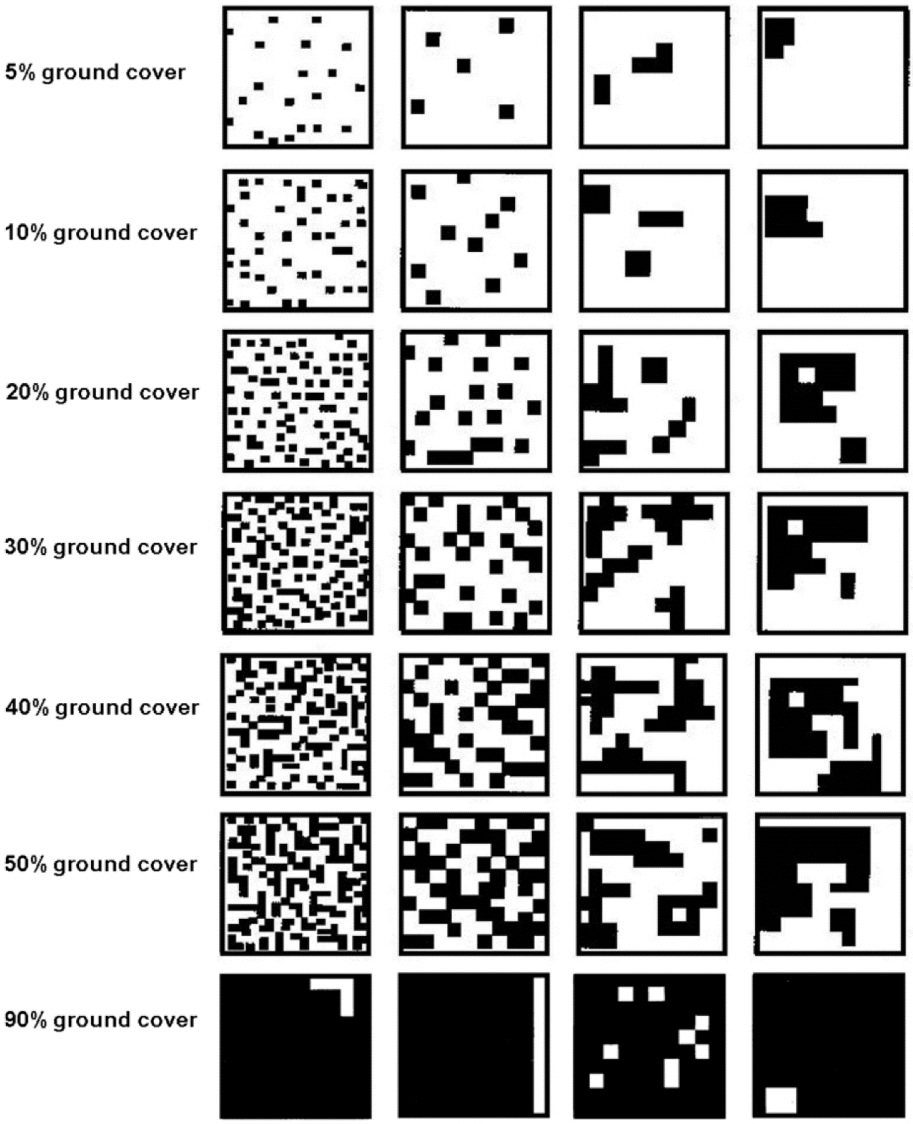

Figure 65: Guide to estimating ground cover percentage (Eyre et al. 2017)

3.7.1.4 Species richness

Species richness is assessed using the method outlined in Eyre et al. (2017) where all vascular plants that occur within a 10 m x 50 m plot area are recorded. The surveyor is to walk along each side of the 50 m transect centreline and record all trees, shrubs, forbs/other species and grasses occurring within 5 m of either side of the centreline. Species that cannot be identified within the field are collected for later identification or sent to the Queensland Herbarium for identification.

3.7.1.5 Stem density

Woody stem density is calculated using methodology adapted from the '*Method for the Establishment and Survey of Reference Sites for BioCondition'* (Eyre et al. 2017). All woody stems for each tree and shrub species are counted within the 10 m x 50 m plot area (i.e. 5 m either side of each 50 m transect). From this data, both total woody stem density as well as the density of each individual tree or shrub species is calculated. The density of species and growth forms on the monitoring sites is then calculated using the following equation:

$$Density\ per\ hectare\ (ha) = Number\ of\ stems\ recorded\ within\ the\ transect\ \times 20$$

3.7.1.6 Recruitment

Recruitment is assessed using methodology adapted from Eyre et al. (2015) whereby recruitment is assessed over the 10 m x 50 m plot (5 m either side of each 50 m transect). Within this plot, the proportion of dominant species found to be regenerating are counted. A regenerating individual is identified as a woody stem species with a diameter at breast height of <5 cm. For each dominant canopy species present, at least one individual must be present as a sapling or seedling for the species to be considered as regenerating. The presence of all dominant species in the regenerative state would make up 100% recruitment.

Where slow-growing species are present within the rehabilitation transect areas described above, additional recruitment metrics will be considered, including: low height relative to others of the same species, occurrence of species not in the original seed mix, and/or evidence of flowering/fruiting.

3.7.1.7 Canopy cover

Tree canopy cover can be used to characterise stand productivity and the distribution and abundance of biomass (Eyre et al. 2017). It refers to the estimation of the percentage canopy cover of the living, native tree layer along a 50 m transect, using the line intercept method (Greig-Smith 1964). For this attribute, the vertical projection of tree canopy cover of the species making up the tree canopy cover is assessed. The vertical projection of the tree canopy over the 50 m transect is recorded as illustrated in Figure 66. The total length of the projected canopy of each layer is then divided by the total length of the tape to give an estimate of percentage canopy cover on the site.

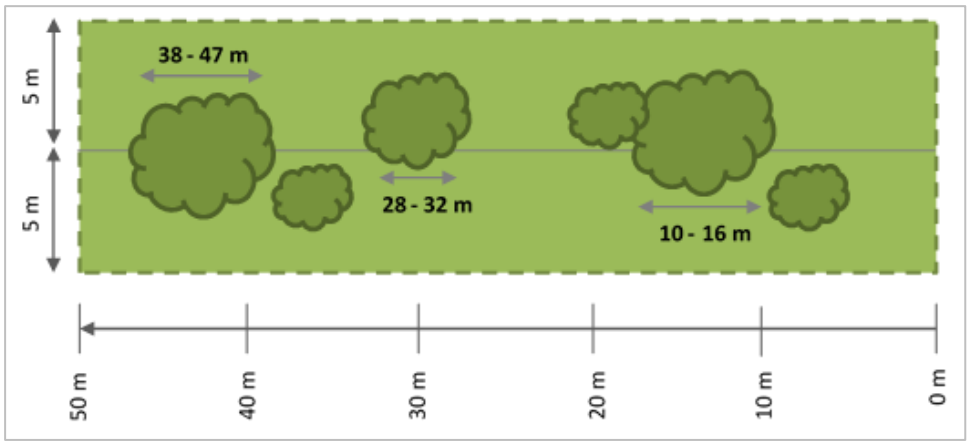

Figure 66: Guide to monitoring canopy cover (after Eyre et al. 2017)

3.7.1.8 Canopy height

Mean canopy height is calculated along with canopy cover and dominant species to provide a structural summary of a vegetation community. The height of woody vegetation is measured from the ground to the tallest live part. Canopy height greater than 5 m is measured using a clinometer or hypsometer. Mean height in metres is recorded for each stratum, as well as the range in individual heights for each stratum.

3.7.1.9 Basal area

Basal area data provides a rapid measure of tree species abundance (importance) in each layer and vegetation community. All woody plants at 1.3 m height are recorded within a 360° sweep, including species located outside the plot. The basal area factor used to convert data is recorded and should include between 8 and 15 counts in the sweep. All stems at breast height (1.3 m) that appear larger than the gap are to be recorded, as well as the species and strata.

3.7.1.10 Photographic monitoring

Photographic monitoring provides a visual record of the vegetation, ground cover, erosion and general appearance of each analogue and rehabilitation site, allowing these sites to be compared over time (Eyre et al. 2015). A digital camera is used to take the photos so that a permanent record can be kept for each site. The process of taking the monitoring photos is as follows:

- the site, date the photo was taken and the direction the photo was taken should be recorded for each photograph taken. A data board included in the photograph can be useful for this purpose;
- the person taking the photograph stands at the star picket which marks the beginning of the 50 m.
- the camera is then aimed directly toward the end of the 50 m transect and a single photograph is taken.
- the person then stands at the star picket which marks the end of the 50 m transect.
- the camera is then aimed directly toward the start of the 50 m transect and a single photograph is taken.

The digital photographs are then downloaded and stored for future reference.

3.7.1.11 Satellite-derived fractional vegetation cover

Fractional vegetation cover (FVC) is defined as that fraction of a satellite imagery pixel representing ground condition across three ground cover classes being:

- photosynthetic vegetation;
- non-photosynthetic vegetation; and
- bare ground

A median value of FVC can be determined for all satellite imagery pixels within a defined polygon area (or set of combined polygons). Subject to certain limitations, a median FVC value can be determined for polygons enclosing a rehabilitation area which is then able to be compared with polygons enclosing a reference area that is representative of unmined land having similar landform, land cover and land use.

Satellite imagery from the Sentinel 2 global earth observation mission acquires imagery on a five-to-12-day interval at wavelengths between 400-2,500 nm. Reflectance indices based on the spectral reflectance profiles of photosynthetic vegetation, non-photosynthetic vegetation and bare ground is calculated and directly correlated with field-collected data to calculate fractional vegetation cover for each rehabilitation and reference polygon. Field calibration and validation are required to be re-established if a significant disturbance occurs (e.g. fire/drought).

Satellite-derived indices will be reported annually based on an appropriate monitoring frequency. However, the frequency of satellite data acquisition will also be influenced by cloud cover or cloud shadow that occludes the study area.

In determining rehabilitation performance, the total cover of rehabilitation areas (the sum of photosynthetic and non-photosynthetic cover) will be compared to the total cover of the reference areas. The median value of each rehabilitation area will be compared against the first quartile of the reference area to assess performance. Rehabilitation will be successful where rehabilitation areas have a median fractional vegetation cover greater than the first quartile of reference areas for at least 85% of all sample times.

The approach undertaken to assess against the first quartile of reference areas allows for a non-parametric comparison of the rehabilitation areas to reference sites while ensuring that variability in vegetation cover can be reasonably assessed and accounted for in determining rehabilitation success. Sampling of both rehabilitation and reference areas will occur at the same time, given the geographical extent of the satellite imagery, ensuring that comparisons are based on consistent environmental factors.

FVC is reported in graphical form with median and interquartile ranges for each rehabilitation polygon and combined reference area polygons. In addition, dates and duration of failure to achieve the target are reported in tabular form with mapping information for sources of non-compliance

Calibration and validation

Satellite imagery from the Sentinel 2 global earth observation mission acquires imagery on a five-to-12-day interval at wavelengths between 400-2,500 nm. Reflectance indices based on the spectral reflectance profiles of photosynthetic vegetation, non-photosynthetic vegetation and bare ground is calculated and directly correlated with field-collected data to calculate fractional vegetation cover for each rehabilitation and reference polygon. Field calibration and validation are required to be re-established if a significant disturbance occurs (e.g. fire/drought).

Limitations

Currently, this method is only to be utilised for relatively low slopes (i.e. not defined waste emplacement batter slopes). Rehabilitation area polygons should be:

- selected with a sufficient buffer to exclude edge effects compromising the outcome; and
- selected to exclude engineered structures, e.g. internal drainage basins and spine drains.

Reference areas should be:

- areas having the same target land use as the rehabilitation area;
- the equivalent extent in hectares to target rehabilitation polygon areas; and
- a selection of at least four non-contiguous polygons.

3.7.1.12 Emerging monitoring technologies

Where emerging technologies can be implemented as a cost-effective means of assessing rehabilitation success, these will be reviewed and introduced as appropriate. An example of such technology is the determination of a normalised difference vegetation index based on aerial imagery; which can be used to assess vegetation cover and vegetative health.

3.7.2 Soil monitoring

Soil monitoring involves the collection of topsoil samples from a maximum depth of 10 cm to obtain quantitative data on the chemical and physical properties of soil. Soil sampling methodology has been adapted from '*Monitoring and Sampling Manual: Environmental Protection (Water) Policy 2009'* (DES 2018b). Soil

sampling is conducted by collecting approximately 200 g samples with a clean non-metallic shovel and bucket every 10 m along the 50 m transect. The first sample is collected at 0 m. These five samples are mixed in the bucket. The final 200 g soil sample is taken from the mix and placed into plastic sample bag. Samples are sent to a National Association of Testing Authorities (NATA) certified laboratory for analysis of indicators of soil nutrition and land contamination.

3.7.2.1 Topsoil characteristics

Topsoil sampling is not considered to be an annual requirement of the rehabilitation monitoring program. It is, however, to be undertaken upon commencement of monitoring, biennially until year 5 and every 5 years thereafter to monitor the development of the soil profile or to address any deficiencies in the chemical composition of the soil that may be detrimental to vegetation health. Topsoil analysis will typically include the following suite of parameters:

- pH;
- EC/chloride concentration;
- exchangeable sodium percentage;
- cation exchange capacity;
- soil carbon;
- macronutrients (nitrogen, phosphorus, potassium and sulphur); and
- micronutrients.

Soil moisture content shall be measured for interpretive purposes only and will not be assessed in determining rehabilitation performance.

Topsoil data collected as part of the monitoring program will ultimately be compiled into a land suitability assessment of the rehabilitated land.

Ideally, rehabilitation site data should reflect that of analogue sites, though data indicating a trajectory to meet performance criteria may be sufficient in supporting the chosen post-mining land use.

Field-based erosion monitoring

An erosion monitoring methodology has been developed by experienced AARC ecologists with consideration to relevant guidelines and research (Neldner et al. 2019, Eyre et al. 2017 and DSITI 2015). Erosion monitoring is to be conducted across all analogue and rehabilitation monitoring locations, simultaneously with vegetation monitoring in the first 3 years post-revegetation. Following 3 years post revegetation, erosion monitoring will primarily be undertaken using LiDAR monitoring. However, ground-truthing may be required (using the following methodology) upon assessment of LiDAR data.

Rehabilitation areas will be inspected to assess the extent of erosion features and an erosion rating for each site will be determined. Erosion features or indicators may include wind or sheet erosion, erosion rills, gullies or tunnels, or signs of slumping.

Erosion at the survey sites is monitored through visual assessment over time. Assessment is undertaken by traversing the 50 m transects and recording the number and average depth of any erosion features or rill lines. Observations of erosion shall be recorded and classified in accordance with Table 52. The overall classification of the erosion on each transect is determined by the higher classification attributed to either the number of rills/gullies or the average depth. For example, a transect may present only one or two rills, but if these are recorded as being 25 cm deep, the transect will be classified as presenting a Moderate erosion classification. Obvious cases of localised settlement that are not causing any subsequent erosion are not counted as instances of erosion. Erosion along revegetated sites will be compared to the landscape scale erosion data captured in the LiDAR monitoring program.

Table 52: Erosion classification

Erosion classification	Minor	Moderate	Severe
Sheet erosion	Shallow soil deposits downslope	Partial exposure of roots; moderate soil deposits downslope, etc	Loss of surface horizon; root exposure; moderate substantial soil deposits downslope
Rill erosion	<0.3m deep<15 rills/transect*	<0.3m deep 15-30 rills/transect*	<0.3m deep>30 rills/transect*
Gully erosion	Absent	>0.3m deep Gullies are linear, continuous, and restricted to primary or minor drainage lines	>0.6m deep Gullies are continuous or discontinuous, and either tend to branch away from primary drainage lines and on to foot slopes, or have multiple branches within drainage lines
Tunnel erosion	Absent	Absent	Present
Mass movement	Absent	Absent	Present

Source: NCST (2009)
* Transect linear 100 m across the contour (Source: Tongway and Hindley (2005)

It should be noted that the placement of the permanent transects may not be representative of the level of erosion across the entire rehabilitation area landforms. To compensate for this, general observations undertaken during the survey are also utilised to assess rehabilitation performance. The location of any severe erosion outside the transect (i.e. tunnels, mass wasting, large gullies) is also recorded and marked with a handheld Global Positioning System (GPS).

The following information is recorded at each site:

- GPS reading of location;
- general description of the type of erosion (gully [> 30 cm], rill line [<30 cm], circular failure, tunnelling etc.) and possible causes, refer to the glossary of terms for definitions of erosion types;
- depth of erosion;
- width of erosion;
- length of erosion;
- where eroded material is being deposited; and
- whether the erosion line is being stabilised by vegetation.

3.7.3 Surface water and groundwater monitoring

Surface water and groundwater sampling will be carried out in accordance with the methodology of the Queensland Monitoring and Sampling Manual (DES 2018). In-situ measurements of pH, dissolved oxygen (DO), oxygen reduction potential (ORP), EC, salinity, total dissolved solids (TDS), and temperature will be recorded with a multi-parameter water quality meter calibrated to the manufacturer's specifications.

Surface water monitoring locations will include:

- The toe of the rehabilitated waste rock emplacements;
- within recreated drainage features such as mine water dam and process water dam;
- Charlevue Creek and Springton Creek (at the locations defined in Attachment 9); and

- water within the residual void lakes (IA1).

Measurements will be taken every three months during flow events that enable surface water runoff to be collected from the surface of rehabilitated waste rock material.

Surface water grab samples will be collected at a depth of 10 to 20 cm where sufficient water is available. Two water samples, one total (unfiltered) and one dissolved (field filtered) will be collected at each site. Water quality samples will be analysed under laboratory testing conditions for the following parameters as outlined in Attachment 5 (Table 32) in section 3.5.4:

- pH;
- electrical conductivity;
- total dissolved solids;
- turbidity;
- total suspended solids;
- sulphate;
- nitrate
- aluminium;
- boron;
- chromium;
- cobalt;
- copper;
- manganese;
- molybdenum;
- nickel;
- selenium;
- zinc; and
- Total Recoverable Hydrocarbons (C6-C9 and (C10-C36).

Groundwater monitoring will be completed at the monitoring bore locations identified in EA Table E1 – Groundwater monitoring locations and frequency (Figure 21) for the parameters identified in Table E2 – Groundwater quality limits, including:

- pH;
- electrical conductivity;
- sulphate;
- aluminium;
- arsenic;
- chromium;
- cobalt;
- copper;
- manganese;
- molybdenum;
- nickel;
- Selenium; and
- Zinc.

Field readings of pH, EC and TDS will be compared against the milestone criteria for RM11. Measurements will also be taken from retained dams and compared against the milestone criteria for RM11. Data for each monitoring event will be compiled and used to identify trends in water quality over time.

3.7.4 Data Analysis, Interpretation and Reporting

3.7.4.1 Laboratory analysis

All soil and water samples collected during rehabilitation monitoring will be sent to a NATA certified laboratory for analysis of the recommended parameters.

In the event that any plants cannot be identified in the field, samples will be sent to the Queensland Herbarium for identification.

3.7.4.2 Progress reporting

A rehabilitation report will be prepared annually (until completion) following the collection of monitoring data to provide a detailed analysis of monitoring results and evaluate rehabilitation progress towards completion criteria. This ongoing evaluation will enable the early detection of unfavourable trends in measured indicators and identify any requirements for adaptive management practices to ensure rehabilitation success and certification in the long term.

3.7.4.3 Interpretation

Rehabilitation monitoring results will be analysed both categorically and temporally. Results obtained from rehabilitation sites will be compared to analogue sites from the same final land use vegetation community. Rehabilitation monitoring results will also be compared with historical data where possible to detect any trends over time. Common variables such as climatic conditions, seasonal variation and other event specific circumstances will also be considered in the analysis of rehabilitation data.

3.7.4.4 Statistical analysis

Given the small disturbance footprint of the Project, statistical analysis will involve the comparison of vegetation and soil monitoring characteristics recorded from analogue sites at the same point in time. The analysis of rehabilitation monitoring results will involve comparing rehabilitation sites generally across the Project using the following analytical methods, where appropriate:

- in relation to quantitative vegetation characteristics, statistical analysis will be undertaken in accordance with the methods described in the milestone criteria, where applicable.
    - Where sample sizes allow for statistical tests to be utilised, rehabilitation performance will be assessed using a t-test or a similar non-parametric test where the data is not normally distributed. Variables measured at reference and rehabilitation sites are considered statistically comparable where no significant difference ($\alpha > 0.05$) is identified.
    - Where sample sizes do not allow for statistical tests to be utilised, rehabilitation performance will be assessed by comparing the mean or median of the rehabilitation sites to the standard deviation of the interquartile range of the reference sites to determine whether there is a significant variation between the reference and rehabilitation sites.
- in relation to vegetation and soil quality characteristics, the mean values +/- 1 standard deviation will be calculated for comparison of analogue and rehabilitation site data; and
- temporal variation will be presented graphically for vegetation and soil quality variables as required to identify any outliers or ongoing trends.

When using BioCondition, an average score with a standard error equivalent to no more than 5% of the scoring range is practicable (Accounting for Nature 2022). Given the similarities between the survey methods, this standard error tolerance has been considered when determining the survey methodology and site selection for QBEIS. The number of expected QBEIS sites required to achieve a standard error equivalent to 5% of the scoring range is strongly influenced by the spatial scale of the landscape being assessed. A standard error assessment was undertaken in Appendix 7 of the *Accounting for Nature Guidelines for developing Methods to assess Native Vegetation Condition – v1.0*, which was used to inform the number of sites included in the selection.

The spatial scale identified in Appendix 7 that is most comparable to rehabilitation areas is the ‘property scale’. At this scale, three to five samples are sufficient to achieve an approximate standard error of 5%. No quantitative scale was provided as part of the definition of ‘property scale’, which is makes it challenging to assess the applicability of this range to a rehabilitation area scale. However, Appendix 7 identifies that each sampling location was greater than 1 km from each other, providing some context for what size area ‘property scale’ represents. Based on this, the spatial scale for rehabilitation areas is significantly less than the property size, given the total area of native ecosystem PMLU areas proposed as part of the PRCP. As such, a modified sampling rate of 1 QBEIS per 9 ha of native ecosystem rehabilitation is proposed to provide a sufficient assessment of variability for the QBEIS assessment.

3.7.5 Maintenance

Significant rainfall events, floods, fire, drought, pest species outbreaks or other factors may result in a requirement to undertake additional maintenance on rehabilitated areas. Maintenance of rehabilitated areas or reparations may also be required where visual observations of rehabilitation and/or rehabilitation monitoring results (refer section 3.5.4) indicate that the expected trajectory towards achieving successful rehabilitation is not being met. Depending on the underlying cause of failed rehabilitation, rectification activities may include:

- earthworks repair of erosion areas;
- re-seeding / replanting failed or unsatisfactory areas;
- supplementary planting of tube stock;
- pest and weed control;
- irrigation of plants;
- additional fertiliser or other ameliorant application to control pH and improve soil structure; or
- repair or alteration of drainage structures.

In the event that maintenance is required, a maintenance plan will be developed that properly assesses the risks of re-entering a rehabilitated area with earthmoving equipment, the sourcing of soils and topsoil, impacts on planned drainage of the site, erosion controls and revegetation methods.

Table 53: Rehabilitation milestone and monitoring measures

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM1: Infrastructure Decommissioning and Removal	Applicable to RA8 Considered to be met when the area can be transitioned to RM4 where applicable.	• Visual inspection following decommissioning and removal	• Infrastructure decommissioned / removed at closure will be subject to strict environment and safety planning requirements including completion inspections to determine if any future maintenance/repair action is required. • These inspections shall include visual monitoring and inspection to determine decommissioning requirements.
RM2: Remediation of Contaminated Land	Applicable to RA8, RA9 Considered to be met when a site suitability statement by a suitably qualified person confirms the uses or activities for which the land is suitable, align to the approved PMLUs of the site.	• Visual inspection to identify potential areas of land contamination and/or certify land as free of contaminants or contaminating materials.	• A preliminary site investigation will be completed by a suitably qualified person. Following a detailed site investigation report, any potential contaminated materials will be removed, and the site will be remediated. Validation testing will confirm contamination removal or remediation has occurred. • Provide certification from an AQP[1] that contaminated land assessment has been undertaken, and site investigation report prepared and submitted, if required.
RM3: Landform Development and Reshaping/Profiling ((RA1, RA2 and RA4)	Applicable to RA1, RA2 and RA4 Considered to be met when all bulk earthworks are completed, and former infrastructure area is assessed as geotechnically stable by a suitably qualified person.	• Visual inspection and document activities. • Provide certification from an appropriately qualified person that design criteria have been met. • Provide certification from an appropriately qualified person that long-term stability has been achieved for relevant landform.	• On completion of construction and reprofiling of the final landform, inspection and reporting will be undertaken to ensure the landform development and reshaping have been undertaken per design specifications. • Additionally, visual inspections will be done to determine if any future maintenance/repair action is required

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM4: Landform development of diversion drains (RA7)	Applicable to RA7 Considered to be met when all bulk earthworks are completed, and former infrastructure area is assessed as geotechnically stable by a suitably qualified person.	• Visual inspection and document activities. • Provide certification from an appropriately qualified person that design criteria have been met. • Provide certification from an appropriately qualified person that long-term stability has been achieved for relevant landform.	• On completion of construction and reprofiling of the final landform, inspection and reporting will be undertaken to ensure the landform development and reshaping have been undertaken per design specifications. • Additionally, visual inspections will be done to determine if any future maintenance/repair action is required
RM5: Landform development of infrastructure areas (RA8) and rehabilitated dams (RA5)	Applicable to RA5, RA8 Considered to be met when all bulk earthworks are completed, and former infrastructure area is assessed as geotechnically stable by a suitably qualified person.	• Visual inspection and document activities. • Provide certification from an appropriately qualified person that design criteria have been met. • Provide certification from an appropriately qualified person that long-term stability has been achieved for relevant landform.	• On completion of construction and reprofiling of the final landform, inspection and reporting will be undertaken to ensure the landform development and reshaping have been undertaken per design specifications. • Additionally, visual inspections will be done to determine if any future maintenance/repair action is required
RM6: Landform development of residual void high wall (RA3)	Applicable to RA3 Considered to be met when all bulk earthworks are completed, and former infrastructure area is assessed as geotechnically stable by a suitably qualified person.	• Visual inspection and document activities. • Provide certification from an appropriately qualified person that design criteria have been met. • Provide certification from an appropriately qualified person that long-term stability has been achieved for relevant landform.	• On completion of construction of the final landform, inspection and reporting will be undertaken to ensure the landform development and reshaping have been undertaken per design specifications. • Additionally, visual inspections will be done to determine if any future maintenance/repair action is required

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM7: Surface preparation	Applicable to RA1, RA2, RA4, RA5, RA7 and RA8 Includes topdressing, contour ripping and soil amelioration (if required) that will increase the possibilities of healthy vegetation establishment. Considered to be met when according to specific criteria from section 3.5.4.	• Record of soil health and suitability assessment undertaken by an appropriately qualified person. • Document placement of topsoil or suitable substitute across reshaped areas. Records to include source, analysis results and any pre-treatments applied • Visually inspection and documentation of contour ripping including depth, spacing and machinery used • Documentation of ameliorants application across reshaped areas. Records to include types, rates and timing of applications.	Regular meetings to track progress of surface preparation and its suitability to transition to the revegetation stage. The following monitoring actions will be undertaken in order to maximize vegetation establishment and minimize any potential soil erosion: • analysis of pH, electrical conductivity (EC), and exchangeable sodium percentage (ESP); • determination if any type of amelioration is needed (e.g gypsum) based on the results of the aforementioned parameters; and • hay mulch application to the rehabilitated (or repaired) area until it reaches a sustained groundcover. A soil health and suitability assessment will be undertaken to determine any amelioration requirements if soil quality characteristics require improvement measures. Ongoing rehabilitation activities to manage and achieve a successful surface preparation will include • repair of erosion prone areas; • application of supplementary topdressing materials, where required; and weed management and control.
RM8: Surface preparation and revegetation of residual void high wall (RA3)	Applicable to RA3 Includes Hydromulch to be placed over the upper high wall (18° slope) and exposed benches	• Visually inspection and documentation of contour ripping including depth, spacing and machinery used • Documentation of ameliorants application across reshaped areas. Records to include types, rates and timing of applications.	• In addition to binders, soil ameliorants and fertiliser can be included as part of the hydromulch composition to improve vegetation growth. • Ameliorants may be required to improve cohesion with the subsoil / topsoil and given local variability in soil quality it is considered appropriate for recommendations to be made following testing of the material to be used in rehabilitation prior to use. • Records to demonstrate that seeding has been undertaken in accordance with the rehabilitation objectives set out in the PRCP.

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM9: Revegetation for grazing	Applicable to RA1, RA2, RA4, RA5, RA8 Considered to be met when minimum sowing rates are achieved, with the understanding that further works may be necessary to meet rehabilitation standards if any remedial works and/or additional planting is needed.	• Document seeding and planting rates/densities • Species richness is assessed using the method outlined in Eyre et al. (2017) where all vascular plants that occur within a 10 m x 50 m plot area are recorded. • The surveyor is to walk along each side of the 50 m transect centreline and record all trees, shrubs, forbs/other species and grasses occurring within 5 m of either side of the centreline	Regular meetings will be held to track the revegetation progress. Ongoing rehabilitation activities to manage and achieve successful revegetation will include: • repair of erosion prone areas; • application of hay mulching (or similar technique) to control erosion at the early stages of seeding (window of erosional risk); • weed management and control; and • re-seeding and/or additional planting when required. Monitoring of new revegetated areas should be conducted annually for the first 5 years and/or until milestone is achieved.
RM10: Revegetation for native ecosystem	Applicable to RA7 Considered to be met when minimum sowing rates are achieved, with the understanding that further works may be necessary to meet rehabilitation standards if any remedial works and/or additional planting is needed.	• Document seeding and planting rates/densities	Regular meetings will be held to track the revegetation progress. Ongoing rehabilitation activities to manage and achieve successful revegetation will include: • repair of erosion prone areas; • application of hay mulching (or similar technique) to control erosion at the early stages of seeding (window of erosional risk); • weed management and control; and • re-seeding and/or additional planting when required. Monitoring of new revegetated areas should be conducted annually for the first 5 years and/or until milestone is achieved.

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM11: Achievement of surface requirements (grazing)	Applicable to RA1, RA2, RA4, RA5 and RA8 Considered to be met when the area has achieved its corresponding land suitability class and has controlled erosion as per the completion criteria described in section 3.5.5.	• Satellite imagery (refer section 3.7.1.11 *Satellite derived fractional vegetation monitoring)* • Species inventory and richness to be recorded at revegetation monitoring sites 3.7.1.2 • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2)	Regular meetings will be held to track progress towards the achievement of surface requirements. Ongoing rehabilitation activities to manage and achieve successful revegetation will include: • repair of erosion prone areas • application of hay mulching (or similar technique) to control erosion at the early stages of seeding (window of erosional risk) • weed management and control: and • re-seeding and/or additional planting when required. Erosion monitoring to identify and control severe or extreme rill and gully erosion as defined in section 3.5.5. Field survey monitoring will be supplemented with remote sensing to improve data analysis and provide a more accurate measures to determine if rehabilitation objectives are being met. Methodologies for successful revegetation are further explained in sections They include the following • vegetation surveys (composition, diversity • erosion rates, invasive plant species) • soil erosion monitoring • photographic monitoring; and • remote sensing

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM12: Achievement of surface requirements (native ecosystem supporting fauna habitat)	Applicable to RA3. Includes groundcover targets to be met as follows: Establishment of native ecosystem to resemble a requirement as per section 3.5.4. Considered to be met when the area has achieved its corresponding land suitability class, surface water quality complies with completion criteria limits and has controlled erosion as per the completion criteria described in section 3.5.5.	• Species inventory and richness to be recorded at revegetation monitoring sites (refer section 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2)	Regular meetings will be held to track progress towards the achievement of surface requirements. Ongoing rehabilitation activities to manage and achieve successful revegetation will include: • repair of erosion prone areas; • application of hay mulching (or similar technique) to control erosion at the early stages of seeding (window of erosional risk); • weed management and control; and • re-seeding and/or additional planting when required. Erosion monitoring to identify and control severe or extreme rill and gully erosion as defined in section 3.5.4 Field survey monitoring will be supplemented with remote sensing to improve data analysis and provide a more accurate measures to determine if rehabilitation objectives are being met
RM13: Achievement of surface requirements (native ecosystem)	Applicable to RA7 Considered to be met when the area has achieved its corresponding land suitability class, surface water quality complies with completion criteria limits and has controlled erosion as per the completion criteria described in section 3.5.5.	• Species inventory and richness to be recorded at revegetation monitoring sites (refer section 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2)	Regular meetings will be held to track the revegetation progress. Ongoing rehabilitation activities to manage and achieve successful revegetation will include: • repair of erosion prone areas • application of hay mulching (or similar technique) to control erosion at the early stages of seeding (window of erosional risk); • weed management and control; and • re-seeding and/or additional planting when required. Monitoring of new revegetated areas should be conducted annually for the first 5 years and/or until milestone is achieved.

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM14: Achievement of surface requirements (riparian corridor)	Applicable to RA10. Considered to be met when the area has achieved its corresponding land suitability class, surface water quality complies with completion criteria limits and has controlled erosion as per the completion criteria described in section 3.5.5.	• Species inventory and richness to be recorded at revegetation monitoring sites (refer section 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2)	Regular meetings will be held to track the revegetation progress. Ongoing rehabilitation activities to manage and achieve successful revegetation will include: • repair of erosion prone areas • application of hay mulching (or similar technique) to control erosion at the early stages of seeding (window of erosional risk); • weed management and control; and • re-seeding and/or additional planting when required. Monitoring of new revegetated areas should be conducted annually for the first 5 years and/or until milestone is achieved.
RM15: Achievement of Stable PMLU – Grazing	Applicable to RA1, RA2, RA4, RA5 and RA8 Considered to be met when the area has achieved its corresponding land suitability class, surface water quality complies with completion criteria limits and has controlled erosion as per the completion criteria described in section 3.5.5.	• Species inventory and richness to be recorded at revegetation monitoring sites (refer 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2) • Surface water and groundwater sampling will be carried out in accordance with the Queensland Monitoring and Sampling Manual (DES 2018). Field readings of pH and EC will be recorded and results will be assessed against relevant milestone criteria.	A combination of field surveys, drone and satellite imagery monitoring will be utilised. Remote sensing is to be used annually until the achievement of the PMLU by monitoring groundcover composition, size and extent of erosion features, and extent of weeds and pests The following assessments will be undertaken to demonstrate that the land has achieved RM15: • closure post-mining soil and land suitability assessments • vegetation, erosion and weed assessments to be provided in a final rehabilitation report • assessment of carrying capacity that demonstrates sustainable grazing • certification that the void low walls are stable and no migration of contaminants to groundwater has or will occur; and Methodologies for monitoring of surface water and soil quality to be applied at this rehabilitation milestone are further explained in 3.7.1

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM16: Achievement of Stable PMLU – Native ecosystem	Applicable to RA7 Considered to be met when the area has achieved its corresponding land suitability class, surface water quality complies with completion criteria limits and has controlled erosion as per the completion criteria described in section 3.5.5.	• Species inventory and richness to be recorded at revegetation monitoring sites (refer section 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2) • Surface water and groundwater sampling will be carried out in accordance with the Queensland Monitoring and Sampling Manual (DES 2018). Field readings of pH and EC will be recorded and results will be assessed against relevant milestone criteria.	A combination of field surveys and satellite imagery monitoring will be utilised. The following assessments will be undertaken to demonstrate that the land has achieved RM16: • closure post-mining soil and land suitability assessments • vegetation, erosion and weed assessments to be provided in a final rehabilitation report • assessment of carrying capacity that demonstrates sustainable native ecosystem Methodologies for monitoring of surface water and soil quality to be applied at this rehabilitation milestone are further explained in 3.7.1.
RM17: Achievement of stable PMLU – riparian corridor	Applicable to RA10. Considered to be met when the area has achieved its corresponding land suitability class, surface water quality complies with completion criteria limits and has controlled erosion as per the completion criteria described in section 3.5.5.	• Species inventory and richness to be recorded at revegetation monitoring sites (refer section 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2) • Surface water and groundwater sampling will be carried out in accordance with the Queensland Monitoring and Sampling Manual (DES 2018). Field readings of pH and EC will be recorded and results will be assessed against relevant milestone criteria.	A combination of field surveys and satellite imagery monitoring will be utilised. The following assessments will be undertaken to demonstrate that the land has achieved RM17: • closure post-mining soil and land suitability assessments • vegetation, erosion and weed assessments to be provided in a final rehabilitation report • assessment of carrying capacity that demonstrates sustainable native ecosystem Methodologies for monitoring of surface water and soil quality to be applied at this rehabilitation milestone are further explained in 3.7.1.

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM18: Achievement of Stable PMLU – Native ecosystem supporting fauna habitat	Applicable to RA3. Considered to be met when the area has evidence of flora recruitment, native fauna rehabilitation and has controlled erosion as per the completion criteria in section 3.5.5	• Species inventory and richness to be recorded at revegetation monitoring sites (refer section 3.7.1.2) • Monitoring of weed species and percentage foliage cover is to be conducted at rehabilitation sites as described in the PRCP. Record of weed management activities undertaken (where recommended in rehabilitation monitoring reports) • Erosion monitoring to be conducted at rehabilitation sites and general observations of 'Severe' erosion across each RA are to be recorded (refer section 3.7.2) • Surface water and groundwater sampling will be carried out in accordance with the Queensland Monitoring and Sampling Manual (DES 2018). Field readings of pH and EC will be recorded and results will be assessed against relevant milestone criteria.	A combination of field surveys, drone and satellite imagery monitoring will be utilised. The following assessments will be undertaken to demonstrate that the land has achieved RM18 • closure post-mining soil and land suitability assessments • vegetation, erosion and weed assessments to be provided in a final rehabilitation report • assessment of carrying capacity that demonstrates sustainable native ecosystem to support fauna habitat • certification that the void high walls are stable and no migration of contaminants to groundwater has or will occur; and Methodologies for monitoring of surface water and soil quality to be applied at this rehabilitation milestone are further explained in 3.7.1
RM19: Achievement of Stable PMLU – retained dams	Applicable to RA6	• Water quality samples will be collected from retained water storage(s) and sent to a NATA certified laboratory for analysis of water quality parameters specified in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG 2018). Results for relevant parameters will be assessed against livestock drinking water guideline values. • Visual inspection to be conducted throughout rehabilitation areas to identify erosion as per section 3.7.2. • Hazard and safety assessment report to conclude that the PMLU is safe for its intended used.	• Water quality data to be compared to guideline levels for livestock drinking water quality (ANZG 2018). • Landholder agreements
RM20: Achievement of Stable PMLU– retained infrastructure	Applicable to RA9	• Hazard and safety assessment report to conclude that the PMLU is safe for its intended used.	N/A

Rehabilitation milestone	Description / criteria	Methodology	Proposed management/ monitoring measure(s)
RM21: Surface water and groundwater demonstrate non-polluting landform	Applicable to all RA's. Considered to be met when surface water and groundwater monitoring data confirms all RA's meet the specific objectives as per the completion criteria in section 3.5.5.	• Surface water and groundwater sampling will be carried out in accordance with the Queensland Monitoring and Sampling Manual (DES 2018). Field readings of pH and EC will be recorded, and results will be assessed against relevant milestone criteria	• An assessment of the long-term monitoring data collected for surface water quality, groundwater quality, and groundwater levels demonstrates all rehabilitated areas achieve the relevant receiving environment objectives outlined in the completion criteria.

Table 54: Management milestone and monitoring measures

Management milestone	Description/criteria	Methodology	Proposed management/monitoring measure(s)
MM1: Achievement of final landform design	Applicable to IA1 IA to be assessed against landform design criteria developed for void (refer to section 3.5.5) Considered to be met when voids are filled to target levels and confirmation voids act as groundwater sinks.	• Visual inspection and document activities. • Provide certification from an appropriately qualified person that design criteria have been met. • Provide certification from an appropriately qualified person that long-term stability has been achieved for relevant landform.	• On completion of construction and reprofiling of the final landform, inspection and reporting will be undertaken to ensure the landform development and reshaping have been undertaken per design specifications. Additionally, visual inspections will be done to determine if any future maintenance/repair action is required
MM2 – Achievement of surface and safety requirements	Bunding and safety warning signage erected around perimeter of void. Considered to be met when void is inaccessible. Voids geotechnically stable and remain as a groundwater sink.	• Surface water and groundwater sampling will be carried out in accordance with the Queensland Monitoring and Sampling Manual (DES 2018). Field readings of pH and EC will be recorded, and results will be assessed against relevant milestone criteria.	• Ongoing monitoring and survey around perimeter of void • A combination of field surveys, drone and satellite imagery monitoring will be utilised Certification that void waterbody is stable and no migration of contaminants to groundwater has or will occur.

Management milestone	Description/criteria	Methodology	Proposed management/monitoring measure(s)
MM3 – Achievement of sufficient improvement	IA to be assessed against landform design criteria developed for void (refer to section 3.5.5) Considered to be met when voids final landform has been assessed to be geotechnically stable.		• Geotechnical survey of voids

Appendix A. PRCP Schedule

Post-mining land uses (PMLU)										
Rehabilitation area	RA1									
Relevant activities	**Waste rock emplacement (>3° slope)**									
Total rehabilitation area size (ha)	530.9									
Commencement of first milestone:RM3	10/12/2028									
PMLU	Grazing									
Date area is available by	10/12/2028	10/12/2031	10/12/2035	10/12/2039	10/12/2044					
Cumulative area available (ha)	93.6	420.8	438.7	457.3	530.9	530.9	530.9	530.9	530.9	530.9
Milestone completed by	10/12/2031	10/12/2035	10/12/2039	10/12/2044	10/12/2048	10/12/2052	10/12/2056	10/12/2060	10/12/2064	10/12/2077
Milestone Reference	**Cumulative area achieved (ha)**									
RM3	67.1	408.0	426.4	457.3	530.9	530.9	530.9	530.9	530.9	530.9
RM7	17.1	18.7	420.8	457.3	457.3	530.9	530.9	530.9	530.9	530.9
RM9		17.1	408.0	438.7	457.3	530.9	530.9	530.9	530.9	530.9
RM11			93.6	426.4	457.3	457.3	530.9	530.9	530.9	530.9
RM15				93.6	420.8	438.7	457.3	530.9	530.9	530.9
RM21										530.9

1) Insert new columns to the yellow table to include further rehabilitation milestone dates.
2) Insert new columns to the blue table to match rehabilitation milestone dates.
3) Insert new rows to the blue table to include additional rehabilitation milestone references.
4) Insert the relevant number in the "Milestone reference" column (i.e. RM1).

Post-mining land uses (PMLU)									
Rehabilitation area	RA2								
Relevant activities	**Waste rock emplacement (<3° slope)**								
Total rehabilitation area size (ha)	207.3								
Commencement of first milestone:RM3	10/12/2031

MM3		35.8	35.8	76.3	76.3	76.3	76.3	76.3

Milestone reference	Rehabilitation milestone	Milestone criteria
RM1	Infrastructure decommissioning and removal	1.With the exception of any infrastructure to remain as part of the post-mining land use (PMLU) or where infrastructure is agreed to be retained by the landholder as evidence by a signed landholder agreement, the following are completed: a)all non-required services disconnected and removed; b)all concrete, bitumen and gravel road material removed; c)all pipelines drained and removed; d)all fencing that is not part of the PMLU removed; e)all remaining infrastructure demolished and/or removed unless agreed to be retained by the landholder; f)all machinery and equipment removed; g)all surface water drainage infrastructure that is not retained in the final landform removed; and h)all rubbish removed.
RM2	Remediation of contaminated land	1.Contaminated Land Investigation Document completed in accordance with the Environmental Protection Act 1994, including a site investigation report, and, where required, a Validation Report and/or a draft Site Management Plan. 2.Contaminated and hazardous material either remediated in-situ or removed/transported to facility lawfully able to accept the material. 3.Suitably Qualified person (SQP) certifies that that no contamination unsuitable for the PMLU remains or is occurring.
RM3	Landform development of waste emplacement (RA1, RA2 & RA4)	1.All bulk landform earthworks (excluding topsoil cover) completed. 2.Slopes of waste rock emplacements and void low walls conform to a maximum slope of 6°. 3.The final landform is assessed to be geotechnically stable by an AQP[1], modelled to achieve a factor of safety of ≥ 1.5. 4.Final landform surveyed and certified by an AQP[1], as constructed per design specifications. 5.No reactive material is present on the land surface.
RM4	Landform development of diversion drains (RA7)	1.The clean water diversions are constructed in accordance with relevant design specifications prepared by an AQP[1]. 2.AQP[1] certifies that the constructed landform is geotechnically stable.
RM5	Landform development of infrastructure areas (RA8) and rehabilitated dams (RA5)	1.All bulk earthworks completed to reshape landform to final design. 2.AQP[1] certifies that the constructed landform achieves design criteria for geotechnical stability with a FOS ≥ 1.5.
RM6	Landform development of residual void high wall (RA3)	1.The final void high walls located within the unconsolidated sediments and saturated tertiary will be constructed at an angle of 18°. 2.The final void high walls located within the Permian geology will be constructed with an overall angle of 55° by constructing 50 m high batters at a maximum angle of 65°, incorporating 15m wide intermediate benches between batters. 3.AQP[1] certifies that as constructed landform achieves design criteria for geotechnical stability with a FOS ≥ 1.5. 4.Safety bunds adjacent to final high wall crest are designed and constructed in compliance with industry best practice and are certified as long-term stable.
RM7	Surface preparation	1.All earthworks completed with placement of topsoil. 2.All surface drainage features installed. 3.Topsoil placed over all reshaped surfaces to a depth of 0.3 m and deep ripping to be undertaken along the contour of slopes. 4.An assessment of placed growth media health and suitability completed by an AQP[1] to confirm soil is suitable for target revegetation outcomes. 5.Soil testing requires the following requirements: a)Soil pH >4.5 to <8; b)EC < 1.0 dS/m; and c)Exchangeable Sodium Percentage (ESP%) <6% (at 0-10cm depth). 6.Where required, ameliorants such as gypsum are added to improve soil quality characteristics at the rates recommended by an AQP[1].
RM8	Surface preparation and revegetation of residual void high wall (RA3)	1.Hydromulch placed over the upper high wall (18° slope) and exposed benches. Before application, an assessment of placed growth media health and suitability is completed by an AQP[1] to confirm hydromulch is suitable for target revegetation outcomes. 2.Where required, ameliorants such as gypsum are added to improve hydromulch quality characteristics at the rates recommended by an AQP[1]. 3.Seed mix incorporated into hydromulch and applied to upper high wall and exposed benches in accordance with a selection of seed mix provided in Attachment 2. a)Revegetation completed for tree/shrub seed mix at a minimum total rate of 4kg/ha and a minimum of 6 native species; and b)Revegetation completed for a ground cover seed mix at a minimum total rate of 12kg/ha and a minimum of 4 native species. 4.Seeding undertaken prior to forecasted rainfall during the wet season. 5.Details to be documented to indicate completion of the milestone: a)GIS files of areas where seeding and/or planting has occurred; b)date the seed mix was applied, or planting of tube stock was carried out; c)if seeding, the seed mix and rate of seeding applied; and d)if planting, the number of tube stock planted.

RM9	Revegetation for grazing	1.Seeding of all topsoiled surfaces completed in accordance with a selection of seed mix provided in Attachment 1. 2.The seed mix sown should comprise a minimum of 25% (by weight) native pasture species and include a minimum of 3 x 3P native species from Attachment 1. 3.Seeding undertaken prior to forecasted rainfall during the wet season. 4.Details to be documented to indicate completion of the milestone: a)GIS files of areas where seeding and/or planting has occurred; b)date the seed mix was applied, or planting of tube stock was carried out; c)if seeding, the seed mix and rate of seeding applied; and d)if planting, the number of tube stock planted. 5.Where required, fertiliser, mulch and ameliorants, such as gypsum, are added to improve growth media quality characteristics at the rates recommended by an AQP[1].
RM10	Revegetation for native ecosystem	1. **RA7:** Seeding of all topsoiled surfaces completed in accordance with a selection of seed mix provided in Attachment 3. a)Revegetation completed for tree/shrub seed mix at a minimum total rate of 3kg/ha and a minimum of 4 native species; and b)Revegetation completed for a ground cover seed mix at a minimum total rate of 16kg/ha and a minimum of 3 native species. 2. **RA10:** Seeding of all topsoiled surfaces completed in accordance with a selection of seed mix provided in Attachment 4. a)Revegetation completed for tree/shrub seed mix at a minimum total rate of 3kg/ha and a minimum of 6 native species; and b)The groundcover seed mix sown should comprise a minimum of 25% (by weight) native pasture species and include a minimum of 3 x 3P native species from Attachment 4. 3.Seeding undertaken prior to forecasted rainfall during the wet season. 4.Details to be documented to indicate completion of the milestone: a)GIS files of areas where seeding and/or planting has occurred; b)date the seed mix was applied, or planting of tube stock was carried out; c)if seeding, the seed mix and rate of seeding applied; and d)if planting, the number of tube stock planted. 5.Where required, fertiliser, mulch and ameliorants, such as gypsum, are added to improve growth media quality characteristics at the rates recommended by an AQP[1].
RM11	Achievement of surface requirements (grazing)	1. **RA2, RA5, RA8:** Rehabilitation polygons have a median fractional vegetation cover greater than the first quartile of reference polygons[2] for at least 85% of all sample times, as determined using the satellite-derived fractional vegetation cover method.[2] [3] [4] 2. **RA1, RA4:** Total percentage of vegetative groundcover to be >70%. 3.Minimum of 3 target species established (Attachment 1). 4.Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 5.No areas of "Moderate" or "Severe" erosion as defined in Attachment 5
RM12	Achievement of surface requirements (native ecosystem supporting fauna habitat)	1.A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2.QBEIS index scores achieve the following milestones based on a novel RE 11.10.3 native ecosystem: a)≥80% established and persistent native groundcover species from Attachment 2 on 18° slopes and intermediate benches. b)>5% native canopy cover on 18° slopes and intermediate benches. c)Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3.No areas of "Moderate" or "Severe" erosion as defined in Attachment 5.
RM13	Achievement of surface requirements (native ecosystem)	1.A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2.QBEIS index scores achieve the following milestones based on a hybrid RE 11.5.2 native ecosystem: a)≥60% established and persistent groundcover species from Attachment 3 within the pasture understory. b)>10% native canopy cover from species listed in Attachment 3. c)Evidence of flora recruitment from rehabilitation monitoring data. d)Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3.Assessment by an AQP[1] confirms that creek beds and banks are trending toward a geomorphically stable condition, and recommendations for management and mitigation actions have been implemented. 4.Incorporate natural features (including geomorphic and vegetation) present at the location of the diversion.
RM14	Achievement of surface requirements (riparian corridor)	1.A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2.QBEIS index scores achieve the following milestones based on a natural RE 11.3.25 native ecosystem: a)≥60% effective groundcover (including organic litter) with ≥30% live groundcover from species listed in Attachment 4. b)>15% native canopy cover from species listed in Attachment 4. c)Evidence of flora recruitment from rehabilitation monitoring data. d)Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3.No areas of "Moderate" or "Severe" erosion as defined in Attachment 5.

RM15	Achievement of Stable PMLU – Grazing	1.Sediment and erosion control structures removed after disturbed areas stabilised. 2.No evidence of erosion classified as 'moderate' or 'severe' as defined by Attachment 5. 3.Drainage follows intended and appropriate drainage paths. 4.Land suitability assessment by an AQP[1] certifies that land has achieved a post mine land suitability class of 3 or better. 5.A species presence that is consistent with those used in the recommended rehabilitation seed mix in Attachment 1. 6.Recommended species selected for revegetation which includes 3P grasses as recommended by Grazing Land Management information provided by NQ Dry Tropics[6] or the Fitzroy Basin Association[7] and are suitable to achieve the approved PMLU. 7.Assessed as Geotechnically stable by an AQP[1] indicating landform stability for a gradient slope of 6 degrees. 8.Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring.
RM16	Achievement of Stable PMLU – Native ecosystem	1.A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2.QBEIS index scores achieve the following milestones based on a hybrid RE 11.5.2 native ecosystem: a)≥70% established and persistent groundcover species from Attachment 3 within the pasture understory. b)>30% native canopy cover from species listed in Attachment 3. c)≥60% of native tree/shrub species listed in the rehabilitation seed mix (Attachment 3) are established and persistent. d)Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3.Geotechnical assessment by an AQP[1] confirms that long-term geotechnical stability has been achieved for each relevant landform. 4.An AQP[1] has certified that diversions being retained in the landform continue to achieve the incorporation of natural features (including geomorphic and vegetation) present at the location of the diversion. 5.Maintain equilibrium and functionality in all substrate conditions at the location of the diversion. A hazard and safety assessment completed by AQP[1] demonstrates hazards in RAs are consistent with the type and severity of hazards typical of neighbouring equivalent land use. Remaining hazards are considered to be low risk with no significant increase in risk expected over time.
RM17	Achievement of Stable PMLU – Riparian corridor	1.A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2.QBEIS index scores achieve the following milestones based on a natural RE 11.3.25 native ecosystem: a)≥60% effective groundcover (including organic litter) with ≥30% live groundcover from species listed in Attachment 4. b)>30% native canopy cover from species listed in Attachment 4. c)≥60% of native tree/shrub species listed in the rehabilitation seed mix (Attachment 3) are established and persistent. d)Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. 3.No areas of "Moderate" or "Severe" erosion as defined in Attachment 5.
RM18	Achievement of Stable PMLU – Native ecosystem supporting fauna habitat	1.A QBEIS assessment is completed by an AQP[1] using the methodology outlined in the latest version of the Neldner et al. 'Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland'. 2.QBEIS index scores achieve the following milestones based on a novel RE 11.10.3 native ecosystem: a)≥80% established and persistent native groundcover species from (Attachment 2) on 18° slopes and intermediate benches. b)>50% native canopy cover on 18° slopes and intermediate benches. c)Evidence of flora recruitment from rehabilitation monitoring data. d)Weed[5] presence is a maximum of 10% of total vegetative groundcover confirmed by an AQP[1] in annual monitoring. Weed[5] management recommendations to be provided in annual reports. 3.Fauna survey report provides evidence of >5 native species inhabiting or utilising high wall ecosystems annually including macroinvertebrates, aquatic vertebrates, avian species, bats, and other mammals. 4.No areas of "Moderate" or "Severe" erosion as defined in Attachment 5. 5.Perimeter safety bunds and fencing adjacent to final high wall crests are designed and constructed to exclude cattle use and prevent erosion. 6.Safety bunds adjacent to final high wall crest are designed and constructed in compliance with industry best practice and safety bunds for high walls are certified as long-term stable. 7.Geotechnical assessment by an AQP[1] confirms that long-term geotechnical stability has been achieved for each relevant landform. 8.Report prepared by an AQP[1] confirms the native ecosystem PMLU has been achieved with consistency to surrounding landscape.
RM19	Achievement of Stable PMLU – retained dams	1.Transfer of ownership agreements in place for all dams to be retained. 2.AQP[1] certifies that all contaminated sediment has been removed from all dams that are not backfilled. 3.Dams to remain for landholder use are safe for stock access. 4.All retained water storages achieve geotechnical and erosional safety and stability as assessed and approved by an AQP[1]. 5.No areas of "Moderate" or "Severe" erosion as defined in Attachment 5. 6.Retained water storage water quality for quality characteristics to be below the trigger values for livestock drinking water defined in Environmental Protection (Water) Policy 2009 Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin, September 2011[8], or the most recent version. 7.Final landform survey confirms no built structures remain other than those that form part of a landholder agreement.

RM20	Achievement of Stable PMLU– retained infrastructure	1.Transfer of ownership agreements in place for all infrastructure to be retained. 2.All retained structures and landforms to be assessed and approved as safe and stable by an AQP[1]. 3.Final landform survey confirms no built structures remain other than those that form part of a landholder agreement.
RM21	Surface water and groundwater demonstrate non-polluting landform	1.Surface water quality results monitored monthly during flow at, but not limited to, downstream locations specific in Attachment 10, must not exceed the limits in Attachment 6, for a minimum of 3 consecutive years. 2.If the surface water quality in the downstream receiving environment exceeds criteria (1), the applicable upstream site must be compared to the downstream site result; and quality measured at a downstream site must be equal to or less than the quality measured at the applicable upstream site, taking into consideration the additional distance travelled in the environment. 3.Groundwater level is monitored quarterly, and all results comply with Level Trigger Thresholds outlined in Attachment 9 at the monitoring locations specified in Attachment 7 for 10 consecutive years. 4.For a minimum of 3 consecutive sampling years, groundwater quality must be monitored quarterly at bored specified in Attachment 7 for all quality characteristics listed in Attachment 8. 5.Groundwater quality results must not exceed the limits in Attachment 8, for 3 consecutive results.

1 Appropriately Qualified Person (AQP) means a person who has professional qualifications, training, skills or experience relevant to the nominated subject matter and can give authoritative assessment, advice and analysis on performance relating to the subject matter using the relevant protocols, standards, methods or literature.
2 Reference polygons for fractional vegetation cover are required to be of Land Class Suitability 3 or 4, or better. A minimum of two additional reference sites will be nominated by 2026, and upon assessment must represent a land suitability class of either 3 or 4, or better.
3 Spectral unmixing algorithm employed in seasonal fractional cover – Landsat, JRSRP algorithm, Australia coverage v1.0 (Beutel et al. 2019)
4 Fractional Cover: Satellite Assessment, AARC 2023, or equivalent, methodology to be used for rehabilitation monitoring
5 Weeds are defined by the Biosecurity Act 2014

1) Insert new rows below the table to record more Rehabilitation Area Milestones for the project
2) Ensure all Rehabiitation Milestones recorded in this table align with those included in the RA sheets in this form.
3) See the PRCP guideline before developing site-specific Rehabilitation Area Milestones

Milestone reference	Rehabilitation milestone	Milestone criteria
MM1	Achievement of final landform design	1.The residual void has been backfilled to the following levels: a)≥65 mAHD for Mine A; and b)≥42 mAHD for Mine B. 2.Updated predictive modelling undertaken by an AQP[1] based on final residual void lake landform which confirms that the void will remain as a groundwater sink.
MM2	Achievement of surface and safety requirements	1.AQP[1] certifies that final void lake landform, including low and high walls, are geotechnically stable and achieved FOS ≥1.5. 2.Adequate bunding in place, confirming to be geotechnically stable by an AQP[1]. 3.Perimeter fencing and signage erected to prevent access to fauna and humans.
MM3	Achievement of sufficient improvement	1.Voids assessed to be geotechnically stable by a AQP[1], achieving: a)a modelled FOS of ≥1.5 for the in-situ pit walls before maximum in-pit water level is reached b)a modelled FOS ≥1.5 for the in-situ pit walls after maximum in-pit water level is reached; and c)a FOS ≥1.5 spoil pit walls above the maximum in-pit water level. 2.Certification from an AQP[1] that water level and quality in the residual void will not cause environmental harm to the surrounding environment, and the void acts as a groundwater sink to the receiving groundwater environment.

1) Insert new rows below the table to record more Rehabilitation Area Milestones for the project
2) Ensure all Rehabiitation Milestones recorded in this table align with those included in the RA sheets in this form.
3) See the PRCP guideline before developing site-specific Rehabilitation Area Milestones

Attachment 1 – Grazing PMLU seed mix

Scientific name	Common name	Minimum application rate (kg/ha)
Bothriochloa bladhii	Forest bluegrass	3
*Bothriochloa ewartiana**	Desert bluegrass	3
Chamaecrista rotundifolia	Roundleaf cassia	1
Chloris gayana	Rhodes grass	2
*Dichanthium sericeum**	Queensland bluegrass	3
Echinochloa esculenta	Japanese millet	5
*Enteropogon acicularis**	Curly windmill grass	3
*Panicum decompositum**	Native millet	3
Stylosanthes hamata cvv. Verano or Amiga	Caribbean stylo	1
Stylosanthes Seabrana cvv. caatinga	Caatinga stylo	1
Themeda triandra	Kangaroo grass	3

*Denotes a 3P pasture species

Attachment 2 – Native ecosystem supporting fauna habitat PMLU seed mix

Scientific name	**Common name**
Canopy/Tree	
Acacia shirleyi	Lancewood
Corymbia clarksonia	Grey bloodwood
Acacia rhodoxylon	Rosewood Wattle
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus exserta	Queensland peppermint
Shrub	
Acacia complanata	Long-pod wattle
Acacia crassa	Curracabah
Alphitonia excelsa	Soap tree
Petalostigma pubescens	Quinine bush
Flinersia dissoperma	Scrub leopardwood
Pittosporum spinescens	Wallaby apple
Groundcover	
Aristida calycina	Dark wiregrass
Cleistochloa subjuncea	Soft grass
Scleria sphacelata	Razor grass
Entolasia stricta	Wiry panic
Eragrostis lacunaria	Purple lovegrass

Scientific name	Common name
Thyridolepis xerophila	
Panicum larcomianum	Larcom's panic grass

Attachment 3 – Native ecosystem PMLU seed mix

Scientific name	**Common name**
Canopy/Tree	
Corymbia citriodora	Lemon-scented gum
Corymbia clarksonia	Grey bloodwood
Acacia rhodoxylon	Rosewood Wattle
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus moluccana	Grey box
Shrub	
Acacia complanata	Long-pod wattle
Acacia crassa	Curracabah
Alphitonia excelsa	Soap tree
Petalostigma pubescens	Quinine bush
Flinersia dissoperma	Scrub leopardwood
Pittosporum spinescens	Wallaby apple
Ground	
Aristida calycina	Dark wiregrass
Cymbopogon refractus	Barbed wire grass
Entolasia stricta	Wiry panic
Eragrostis sororia	Lovegrass

Scientific name	Common name
Enneapogon lindleyanus	Lindley nineawn
Perotis rara	Comet grass
Panicum effusum	Hairy panic

Attachment 4 – Riparian corridor PMLU seed mix

Scientific name	Common name
Canopy/Tree	
Corymbia clarksoniana	Grey bloodwood
Corymbia tessellaris	Moreton Bay ash
Eucalyptus crebra	Narrow-leaved ironbark
Eucalyptus tereticornis	Forest red gum
Eucalyptus camaldulensis	River red gum
Shrub	
Alphitonia excelsa	Soap tree
Acacia salicina	Willow wattle
Alstonia constricta	Bitterbark
Petalostigma pubescens	Quinine bush
Brachychiton rupestris	Queensland Bottle tree
Melaleuca trichostachya	Narrow-leaved honey myrtle
Groundcover	
Arundinella nepalensis	Reedgrass
Aristida personata	Purple wiregrass
Heteropogon contortus	Black speargrass
Lomandra longifolia	Spiny-head mat-rush

Scientific name	Common name
Themeda triandra	Kangaroo grass
Paspalidium jubiflorum	Warrego summer grass

Attachment 5 – Erosion classification framework

Erosion classification	Minor	Moderate	Severe
Sheet erosion	Shallow soil deposits downslope	Partial exposure of roots; moderate soil deposits downslope, etc	Loss of surface horizon; root exposure; moderate substantial soil deposits downslope
Rill erosion	<0.3m deep<15 rills/transect*	<0.3m deep 15-30 rills/transect*	<0.3m deep>30 rills/transect*
Gully erosion	Absent	>0.3m deep Gullies are linear, continuous, and restricted to primary or minor drainage lines	>0.6m deep Gullies are continuous or discontinuous, and either tend to branch away from primary drainage lines and on to foot slopes, or have multiple branches within drainage lines
Tunnel erosion	Absent	Absent	Present
Mass movement	Absent	Absent	Present

Attachment 6 – Surface water quality limits

Parameter	Unit	Limit	Comment on limit
Physico-chemical and ions			
Ammonia	µg/L	20	Mackenzie River WQO
Oxidised nitrogen	µg/L	60	Mackenzie River WQO
Organic nitrogen	µg/L	420	Mackenzie River WQO
Total nitrogen	µg/L	775	Mackenzie River WQO
Nitrate	µg/L	700	Mackenzie River WQO
Filterable Reactive Phosphorus	µg/L	20	Mackenzie River WQO
Chlorophyll a	µg/L	5	Mackenzie River WQO
Dissolved oxygen	% sat.	85 - 110	Mackenzie River WQO
Turbidity	NTU	50	Mackenzie River WQO
Suspended solids	mg/L	110	Mackenzie River WQO
Total dissolved solids	Mg/L	3000	Mackenzie River WQO
pH	pH unit	6.5 - 8.5	Mackenzie River WQO
Electrical conductivity	µS/cm	Baseflow: 310 High flow: 210	Mackenzie River WQO
Sulphate	mg/L	10	Mackenzie River WQO
Dissolved metals			
Aluminium	µg/L	55	ANZG 2018
Arsenic	µg/L	13	ANZG 2018
Cadmium	µg/L	0.2	ANZG 2018
Chromium	µg/L	1	ANZG 2018
Copper	µg/L	1.4	ANZG 2018

Parameter	Unit	Limit	Comment on limit
Lead	µg/L	3.4	ANZG 2018
Mercury	µg/L	0.06	ANZG 2018
Nickel	µg/L	11	ANZG 2018
Zinc	µg/L	8	ANZG 2018
Boron	µg/L	370	ANZG 2018
Cobalt	µg/L	–	ANZG 2018
Manganese	µg/L	1900	ANZG 2018
Molybdenum	µg/L	–	ANZG 2018
Selenium	µg/L	5	ANZG 2018
Silver	µg/L	0.05	ANZG 2018
Uranium	µg/L	–	ANZG 2018
Vanadium	µg/L	–	ANZG 2018

Notes:

- All metal and metalloids must be measured as “dissolved” (from analysis of a field filtered sample) and total “unfiltered”
- Limits for metals and metalloids apply to dissolved results
- *ANZG (2018) Aquatic ecosystem protection for moderately disturbed system (95% protection)*

Attachment 7 – Groundwater monitoring locations and frequency

Site	Bore ID	Easting (GDA94, Zone 55)	Northing (GDA94, Zone 55)	Bore Depth (m)	Groundwater Unit Monitored	Monitoring Frequency
2	DW7067W	730781	7382394	100-14	Permian	Quarterly

1. STARTING PLANNED COMMUNICATIONS

1.1. OVERVIEW

Magnetic South Pty Ltd.'s primary focus for its Dingo West coalmine project is to secure an environmental authority (EA) and mining lease (ML).

Mining engineering, law, and environmental sciences form a draft environmental management plan (EMP), and inform draft environmental authority conditions – leading to the Land Court of Queensland (LCQ) recommendation of an environmental authority and a mining lease, for Ministerial approval.

Dingo West project's small scale, Magnetic South's freehold land ownership, isolated location enabling control of all land management issues, ready connectivity to infrastructure, and distance from urban and commercial land uses, are factors to reduce the demand for a wide public consultation process, as commonly required by Terms of Reference (TOR) for resource projects.

Magnetic South Pty Ltd and AARC Environmental Solutions Pty Ltd can document activities within current project activities involving communication as consultation.

Method, rationale, and tools are included in this Strategic Communications Framework (SCF) to start capturing information which can be regarded in the Environmental Management Plan, and provide content to a public consultation report. It mentions measures that can be increased if required.

Central Highlands' recent history and community are founded in agriculture (grazing, grain) and resources. The industry has good reputation in the region. Agriculture and community have connectivity with resources as an employer, user of goods and services and infrastructure benefactor. Resources bring new local economic cycles.

None the less, sensitivities and ambivalence to resources prevail. A long prevailing overwhelming empathy for agriculture, environmental propositions required of resources projects, approval processes, land access, fair compensation, and specific interest movements, are factors to be addressed.

A sensitive planned entry to region can be used to distinguish Dingo West and Magnetic South, and support the Dingo West project's public entry into the statutory approval regime, project planning and development, and lead to confident investment.

Dingo West and Magnetic South need to be distinguished from previous projects and companies, and create reputation for a new project that addresses contemporary expectations.

1.2. OVERVIEW OF PURPOSE

1.2.1. Main purpose

A contained, but systematic, strategic communications process can meet Queensland Government requirements if undertaken by a structured documentation method.

The process must support the engineering, law and environmental management pathways to statutory approval, and project development. It must support co-ordination and inform at least seven project strategies:

- Preparation of the applications for Mining Lease, Environmental Authority, Environmental Management Plan (EMP), agency assessment and Land Court;
- Promote the primacy and integrity of the well - tested scientific and technical assessment regime codified in Australian Government and Queensland Government statute, as the basis of government decision-making;
- Project design, refinement and feasibility leading to ready development;
- Assist plan regional economic infrastructure compatibility;
- Inform future development, operational economies, and leverages;
- Increase investor value - maintain investment value and reputation.
- Investor confidence – support incremental increase of investment;

1.2.2. Collateral purposes

A strategic communications process has collateral purposes:

- Decrease the body of issues and objections to be assessed in statutory application consideration, and increase the body of understanding and support;
- Scope the bases of collaboration for future infrastructure, business opportunities, and fair treatment;
- Scope Magnetic South's preferences for regional economic, infrastructure, industry and community proposals;
- Establish a network of stakeholder relationships, anticipated to provide trustworthy information about regional directions, intelligence on issues, and advice;
- Foreshadow "reasons to engage" later in the project's life, over the long assessment period, so as reduce communications vacuums, in which misunderstanding and message fatigue arise.
- Avoid roping-in to the wide and ongoing resource and global energy debate, and exposure to assorted demands.

1.3. OVERVIEW - COMMUNICATIONS AND CONSULTATION BEFORE EMP

Communications needs to be structured, timed and sequenced to match project planning and EMP studies. It must aim to fulfil obligations for the EMP process to satisfy Queensland Government expectations.

The intensity must respond to needs including:

- Intelligence to inform the project's studies and planning;
- Early resolution of issues that may be considered by the Land Court;
- Cultivation of lines of communication for decision-makers, advisors and informants to communicate advice and information;
- Project scale and significance, associated infrastructure, regional economic development directions, and the community;
- Enquiries relevant to baseline studies, potential economic, natural environmental impacts, EMP iterations, and mine project planning;
- Nature and extent of the prevailing issues;
- Need to establish and maintain continuing relationships that enable two-way communication with stakeholders/informants at all levels; and
- Iterative consolidation of the foundational proposition and the refinement of the carry-forward project proposal.

1.4. SITUATION ANALYSIS

Magnetic North Pty Ltd proposes to extract coal resource from its Dingo West Coal Mine project, located near the township of Dingo, in the Central Highlands Regional Council area.

An Environmental Management Plan (EMP), Mining Lease (ML) and Environmental Authority (EA), ready access to the resource, transport infrastructure, a favourable operating environment, and economic supply chains for inputs and outputs, create a project proposition.

Mining engineering, law, environmental management science, and strategic project communications, are intertwined to construct the value proposition. Environmental management science studies are the foundation of the Queensland Government's ML and EA assessment.

Strategic communications must create a favourable environment carefully, to overcome the complexities and sensitivities confronting the resources industry.

2. METHOD

2.1. OVERVIEW

Information captured by Magnetic South and AARC Environmental Solutions Pty Ltd during current activities in field, in region, in government and with scientific/technical consultants can be recorded, as evidence of consultations with stakeholders' that have legitimate interest. These are foundations of a consultation report.

Records of advice, findings and information can be captured to demonstrate the acceptability of Magnetic South's proposition on issues, and matters it is required to address. These inform the environmental management plan, decrease issues, and create useful leverages.

The need for selected wider public consultation may be justified by the findings. This framework summarizes the processes commonly used to satisfy consultation requirements. It also forms a rationale to assist Magnetic South and AARC target consultation closely, by providing method as to how to differentiate necessary, from unnecessary. It can demonstrate that Magnetic South and AARC have consulted legitimate stakeholders.

This framework details a structured approach for Magnetic South and AARC to capture what can be regarded as consultation, and document it. The framework document can be used to demonstrate to the Queensland Government that Magnetic South and AARC has undertaken consultation methodically. It forms part of a report, and future negotiation with Queensland Department of Environment and Science on the level of consultation needed for this project

2.1.1. Method – the basics

The SCF is based on the following foundational method:

- Identification of stakeholders (community of legitimate interest) for the project
- Identification of issues, opportunities and key messages relating to the project;
- Selection and planned application of engagement tactics to communicate meaningfully with stakeholders, providing information and encouraging informed feedback;
- Effective channelling of findings, feedback, issues, ideas and opportunities to the project team, and ensuring completion of the feedback loop;
- Informing the EMP process by investigation of stakeholder issues and concerns; and
- Cyclic review of communications and adequacy.

2.1.2. Method implementation

The consultation program to be undertaken by Magnetic South and AARC will contain two strands of activities:

1. **Incidental** project planning activities, which entail communications and enquiry, that may captured to inform the EMP, and be regarded as consultation; and
2. **Planned** specific consultation with selected stakeholders to address common terms of reference for projects' MP's, and to inform the larger project business case and the company business development proposition.

The Queensland Government may require some planned consultation with stakeholders to ensure that all issues, opportunities and concerns are explored thoroughly. This framework proposes methods to utilize incidental communications activities, and plan selected stakeholder consultation, intertwined for economy.

Communications commonly reveals a range of information not necessarily material to the scientific, technical and legal assessment of the EMP. However, matters useful to the project, business proposition and Magnetic South's long-term agenda should be also be captured, and their use be considered.

Some matters may create leverage and project acceptance with some stakeholders.

2.1.3. Three rounds of implementation

The communications and consultation process in advance of the EMP can comprise three rounds, in advance of submission of the EMP:

2.1.3.1. Advising intent and scoping selected issues

- Advising selected government and industry-level stakeholders of intent to initiate a project with careful and considered planning;
- Advising of method, and initiating enquiry on selected issues and opportunities; and
- Scoping issues and opportunities to refine the draft project proposition

2.1.3.2. Testing the proposition

- Testing the project proposition's fit with regional, industry and community issues and opportunities, with selected government, industry, business and specific interest stakeholders; and
- Scoping Magnetic South's opportunities to enhance the project and establish foundations for collateral business and investment opportunities.

2.1.3.3. Finalization of expected communications and consultation

- Consultation with government, industry, business, specific stakeholders and selected groups advising of the project proposition informed by studies, planning information and the advice of stakeholders that has been gleaned during communications and consultation; and
- Submission of EMP with communications and consultation report.

2.1.4. Focus on EMP

Communications must focus on the core statutory applications and assessment process to scope and inform issues and opportunities relating to the statutory baseline studies in four ways:

- Draw out and capture issues that the applicant must address in the EMP;
- Increase awareness of the project's genuine compatibility with the economic, social and natural environments, so as to reduce the body of likely objection;
- Increase the body of support and confidence in the project; and
- Commence action on the operational project's inclusion in economic infrastructure, regional business and favourable employment environment.

3. ESTABLISHING A FRAMEWORK LEADING TO THE LONGER TERM

3.1. PRINCIPLES

The program should strive to be focussed, economical, and avoid inadvertently fomenting conflicts tenuously linked to global energy and resources agendas.

It can be based on the following principles:

- Identification of decision-makers and demonstrably-genuine stakeholders;
- Identification of issues for resolution and opportunities that would support the future narrative of a project proposition compatible with the EMP and EA;
- Selection of tactics and tools to communicate meaningfully and positively with decision-makers and stakeholders, provide information and encourage informed feedback;
- Effective channelling of findings, feedback, issues, ideas and opportunities, to completion of the feedback loop;
- Commencement of action to scope useful opportunities and relationships;
- Inform EMP and EA formation by investigation of decision-makers' responsibilities;
- Carry forward a regional economic infrastructure and business opportunity agenda; and
- Continuously review the relevance and orientation of the program.

3.2. DECISION-MAKERS AND OTHER STAKEHOLDERS

At commencement, the program should identify relevant decision-makers and other stakeholders, to presage understanding of their official role and potential deliverables, so as to inform detailed engagement planning. This should include distinguishing decision-makers whose formal role informs the statutory assessment process, and other stakeholders who may be helpful, in some future way.

A schedule decision-makers and stakeholders needs be developed to guide program planning.

A prescribed set of steps needs to be prepared to guide dealings with selected decision makers and stakeholders. A sub-plan is required for each decision, and milestone.

Some positioning and authorizations will be required so as to ensure compliance with the *Integrity Act 2009 (Queensland).*

It is recommended that the program commence with a focus on official officeholders, who may be a continuing conduit, and stakeholders of prominent responsibility. This focus would enable some expectation of fair dealing and integrity, obligated by the integrity principles attaching to formal roles and office.

3.3. STARTING POINT FOR CONSULTATION

The project's milestones direct the selection of communications targets and stakeholders. Milestones lead to stepped process, stepped analysis of the milestones, determine relevance of stakeholders to the project's milestones, stakeholder genuine interest, information required both ways, and the priority for action by them to advance the process.

3.4. ASSESSMENT MATRIX – THE PROJECT PROCESS AND MILESTONES

Magnetic South's scheduling of the project's milestones (environmental studies, mining engineering, law) from concept to commercial actualization will assist selection of communications and consultation. The overviews provided by John T Boyd, AARC and Hopgood Ganim Lawyers will inform identify the milestones of the immediate future. Preparation of a flow chart diagram would illustrate the process flow, and be available for communication use.

Listing the stakeholders and decision-makers in the milestones, the legitimacy of stake, action required, actions agreed, and preferred outcomes/outputs will assist tailor communications activities to what is needed and prompt listing what incidental communication and planned communication should be captured.

The drafting tools *Stakeholder Assessment Prompter (001) and Stakeholder Assessment Notes Drafter (002)* can be used to commence action plans for each set of stakeholders or individuals.

The prompts to listing the milestones and stakeholders include:

- The steps and milestones in the EMP process to Land Court consideration;
- Distinguish the steps external to Magnetic South that require action by others;
- List the essential permissions, and actions needed to maintain progress (internal permissions, information requirements, statutory permissions, regulatory approval, infrastructure planning inclusion, external services agreements, commercial collaborations, advocacy and potential interventions);
- List the preferred outcomes and outputs for each milestone, and any relevant aids or obstructions; and
- List the propositions for natural environment, and economic development and community.

4. POTENTIAL STAKEHOLDERS

Stakeholders will influence project assessment and progression based on their formal role, influence on assessment decision-making, project impact on them, project impact on their interests, and their specific interest or cause.

4.1. IDENTIFICATION OF STAKEHOLDERS

Identification of stakeholders for inclusion should be undertaken based on the following criteria:

- Responsibility or interest according to formal role (authority, place in progressing project assessment, advice, scientific and technical information, place in decision-making, or other official function);
- Direct impact (project operations that may impact materially on their interests) or indirect impact (economic, social and natural environment in which they operate business or reside);
- Quasi-formal and informal roles (special interest group, peak industry body, representation and advocacy group); and
- Specific action, agreement or endorsement expected by role, impact or justifiable consideration.

The above criteria should be used to consider inclusion or not of stakeholder and assist form categories for reporting. The drafting tools *Stakeholder Assessment Prompter (001) and Stakeholder Assessment Notes Drafter (002)* include categorization prompts, to assist sorting.

4.1.1. External and community stakeholders

The following categories are listed to assist which common types of stakeholders should be included in consultation

4.1.1.1. Elected representatives

- Federal
- State
- Local Government
- Region of LGA's and urban and regional planning collaborations
- Portfolio responsibility, referral, reference and decision-making

4.1.1.2. Agencies

- Approval, referral, advisory, industry sector, community sector, economic, social and natural environment
- Federal
- State
- Local Government
- Statutory and regulatory
- Business entities

4.1.1.3. Commercial

- Commercial collaborators
- Commercial supporters
- Peak industry bodies and regional affiliates
- Supply chain partners in project
- Transport, logistics and communications – use and capacity
- Supply chains internal to company and future MN reach

4.1.1.4. Landowners and occupiers

- Owners and occupiers directly impacted or influenced by project – land use, tenure, continuity of business, resources, access
- Owners and occupiers indirectly directly impacted or influenced by project
- Industry and business sector impacted or influenced – capacity and continuity of business

4.1.1.5. Area and region stakeholders

- Geographic area, residents, occupiers, business operators and services providers – town and settlements, corridor residents and occupiers
- Area development organisations
- Infrastructure planners and providers
- Infrastructure operators
- Services providers and suppliers
- Services operators – in locality
- Industry sector leaderships – competitive advantage, comparative advantage and specialisations
- Industry organisations
- Industry peak bodies and branches
- Industry research and development organisations
- Industry development and sectoral development

- Industry professional organisations
- Education, training and recruitment
- Business organisations
- Marketing and productivity groups

4.1.1.6. Specific interest

- Organisations – economic, human services, community services, and natural environment
- Individuals – expertise and knowledge, professional qualifications, calling or profession, recognised personal interest, and respected community or industry sector leadership through culture, tradition or service.

4.2. PRIORITISATION OF ACTIONS NEEDED OF STAKEHOLDERS

Prioritisation and scheduling of communication activities is essential so as to ensure that stakeholders take the action requested or expected, when progress, continuity and support is actually needed, to maintain progress.

The tools *Stakeholder Assessment Notes Drafter (002)* and *Stakeholder Contact Planner (003)* can be used to assist determine actions required and priority. These drafters can form a record of the proposed action to be undertaken by the project team.

Some engagement activities may need to be a series of interactions culminating in positive action by stakeholders, or ceasing negative action that detracts from progress.

For each stakeholder (individual roles and groups), a discrete prescription should be prepared as to what information is given by Magnetic South and AARC, what is to be asked for, what action is needed of the stakeholder, and Magnetic South/AARC's proposition.

The longer play should be considered - actions needed to lead to approval, project commencement and operations

Prioritisation and scheduling of engagement activities may be guided by the following:

- What actions and other assistance is critical to progressing assessment and project milestones;
- What proposition, agreement, actions, support, endorsement or positive action needed to maintain continuity;
- Times at which desired action must happen;
- Specific deliverables for each stakeholder by role, group or other consideration;
- Propositions, information, solutions to issues or actions which genuinely satisfy stakeholders, and achieve positive response; and
- Sequence of agreements, actions or information set anticipated for each stakeholder or cluster for their period of interest, influence, or for the life of the project.

5. KEY ISSUES AND HOLDING STATEMENTS

5.1. KEY ISSUES

Determination of what may be issues and what key messages and holding statements can be discovered through internal discussion and desktop review.

Some bridging communications strategy may be required to reasonably distinguish Magnetic North from the previous owners and other projects.

Magnetic North may need to incrementally develop iterations of its approach to various issues and opportunities. Changes can be used to demonstrate that Magnetic North has aimed at resolving concerns so that a compatible project is being planned.

Early government engagement to support continuity of project concept scoping is useful to give assurance that communication with stakeholders at all levels is competent and positive outcomes-focussed.

After the first rounds of consultation some incremental increase in communications intensity may be needed.

Resource industry and company experience suggests that a range of project-wide, field and transport corridor issues need be considered at an early time.

5.1.1. Region-wide issues

Although Dingo West is small scale in the region perceptions may arise that all together projects and associated infrastructure network could overwhelm the region's landscape, environment, rural economy and community.

A **primary key message** at the start is that the project's approach is competent and directed to fitting into regional infrastructure planning, environmental management, and coexistence with other industries, community infrastructure and community life.

The **second key message** is that this project must be included in regional infrastructure forward planning agenda - connecting corridors, water supply capacity and reticulation and energy reticulation need be included in the Queensland Government infrastructure. All level of governments' commitment to the Galilee Basin State Development Area declaration and collateral regional economic planning needs early review.

Third key message focus should be on legacy perceptions. Whilst Magnetic South is a new owner of Dingo West, legacy issues, perceptions and anxieties may need to be assessed and addressed. Any need to address future understanding; acceptance and cooperation of landowners may require significant early attention.

The fourth key message focus is the sensitivity towards the coal industry relating to future global energy and global warming. Whilst these are issues above the project, there is potential for activities by groups and individuals who could be opposed to obstruct land access for exploration and field activities, allege underground and surface water capacity impacts, depict transport corridor and safety hazards and caution alleged reduction in agricultural production area. Competition for water resources, roads and infrastructure has been identified as critical concerns by key agri-political organisations.

The **fifth** key message area is in integrity of project proponent baseline studies and government assessment, being based on science and law. Assurance needs to be given that the standard of the EMP/EIS process is defined by the Queensland Government, will aim to identify issues, justify key propositions and deliver unambiguous defined approaches answer to all matters raised, for Land Court of Queensland examination.

5.1.2. Project-wide issues

Key project-wide issues include but are not limited to

- The potential scale and impacts of all Central Highlands projects combined;
- Political, community and media concern with the expansion of the coal industry to service new and emerging markets;
- Carbon emissions goals, commitments and legislation;
- Issues around green house gas, emissions trading, carbon sequestration, commitment to sustainability;
- Potential environmental impacts of the region's coal mines, transportation corridors and associated facilities;
- Harmonisation of co-development agreement propositions with approval processes and land tenure;
- Impact of land tenure on freehold and public landholdings, and continuity of land use activities and agricultural production;
- Effective community collaboration and cross-industry sector collaboration, use of shared and existing infrastructure, and potential mandated use;
- Competition for land area and scientifically-sound opportunities for vegetation clearing offsetting obligations and biodiversity offsetting to satisfy rehabilitation and biodiversity obligations against agricultural production growth needs;
- Environmental health and safety risk exposure arising over the composite footprint – silicosis and similar respiratory disease stimulation; dust and respiratory sensitivities;
- Demand impacts on townships' facilities and services such as housing, hospitals, human services, existing government services, recreation facilities, reticulated water and sewerage (if relevant), schools, fire and emergency services;
- Increased heavy transport use of main inter-regional access routes;
- Impacts of increased vehicle numbers and trip frequency within settled areas and on the intra-regional road network;
- Housing provision and affordability impacts on existing and new residents;

- Size location, and availability of some dedicated camps in competition with other planned urban and regional development;
- Social and behavioural tensions between existing resident population and new continuing, temporary and occasional residents.
- Competition against existing business for workforce resources; and
- Impact on the markets of regionally based businesses through consequent business attraction.

5.1.3. Field issues

Issues related to coal field activities include but are not limited to:

- Land access practices and frequency of site entry for non-MS freehold lands;
- Fair dealing and collaboration in land tenure and acquisition;
- Potential impacts on existing land use associated with geophysical exploration, ongoing groundwater monitoring and field survey activities;
- Management of potential damage from drilling activities;
- Alienation and sterilisation of agricultural land;
- Potential impact of groundwater drawdown;
- Potential local area shallow groundwater drawdown;
- Perceptions of contamination of aquifers;
- Limited sustainability of water supply from bores, wells and surface sources;
- Watercourse diversion – Springton Creek;
- Disturbance of agricultural activities including grazing, cropping, pasture improvements, fencing integrity and existing low-grade farm roads;
- Field exploration and development road intrusion onto productive land capacity;
- Reduction of the aggregate land pool available for agricultural production;
- Stock safety;
- Spread of exotic weed infestation;
- Concern with impacts on vehicle traffic and roads crossing watercourses;
- Reduction of vegetation communities of significance;
- Restoration, rehabilitation - standards, sequence– exploration, operations
- Implication of overlap of licences and associated activities;
- Harmonisation of co-development agreement partners field activities to reduce aggregated impacts and frequency- if any;
- Field activities that disturb land surfaces and have potential to impact cultural heritage places and materials.

5.1.4. Mine site issues

- Hours of operation, frequency of blasting, vehicle movements;
- Water competition, interruption of flows, drawdown;
- Escape of below discharge quality water, wastewater treatment standards, and failure of tailings dams – if any, extended rain event water retention capacity, levees;
- Immediate area impacts on water quality and turbidity;
- On-site fire and explosion;
- Fire escape from site to surrounding grazing and cropping areas;
- Erosion influence on watercourses and surrounding areas;
- Influence on salt surface emergence;

- Release of contaminants and undesirable inorganic concentrations on ground surface and subsequent land contamination;

5.1.5. Transport corridor issues

Issues may include but are not limited to:

- Prospective routes and impacts of the rail loop.
- Haul routes – if relevant;
- Compulsory land acquisition for transport corridor routes;
- Land access, topographic survey and geophysical survey activities may intrude on land use activities and create impacts beyond the Magnetic South freehold land;
- Uncertainty about property configuration disturbance and dissection of productive areas;
- Construction phase transport of major equipment disturbance beyond negotiated corridors; and
- Train movements, hours of operation and frequency.

5.2. KEY MESSAGES AND HOLDING STATEMENTS

Themes will be useful to form groups of key messages and holding statements.

Anticipation of issues, propositions and key messages in response to issues will contribute to consolidation of the proposition to the stakeholder community.

Information to be contained in any initial advice statements and potential terms of reference will consolidate and confirm the proposition to the stakeholder community.

An incremental tree, trunk, branch and shoots mapping approach should be applied to issues identification, to support thoroughness in scoping issues, impacts and consequences.

5.2.1. Analysis of issues and risk assessment

Early propositions can be made to establish logic for longer-term amelioration of issues and stakeholder aspirations. Issues are anticipated to arise in exploration and land access, project assessment process, and the project's location, form, scale, infrastructure network, establishment and operational impacts.

Two forms of issues assessment should be used to inform holding statements and key messages. The tools *Stakeholder Category Issues (005*) and *Issues Action and Response (006*) can be used to interrogate issues, and form key messages and holding statements.

Position statements and key messages need be developed to bridge the gap between the period of former proponent relinquishment of interest and Magnetic South's future intentions being public.

Magnetic South could undertake a risk assessment that includes issues, the risk or harm, probability of occurrence, severity, rating and potential action to reduce or

mitigate risk. Assessment will assist development of propositions and key messages that define action and support achievement of desired outcomes.

Some caution is needed as to the level of effort and resource applied to this analysis, as intuition of the project team would envisage a clear proposition as to the impact of otherwise of issues.

5.2.2. Key issues themes and issues tree

Preliminary consideration of project information suggests that the issues and key message can be categorised into a hierarchy of common themes:

- Company
- Project
- Approval and authorities processes (e.g. exploration permit for coal, baseline studies, environmental impact statement/environmental management plan (EIS/EMP), supplementary EIS/EMP, mining lease application, Land Court, environmental authority, rehabilitation standard and bond)
- Project benefits
- Project-wide issues – geographic and spatial distribution of discrete mine operational activities, infrastructure and connectivity
- Timing and sequencing of development and infrastructure
- Field exploration – access, resolution of tenure, potential field activity impacts, property valuation
- Field development activities - drilling activities, monitoring and access
- Site development
- Project site infrastructure - connectivity and demand on regional water supply, rail and road network
- Infrastructure connectivity and impact on local roads network
- Traffic
- Project site development
- Site operations
- Rehabilitation
- Continuing land use and coexistence with agriculture
- Business and supply chain connectivity
- Employment
- Worker accommodation and transport
- Community, social and human services

5.2.3. Sub-themes and sets of branch issues

Sets of issues and key messages can be prepared around significant core issues such as land access and acquisition of appropriate tenure, access to land during exploration, ground water, surface water flows, watercourse impacts, coexistence with agriculture, impacts and propositions for harmonisation of mining population with townships and settlement.

Branches and clusters of issues appear to form from several of the main themes; such as site development initiates the following issues:

- Site exploration and drilling
- Clearing for plant and fences
- Construction of plant
- Site clearing for pre-excavation
- Stockpiling of spoil
- Pit excavation
- Site and pit management
- Coal handling and processing plant
- On-site movement of plant, equipment, employees, service providers
- Stockpiling of raw resource

Although detailed planning may not be commenced, enunciation of known principles and practices may assist assurance of stakeholders.

6. COMMUNICATION TOOLS

Only selected tactics and tools will be needed at the outset. Findings after completion of round one will inform refinement for continuity.

Selection of communications tactics and tools is guided by considerations including:

- The detail of the project and infrastructure to be considered over time;
- Suitability of the tactics and tools to be effective, economical, and discreet;
- Analysis of the objectives, desired outcomes and actions expected of decision-makers and other stakeholders, and the actions needed to secure these;
- Potential to achieve a desirable level of understanding, and response;
- Constraints on achieving engagement and authorized assistance;
- Reasonableness of logistics, deliverability, human resources and economy;
- Dedicated time availability of project team members;
- Potential value and risks of the tactics and tools to inform, and resolve issues;
- Potential to optimise access to information, participation, and feedback; and
- Potential for leveraging.

6.1.1.1. Specified Stakeholder engagement

- Interviews with stakeholders – to gain regulatory, regional planning, economic development, community development, geographic, community, and industry sector contexts and aspirations;
- Private briefings to stakeholders – to selected stakeholders to communicate information, the project proposition, the process and opportunities to participate – sought by direct request;
- Elected member briefings – permission to enter region and seek advice; and
- Group briefings – selected targeted business groups, potential supply chain partners, special interest groups to whom invitation has been offered directly.

6.1.1.2. Direct controlled engagement

- Community information events – information presentation, specialist interaction, feedback collection, establishment of participation pathways;
- Static displays –information, offering contact, inviting advice comment;

- Regional office and depot – continuing offer of evolving information, maintaining ease of contact, feedback and comment;
- Group presentations – selected prequalified audiences - information targeted at the interests of the audience, promotion of access to information, participation and issues resolution process availability;
- Issues workshops – scoping of issues with experience and expertise;
- Key stakeholder focus groups – controlled scoping of unspecified issues and propositions;
- Regulatory agency, referral agency, and government stakeholder workshops – harmonisation of process and resolution of issues;
- Coalition of interest workshops – industry shared interest stakeholders to generate benefit propositions and mitigations to issues;
- Social licence proposition – scoping of collaborations for economic development, community development, and natural environment enhancement; and
- Targeted individual stakeholder communication – personal meetings, telephone, e-mail, and individual responses and propositions.

6.1.1.3. Indirect engagement

- Selected cluster group letters – providing information, offering contact, inviting feedback and comment;
- Contact cards – project introduction, offering access to information;
- Media releases;
- Newspaper and magazine display advertisements;
- Radio and television commercials – promote position on issues, offer access to information, invite to events, invite contact;
- Advertorials; and
- Surveys – scope issues.

6.1.1.4. Feedback mechanisms

- Free call telephone line – separate to company entity
- Freepost
- E-mail addresses

6.1.1.5. Supporting collateral

- Briefing notes
- Maps, illustrations and technical drawings
- Facts sheets
- Question and answer – holding statements sets
- Brochures
- Newsletters
- Monographs
- Project studies summary reports
- Regulatory agency reports
- Research reports
- Discussion papers
- Interpretative displays – individual topics and series

- Websites
- E-mail
- Social media – managed and priority limited

6.2. TEAM MEMBERS AND CONSULTANTS

The activities of company members and all consultants in incidental and purposeful communications should be captured. All project team members and selected external service providers should be required to report all stakeholder interactions.

All should be receive a minimum verbal brief of the communications structure, the key messages and holding statements, and the tools for information capture.

Magnetic North should place the expectation that key messages and statements be delivered as best can be in the circumstances of engagement, and that information capture sheets are completed and forwarded to Magnetic North and AARC to ensure that issues and opportunities are addressed adequately.

Verbal briefing should cover the following topics, but relevant to the specific role:

- The intent of communications to be captured to support the EMP:
- The types of methods and tools being used by Magnetic South and AARC;
- Collateral such as stylised drawings and diagrams available from AARC;
- Outline of the rounds of communication activities;
- What is the usefulness of incidental communications for Magnetic South;
- Adopted key messages:
- Need to follow key messages, avoid information/enquiry gaps arising, and extend use;
- The need to advise Magnetic South and AARC immediately of any sensitivities requiring action or response;
- Advise of any information gaps and risk areas; and
- Feedback mechanisms – potential actions to resolve any issues.

The tools *Stakeholder Contact Planner (003)* and *Stakeholder Contact Record (004)* should be used.

7. EXECUTION – STARTING TO CAPTURE INFORMATION, ACT AND RECORD

AARC will prepare and transcribe communications events notes captured by the team, placing information into a matrix of themes structured from the issues lists, and a matrix segmented to the sequence of milestones, and time.

The following details is required:

- Record details of stakeholders;
- Project team notes of interactions with stakeholders;

- Capture file links to collateral documents used in meetings/interviews – technical drawings, geographic locations, infrastructure, lands, properties and improvements;
- Distinguish project team interactions with impacted persons, as distinct from wider stakeholders;
- Record actions taken by the team in response to stakeholder inputs, advice, comment, and completion of feedback;
- Save to file any documentation that illustrates the subject of communication (oral communication notes, letters, e-mails, reports, minutes and agreed action reports); and
- Assimilate with other information systems' functions such as land information systems (LIS), geographic information systems (GIS), digital mapping, and photography.

8. EVALUATION

Evaluation should be undertaken of the process and the information documented in a cyclic manner, according to the amount of information collected.

8.1. EVALUATION METHODS

Evaluation should be undertaken at the completion of the each round of communication, so as to assess the adequacy of the communication activities, draw out prompts to maintain continuity, consolidate, recover performance if needed, and reorientate or change.

Evaluation could be undertaken at the same time the project team evaluates progression of the project milestones.

8.2. EVALUATION CRITERIA

Input and output assessment should specifically focus on the adequacy of the communications program actual delivery, and response to regulatory agency requirements.

Overarching prompts include:

- Achievement of stakeholder desired actions;
- Delivery on principles for engagement;
- Inputs;
- Outputs; and
- Overall progress.

8.2.1. Input prompts

- Documentation of planning, implementation and auditing of engagement and communication activities for each component or phase – to demonstrate compliance with requirements;
- Response to issues – methods and results;
- Adherence to adopted protocols and guidelines;
- Adherence to regulatory process integrity; and

- Other measures negotiated with regulatory agencies.

8.2.2. Output prompts

- Access – reach of communication;
- Equity and inclusiveness;
- Responsiveness – timeliness and completion of response to enquires, requests, comment, feedback, communications and engagement opportunities;
- Accountability and integrity – compliance to mandated terms of reference and policy; and
- Measure of reach, mitigation strategies delivery, communication and collateral

Measurement may include:

- Proportion of anticipated stakeholders engaged;
- Response to participation opportunities;
- Increase of awareness and knowledge of project process;
- Project team's relationship with stakeholders and frequency of contact; and
- Standards of documentation and reporting.

8.2.3. Evaluation reporting

Reporting on evaluation should comprise findings of the evaluations, and include:

- Effectiveness of how stakeholders were informed, consulted, involved, invited to collaborate and empowered, as described by the International Association for Public Participation *IAP 2 Public Participation Spectrum*;
- Fairness of the process;
- Compliance with company values, policies and adopted directions;
- Effectiveness of the engagement against the situation on commencement and the situation prevailing at the time of evaluation; and
- Internal team performance capability evaluation.

9. GETTING STARTED - THE SEQUENCE

The purposes and objectives of each execution phase must be confirmed.

Purpose, objectives and summary information must be documented, so as to guide purposeful engagement and accumulate recordable communication, responses and advice, and record integrity of dealing.

Program timing, target focus and messaging can be slowed and narrowed, so as to avoid distracting government and other focus at some periods.

Program activity timing needs to be considered, so as to distract from the primacy of scientific assessment and advice, and to avoid "public poll" enquiries, outside legitimate processes.

The first steps:

1. Brief all team members on the strategic communications framework, their role, and use of capture tools;
2. Commence use of information collection tools in contact to all team members and consultants;
3. Define the project process, scope the milestones' delivery essentials and timelines;
4. Identify regulatory agency engagement requirements;
5. List the incidental activity stakeholders and planned communication stakeholders;
6. Define the stakeholder interests to be addressed and actions needed;
7. Prioritize the actions required of stakeholders, including listing in which rounds communications is needed;
8. Prepare an action set for each stakeholder:
9. Assess the risks and probability around issues and opportunities – list proposed responses;
10. Define the key messages for the first round's issues/opportunities, addressing risks;
11. List potential stakeholder communications activities for each round prepare a matrix of stakeholders, types of contact, collateral to be provided, and points in the process in which contact is made:
12. Prepare collateral – briefing notes, spatial relationship drawings;
13. Schedule the first round of communications activities - prioritizing incidental stakeholder engagement with planned;
14. Extend use of information collection tools in contact to all team members and consultants;
15. Magnetic North and AARC review collected information, and record into database;
16. Alternately, Magnetic North and AARC refer matters for further to selected team member for action;
17. Respond to source of issue opportunity as necessary;
18. Incrementally construct report to inform EMP report;
19. Amend holding key messages and holding statements; and
20. Review recorded information to inform refinement.

10. THE TOOLS

The following tools form part of this methodology, and are provided in IT file formats.

- Stakeholder Assessment Prompter (001),
- Stakeholder Assessment Notes Drafter (002),
- Stakeholder Contact Planner (003),
- Stakeholder Contact Record (004),
- Stakeholder Category Issues (005), and
- Issues Action and Response (006)

11. COMMENCING THE CONSULTATION REPORT

A consultation report can be commenced at an early time; the structure needs to contain the following elements:

- Summary – project overview, EMP/EIS process, consultation, findings
- Project background
- The voluntary EMP/EIS process
- Stakeholder framework methodology - consultation methodology
- Key stakeholders
- Issues and messages foreshadowed
- Incidental stakeholder consultation
- Planned stakeholder consultation
- Communications tools
- Summary of activities
- Findings of the initial project scoping activities, justification of intensity of consultation, and conclusions as to approach and potential issues;
- Stakeholder management, reporting and response to issues;
- Findings in details – records of issues
- Leveraging potential;
- Evaluation;
- Summary of findings, conclusions and settlement of issues; and
- Recommendations.

12. APPLICATION PHASE

Activities during the period leading up to submission of the Environmental Management Plan can refined, so as to adequately respond to the Queensland Government's standard Terms of Reference. Enquiry should be made to Queensland Department of Environment and Science to ascertain any specific requirements.

Some intensified activity may be necessary during agency assessment and Land Court of Queensland consideration of the Mining Lease and Environmental Authority applications. Specifically, Magnetic North and AARC need to be aware of the process and timing of public advertisement of the EMP, by DECS, so that integrity and fair dealing is maintained.

12.1. REGIONAL ECONOMIC INFRASTRUCTURE CONNECTIVITY PHASE

Regional economic infrastructure compatibility forms an opportunity for the project to gain development and operational phase economies from future regional economic infrastructure planning. Magnetic North should scope participation in selected planning forums.

Representation on future infrastructure demand can stimulate future beneficial regional economic infrastructure provision, which might obviate direct project expense liabilities.

Some Commonwealth, Queensland and Local government regional planning and area development initiatives need be monitored at a modest level, so as to maintain a watch for any leverage opportunities, and to gain any emerging intelligence.

Scoping infrastructure utility and benefit should promote awareness of the project's needs in the regional economic infrastructure planning agenda, future infrastructure planning and delivery, land use provision and avoidance of land use conflicts.

12.2. FUTURE BUSINESS OPPORTUNITIES AND LEVERAGE PHASE

The program should target businesses to provide reasons to engage for the dissemination of project information, build the body of support, and diminish any issues that exist, in a closed and targeted manner.

Focus should be on drawing out any future development and operational economies, connecting with business opportunities for favourable operating conditions, create future supply chain economies, and any plausible leverage.

13. LAST WORDS – PRIMACY OF SCIENCE AND LAW

The SCF program should promote confidence in the well-established and well-informed Queensland Government processes for consideration of Mining Leases and Environmental Authorities.

A significant, but often overlooked, premise is that projects are assessed in the Land Court of Queensland on the law and environmental management proposition (draft Environmental Authority) reached by the assessment agencies. It must be a constant that project assessment in the Land Court and at Ministerial level are matters of science and law and should not be subject to political will or external poll.

Prerequisite to carrying this premise throughout the project is preparation of a suite of propositions, which may require modest refinement over time. A suite must be prepared quietly, whilst Magnetic North canvasses agreement as to how it enters regional Queensland.

Planning and execution should build project certainty and confidence at each point in process and time, consideration of the EMP iterations, expert witness to the Land Court report compilation, the expert witness conclaves, and culminating in Land Court of Queensland consideration.

1.0 INTRODUCTION

AARC Environmental Solutions Pty Ltd (AARC) was commissioned by Magnetic South Pty Ltd (Magnetic South) to prepare an Aquatic Ecology Assessment for the Gemini Project (the Project), located approximately 110 kilometres (km) east of Emerald and 125 km west of Rockhampton in the Bowen Basin of Central Queensland (Figure 1). The small rural townships of Bluff and Dingo are located approximately 15 km east and 3 km west of the Project, respectively (Figure 1). The Project is a proposed metallurgical open-cut coal mine and associated infrastructure, producing Pulverised Coal Injection (PCI) coal and Coking Coal products for export for steel production.

An assessment of aquatic ecological values was conducted within Exploration Permit Coal (EPC) 881 (herein referred to as the study area). This assessment forms part of the supporting studies required for the Project's approval processes.

1.1 SCOPE OF STUDY

To assess the ecological values of aquatic ecosystems within the study area, the following scope of works was undertaken:

- Database searches to identify aquatic species of conservation significance known or with potential to occur in the region (Appendix A);
- Field surveys employing standard methodologies derived from the *Terrestrial Vertebrate Fauna Survey Guidelines of Queensland* (Eyre et al. 2018) and *Methodology for Survey and Mapping of Regional Ecosystems and Vegetation Communities in Queensland Version 4.0* (Neldner et al. 2017) to identify aquatic flora and fauna species inhabiting the study area, particularly species of conservation significance[1];
- Surface water quality, stream sediment sampling, macroinvertebrate sampling, fish and crustacean sampling and analyses in accordance to the *Australian River Assessment System (AusRivAS) Physical Assessment Protocol* (Parsons et al. 2002b), the *Queensland AusRivAS Sampling and Processing Manual* (DNRM 2001) and the *Monitoring and Sampling Manual: Environmental Protection (Water) Policy 2009* (DES 2018b); and
- Preparation of an assessment report describing the aquatic ecological values identified on site, potential impacts of the Project, management strategies to minimise the impacts associated with the proposed mining activities, and offset requirements.

[1] 'Species of conservation significance' or 'threatened species' when referred to within this document are references to species listed as Near Threatened, Vulnerable or Endangered under the Queensland *Nature Conservation Wildlife Regulation 2006* or Vulnerable, Endangered, Critically Endangered, migratory under the *Environmental Protection and Biodiversity Conservation Act 1999*.

1.2 PROJECT OVERVIEW

The main activities associated with the Project include:

- Exploration activities continuing in order to support mine planning;
- Development of a Mine Infrastructure Area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, explosives magazine and sewage, effluent and liquid waste storage;
- Construction and operation of a Coal Handling Preparation Plant (CHPP) and coal handling facilities adjacent to the MIA (including Run-of-Mine (ROM) coal and, product stockpiles and rejects bin/overflow [coarse and fine rejects]);
- Construction and operation of a surface conveyor from the product stockpiles to a Train Load Out (TLO) facility and rail loop connecting to the Blackwater-Gladstone Branch Rail to transport product coal to coal terminals at Gladstone for export;
- Construction of access roads from the Capricorn Highway to the MIA, and to the TLO facility;
- Installation of a raw water supply pipeline to connect to the Blackwater Pipeline network;
- Construction of a 66 kilovolt (kV) transmission line and switching/substation to connect to the existing regional network;
- Other associated minor infrastructure, plant, equipment and activities;
- Development of mine areas (open cut pits) and out-of-pit waste rock emplacements;
- Drilling and blasting of competent waste material;
- Mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers);
- Mining up to 1.9 Million tonnes per annum (Mtpa) ROM Coal – average 1.8 Mtpa for a construction/production period of approximately 20 years;
- Progressive placement of waste rock in:
    - Emplacements, adjacent to and near the open cut voids;
    - Mine voids, behind the advancing open cut mining operations;
- Progressive rehabilitation of waste rock emplacement areas and mined voids;
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works). Material will be sourced from local quarries where required;
- Disposal of CHPP rejects (coarse and fine rejects) in out of pit spoil dumps, and in-pit behind the mining void;
- Progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access; and

- Development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, and drains.

Existing local and regional infrastructure, facilities and services would be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

1.3 CURRENT LAND USE

The land within the study area is currently used for low intensity cattle grazing and resource exploration activities. The Capricorn Highway and a number of publicly gazetted roads including Charlevue, Cooinda, Red Hill, Normanby, and Ellesmere roads dissect the study area.

Located directly north of the study area is the Taunton National Park (Scientific), (Taunton Nation Park), a scientific reserve under the *Land Act 1994 (Queensland)*, with the aim of protecting a population of Bridled nail-tail wallabies. A small section of the Taunton National Park of around 2.5 hectares (ha) occurs within the study area.

1.4 LOCAL WATERWAYS AND TOPOGRAPHY

The study area lies within the Fitzroy River Basin, which encompasses an area of 142,545 square kilometres (km^2) and contains the Comet, Connors, Dawson, Don, Nogoa and Mackenzie Rivers, which make up its six sub-catchment areas (BoM 2018; DES 2018a). The study area lies within the Mackenzie River sub-catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River catchment.

Charlevue Creek traverses the study area in a north-easterly direction. This watercourse begins within the boundaries of Blackdown Tablelands National Park, flowing north-east before joining with Springton Creek and the Fitzroy River, and eventually into the Pacific Ocean approximately 46 km north of Gladstone. Stanley Creek and Springton Creek cross the study area in the north-west and south-east, respectively. These two creeks also eventually converge with the Mackenzie River. First and second order streams associated with Charlevue Creek and Springton Creek also occur in the study area. Figure 2 shows the extent and location of the waterways within the study area.

Springton Creek and Charlevue Creek are defined watercourses under the *Water Act 2000 (Queensland).* Springton Creek and Charlevue Creek within the study area are 5th order streams. Stanley Creek is a 2nd order stream.

Topography of the land varies from flat to undulating, with elevation within the study area ranging between 120 metres (m) and 150 m. The landscape is influenced by Charlevue Creek, which has a lower elevation than the surrounding landscape. The topography of the study area is representative of the surrounding region.

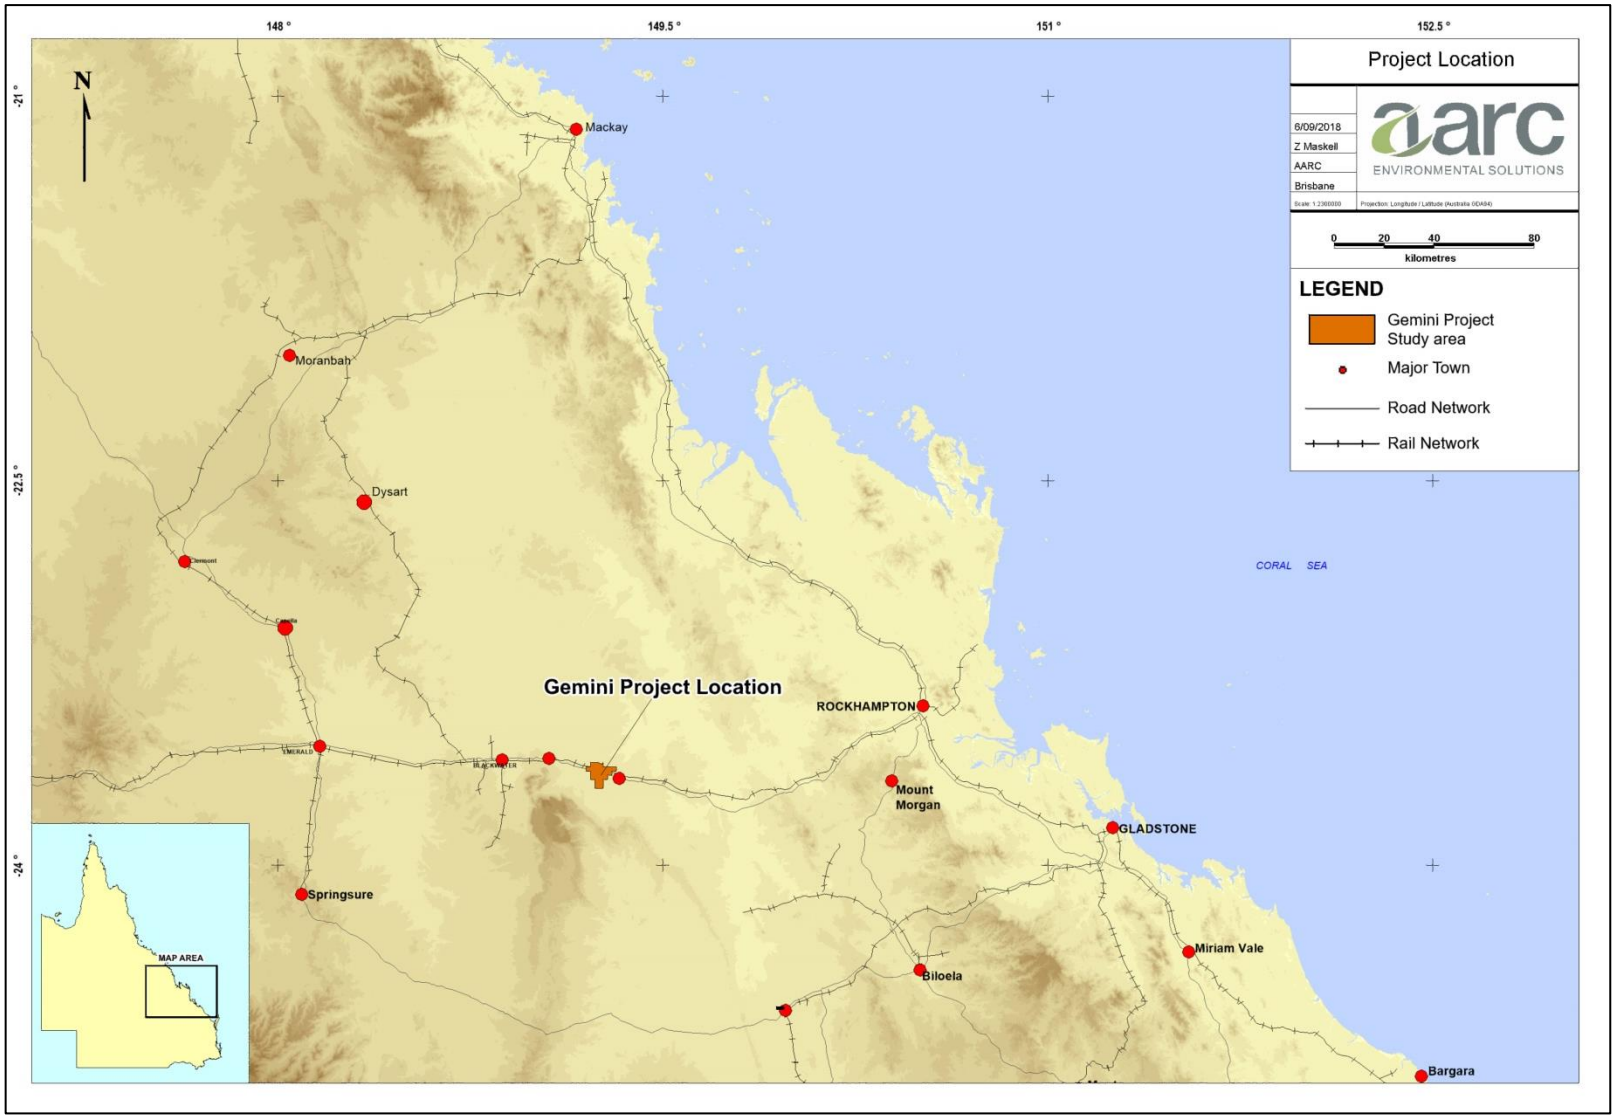

Figure 1 Project and Study Area Location

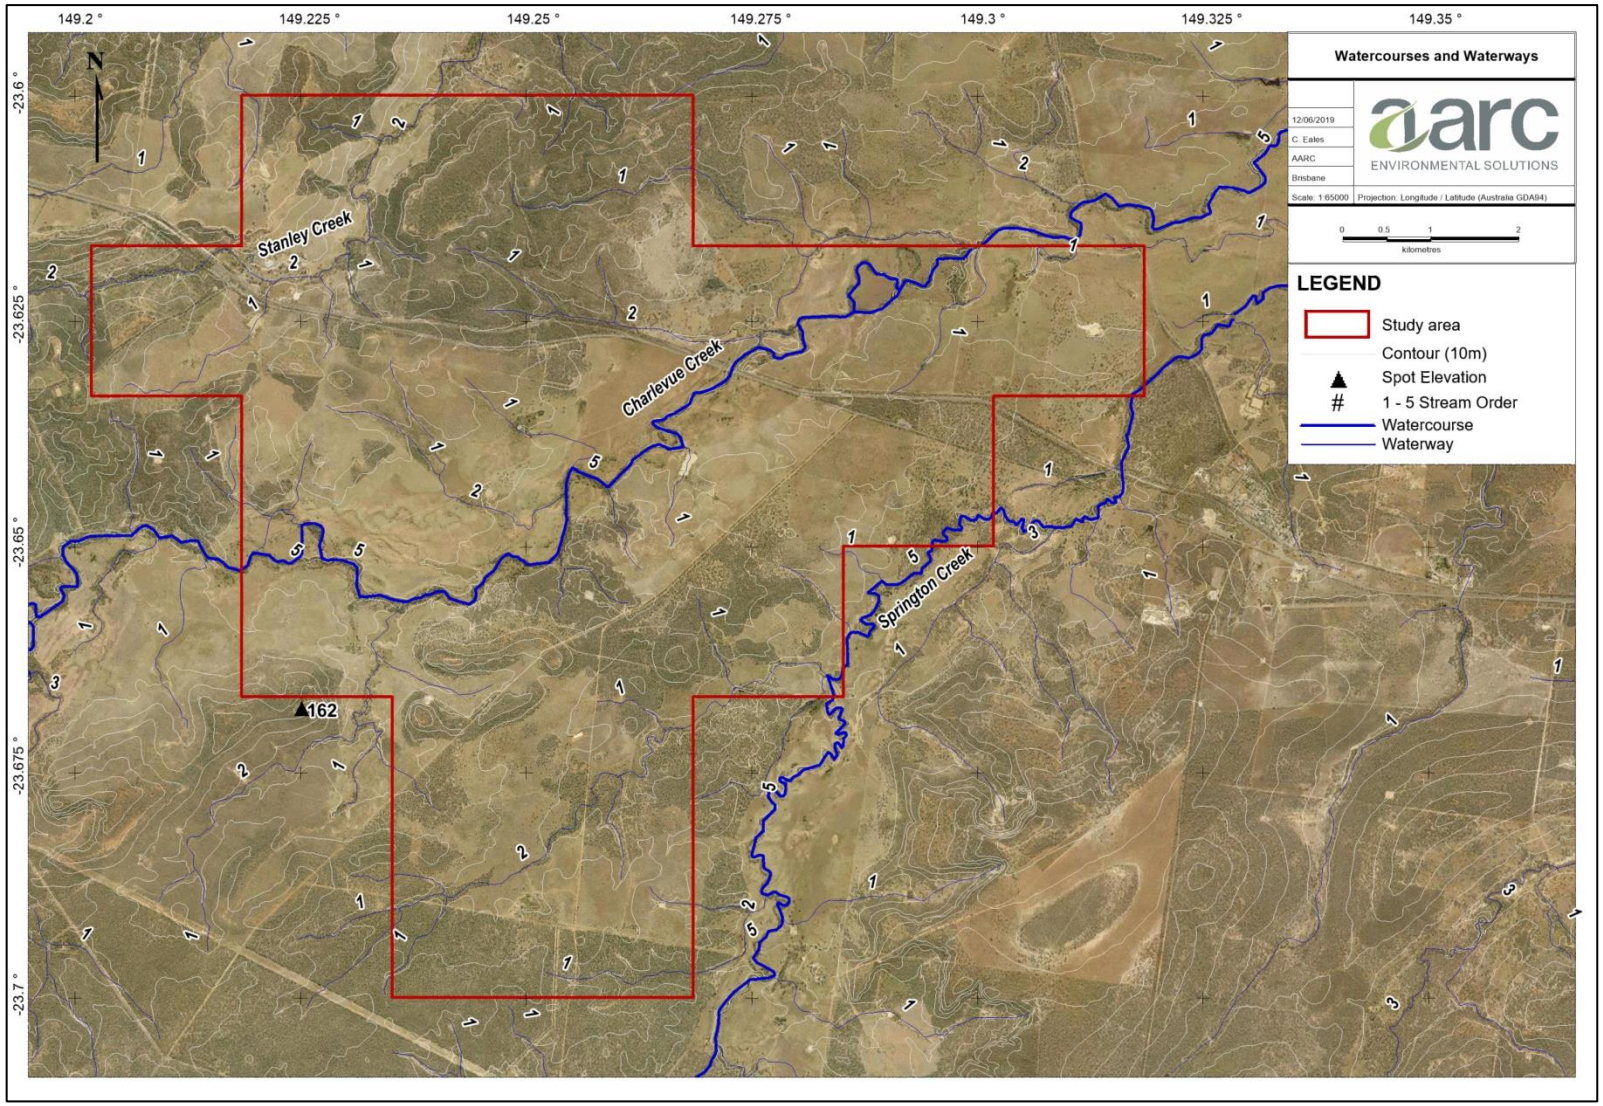

Figure 2 Waterways and topography associated with the study area

1.5 GEOLOGY

The geology of the region is dominated by its position within the Bowen Basin, one of Queensland's largest depositional regions, which formed through a period of rifting and subsidence lasting from the Early Permian - Mid-Triassic. The area is dominated by clastic sedimentary rocks of marine and lacustrine origin, including sandstones, conglomerates, mudstones, siltstones and coal (Geoscience Australia 2018).

The coastal and inland depositional environments which created these deposits allowed for the formation of extensive coal seams throughout the Bowen Basin, with the anoxic deposition of organic matter subsequently compacted and de-volatised through compression and increased temperatures (Brooks & Smith 1969).

Generally, coal seams found in the east-central part of the basin contain higher quality coking coal deposits, with rank falling below coking range farther south and west (Hutton 2009). The high-quality coal measures are of Permian age, buried less than 60 m from the surface (Mutton 2003).

1.6 REGIONAL CLIMATE

The regional climate is classified as semi-arid, characterised with warm dry summers and warm winters. Climate data for the study area has been sourced from Scientific Information for Land Owners (SILO) climate database (Queensland Government), which operates by interpolating data from the Commonwealth Bureau of Meteorology (BoM) into a single point data drill.

Figure 3 shows predicted average temperature and rainfall for the area from January 1999 to July 2019. The data indicates the annual mean rainfall for the region is highest between December and March with the maximum average occurring in December (111.5 millimetres (mm)).

The hottest months typically occur between October and March while the coolest months occur between May and September. The highest mean maximum temperature typically occurs in December (34.2 degrees Celsius (°C)) and the lowest mean minimum temperature in July (8.5°C). The mean annual maximum temperature for the region is predicted to be 29.8°C and the mean annual minimum temperature is predicted to be 16°C.

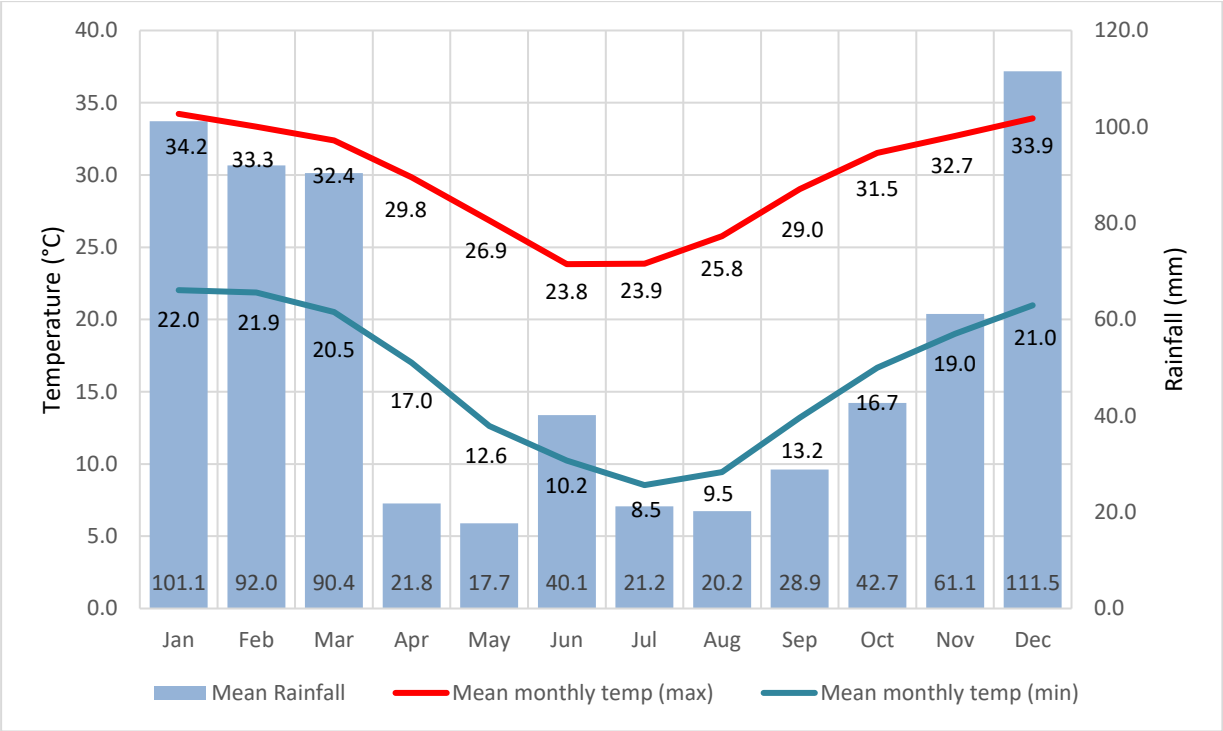

Figure 3 Mean temperature and rainfall data for the region (Source: SILO)

2.0 RELEVANT LEGISLATION AND POLICY

Commonwealth and State legislation and policies relevant to the assessment of aquatic ecological values on the study area are discussed below.

2.1 ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999

Under the Commonwealth *Environmental Protection and Biodiversity Conservation Act 1999* (EPBC Act), an action requires approval from the Federal Environment Minister if the action has, will have, or is likely to have a significant impact on a Matter of National Environmental Significance (MNES).

An EPBC Referral (2010/5775) was lodged in 2010 for the Gemini Project previously known as the Dingo West Project by Dingo West Pty Ltd, which was declared 'Not a Controlled Action if undertaken in a Particular Manner' in July 2011.

The Particular Manner Decision conditions (EPBC 2010/5775) are as follows:

1. *To prevent downstream impacts to the Fitzroy River Turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate pits in a manner that prevents surface water from entering the pit during a 1:1000 year flood event (as indicated in flood modelling at Attachment A).*

2. *To prevent downstream impacts to the Fitzroy River Turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate dams in a manner that prevents surface water from entering or damaging the dams during a during a 1:1000 year flood event (as indicated in flood modelling at Attachment A).*

The Gemini Project complies with the Particular Manner Decision (EPBC 2010/5775). Furthermore, the level of impact to MNES have been assessed to be no greater than those described in the EPBC Referral (20105775).

2.2 NATURE CONSERVATION ACT 1992

The most relevant components of the Queensland *Nature Conservation Act 1992* (NC Act) to the Project, are the sections which pertain to Wildlife and Habitat Conservation. The classes of wildlife to which the NC Act applies includes protected wildlife, which is defined as Extinct wildlife; Endangered wildlife; Vulnerable wildlife; Near Threatened wildlife; and Least Concern wildlife. Species listed under the above classes are published in the associated *Nature Conservation (Wildlife) Regulation 2006* (NCWR).

'Threatening processes' are also relevant to wildlife and habitat conservation. The NC Act defines 'threatening processes' as any process that is capable of:

a) threatening the survival of any protected area, area of major interest, protected wildlife, community of native wildlife or native wildlife habitat; or

b) affecting the capacity of any protected area, area of major interest, protected wildlife, community of native wildlife or native wildlife habitat to sustain natural processes.

The NC Act is relevant to the Project for any protected flora or fauna species (as detailed in the NCWR) found in the study area.

2.3 BIOSECURITY ACT 2014

The Queensland *Biosecurity Act 2014* (Biosecurity Act) provides comprehensive biosecurity measures to safeguard our economy, agricultural and tourism industries, environment and way of life, from pests (e.g. wild dogs and weeds), diseases (e.g. foot-and-mouth disease), and contaminants (e.g. lead on grazing land).

Biosecurity matters are separated into three broad categories:

- A '**prohibited matter'** is a biosecurity matter that is not found in Queensland but would have a significant adverse impact on our health, way of life, and the economy or the environment if it entered the State. Prohibited matters must be reported to Biosecurity Queensland within 24 hours and all reasonable steps taken to minimise the risks of the prohibited matter and not make the situation worse;

- A '**restricted matter'** is a biosecurity matter found in Qld and has a significant impact on human health, social amenity, the economy or the environment. Restricted matters are further broken down into seven categories, with each category placing restrictions on the dealings with the biosecurity matter or actions required to be taken to minimise the spread and adverse impact of the biosecurity matter;

- An '**other matter'** is a biosecurity matter that is not a prohibited or restricted matter. Everyone is obligated to take all reasonable and practical steps to minimise the risks associated with other biosecurity matters under their control.

The Biosecurity Act is relevant to the Project in regard to the control and management of invasive plant and animal species.

2.4 QUEENSLAND ENVIRONMENTAL OFFSETS FRAMEWORK

The Queensland environmental offsets framework consists of the *Environmental Offsets Act 2014*, *Environmental Offsets Regulation 2014*, and the *Queensland Environmental Offsets Policy (Version 1.7*) (DES 2019). The offsets framework requires environmental offsets to be delivered where an activity is likely to result in a significant residual impact on a prescribed environmental matter. The *Significant Residual Impact Guideline* (DEHP 2014) is used to determine whether the residual impacts are significant.

Prescribed Environmental Matters include:

- Matters of National Environmental Significance (MNES);
- Matters of State Environmental Significance (MSES) (outlined below); and
- Matters of Local Environmental Significance (MLES).

MSES are defined in Schedule 2 of the *Environmental Offsets Regulation 2014*, and comprise:

- Regulated vegetation including:
    i. Endangered and Of Concern regional ecosystems;
    ii. Regional ecosystems (REs) that intersect areas shown as wetlands on the Vegetation Management Wetlands map;
    iii. REs located within a defined distance from the defining banks of a relevant watercourse or relevant drainage feature; or

iv. REs mapped as essential habitat for endangered and vulnerable flora and fauna;

- Areas that provide connectivity and maintain ecosystem functioning;
- Mapped wetlands and watercourses including:
    i. Wetland protection areas, or areas of high ecological significance as shown on the Map of referable wetlands; or
    ii. High ecological value waters (as defined under the *Environmental Protection (Water) Policy 2009*);
- Designated precincts in a strategic environmental area under the *Regional Planning Interests Regulation 2014*;
- Protected wildlife habitat, which includes;
    i. High risk areas on the flora survey trigger map;
    ii. Areas that contain endangered or vulnerable plants;
    iii. Non-juvenile koala habitat trees in certain areas of south-east Queensland; or
    iv. Habitat for endangered, vulnerable and special least concern animals;
- Protected areas and highly protected zones of State marine parks;
- Fish habitat areas;
- Waterways providing for fish passage;
- Marine plants; and
- Legally secured offsets.

2.5 FISHERIES ACT 1994

This state legislation protects all aquatic ecosystems from unauthorised disturbance. The main purpose of the Queensland *Fisheries Act 1994* (Fisheries Act) is to provide for:

- the protection of fisheries;
- the protection of marine fish;
- the protection of marine plants; and
- the facilitation of management plans.

As of the 3rd July 2017, the Fisheries Act requires waterway barrier works to be developed in accordance with the accepted development requirements. The accepted development requirements are those outlined in *Accepted development requirements for operational work that is constructing or raising waterway barrier works* (DAF 2018).

2.6 ENVIRONMENTAL PROTECTION (WATER AND WETLAND BIODIVERSITY) POLICY 2019

The *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* (EPP (Water and Wetland Biodiversity)) is subordinate legislation under the *Environmental Protection Act 1994*. The EPP (Water and Wetland Biodiversity) provides a framework for:

1. identifying environmental values (EVs) for Queensland waters, and deciding water quality objectives (WQOs) to protect or enhance those EVs; and

2. including the identified EVs and WQOs under Schedule 1 of the EPP (Water and Wetland Biodiversity).

The EPP (Water and Wetland Biodiversity) is relevant to the Project with regard to the protection of EVs occurring in the Mackenzie River sub-basin and associated tributaries.

The EVs and WQOs for waters occurring on or surrounding the study area are provided in the document titled *Environmental Protection (Water) Policy 2009; EPP (Water) for the Mackenzie River Sub-basin EVs and WQO Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin'* (DEHP 2011a).

3.0 DESKTOP ASSESSMENT

A desktop assessment was conducted to collate information on aquatic ecological values identified in the region. These searches include previous surveys, community records and other sources. A review of databases was conducted to inform the specific field survey techniques to target certain aquatic flora and fauna species known from the region.

All database searches were based on either the Lot/Plan, the study area, or a central coordinate point, depending on the database search undertaken. Database search results can be found in Appendix A. The following databases searches were undertaken:

1. Environmental Reports Online (search based on study area);
    a. Aquatic Conservation Assessments;
    b. Matters of State Environmental Significance;
    c. Regional Ecosystems;
2. Environmentally Sensitive Area (ESA) Mapping (search based on study area);
3. Protected Plants Flora Survey Trigger Map (search based on central coordinate point);
4. EPBC Act Protected Matters Search Tool (PMST) (two searches based on central coordinate point with 20 km and 50 km buffers);
5. Regulated Vegetation Management Report (search based on Lot/Plan);
6. Wildlife Online Species List Request (two searches based on central coordinate point with 10 km and 50 km buffers);
    a. Rare and Threatened Species;
    b. Introduced Species; and
7. Department of Environment and Science (DES) interactive Wetland*Maps* database and Map of Referable Wetlands; and
8. WildNet Records Conservation Significant Species List (search based on circular area selected over the study area to reflect a 'central point with buffer'; area selected was roughly equivalent to a 20 km buffer with a report area of greater than 285,000 ha).

Additional resources that provide species records and related information such as the Atlas of Living Australia (ALA) and Queensland Museum were consulted where appropriate to support likelihood desktop study.

The following sections address items of nature conservation relevant to the study area identified within the desktop assessment.

3.1 SPECIES OF CONSERVATION SIGNIFICANCE

No aquatic flora species of conservation significant were identified by the desktop searches. Database searches identified four fauna species of conservation significance with potential to occur within 50 km of the study area.

A detailed assessment of the likelihood of species of conservation significance occurring within the study area was completed prior to conducting the field survey, for the purpose of determining targeted species and to guide field survey methodology. The detailed assessment was based on the knowledge of ecologists, habitat suitability and scientific literature.

The detailed assessment of likelihood of occurrence considered that all four of the species identified by the desktop assessment were unlikely to occur within the study area (Table 1).

The Fitzroy River turtle was previously identified as potentially being impacted by the Dingo West Project by the EPBC Referral Decision (2010/5775). The potential impact of the Gemini Project on the Fitzroy River turtle is assessed in Section 9.1.2.

Table 1 Fauna Species of Conservation Significance identified by Desktop Searches

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Fish						
Maccullochella peelii Murray cod	V	NL	Species or species habitat **may** occur within area (0-10 km)	No records	The species lives in a wide range of habitats, from clear, rocky streams to slow flowing, turbid rivers and billabongs (DoEE 2018a).	Unlikely This species was returned in the 10 km PMST search as may occur. No records of this species were recorded within 50 km of the study area. The watercourses present within the study area are ephemeral in nature and only run during periods of high rainfall.
Reptiles						
Crocodylus porosus Salt water crocodile	Ma, Mi	V	Species or species habitat **likely** to occur within area (10-50 km)	No records	Salt-water crocodiles are restricted to coastal waterways and floodplain wetlands within Queensland.	Unlikely Only ephemeral waterways are present within the study area with limited to no water persisting throughout the year. Salt-water crocodiles are known to inhabit the lower reaches of rivers. This species was returned in the 10 km PMST search as likely to occur. There are no records of this species have occurred within 50 km of the study area. Given the habitat requirements of this species it would not occur within the study area.
Elseya albagula Southern snapping turtle	CE	E	Species or species habitat **likely** to occur within area (0-10 km) Species or species habitat **known** to occur within area (10-50 km)	2 (10-50 km)	The Southern snapping turtle is only found in the Burnett, Fitzroy, Raglan and Mary river drainages of south-east Queensland. It prefers permanent flowing water habitats where there are suitable shelters and refuges (e.g. fallen trees) (DES, 2017). Found only in Queensland in the Fitzroy, Mary and Burnett Rivers and associated smaller drainages in south eastern Queensland (DoEE, 2018b).	Unlikely No permanent watercourses occur within the study area. No records within 10 km of the Project on Wildlife Online, ALA, or WildNet but 2 records occur between 10 and 50 km. However, this species was returned in the 10 km PMST search as likely occur, and as known to occur between 10 and 50 km. Given the habitat requirements of this species it would not occur within the study area.
Rheodytes leukops Fitzroy River turtle	V	V	Species or species habitat **likely** to occur within area (0-10 km) Species or species habitat **known** to occur within area (10-50 km)	1 (10-50 km)	The Fitzroy River turtle is limited to the Fitzroy River catchment in central Queensland. Previously thought to prefer shallow (<2.0 m) riffle zones with high water velocities, the species is now known to occupy large pools (>1 km long; >2 m deep) and reservoirs. This species will nest in alluvial sand-loam riverbanks (Curtis et al. 2012).	Unlikely No suitable habitat for this species occurs in the study area. No records within 10 km of the study area on Wildlife Online, ALA, or WildNet however, 1 record occurs between 10 and 50 km. A review of ALA records indicate this species is associated with the waters of the Mackenzie River and Fitzroy River.

3.2 WETLAND HABITATS

A review of the Department of Environment and Science (DES) interactive Wetland*Maps* database and the Map of Referable Wetlands indicated three types of waterbodies are potentially present within the study area. Riverine wetlands have been identified in association with the Charlevue Creek. Several small riverine, palustrine and lacustrine wetlands are mapped as potentially present within the study area (Figure 4). All of the lacustrine and palustrine wetlands within the study area have been identified as artificial (farm) dams or not present during previous terrestrial ecology surveys (AARC 2019). Riverine wetlands (corresponding with riverine vegetation) have been discussed in the Terrestrial Ecology Assessment (AARC 2019). No wetlands of national or international importance have been recorded within the study area or surrounds. One High Ecological Significance (HES) wetland occurs approximately 4 km east of the study area (Figure 4). The potential impact on this HES wetland has been addressed in the Terrestrial Ecology Assessment (AARC 2019).

The Aquatic Conservation Assessments defines the study area as having a sub-catchment conservation significance of medium, indicating that these wetlands have varied combinations of high and medium values amongst the assessment criteria.

3.3 WATERWAYS FOR FISH HABITAT

Waterways, as defined by the Fisheries Act, include rivers, creeks, streams, watercourses or inlets of the sea.

The *Queensland Waterways for Waterway Barrier Works* (DAF 2013) mapping indicates the level of 'risk' associated with undertaking waterway barrier works within Queensland waterways. Waterways with higher stream orders, steeper slopes, higher flow rates, greater number of fish present and fish with stronger swimming abilities obtain a higher level of risk.

Charlevue Creek and Springton Creek are mapped as being at major risk of adverse impact from waterway barrier works on fish movement. Stanley Creek is mapped as being of moderate risk of adverse impact. Tributaries of the streams are mapped within the study area as being of either low, moderate or high risk of adverse impact from waterway barrier works on fish movement.

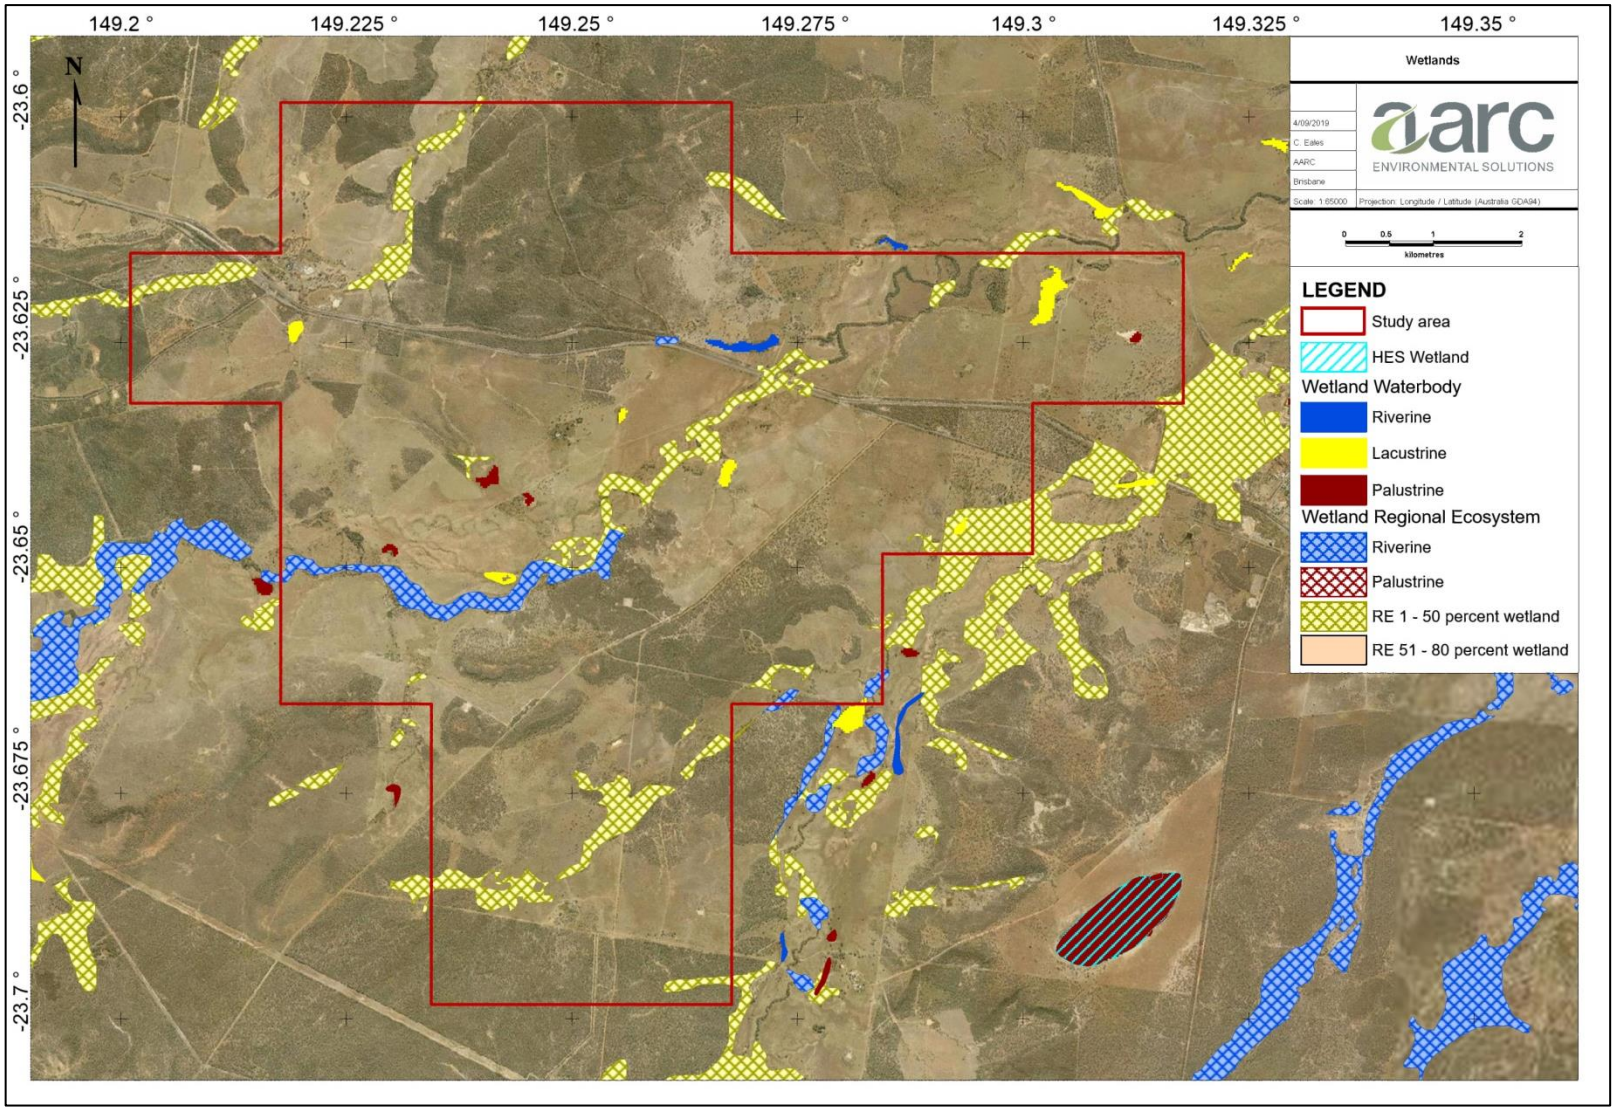

Figure 4 Wetland Habitats

4.0 ENVIRONMENTAL VALUES AND OBJECTIVES

4.1 ENVIRONMENTAL VALUES

The waterways of the Project fall within the Mackenzie River catchment. The *EPP (Water) Central Queensland Map Series (WQ1304 – Mackenzie River Sub-basin)* (DEHP 2011b) identifies several waterways on and surrounding the study area.

Environmental Values are defined as the qualities of water that make it suitable for supporting aquatic ecosystems and a variety of human water uses (DEHP 2013a). The EPP (Water and Wetland Biodiversity) specifies that the EVs for this catchment are those set out in the '*EPP (Water) for the Mackenzie River Sub-basin EVs and WQO Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin'* (DEHP 2011a).

This document identifies ten EVs in the Mackenzie River sub-basin, two of which are deemed as relevant EVs for the waters surrounding the study area; namely protection of aquatic ecosystem values, and suitability for stock watering. The waters within and directly surrounding the study area are defined as moderately disturbed waters by the '*EPP (Water) for the Mackenzie River Sub-basin EVs and WQO Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin'* (DEHP 2011a).

4.1.1 Water Quality Objectives

The *EPP (Water) for the Mackenzie River Sub-basin EVs and WQO Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin* provides WQOs to support and protect the different EVs identified for waters within the Mackenzie River southern tributaries. WQOs are provided in two main parts;

1. For the purposes of protecting the aquatic ecosystem EV; and
2. For EVs other than aquatic ecosystems (human use EVs such as stock watering).

The guideline WQOs for the protection of aquatic ecosystems and for stock watering are provided in Table 2.

Table 2 WQO Guideline Values

Mackenzie River Sub-basin EVs and WQO Basin No. 130 (part)		
Management Intent (level of protection)	**WQOs to protect EV**	
	Parameter	**Water Quality Objective**
	Water	
Aquatic ecosystem *(moderately disturbed)*	Ammonia N	<20 µg/L
	Oxidised N	<60 µg/L
	Organic N	<420 µg/L
	Total nitrogen	<7 µg/L
	Filterable reactive phosphorus	<20 µg/L
	Total phosphorus	<160 µg/L
	Chlorophyll a	<5.0 µg/L
	Dissolved oxygen	85% – 110% saturation
	Turbidity	<50 NTU
	Suspended solids	<110 mg/L

Mackenzie River Sub-basin EVs and WQO Basin No. 130 (part)		
Management Intent (level of protection)	**WQOs to protect EV**	
Aquatic ecosystem *(moderately disturbed)*	pH	6.5 – 8.5
	Conductivity (EC) baseflow	<310 µS/cm
	Conductivity (EC) high flow	<210 µS/cm
	Sulphate	<10 mg/L
	Macroinvertebrates	
	Taxa richness (composite)	12–21
	Taxa richness (edge habitat)	23–33
	PET taxa richness (composite)	2–5
	PET taxa richness (edge habitat)	2–5
	SIGNAL index (composite)	3.33–3.85
	SIGNAL index (edge habitat)	3.31–4.20
	% tolerant taxa (composite)	25–50%
	% tolerant taxa (edge habitat)	44–56%
Stock watering	**Water**	
	Total Dissolved Solids	3000 mg/L
	Aluminium	5 mg/L
	Arsenic	0.5 (up to 5) mg/L
	Beryllium	ND
	Boron	5 mg/L
	Cadmium	0.01 mg/L
	Chromium	1 mg/L
	Cobalt	1 mg/L
	Copper	0.4 (sheep), 1 (cattle), 5 (pigs), 5 (poultry)
	Fluoride	2 mg/L
	Iron	not sufficiently toxic
	Lead	0.1 mg/L
	Manganese	not sufficiently toxic
	Mercury	0.002 mg/L
	Molybdenum	0.15 mg/L
	Nickel	1 mg/L
	Selenium	0.02 mg/L
	Uranium	0.2 mg/L
	Vanadium	ND
	Zinc	20 mg/L

Notes:

EC electrical conductivity
ND no data
µg/L micrograms per litre
mg/L milligrams per litre
NTU Nephelometric Turbidity Units
µS/cm microSiemens per centimetre
PET – Plecoptera, Ephemeroptera, Trichoptera

4.1.2 Stream Sediment Quality Objectives

Baseline levels of metals in stream sediments are important, to investigate the accrual of any pollutants. Stream sediment quality objectives for the study area are adopted from the *Default Sediment Quality Guideline values* (SQG) (ANZECC & ARMCANZ 2000a) (Table 3).

Table 3 ANZECC Stream Sediment Quality Guideline Objectives

Contaminant	Sediment Quality Guideline Value (mg/kg)	
	Low Value	High Value
Arsenic	20	70
Cadmium	1.5	10
Chromium	80	370
Copper	65	270
Lead	50	220
Nickel	21	52
Mercury	0.15	1
Zinc	200	410

Note: mg/kg – milligrams per kilogram

5.0 METHODOLOGY

Two field surveys were undertaken by AARC ecologists within the study area on the 23rd and 24th February 2018, and from the 3rd to 9th of April 2019.

The standard methodologies described in Sections 5.3 to 5.7 were used to survey:

- Surface Water Quality;
- Stream Sediment Quality;
- Creek Ecology;
    - Physical Assessment;
    - Habitat Bioassessment;
    - Condition Assessment;
    - Macroinvertebrate Sampling;
    - Fish and Crustacean Sampling
- Riparian and Aquatic Vegetation; and
- Riparian Zone Vertebrate Fauna.

Only surface water sampling and stream sediment sampling was conducted in February 2018; all other methods were employed by the April 2019 survey.

5.1 FIELD SURVEY WEATHER CONDITIONS

February 2018 Survey

In the week preceding the February 2018 survey a total of 76.8 mm of rainfall was recorded (February 2018) at the Blackdown Tablelands AL weather station (035186) located approximately 14.2 km south-west of the study area. A total of 470.6 mm of rain fell in the preceding three months to the survey.

April 2019 Survey

Conditions during the subsequent survey (April 2019) were mostly fine, with no rainfall occurring during the survey. In the preceding three months a total of 349.6 mm was recorded by the Blackdown Tablelands AL weather station, of which 93.4 mm fell in the two weeks leading up to the survey.

In the preceding six years (2013 to 2018) rainfall varied across both the wet and dry seasons (Figure 5). The total annual rainfall for 2013, 2015, 2016 and 2017 was fairly consistent, whilst 2014 and 2018 saw a drop in both the wet season rainfall and the total annual rainfall.

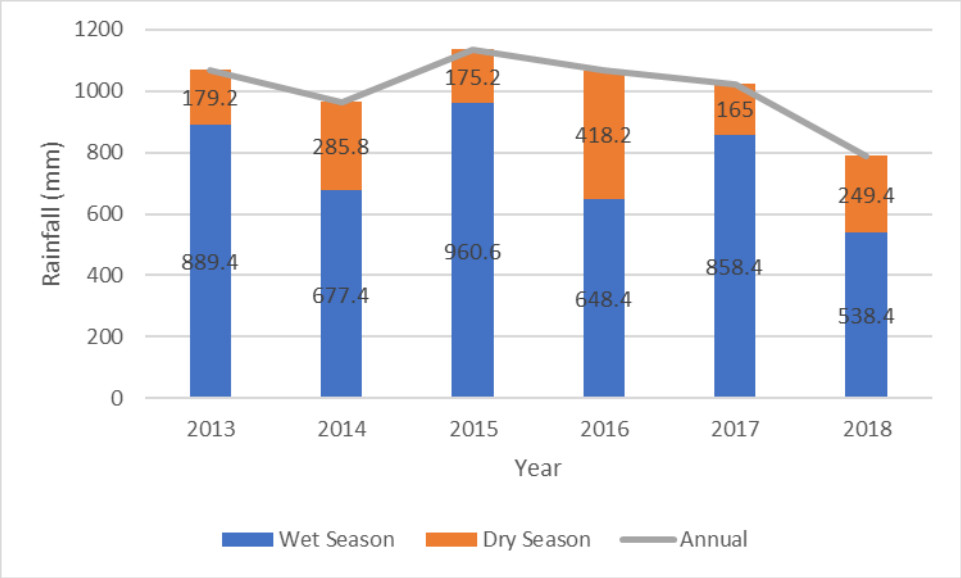

Figure 5 Regional Seasonal Rainfall Trends for 2013 – 2018 (Source: BoM 2019)

5.2 SAMPLING SITES

The desktop selection of sampling sites was based on two primary objectives:

- Spatial distribution across the study area; and
- Capturing ‘entry’ and ‘exit’ points of waterways traversing the Project, to collect suitable baseline data for ‘reference’ and 'impact’ sites that could be utilised in any long-term monitoring programs.

Table 4 describes each sampling site and sampling location (Table 5), details the survey methods used at each sampling site. The location of the aquatic sampling sites and the surface water sampling sites are shown in Figure 6.

Table 4 Sampling Site Locations

Site Code	Reference Location	Easting	Northing
DWR1	Located on southern side of highway along Stanley Creek. Upstream of DWI1.	0725805	7386321
DWR4	Located along depression on intermittent creek.	0729204	7383227
DWR5	Located along unnamed waterway that flows into Charlevue Creek in south-western boundary of the EPC.	0727640	7381080
DWR6	In south-western area of EPC, located along a depression area on unnamed waterway that feeds into Springton Creek.	0728513	7378595
DWI1	Located along Stanley Creek, northern side of highway at northern boundary of EPC. Downstream of DWR1.	0728501	7388431
DWI3	Located along unnamed waterway that flows into Charlevue Creek. North-eastern boundary of EPC.	0731394	7387482
DWI6	Located along Springton Creek, outside of EPC. Located at bridge along highway.	0736131	7383371
DWI8	Located along upstream of Springton Creek along unnamed waterway.	0731237	7378414
DWI9	South-eastern boundary of EPC, on unnamed waterway that feeds into Springton Creek eventually.	0731262	7377611
DAR1	Upstream site along Charlevue Creek, on western EPC boundary	0726345	7382842
DAI1	Located along Charlevue Creek, downstream of DAR1.	0728076	7382226
DAI2	Located along Charlevue Creek, downstream of DAR1 and DWI1.	0729813	7382850
DAI3	Located along Charlevue creek, downstream of DAR1, DAI2 and DWI1. Upstream of DAI4. South of highway.	0730973	7384370
DAI4	Located along Charlevue creek, downstream of DAR1, DAI2, DAI3. North of highway.	0732590	7385626

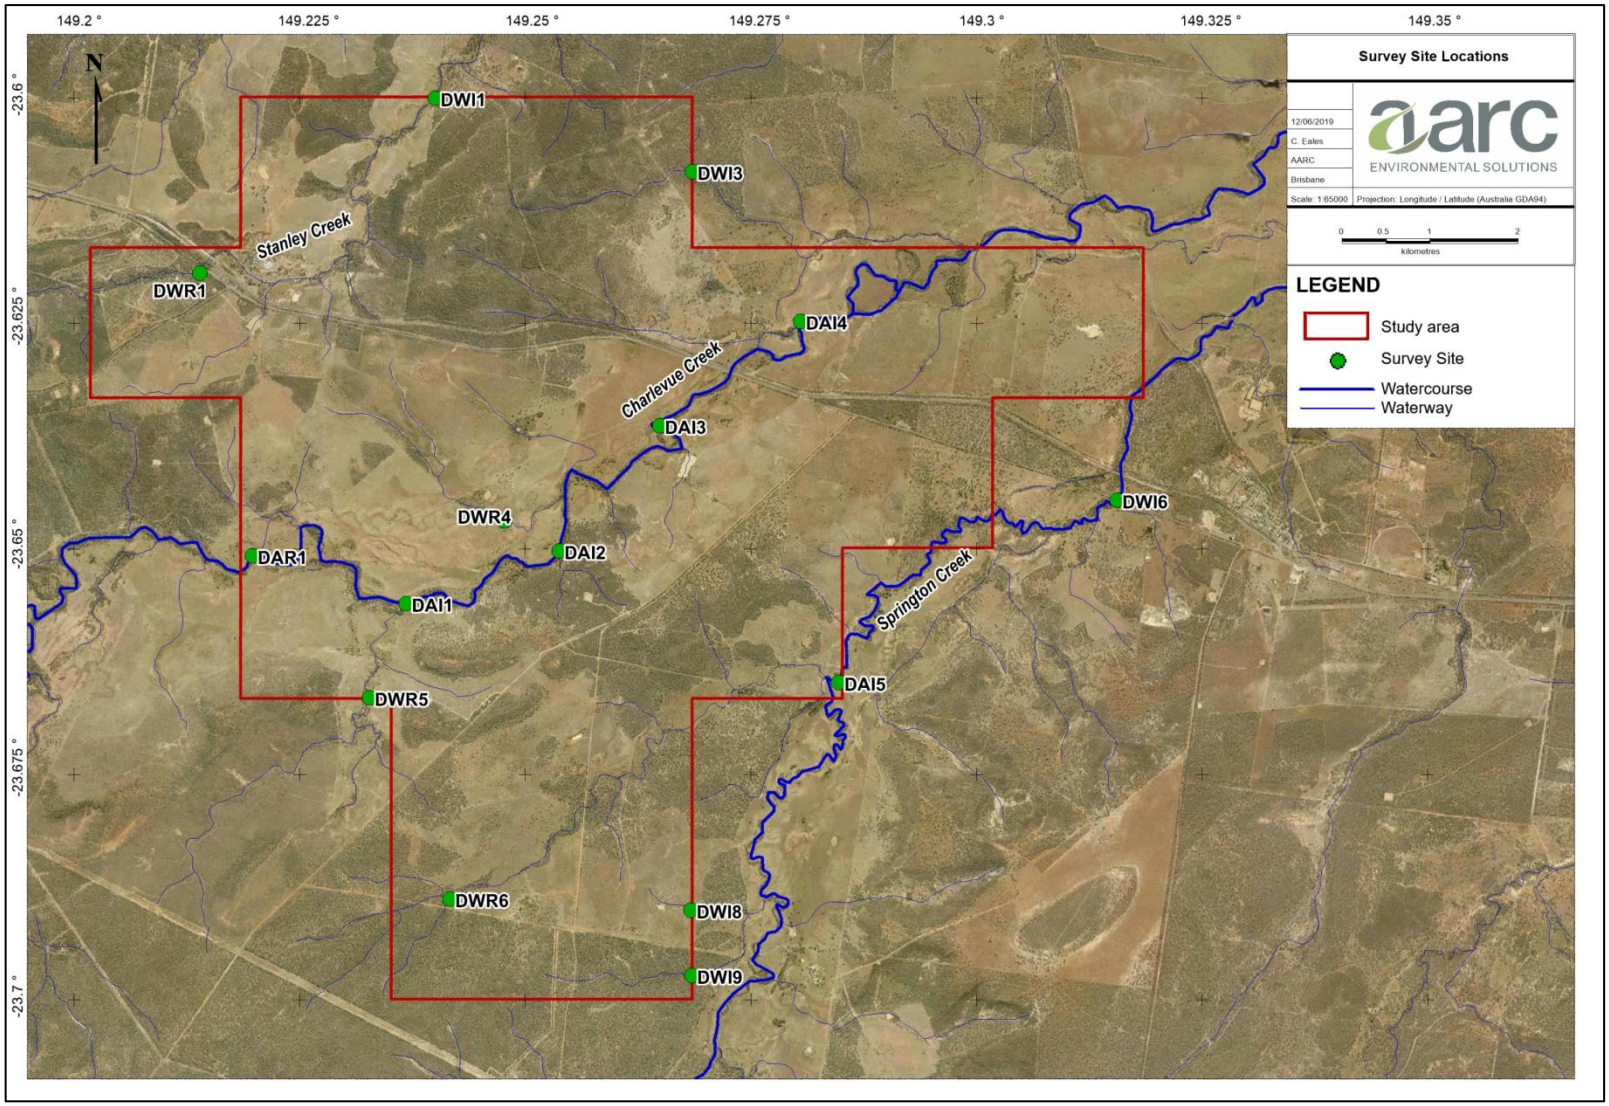

Figure 6 Location of Survey Sites

5.3 SURFACE WATER SAMPLING

Water quality sampling was carried out in accordance with the *Monitoring and Sampling Manual: Environmental Protection (Water) Policy 2009* (DES 2018b) methodology. Field readings of pH, dissolved oxygen (DO), turbidity, electrical conductivity (EC) and temperature were also recorded. In-situ measurements were collected using a multi-parameter water quality meter that is laboratory calibrated to the manufacturers' specifications.

Grab samples were collected at a depth of 10 to 20 cm where sufficient water was available. Several water samples were collected at each site (where possible) in analyte specific sterilised collection bottles and a suite of parameters tested. All water samples were kept on ice or refrigerated during storage and transport to a National Association of Testing Authorities (NATA) accredited laboratory for analysis.

5.4 STREAM SEDIMENT QUALITY

Stream sediment quality sampling was undertaken in accordance with the *Monitoring and Sampling Manual EPP (Water) 2009* (DES 2018b). Five sub-samples (approximately 500 grams (g)) each) of stream-bed substrate was taken at 10 m intervals along a 50 m transect in the river bed. Sub-samples were collected using a non-metallic shovel and mixed in a plastic bucket to obtain a composite sample. A representative 500 g sample is taken from the sub-sample composite and sent to a NATA accredited laboratory for analysis of trace metals and particle size.

5.5 CREEK ECOLOGY

5.5.1 Physical Assessment

This assessment method utilises monitoring techniques adapted from the following environmental sampling manuals:

- *AusRivAS Physical Assessment Protocol* (Parsons et al. 2002b, p.5); and
- *Queensland AusRivAS Sampling and Processing Manual* (DNRM 2001).

The monitoring methodologies utilised in the aquatic ecology assessments are presented in Table 6. The physical assessment does not require the presence of water and was consequently undertaken at all sampling sites.

Table 6 Physical Assessment Methodology

Characteristic	Monitoring Methodology
Bank Shape	Categorise the predominant shape of the left and right banks along the length of the monitoring site in accordance with the AusRivAS physical assessment categories for bank shape (i.e. concave, convex, stepped, wide lower bench or undercut).
Bank Slope	Categorise the predominant slope of the left and right banks along the length of the monitoring site in accordance with the AusRivAS physical assessment categories for bank slope (i.e. vertical, steep, moderate, low or flat).
Factors Affecting Bank Stability	Identify disturbance factors present that may negatively influence bank stability of either the left or right bank.
Artificial Bank Stability Features	Note the presence of any artificial bank protection measures.
Large Woody Debris	Visually estimate the percent cover of large woody debris within the lower embankment and channel area, along a length of stream that is equal to the length of the monitoring site. Large woody debris includes logs and branches greater than 10 centimetre (cm) in diameter.
Turbidity, Water and Sediment Oils and Odours	Visually assess and categorise the presence of oily residues or odours in surface water and stream sediments at the aquatic sites.
Bare Ground	Note the extent of bare ground including eroded areas or those not supporting vegetation, due to some form of disturbance that would otherwise be expected to be vegetated.
Exposed Tree Roots	Note whether tree roots are exposed due to any disturbances.
Gully Erosion	Record any visible gully erosion adjacent to the watercourse.
Bank Slumping	Record any evidence of slumping banks along the watercourse.
Local Catchment Erosion	Note the erosion in the surrounding catchment on the approach to the site.

5.5.2 Habitat Bioassessment

A habitat assessment was performed at selected sites using a modified version of the AusRivAS protocols developed by the former Department of Natural Resources and Mines (Conrick & Cockayne 2001). AusRivAS is a nationally standardised method for undertaking an assessment of the biological health of inland rivers within Australia.

The assessment considers morphological characteristics of waterways only; including the broad habitat type, channel pattern, water level and flow, substrate character and cover, bed and bank stability, and riparian cover at each site. Each surveyed site was given a score out of 135, with higher numbers indicating favourable habitats normally associated with healthy waterways. Habitat assessments were completed at all sites in 2019. Table 7 provides a framework for interpreting habitat assessment scores.

Table 7 Key to AusRivAS Habitat Assessment Scores

Habitat Assessment Score	Interpretation
0 – 35	Habitat is poor. There is limited habitat availability for in-stream fauna. There is little variation in velocity and depth of water, and the creek bed consists of a single sediment type. The water body typically consists of a small, shallow pool. Streamside vegetation, if present, consists of grasses and sedges. There is moderate to significant erosion on the banks.
36 – 70	Habitat variety is moderate. This could be due to leaf litter and other vegetation or detritus in the water, or the presence of boulders and rocks. The streamside vegetation consists mainly of grasses and sedges. There is moderate evidence of bank erosion, and the percentage of vegetative cover on the banks is less than 50%.
71 – 100	Habitat is relatively good. The bank is stable, there is variety in depth and velocity within the water body and substrate type is variable and tending towards boulders and rocks. Streamside vegetation is of trees and shrubs, adding to the bank stability. The percentage of streamside cover by vegetation is relatively high.
101 – 135	Indicates a pristine and favourable habitat. There is no bank erosion and the dominant vegetation is trees. There is great variety in depth and velocity, and the habitat is quite complex, offering many types of protection for fauna. This is usually afforded by logs and branches, leaf litter, variety in substrate type, variety in water depth, and presence of vegetation living within the water body.

5.5.3 Condition Assessment

The condition assessment is an evaluation of the possible impacts to aquatic environmental values caused by major disturbances within the waterway. Each category is scored from one to five, one indicating a ‘very major’ disturbance, and five indicating an ‘indiscernible’ disturbance. This assessment evaluated the influence of:

- agriculture upstream;
- major extractive industry (current or historical) upstream;
- major urban area upstream;
- major point source wastewater discharge upstream;
- dam or major weir;
- alteration to seasonal flow regime;
- alteration to the riparian zone;
- erosion and damage by stock on riparian zone and banks;
- major geomorphological change on stream channel; and
- alteration to instream conditions and habitats.

5.5.4 Macroinvertebrate Sampling

Macroinvertebrate sampling was conducted in accordance with the AusRivAS sampling and assessment methodology as outlined by the *Queensland Monitoring and Sampling Manual: Environmental Protection (Water) Policy 2009* (DES 2018b).

Along a ten metre stretch of the waterbody, a 250 micrometre D-frame net was used to sample macroinvertebrates at each sampling site containing sufficient suitable aquatic habitat (refer Table 5). The nets were checked thoroughly for damage before use and washed between sites to ensure no cross contamination of samples. This procedure targets various micro-habitats where available, including riffles, runs, pools and edge/backwaters. Due to the ephemeral nature of the creeks and in the receiving environment, micro-habitats available for sampling were limited to pool and edge habitats. Ideally site sampling should include sampling in shallow and deep sections to target the various micro-habitats, however this was not possible in any of the sites due to the limited water levels. Macroinvertebrates were live picked on-site, samples preserved, and sent for taxonomic identification to an AusRivAS accredited laboratory.

Data collected was assessed using a range of indices including:

- Total Abundance;
- Taxa Richness;
- Plecoptera, Ephemeroptera and Trichoptera (PET) Richness;
- SIGNAL 2 Biotic Index;
- Community composition; and
- Percentage Tolerance Taxa.

5.5.5 Fish and Crustacean Sampling

Fish and crustacean sampling was conducted at five sites in April 2019 using box traps and opera house traps.

- Baited aquatic traps (three opera house traps and three box traps per site) (0.5 mm mesh) were deployed at the sites detailed in Table 5 to sample small bodied fish and crustaceans. A total of 30 collapsible, baitfish traps were deployed within the range of microhabitat types present within the site (i.e. littoral margin, among snags, open water) for four nights across the sites.

All captured aquatic fauna were identified, counted and measured for total length. Any exotic species captured were euthanized in accordance with permit conditions, and all native species were released at the site of capture. No wounds, lesions or deformities on captured aquatic fauna were recorded.

5.6 RIPARIAN AND AQUATIC VEGETATION

The *Gemini Project Terrestrial Ecology Assessment* (AARC 2019) conducted for the Project has surveyed and described the flora values of the study area including vegetation communities identified. For the aquatic ecology assessment, a meandering 100 m transect in the riparian corridor at each sampling site was walked recording the riparian vegetation species encountered.

5.7 RIPARIAN ZONE VERTEBRATE FAUNA

The *Gemini Project Terrestrial Ecology Assessment* (AARC 2019) conducted for the Project has surveyed and described the vertebrate fauna values of the study area. For the aquatic ecology

assessment several fauna surveying methodologies were undertaken in the riparian zone across several sites (DAR1, DAI1, DAI2, DAI3, DAI4, and DAI5). Survey effort was consistent across these six sites. A description of the additional techniques employed to survey the fauna occurring within the riparian zones in the study area are detailed below.

Bird Surveying

Dedicated searches for birds were conducted visually and aurally during early mornings during peak avian activity. A minimum of one hour of bird surveying at each of the six sites was conducted in the early morning or late afternoon when bird activity was highest. In addition, opportunistic diurnal searches were also conducted on foot in areas considered likely to have high avian diversity (e.g. vegetated watercourses or dams), or likely to contain cryptic or threatened bird species.

Spotlighting

Spotlighting was carried out in the early evenings (before midnight) during the April 2019 to maximise encounter rate of nocturnal wildlife such as night birds and arboreal mammals primarily active at night. Two spotlighting techniques were employed:

1. Foot traverses: Dedicated spotlighting events were undertaken on foot at each of the six sites. Searches were undertaken over two events where possible, one within the first hour following nightfall, and one after the first hour. Two ecologists randomly traversed the area with spotlights and binoculars, and wherever possible, bark crevices and tree hollows were examined. A slow walking speed (approximately 1 km per hour) was maintained across the length of the survey area to fully facilitate intensive listening and thorough visual searching.

2. Vehicle searches: During any driving on the study area after dark, spotlighting was conducted by the passenger/s from the slow-moving vehicle, to maximise study area coverage that cannot be achieved with foot traverses alone. Spotlights were used to scan trackside vegetation for arboreal and ground-dwelling wildlife.

Call Playback

Several nocturnal bird species are highly cryptic; occurring in naturally low population densities, are wide-ranging, and call infrequently. Detection rates are typically low without solicitation in the form of playback of pre-recorded calls to elicit a response (Kavanagh and Peake 1993; Debus 1995). Detectability of smaller nocturnal bird species such as the Southern boobook (*Ninox novaeseelandiae)* and Australian owlet nightjar (*Aegotheles cristatus)*, and the arboreal marsupial Yellow-bellied glider (*Petaurus australis)* also increase with playback of large owl calls. Smaller, cryptic arboreal species such as Squirrel glider (*P. norfolcensis)* and Sugar glider (*P. breviceps)* can also respond to owl call playback. In addition, call playbacks can be utilised for the identification of cryptic amphibian species such as the Tusked frog (*Adelotus brevis*). During the 2019 survey call playbacks were conducted at sites specified in Table 5, the species targeted included:

- Tusked frog *(Adelotus brevis);*
- Powerful owl *(Ninox strenua);*
- Australian owlet nightjar *(Aegotheles cristatus);*
- Southern boobook *(Ninox novaeseelandiae)*; and
- Greater glider *(Petaurus volans).*

Call playback is undertaken prior to spotlighting foot traverses to minimise the chance of spooking species capable of leaving the area undetected. A series of species call would be selected depending on the surrounding habitat suitability, and each would be played for three minutes, followed by a two-minute listening period, with the cycle repeated three times for each species. Calls were played using a megaphone and loud enough so that the softest call could be heard 100-200 m away. Following the completion of all playback cycles, the area would then be spotlighted as described above.

Habitat Searching

To further enhance the likelihood of detecting small cryptic species, dedicated diurnal searches were conducted at each of the six sites. This was spread over several events, two per site, during the survey period. Additional habitat searches were carried out during aquatic trap checks and while conducting vegetation transects. Searches were typically undertaken during the late morning, allowing for reptile activity to increase with rising temperatures, but before the maximum heat of the day. Searching techniques involve the careful rolling of rocks and logs, rustling through leaf litter, and peeling back of exfoliating bark from standing trees. For targeted reptile species, dedicated searches were conducted opportunistically when preferred habitat was encountered (e.g. Gilgai formations or dense ground debris).

Evidence of wildlife such as the identification of tracks, scats and other signs of occupation (e.g. tree trunk scratches) was also conducted during these habitat searches. For scats not identifiable in the field, they were collected and sent to a scat analysis expert (Barbara Triggs) for identification of the species responsible for the scat and/or where possible, the identification of prey species material present in predator scats.

Incidental Recordings

Throughout the April 2019 survey, ecologists were traversing the study area on foot and by vehicle every day for numerous hours whilst conducting routine survey activities (e.g. driving between sites, checking traps, vegetation transects, sampling etc.). The ecologists remained alert and would record numerous wildlife species as observed or heard during the survey period. As with the habitat searches, this included signs or evidence of wildlife, and included constant vigilance for raptor nests. All areas of the study area have been visited by ecologists throughout the surveys.

6.0 RESULTS AND DISCUSSION

6.1 SURFACE WATER QUALITY

The results from the 2018 and 2019 analysis were compared to the EPP (Water) WQOs (Table 8 to Table 15). Data analysis and interpretation of surface water quality results were referred to the *EPP (Water) WQO for the protection of aquatic ecosystems in the Mackenzie River Sub-basin Waters – southern tributaries (WQ130)*. Exceedances of the EPP WQO are highlighted orange in the tables below. In order to assess the health of each watercourse, the analysis results were compared within each major watercourse and drainage feature ;Charlevue Creek, Stanley Creek and Springton Creek.

The following parameters exceeded the WQO at the Project:

Charlevue Creek:

- Physico-chemical parameters;
    - pH (2019), turbidity (2018, 2019), sulphate (2019), ammonia (2018, 2019), dissolved oxygen (2018, 2019)
- Petroleum hydrocarbons (2018).

Stanley Creek:

- Physico-chemical parameters;
    - Turbidity (2018); sulphate (2018); ammonia (2018), dissolved oxygen (2018)
- Dissolved Metals;
    - Chromium (2018)
- Petroleum hydrocarbons (2018).

Springton Creek:

- Physico-chemical parameters;
    - pH (2019); turbidity (2018, 2019); ammonia (2019), dissolved oxygen (2018-2019)
- Dissolved metals;
    - Manganese (2018);
- Petroleum hydrocarbons (2018).

Exceedances of WQOs for turbidity across all sites and years were observed. Turbidity is an indicator of water quality, where clear water is typically considered part of a healthy system. Exceedances of this parameter can indicate soil erosion, runoff, pollution, and algal blooms; however, some waterways can have naturally high levels of suspended solids and turbidity (Fondriest Environmental Inc. 2014). However, the WQO set for the Mackenzie River Sub-basin indicate that high levels of turbidity are not natural, and increased levels can lead to impaired water quality for both aquatic flora and fauna.

Low levels of DO were observed across all sample sites and occurred in 2018 and 2019 at a variety of sites. These low levels of dissolved oxygen were recorded in stagnant pools along ephemeral waterways. Stagnant pools in intermittent streams naturally experience values of DO below 50 per cent saturation (DEHP 2011a). As such the exceedances observed in relation to the study area are not a reliable indicator of system long term health.

Analysis showed that petroleum hydrocarbons for Charlevue Creek (DWR5, DAI1, DAI2, DAI3, and DAI4), Stanley Creek (DWR1) and Springton Creek (DAI5 and DWI6) exceeded WQO values. At Charlevue Creek the upstream site along an unnamed waterway; DWR5 had the highest exceedance of petroleum hydrocarbons. This unnamed waterway feeds into Charlevue Creek at site DAI1. Only the sites located downstream of DWR5 on Charlevue Creek exceeded this parameter. Sites DAR1

(upstream) and DWR4 (on a neighbouring waterway) did not exceed the WQOs. This indicates that DWR5 may be a source of the petroleum hydrocarbons recorded further downstream. These areas are currently used for agricultural and pastoral purposes and the presence of petroleum hydrocarbons may have been the result of those practices. These results represent important baseline data for future monitoring as repeat exceedances in petroleum hydrocarbons may indicate an existing and consistent local source of petroleum hydrocarbons.

Given the higher carbon chain fractions being reported, possible sources include; crude oil, heavy fuel oils, lubricating oils, asphalts and pitch and even waxes and other related products. Sites DWR1 and DWI6 occur along the Capricorn Highway and are possible point sources for the petroleum hydrocarbons observed at these locations.

Macroinvertebrate sampling provides a good indication of aquatic ecosystem health due to their sensitivity to a variety of factors such as turbidity, DO, pollutants and salinity. Water quality at the study area had high turbidity, presence of petroleum hydrocarbon pollutants and very low levels of DO. It is anticipated that macroinvertebrate sampling results will be consistent with a degraded system.

6.2 STREAM SEDIMENT QUALITY

Analytical results produced for the stream sediment samples have been compared against SQG values for stream sediment quality at all sampling sites (Table 16, Table 17, Table 18).

The chemistry of all stream sediment sample sites is well below the relevant SQG low and high trigger values for all parameters except nickel (Table 16). Nickel results only exceeded the SQG low trigger value at DWR6 during the 2018 and 2019 sampling. This site is located along an unnamed waterway which feeds into Springton Creek at DAI5. The results for cadmium, and mercury were below the limit of reporting (and SQG values).

Table 16 Stream Sediment Total Metals Results

Site		Total Metals (mg/kg)

Stream sediment was collected from Stanley Creek, Charlevue Creek and Springton Creek at all sites across 2018 and 2019. Particle size analysis (Table 17) and particle size classification (Table 18 and Figure 7) show Stanley Creek at the site DWR1 the stream sediment is predominantly sand, with small amounts of clay (17-33%) and silt (7-27%). However further downstream along Stanley Creek, the stream sediment is characterised as sand (92-96%) with minor contributions of gravel, silt and clay.

Along Springton Creek stream sediment levels vary between sites but remain consistent across sample years. Springton Creek itself is characterised by predominantly sand, with consistent levels of clay and silt.

Charlevue Creek stream sediment is characterised by high percentages of sand (56-94%) at the majority of sites (excluding DAI1, DWR4, DAI2, and DAI4) with variable levels of clay (1-24%) and silt (1-17%). Though minor, the presence of gravel was recorded across the sites along Charlevue Creek. Sites DAI1, DWR4, DAI2, and DAI4 presented lower levels of sand (9-45%) and higher percentages of fine sediments (clay 25-41% and silt 17-66%). Of these sites only DWR4 had higher levels of fine particles

during both the 2018 and 2019 sample periods. This site was located along a natural depression which flows into Charlevue Creek.

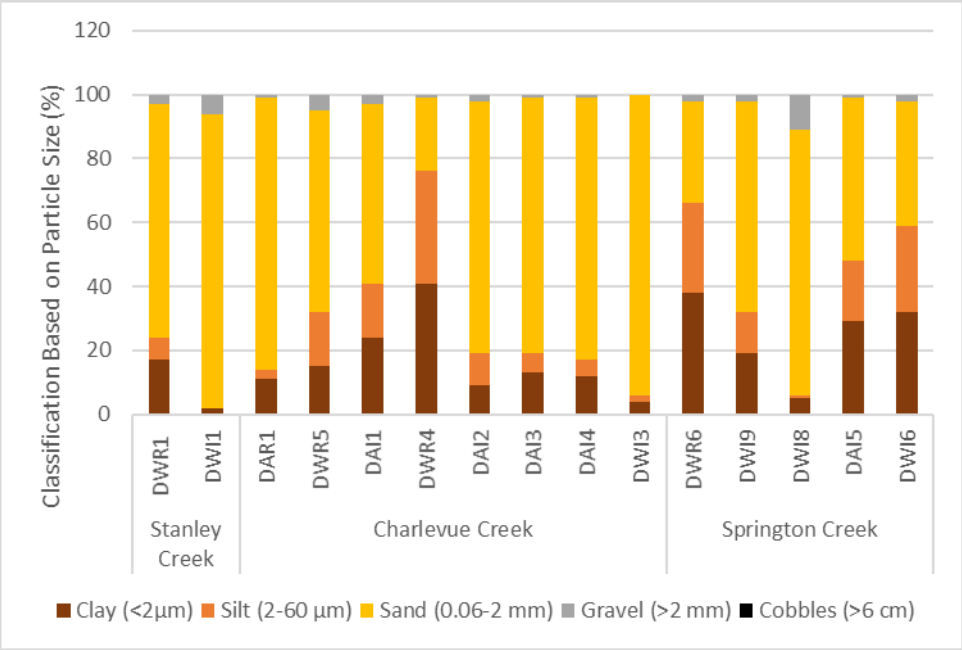

Figure 7 Stream Sediment Particle Size Analysis

6.3 CREEK ECOLOGY

6.3.1 Physical Assessment

At all sites the full AusRivAS Physical Assessment Protocol (Parsons et al. 2002a) was followed, and the data collected at each site along with photos of each site is provided in Appendix B. Table 19 provides the erosion specific observations at each site. No flow was recorded at most sites with baseline flow recorded only at site DWI6.

The effects of erosion on the banks of the receiving waters was evident across all survey sites. The leading cause of local erosion appeared to be stock access, with runoff and the influence of edge effects from historic clearing also promoting degradation. Large rainfall events each year would cause increased runoff, potentially washing sediment away from the bank and depositing it into the creeks. Cattle compact soil structures and trample vegetation; both leading to increased erosion. The impact of large woody debris at the sites was minimal and not considered significant.

Table 19 Erosion Observations at AARC 2019 Sites

Site	DWR1	DWR4	DWR5	DWR6	DWI1	DWI3	DWI6	DWI8	DWI9	DAR1	DAI1	DAI2	DAI3	DAI4	DAI5
Bare Ground	Low	Low	Low	None	None	Low	Low	*Mod	Low	*Mod	*Mod	Low	Low	Some	Low
Exposed Tree Roots	Low	None	Low	None	None	Low	Some	*Mod	None	Low	Low	*Mod	Some	*Mod	Low
Gully Erosion	Low	None	Low	Low	None	Some	*Mod	^Ext	Low	None	Low	Some	Some	Some	Some
Bank Slumping	None	None	Some	None	None	*Mod	*Mod	*Mod	Low	Some	Low	Some	*Mod	*Mod	Low
Local Catchment Erosion	None	None	*Mod	Low	Some	*Mod	Some	Some	Some	Low	^Ext	Low	Some	Some	Some

*Mod – Moderate
^Ext – Extensive
Note: Observations were scored according to the following categories [None, Low (1-10%), Some (10-50%), Moderate (50-75%), or Extensive (>75%).

6.3.2 Habitat Bioassessment

This assessment considered the morphological characteristics of waterways (as specified in Section 5.5.2), with 135 representing a perfect score for a healthy waterway. Habitat assessments were completed at all sites.

The habitat bioassessment scores from the aquatic sites within the sampling environment primarily fell into the moderate and good categories (Figure 8), with the exception of one site DWR1 which was classed as excellent. These results are indicative of the general health of the river and the surrounding systems, it does not consider the quality of the water present. The following broad habitat types were recorded in and adjacent to the study area; non-riverine wetlands, ephemeral streams and farm dams.

Figure 8 Habitat Bioassessment Scores

6.3.3 Condition Assessment

The condition assessment considered the impact/influence of ten different upstream activities on the waterways (as outlined in Section 5.5.3) with 50 representing the maximum score (no impact) and ten representing the minimum score (full impact). Impact assessments were completed at all sites and site assessment scores are presented in Figure 9.

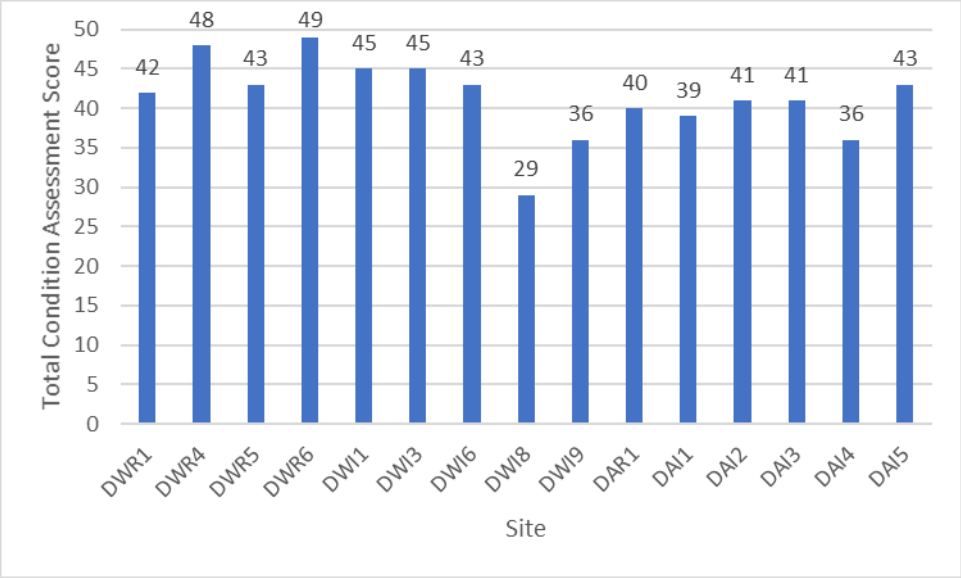

Figure 9 Condition Assessment Scores

DWI8 had the lowest rating of 29, indicating that this site was influenced by upstream activities to a higher degree than the other sites. This site was one of two sites that received a rating of 1 (very major impact). DWI8 received a rating of 1 for the influence of alterations to the riparian zone. This site had been heavily cleared and showed signs of significant erosion. DAI1 was the other site that received the rating of 1, this was for the impact of erosion and damage from stock on the riparian zone. DWR6 had the highest rating of 49 indicating that the influence of activities upstream of this site had minimal impact.

6.3.4 Macroinvertebrate Sampling

Macroinvertebrate results from the 2019 survey have been summarised by calculating total abundance, taxonomic richness, PET taxa richness, SIGNAL 2 scores, community composition and percent tolerant taxa. Where applicable, these indices have been compared to relevant WQO for macroinvertebrates in the Mackenzie River Sub-basin. Nine sites were sampled for macroinvertebrates during the 2019 survey (DAI1, DAI2, DAI3, DAI4, DAI5, DAR1, DWR5, DWI6, and DWI9).

During sampling baseline flow was present at one site (DWI6), with the remaining sites having only standing pools of water with no flow, conditions which can impact the abundance and richness of macroinvertebrate taxa found. Due to the ephemeral nature of the waterways being sampled, habitats for macroinvertebrate sampling were limited to only edge (or bank) habitats during the 2019 survey.

The taxa composition of macroinvertebrates is used to provide an estimate of a waterbody's health. Macroinvertebrates are sensitive to a variety of factors such as turbidity, DO, pollutants in waterways and salinity. The surface water quality results support the low macroinvertebrate diversity, lack of PET taxa and low Signal 2 scores recorded across the study area.

6.3.4.1 Total Abundance

Total abundance of macroinvertebrates sampled at aquatic sites within the 2019 survey varied significantly between sites. A complete list of all identified macroinvertebrates is available in Appendix C.

Macroinvertebrate abundance ranged from three (DAI3) to 625 (DWR5) (Figure 10). Fluctuation in total abundance is expected due to habitat availability for macroinvertebrates and the varying nature of the waterways sampled. Sites DWR5, DAR1, DAI1, DAI2, DAI3 and DAI4 all occur along or in close relation

to Charlevue Creek. DAI5, DWI6 and DWI9 occur along Springton Creek or a tributary that flows into Springton Creek.

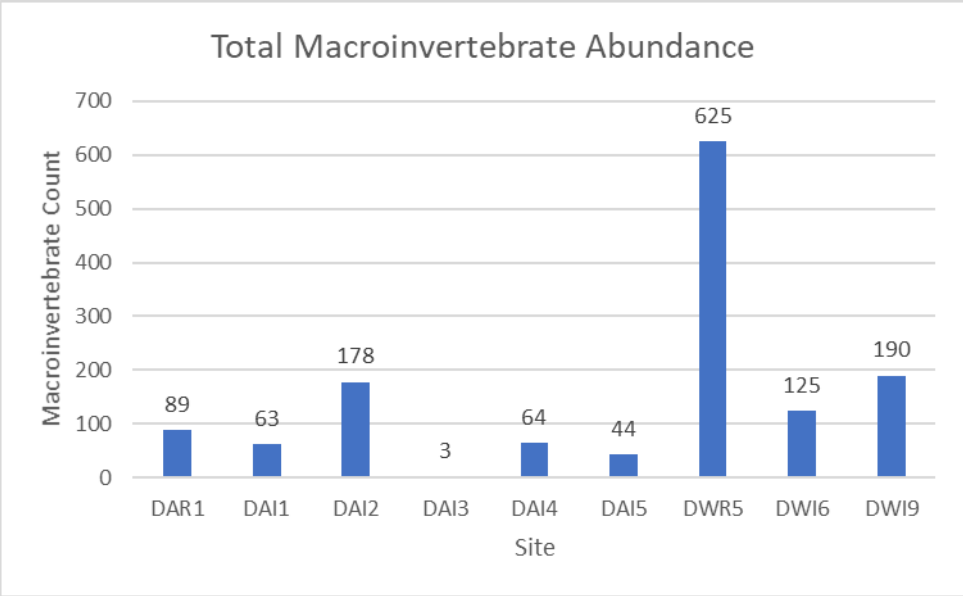

Figure 10 Macroinvertebrate Abundance

6.3.4.2 Taxonomic Richness

Taxonomic richness recorded at the sites is shown in Figure 11; none of the sites sampled reached the lower WQO for taxonomic richness. The site that came closest was DAI2 which occurs along Charlevue Creek. This is an indicator of poor habitat quality and only a small number of macroinvertebrate taxa were recorded in the available habitat. Two sites had very low taxonomic richness with only three (DAI3) and four (DAI5) taxa recorded.

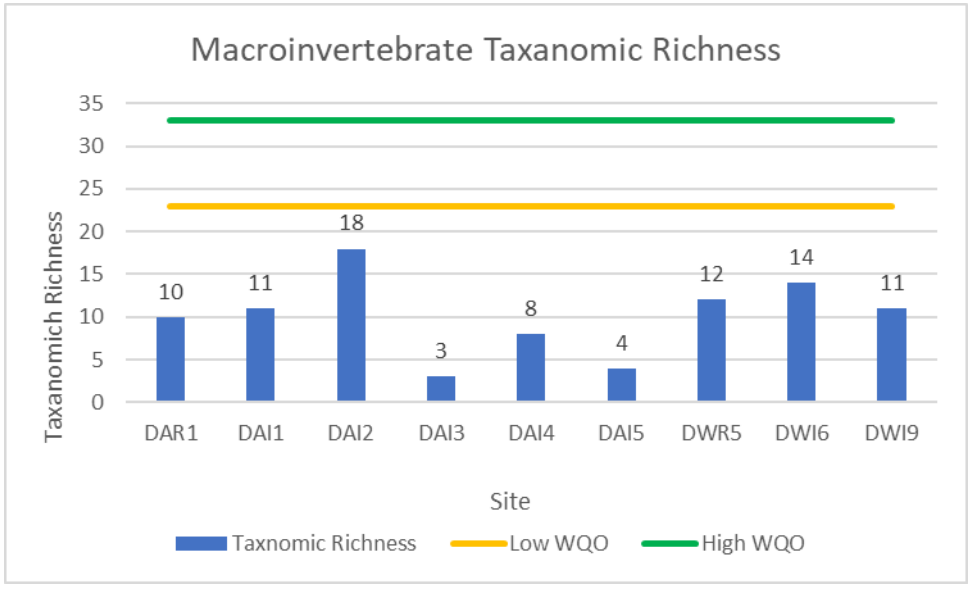

Figure 11 Macroinvertebrate Taxonomic Richness

6.3.4.3 PET Taxa Richness

The PET taxa are three orders of macroinvertebrate that are particularly sensitive to disturbance. They require favourable water quality conditions and diverse habitat to survive. PET taxa richness in ephemeral waterbodies tends to be low, due to the naturally harsh conditions in these waterways (i.e. poor water quality and low habitat diversity). However, trending declines in the number of PET taxa at a site may be an indication of pollution or poor water quality. Only four sites were found to support PET taxa (DAR1, DAI1, DAI2 and DAI4). These sites were found to only contain one PET taxa from the Ephemeroptera order. No other PET taxa were identified at the other sites. No sites were found to meet the lower WQO for PET taxa richness. The low levels of PET taxa sampled is likely due to the lack of available habitats during the sampling events and a lowered health of the water available for sampling.

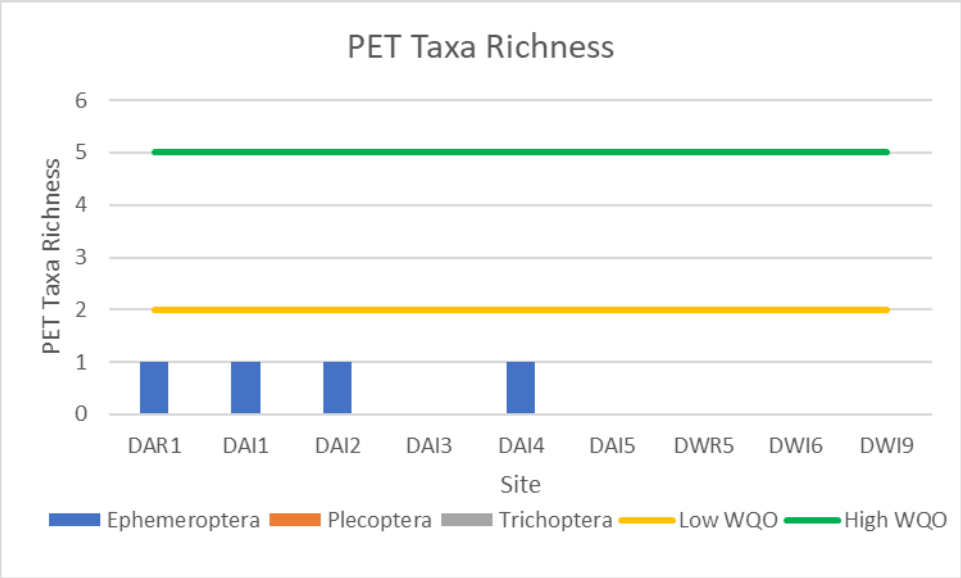

Figure 12 PET Taxonomic Richness

6.3.4.4 SIGNAL 2 Scores

Each macroinvertebrate family is allocated a score between 1 and 10 to represent their sensitivity to specific environmental conditions and varying levels of pollution. A lower score indicates that the macroinvertebrate family can tolerate a range of environmental conditions and common forms of water pollution; while a higher grade indicates that the macroinvertebrate family is sensitive to most forms of pollution.

The SIGNAL 2 scores recorded (Figure 13) indicated poor habitat availability and environmental conditions. All sites except one (DAI3) site fell below the lower WQO. Factors that would have influenced these results include the flow conditions at the site and the ephemeral nature of the waterways. Taxa found in ephemeral waters vary largely with rainfall events and as flow conditions change. Low abundance of sensitive macroinvertebrate taxa is likely to result from the environmental conditions.

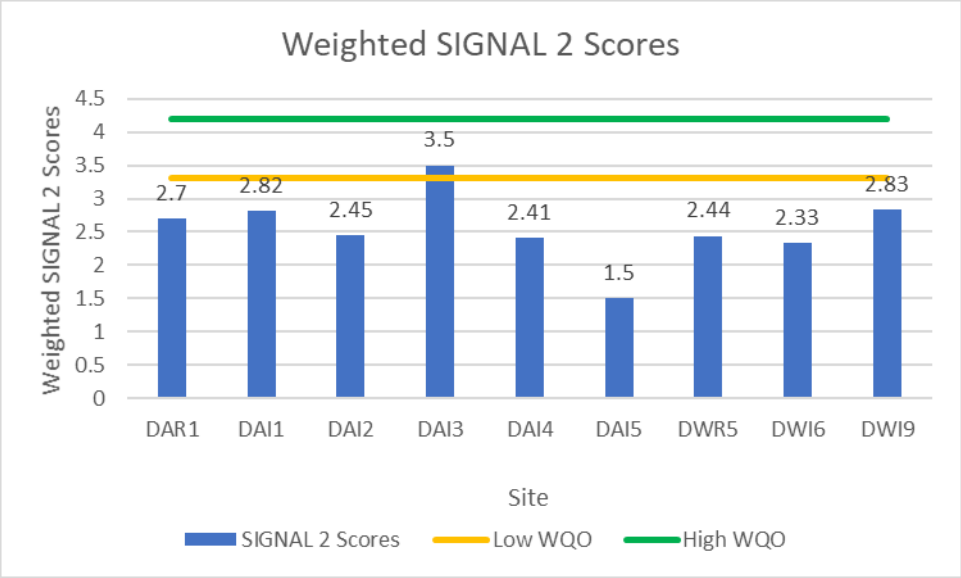

Figure 13 Macroinvertebrate SIGNAL 2 Site Scores

6.3.4.5 SIGNAL 2 Bi-Plot

A SIGNAL 2 bi-plot was created for the aquatic sites to demonstrate the level of pollution and suitability of the site for macroinvertebrate habitation (Figure 14). Sites that fall into quadrant 4 exhibit levels of pollutants that reflect urban, industrial, or agricultural pollution. Sites in quadrant 3 indicate the presence of harsh physical environments or toxic pollution. Sites in quadrant 2 reflect waters which are high in nutrients or salinity. Sites in quadrant 1 are indicative of favourable water quality and minimal levels of disturbance. All sites fell within quadrant 4 which is consistent with what the sites are exposed to, as the sites are exposed to anthropogenic pollutions (urban/industrial developments), agricultural pollution, and downstream effects of dams.as all were open to human and livestock access.

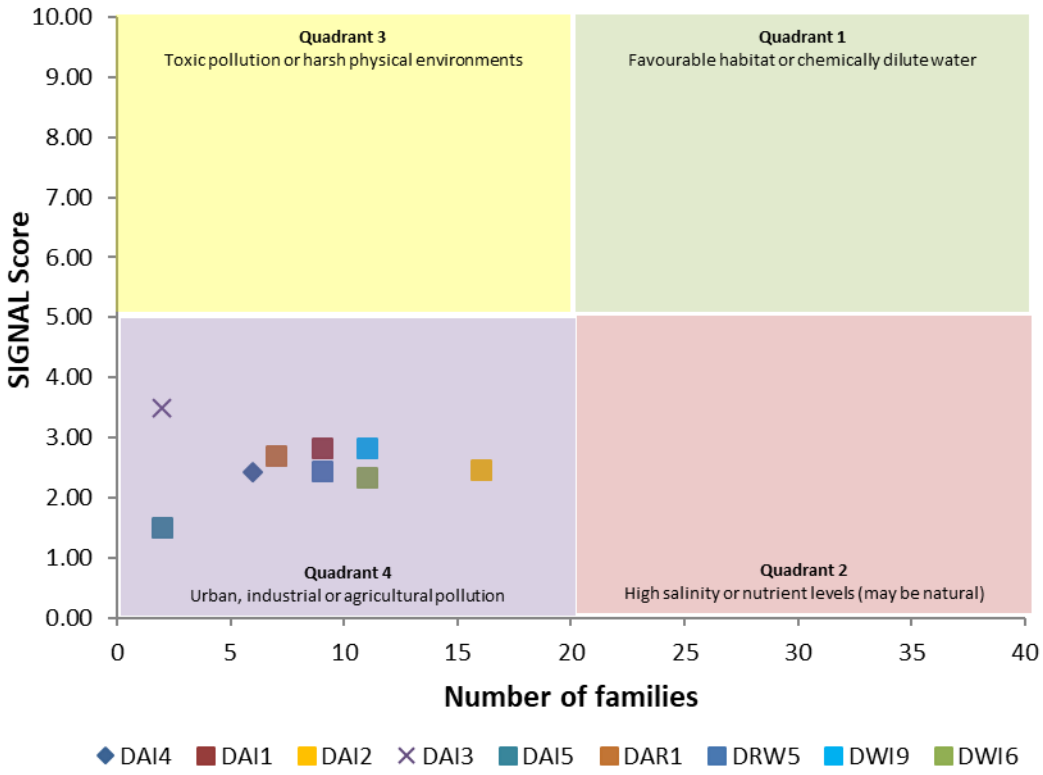

Figure 14 Macroinvertebrate SIGNAL 2 Bi-Plot

6.3.4.6 Percent Tolerant Taxa

This index is based on the proportion of taxa that are rated as having a tolerant sensitivity grade (SIGNAL grades 1, 2 and 3). A higher proportion of tolerant taxa were recorded than the WQOs at all sites, only one site did not exceed the high WQO (DAI3). It should be noted that DAI3 had only 3 macroinvertebrates recorded, as such this result is not a true reflection of the macroinvertebrate population present at DAI3.

Typically, high proportions of tolerant taxa are reflective of poor health in the creek. This is indicative of ephemeral creeks; as the more resilient macroinvertebrate taxa survive. Figure 15 compares the percentage of tolerant taxa found at each site. Most of the taxa sampled were generalist taxa that are tolerant to higher levels of disturbance and higher salinity concentrations.

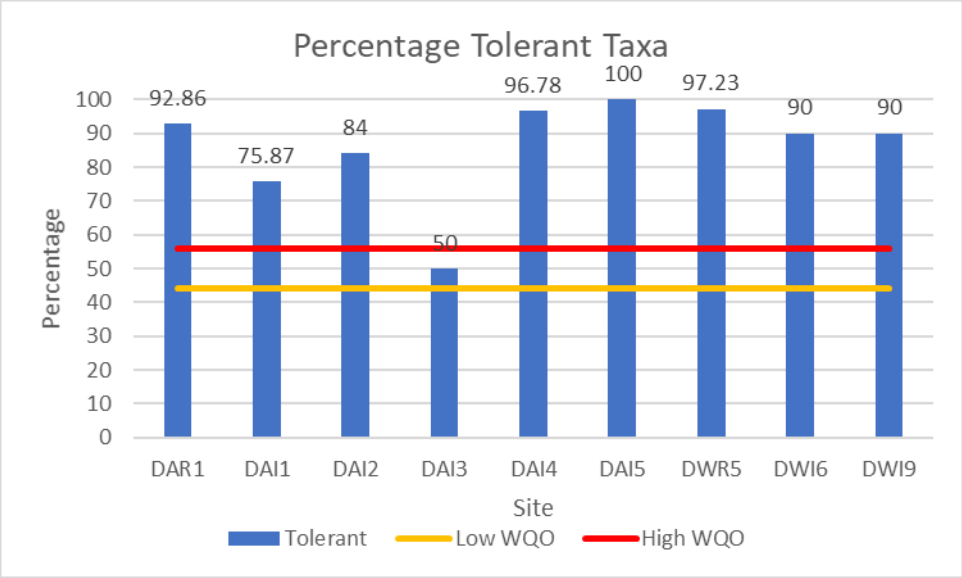

Figure 15 Percentage of Tolerant Macroinvertebrate Taxa

6.3.4.7 Community Composition – AusRivAS Predictive Modelling

Macroinvertebrate community composition was interpreted by running data through an AusRivAS predictive modelling program. This model is used to predict macroinvertebrate assemblages that are expected to occur within a site in the absence of impact. This model is then used to compare the expected macroinvertebrate assemblage to that of the assemblage of macroinvertebrates collected during site sampling.

Observed versus Expected (O/E) taxa score is a ratio of the number of macroinvertebrate families observed onsite to that of the number of families expected; this provides a measure of biological impairment at the sample site. Five bands are used to categorise O/E taxa scores based on their biological condition;

- Band X indicates that the site is more biologically diverse than anticipated;
- Band A indicates that the site is similarly biologically diverse as expected and is therefore not negatively impacted by any conditions onsite; and
- Bands B, C, and D reflect environments with increasingly impaired health impacting on the diversity of macroinvertebrate assemblages.

Table 20 show the results of the AusRivAS predictive modelling assessment. All sample sites fell within or below Band B, indicating that the sites are potentially impacted either by water quality and/or the availability of macroinvertebrate habitats.

DAI1, DAI2, DAI5 and DWI9 received scores within the assessment Band B indicating that these sites are significantly impaired and exhibit fewer than expected taxa. Evidence of disturbance from cattle grazing was recorded at these sites and is likely the major contributor to the impaired scores. Sites DAR1, DAI4, DWR5 and DWI6 fell within Band C indicating that these habitats are severely impaired resulting in a lowered macroinvertebrate biodiversity. DAI3 received the lowest score falling within Band D, indicating that it is highly degraded and has extremely poor water and/or habitat quality. This site had the lowest macroinvertebrate abundance and macroinvertebrate taxa recorded.

Table 20 AusRivAS Predictive Modelling Results

Sample ID	O/E Taxa Score (OE50)	Habitat used for overall site assessment	Overall sample assessment band	Bandwidth-Upper limit
DAR1	0.29	Edge	C	0.37
DAI1	0.40	Edge	B	0.79
DAI2	0.70	Edge	B	0.79
DAI3	0.00	Edge	D	0
DAI4	0.10	Edge	C	0.37
DAI5	0.50	Edge	B	0.79
DWR5	0.30	Edge	C	0.37
DWI6	0.30	Edge	C	0.37
DWI9	0.40	Edge	B	0.79

6.3.5 Fish and Crustacean Sampling

6.3.5.1 Crustaceans

Blue claw crayfish (*Cherax destructor*) were captured at all aquatic trap sites, except one (DAI3). The Inland freshwater crab (*Austrothelphusa transversa*) was captured at DAR1, DAI1, DAI2, and DAI5. The Inland freshwater crab can burrow up to one metre deep in heavy clay to avoid desiccation during periods of prolonged estivation (Nathan 2016). Two Freshwater shrimp (*Paratya australiensis*) were captured at DAI4.

Crustacean species living in highly ephemeral waterways display their own unique adaptation to cope with the harsh environment. Many crustaceans can survive long periods outside of a waterbody by extracting oxygen from air with their gills. This can only occur if the gills are kept moist so many species dig burrows to avoid desiccation and remain underground in estivation until water returns to the system. Mechanisms for desiccation resistance are observed in many species, including those that were identified during field surveys.

6.3.5.2 Fish

Australia yields a low diversity of fish species predominantly due to its large areas of arid and semi-arid land, as well as the ephemeral nature of large areas of catchments (Allen et al. 2002). Due to the ephemeral nature of the waterways present within the study area the overall habitat available to freshwater species is relatively low. For most of the year, the waterways onsite are vastly unconnected with other aquatic habitats. Resulting in shallow still pools of water with limited refuge, breeding or feeding areas.

The 2019 aquatic survey identified two species of fish; Agassiz's glassfish (*Ambassis agassizii*), and Spangled perch (*Leiopotherapon unicolor*). The Agassiz's glassfish was recorded at DAI4 and DAI5, while the Spangled perch was recorded at DAI2 and DAI4.

All fish species recorded in the study area are considered to be common or widespread species in the Mackenzie River Sub-basin. Fish species of the study area can be generally considered either a 'small-bodied' species (Agassiz's glassfish) or a moderately sized species (Spangled perch). Most of the fish species recorded in the study have adaptations that allow rapid colonization and/or exploitation of ephemeral pool habitats;

- they are all generalist species (i.e. flexible dietary and habitat requirements); and/or
- some species (e.g. Spangled perch and Agassiz's glassfish) are able to move rapidly to newly created pools.

Such adaptations are necessary for exploiting the temporary habitat resources within the study area.

6.4 RIPARIAN AND AQUATIC VEGETATION

Riparian vegetation condition, species presence and plant health were assessed at each aquatic site. For the purposes of this survey, vegetation monitoring at each site was conducted along a 50 m transect, recording aquatic and riparian species within the riparian zone.

6.4.1 Vegetation Assessment

A full list of species is provided in Appendix D and photos of the sites are provided in Appendix B with the AusRivAS Physical Assessment Site information.

The total number of flora species sampled across the surveys at all the sites was 111. A total of 40 species were introduced species; eight of which are commonly used as pasture grasses or livestock feed. Of the remaining introduced species, the Velvety tree pear (*Opuntia tomentosa)*, Mimosa (*Mimosa pigra*), Lantana (*Lantana camara*) and Parthenium weed (*Parthenium hysterophorus*) are declared Weeds of National Significance (WoNS) and Restricted Invasive species under the Biosecurity Act. Three additional flora species recorded within the study area are classed as Restricted Invasive species under the Biosecurity Act, these include Mother of millions (*Bryophyllum delagoense*), Mother of thousands (*Bryophyllum daigremontianum*) and Rubber vine (*Cryptostegia grandiflora*). Noogoora burr (*Xanthium pungens*) is classed as other Invasive Plants under the Biosecurity Act.

The riparian vegetation exhibited no signs of dieback, and constituted a mixture of low to moderate disturbance, and were located within both remnant and non-remnant environs (Table 21). Total species richness at each site varied between 11 and 30 species, incorporating between three and twelve introduced species (Figure 16). There was a fairly consistent species composition present with a mix of sedges, grasses, forbs, and trees and shrubs present at all sites, except for DWR4 which lacked any tree or shrub species (Figure 17). No in-stream aquatic macrophytes were recorded within the study area.

Table 21 Vegetation Assessment

Parameter	Remnant Riparian Vegetation	Level of Disturbance	Presence of Dieback
DWR1	Yes	High	No
DWI1	Yes	Low	No
DWR4	No	Low	No
DWR5	Yes	Moderate	No
DWR6	Yes	Low	No
DAR1	Yes	Low	No
DAI1	Yes	Low	No
DAI2	Yes	Moderate	No
DAI3	Yes	Moderate	No
DAI4	Yes	Moderate	No
DWI3	Yes	Low	No
DAI5	Yes	Moderate	No
DWI6	Yes	Moderate	No
DWI9	Yes	Low	No
DWI8	No	Moderate	No

Note the level of disturbance was categories based on observed levels of human impact (including land clearing), pastoral animal and feral animal impacts, disturbance from agriculture and riparian vegetation alteration (including the presence of introduced species). Categories included low, moderate and high.

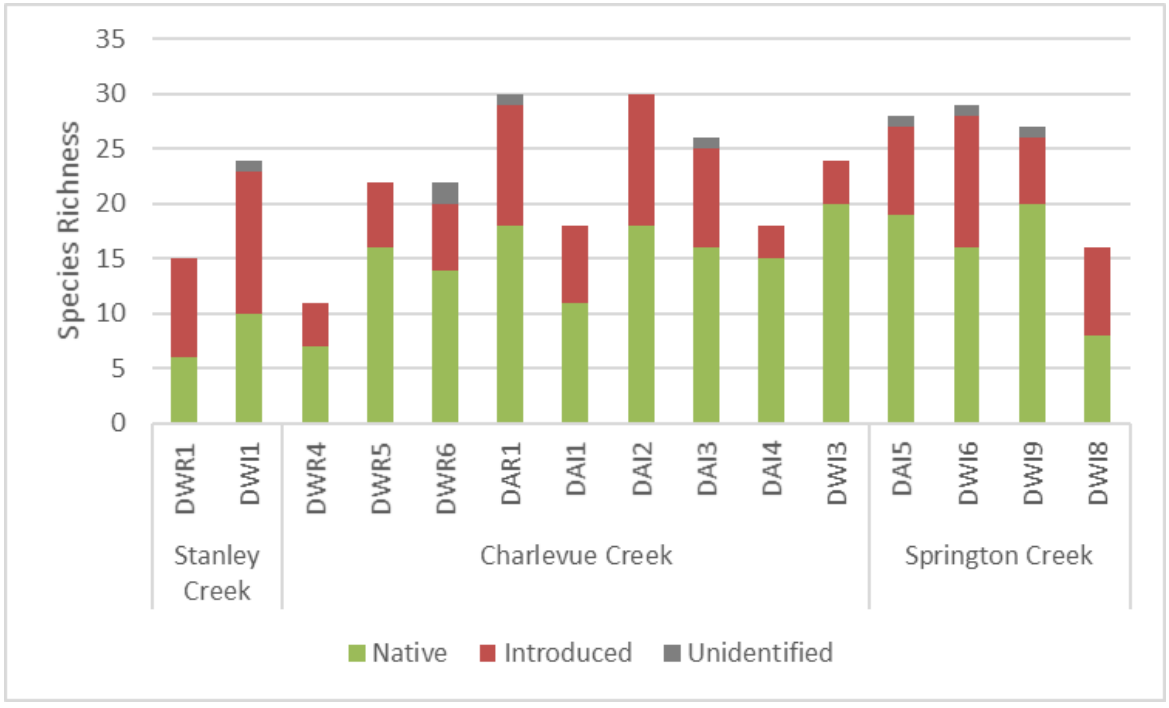

Figure 16 Vegetation Species Richness

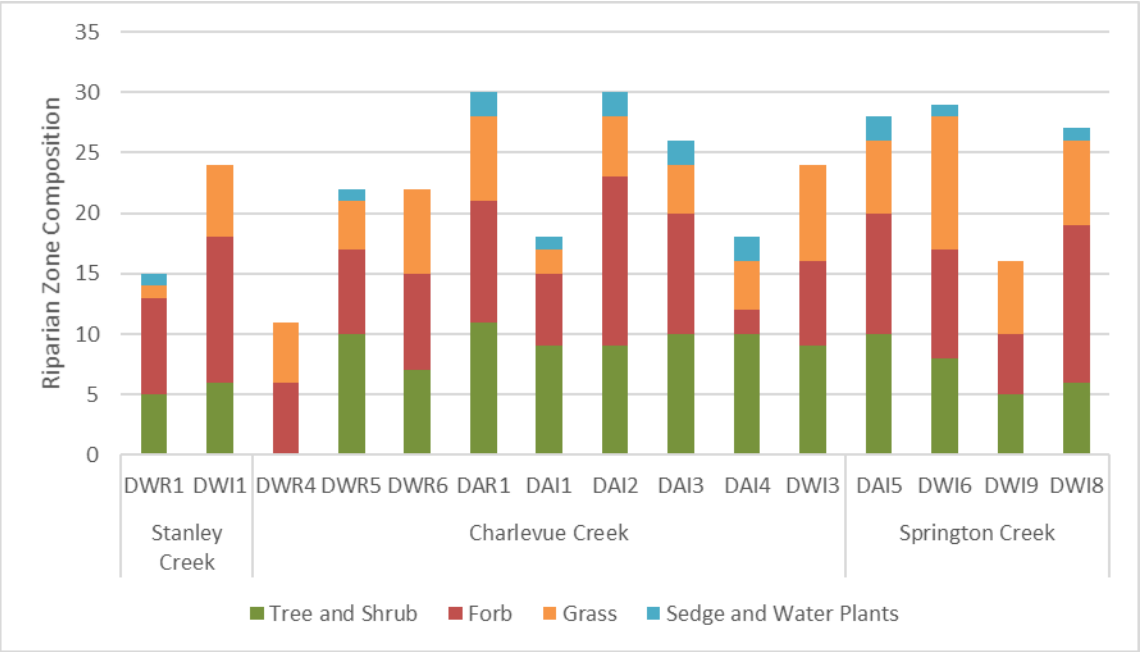

Figure 17 Vegetation Species Composition

6.4.2 Flora of Conservation Significance

No flora species of conservation significance were observed within the riparian zone during the surveys.

6.5 WETLANDS

There are several small non-riverine wetlands of medium conservation significance mapped by the Department of Environment and Science (DES) within the study area. These all occur in close association with Charlevue Creek which runs through the centre of the study area. These wetlands are ephemeral and do not hold water throughout the year. At the time of the 2019 sampling no water was present within the mapped wetland areas and therefore no aquatic assessment was able to be completed.

6.6 RIPARIAN ZONE VERTEBRATE FAUNA

Two amphibian species were identified during the surveys including one introduced species, the Cane toad (*Rhinella marina*), and one native species, the Bumpy rocket frog (*Litoria inermis*) (Photo Plate 1). The Cane toad was identified at DAI1 and the Bumpy rocket frog was observed at DAI5.

Eight reptile species were identified during the field surveys, including the Keelback snake (*Tropidonophis mairii*) (Photo Plate 2), Tommy Roundhead (*Diporiphora australis*), Dubious dtella (*Gehyra dubia*) and several skink species (Appendix E).

A total of 54 bird species representing 31 families were identified by the surveys. A list of the bird species recorded is provided in Appendix E. No migratory bird species were identified during the field survey within the study area. One Marine species was detected during the field surveys; the Rainbow bee-eater (*Merops ornatus*).

Two mammal species were identified rarely, the Common brushtail possum (*Trichosurus vulpecula*) and Greater glider (*Petauroides volans volans*). Greater gliders are classified as Vulnerable under both the EPBC Act and the NC Act. The Greater glider was recorded along Charlevue Creek at DAI1 and DAI2.

No aquatic fauna species of conservation significance were observed during surveys.

Photo Plate 1 Bumpy rocket frog

Photo Plate 2 Keelback snake at DAI2

6.7 SUMMARY OF AQUATIC VALUES

The waterways of the study area are ephemeral, experiencing periodic flows. Charlevue Creek and Springton Creek are determined watercourses under the *Water Act 2000*. Extensive clearing for agricultural purposes has been undertaken across much of the study area including the removal of riparian vegetation. The removal of riparian vegetation and direct stock access to the waterways has resulted in bank instability, erosion and occurrence of weeds.

Surface water quality was found to be generally poor. At the time of sampling there was no surface flow. Results for physico-chemical parameters were outside the WQO guideline values for the protection of aquatic ecosystems at many sites including pH, dissolved oxygen, turbidity, ammonia, and sulphate (as SO_4^{2}). Petroleum hydrocarbons were found to exceed WQO guideline values at several sites, considered likely due to the highway and agricultural practices.

Stream sediments were found to contain a high proportion of sand particles with some sites containing a mixture of silt and clay. Metal concentrations in stream sediment were generally low, except for nickel levels at site DWR6.

Macroinvertebrate diversity, abundance and PET richness were generally low. SIGNAL scores were correspondingly low and consistent with the expected results for ephemeral streams in an agricultural setting. The AusRivAS predictive modelling assessed the aquatic environments at the sample sites as significantly impaired to highly degraded. While impaired habitats is common in ephemeral creeks, the extent and severity of the impairment indicates low waterway health.

The diversity and abundance of fish and crustaceans was found to be low.

7.0 POTENTIAL IMPACTS

The aquatic ecology values within the study area are limited to riverine ecosystems including Charlevue and Springton Creeks and some tributaries. The creeks are highly ephemeral, experiencing periodic flows only following rainfall events. Past clearing for agricultural purposes has been undertaken across much of the study area including the removal of riparian vegetation. The removal of riparian vegetation and direct stock access to the waterways has resulted in bank instability, erosion and occurrence of weeds.

The Project (Figure 18) has potential to impact on aquatic ecology values through:

- The release of mine affected water to the receiving waterways and associated impacts to ecosystem health;
- Potential for spills and leaks from the mining operation to cause contamination in the receiving waterways;
- Direct impacts to riverine ecosystems via land disturbance for vehicle crossings or diversions of drainage features;
- Risk of increased erosion from cleared lands or mine infrastructure such as spoil dumps, resulting in increased sediment loads entering the aquatic ecosystems; and
- Impediments to fish or other aquatic fauna movements due to the construction of crossings or other infrastructure.

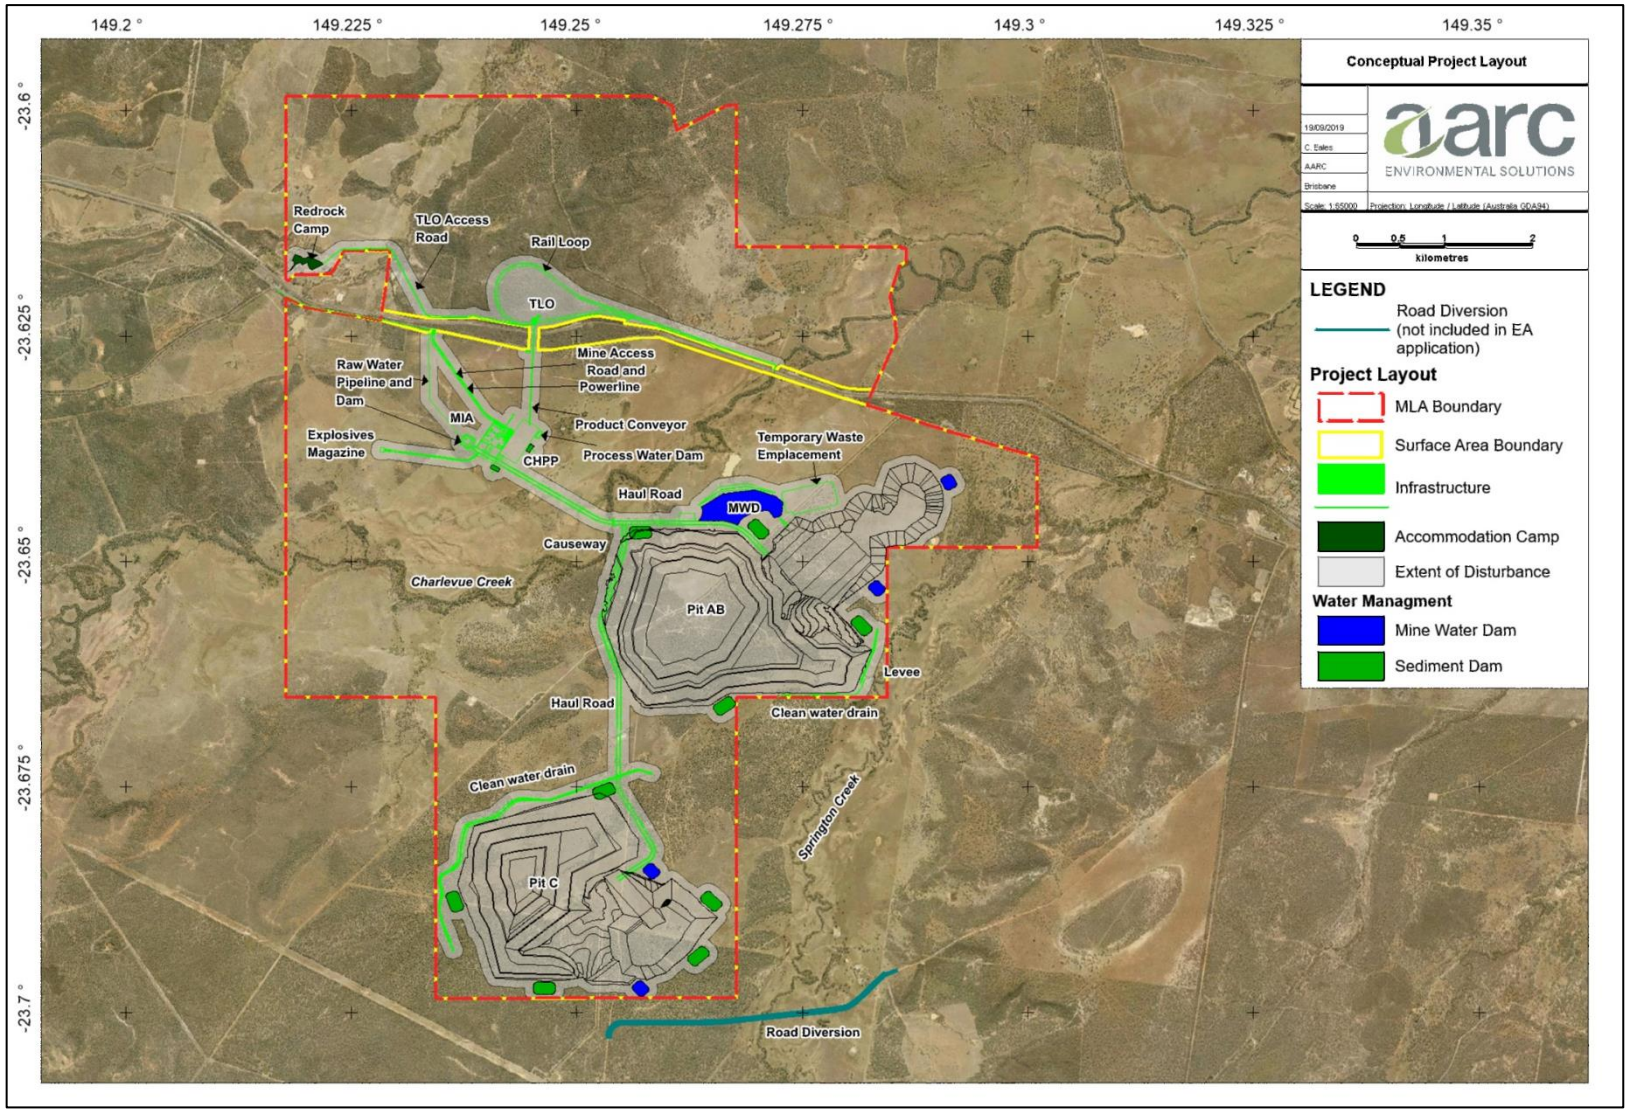

Figure 18 Conceptual Project Layout

8.0 MITIGATION STRATEGIES

Aquatic ecology values are primarily attributed to Charlevue and Springton Creeks within the MLA. The following mitigation measures will be implemented to protect existing values:

- Sediment and erosion control structures will be installed and maintained near all at risk areas to prevent sediment release to wetlands;
- Crossing design should provide for the fish passage during low and high flow events;
- The release of Mine Affected Water, will be in accordance with the quality controls provided by the model mining conditions;
- Fuel and hazardous liquids will be stored in a bunded facility, in accordance with Australian Standards;
- A Spill and Emergency Management plan will be implemented during construction and operation to minimise the risk of contaminant release to aquatic ecosystems;
- The Project open pits will be appropriately bunded or located in a manner that prevents surface water from entering the open pits during a 1:1000 year flood event and the Project dams will be appropriately bunded or located in a manner that prevents surface water from entering or damaging the dams during a 1:1000 year flood event (consistent with the 'Not a Controlled Action if undertaken in a particular manner' EPBC Referral decision); and
- A Receiving Environment Monitoring Program (REMP) will be implemented and will include monitoring of water, sediments, riparian / riverine vegetation health and biological indicators in aquatic environments.

9.0 PROJECT ENVIRONMENTAL OFFSETS

The offsets framework requires environmental offsets to be delivered where an activity is likely to result in a significant residual impact on a prescribed environmental matter. The *QEOP Significant Residual Impact Guideline* (DES 2014b) is used to determine whether residual impacts are considered to be significant.

Prescribed environmental matters (MSES) are listed in Schedule 2 of the Environmental Offsets Regulation. The following prescribed matters were mapped or identified within the Project area by the aquatic ecology surveys:

- Fish habitat areas and waterways providing for fish passage (under the *Fisheries Act 1994*);
- A habitat for an animal that is endangered wildlife or vulnerable wildlife, or a special least concern animal is a matter of State environmental significance; and
- a wetland—of high ecological significance shown on the map of Queensland wetland environmental values.

9.1 ASSESSMENT OF PRESCRIBED MATTERS IDENTIFIED IN THE STUDY AREA

9.1.1 Fish Passage

Charlevue Creek is mapped as being at major risk of adverse impact from waterway barrier works on fish movement. Stanley Creek is mapped as being of moderate risk of adverse impact. Tributaries of the streams are mapped within the study area as being of either low, medium or high risk of adverse impact from waterway barrier works on fish movement. As described above, the Project will require:

- The crossing of Charlevue Creek (mapped as major risk);
- The Stanley Creek crossing (mapped as moderate risk);
- The development of clean water drains along a tributary of Springton Creek (and/or its tributaries) (mapped as low to moderate risk); and
- The disturbance of first and second order waterways (mapped as low to moderate risk).

The *Queensland Environmental Offsets Policy: Significant Residual Impact Guideline* (DEHP 2014) is designed to assist in determining whether or not the impacts of a project will, or is likely, to have a significant residual impact on a MSES.

As stated in the significant residual impact guidelines:

> ***Passage*** *for fish, means the natural movement patterns of fish species required to maintain the biological integrity of the species.*

When assessed against the MSES significant residual impact guidelines (Table 22), the Project is considered unlikely to result in a significant residual impact on the waterways providing for fish passage. Based on the assessment, no offsets under the *Environmental Offset Regulation 2014* for waterways providing for fish passage are considered to be required for the Project.

Table 22 MSES Residual Impact Assessment of Waterways providing for Fish Passage

Significant Residual Impact Criteria	Ecological Assessment
Will the action result in the mortality or injury of fish?	No, the Project would not result in the mortality or injury of fish • The habitat within the study area offers limited habitat for fish species as the water systems are ephemeral and only flow during high rainfall events. • All waterway crossings (Charlevue Creek and Stanley Creek) would be constructed in consideration of the *Accepted development requirements for operational work that is constructing or raising waterway barrier works* (DAF 2018), so as not to create a barrier to fish movement; and • The development of the clean water drains along the Springton Creek tributary would be designed to replicate natural features where possible with the aim of providing similar conditions to the original waterway, so as to provide habitat and refuge for fish inhabiting or passing through the diversion.
Will the action result in conditions that substantially increase risks to the health, wellbeing, and productivity of fish seeking passage such as through the depletion of fishes energy reserves, stranding, increased predation risks, entrapment or confined schooling behaviour in fish?	No, the Project will not result in conditions that substantially increase risks to the health, wellbeing and productivity of fish seeking passage within the site. Given the intended design of the waterway crossings and the design of the Springton Creek tributary clean water drains that will be implemented, the Project is unlikely to result in the depletion of fishes' energy reserves, stranding fish, increase the risk of predation, entrapment or confined schooling behaviour in fish.
Will the action reduce the extent, frequency or duration of fish passage previously found at a site?	No, the habitat within the study area offers limited habitat for fish species as the water systems are ephemeral and only flow during high rainfall events. The Project will not reduce the extent, frequency or duration of fish passage within the site because the Project will ensure that: • All waterway crossings (Charlevue Creek and Stanley Creek) would be constructed in consideration of the *Accepted development requirements for operational work that is constructing or raising waterway barrier works* (DAF 2018), so as not to create a barrier to fish movement; and • The development of the clean water drains along the Springton Creek tributary would be designed to replicate natural features where possible with the aim of providing similar conditions to the original waterway, so as to provide habitat and refuge for fish inhabiting or passing through the diversion.
Will the action substantially modify, destroy or fragment areas of fish habitat (including, but not limited to in-stream vegetation, snags and woody debris, substrate, bank or riffle formations) necessary for the breeding and/or survival of fish?	No, the Project will not substantially modify, destroy or fragment areas of fish habitat necessary for breeding and/or the survival of fish, as the Project will ensure that: • All waterway crossings (Charlevue Creek and Stanley Creek) would be constructed in consideration of the *Accepted development requirements for operational work that is constructing or raising waterway barrier works* (DAF 2018), so as not to create a barrier to fish movement; and • The development of the clean water drains along the Springton Creek tributary would be designed to replicate natural features where possible with the

Significant Residual Impact Criteria	Ecological Assessment
	aim of providing similar conditions to the original waterway, so as to provide habitat and refuge for fish inhabiting or passing through the diversion. Several unnamed tributaries of the Springton Creek and Charlevue Creek are expected to be removed or otherwise impacted by mining activities. These waterways have been mapped as low to moderate risk of impact of fish passage. These waterways are of low stream orders (1 or 2) and are ephemeral. These waterways are not considered to provide fish habitat necessary for the breeding and/or the survival of fish.
Will the action result in a substantial and measurable change in the hydrological regime of the waterway, for example, a substantial change to the volume, depth, timing, duration and frequency of flows?	No, The Project is unlikely to result in substantial and measurable changes in the hydrological regime of the waterways within and around the study area. The volume, depth, timing, duration and frequency of flows are anticipated continue to reflect the ephemeral and variable flow nature of the waterways around the study area.
Will the action lead to significant changes in water quality parameters such as temperature, dissolved oxygen, pH and conductivity that provide cues for movement in local fish species?	No, given the water management measures that will be implemented (Section 8.0), the Project is unlikely to decrease the quality of habitat for fish utilising the study area or lead to a significant change in water quality parameters. The Project will also ensure that any water releases will be managed in accordance with the EA conditions (once developed).

9.1.2 Fitzroy River Turtle

The *Queensland Environmental Offsets Policy: Significant Residual Impact Guideline* (DEHP 2014) is designed to assist in determining whether or not the impacts of a Project will, or is likely to, have a significant residual impact on a MSES.

An assessment of the potential impact of the Project on the Fitzroy River turtle using the MSES significant impact criteria is presented in Table 23.

Table 23 Fitzroy River turtle MSES Significant Residual Impact Assessment

Significant Residual Impact Criteria	Ecological Assessment
Will the action lead to a long-term decrease in the size of local population of a species?	No, the habitat within the study area is not suitable for this species as the water systems are ephemeral and only flow during high rainfall events. The Project includes measures to prevent downstream impacts to the Fitzroy River turtle, specifically the: • appropriately bunding or location of pits in a manner that prevents surface water from entering the pit during a 1:1000 year flood event; • appropriately bunding or location of dams in a manner that prevents surface water from entering or damaging the dams during a during a 1:1000 year flood event.
Will the action reduce the extent of occurrence of the species ?	No, the proposed Project disturbance and downstream water releases are unlikely to reduce the potential area of occupancy for the Fitzroy River turtle.

Significant Residual Impact Criteria	Ecological Assessment
Will the action fragment an existing population into two or more populations?	No, the Project would not fragment an existing population into two or more populations.
Will the action result in genetically distinct populations forming as a result of habitat isolation adversely?	No, given the water management measures to prevent downstream impacts to the Fitzroy River turtle the Project is unlikely to result in genetically distinct populations forming.
Will the action disrupt ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species?	No, given the water management measures to prevent downstream impacts to the Fitzroy River turtle the Project is unlikely to disrupt an ecologically significant location of this species.
Will the action result in invasive species that are harmful to the species becoming established in the species habitat?	No, while the Fitzroy River turtle is vulnerable to predation on nests from introduced pest species; pest management strategies will be implemented to minimise the risk of introduced pest species (such as feral pigs, *Sus scrofa*) predating on the Fitzroy River turtle.
Will the action introduce disease that may cause the population to decline, or interfere with the recovery of the species?	No diseases are known for the species that could be caused by mining activities and cause the species' population to decline, nor would actions associated with mining activities interfere substantially with the recovery of the species.

When assessed against the MSES significant residual impact guidelines, the Project is considered unlikely to result in a significant residual impact on the Fitzroy River turtle. Based on the assessment, no offsets under the *Environmental Offset Regulation 2014* for the Fitzroy River turtle are considered to be required for the Project.

9.1 OFFSETS REQUIREMENTS

There are no aquatic MSES environmental offset requirements to be delivered under the Queensland legislation as part of this Project.

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or Area of Interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "Central co-ordinates" option, the resulting assessment area encompasses an area extending from 2km radius from the point of interest.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 1994). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no values have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Please direct queries about these reports to: biodiversity.planning@des.qld.gov.au

Summary Information

Tables 1 to 8 provide an overview of the AOI with respect to selected topographic and environmental values.

Table 1: Area of interest details: epc: 881

Size (ha)	7,219.57
Local Government(s)	Central Highlands Regional
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda
Catchment(s)	Fitzroy

The following table identifies available Biodiversity Planning Assessments (BPAs) and Aquatic Conservation Assessments (ACAs) with respect to the AOI.

Table 2: Available Biodiversity Planning and Aquatic Conservation Assessments

Assessment Type	Assessment Area and Version
Biodiversity Planning Assessment(s)	Brigalow Belt v2.1
Aquatic Conservation Assessment(s) (riverine)	Great Barrier Reef Catchments v1.3
Aquatic Conservation Assessment(s) (non-riverine)	Great Barrier Reef Catchments v1.3

Table 3: Remnant regional ecosystems within the AOI as per the Qld Herbarium's 'biodiversity status'

Biodiversity Status	Area (Ha)	% of AOI
Endangered	6.41	0.09
Of concern	236.35	3.27
No concern at present	1,816.18	25.16

The following table identifies the extent and proportion of the user specified area of interest (AOI) which is mapped as being of "State", "Regional" or "Local" significance via application of the Queensland Department of Environment and Science's *Biodiversity Assessment and Mapping Methodology* (BAMM).

Table 4: Summary table, biodiversity significance

Biodiversity significance	Area (Ha)	% of AOI
State Habitat for EVNT taxa	0.0	0.0
State	887.22	12.29
Regional	325.7	4.51
Local or Other Values	1,126.39	15.6

Table 5: Non-riverine wetlands intersecting the AOI

Non-riverine wetland types intersecting the area of interest	#
Number of Palustrine wetlands	4
Number of Lacustrine wetlands	2

Non-riverine wetland types intersecting the area of interest	#
Total number of non-riverine wetlands	6

NB. The figures presented in the table above are derived from the relevant non-riverine Aquatic Conservation Assessment(s). Later releases of wetland mapping produced via the Queensland Wetland Mapping Program may provide more recent information in regards to wetland extent.

Table 6: Named waterways intersecting the AOI

Name	Permanency
CHARLEVUE CREEK	Non-perennial
SPRINGTON CREEK	Non-perennial
STANLEY CREEK	Non-perennial

Refer to **Map 1** for general locality information.

The following two tables identify the extent and proportion of the user specified AOI which is mapped as being of "Very High", "High", "Medium", "Low", or "Very Low" aquatic conservation value for riverine and non-riverine wetlands via application of the Queensland Department of Environment and Science's *Aquatic Biodiversity Assessment and Mapping Method* (AquaBAMM).

Table 7: Summary table, aquatic conservation significance (riverine)

Aquatic conservation significance (riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0
High	0.0	0.0
Medium	7,219.57	100.0
Low	0.0	0.0
Very Low	0.0	0.0

Table 8: Summary table, aquatic conservation significance (non-riverine)

Aquatic conservation significance (non-riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0
High	0.0	0.0
Medium	10.88	0.15
Low	0.0	0.0
Very Low	0.0	0.0

Biodiversity Planning Assessments

Introduction

The Department of Environment and Science (DES) attributes biodiversity significance on a bioregional scale through a Biodiversity Planning Assessment (BPA). A BPA involves the integration of ecological criteria using the *Biodiversity assessment and Mapping Methodology* (BAMM) and is developed in two stages: 1) **diagnostic criteria**, and 2) **expert panel criteria**. The diagnostic criteria are based on existing data which is reliable and uniformly available across a bioregion, while the expert panel criteria allows for the refinement of the mapped information from the diagnostic output by incorporating local knowledge and expert opinion.

The BAMM methodology has application for identifying areas with various levels of significance solely for biodiversity reasons. These include threatened ecosystems or taxa, large tracts of habitat in good condition, ecosystem diversity, landscape context and connection, and buffers to wetlands or other types of habitat important for the maintenance of biodiversity or ecological processes. While natural resource values such as dryland salinity, soil erosion potential or land capability are not dealt with explicitly, they are included to some extent within the biodiversity status of regional ecosystems recognised by the DES.

Biodiversity Planning Assessments (BPAs) assign three levels of overall biodiversity significance.

- **State significance** - areas assessed as being significant for biodiversity at the bioregional or state scales. They also include areas assessed by other studies/processes as being significant at national or international scales. In addition, areas flagged as being of State significance due to the presence of endangered, vulnerable and/or near threatened taxa, are identified as "State Habitat for EVNT taxa".
- **Regional significance** - areas assessed as being significant for biodiversity at the subregional scale. These areas have lower significance for biodiversity than areas assessed as being of State significance.
- **Local significance and/or other values** - areas assessed as not being significant for biodiversity at state or regional scales. Local values are of significance at the local government scale.

For further information on released BPAs and a copy of the underlying methodology, go to:

http://www.qld.gov.au/environment/plants-animals/biodiversity/planning/

The GIS results can be downloaded from the Queensland Spatial Catalogue at:

http://qspatial.information.qld.gov.au/geoportal/

The following table identifies the extent and proportion of the user specified AOI which is mapped as being of "State", "Regional" or "Local" significance via application of the BAMM.

Table 9: Summary table, biodiversity significance

Biodiversity significance	Area (Ha)	% of AOI
State Habitat for EVNT taxa	0.0	0.0
State	887.22	12.29
Regional	325.7	4.51
Local or Other Values	1,126.39	15.6

Refer to **Map 2** for further information.

Diagnostic Criteria

Diagnostic criteria are based on existing data which is reliable and uniformly available across a bioregion. These criteria are diagnostic in that they are used to filter the available data and provide a "first-cut" or initial determination of biodiversity significance. This initial assessment is then combined through a second group of other essential criteria.

A description of the individual diagnostic criteria is provided in the following sections.

Criteria A. Habitat for EVNT taxa: Classifies areas according to their significance based on the presence of endangered, vulnerable and/or rare (EVNT) taxa. EVNT taxa are those scheduled under the *Nature Conservation Act 1992* and/or the

Environment Protection and Biodiversity Conservation Act 1999. It excludes highly mobile fauna taxa which are instead considered in Criterion H and brings together information on EVNT taxa using buffering of recorded sites or habitat suitability models (HSM) where available.

Criteria B. Ecosystem value: Classifies on the basis of biodiversity status of regional ecosystems, their extent in protected areas (presence of poorly conserved regional ecosystems), the presence of significant wetlands; and areas of national importance such as the presence of Threatened Ecological Communities, World Heritage areas and Ramsar sites. Ecosystem value is applied at a bioregional (**B1**) and regional (**B2**) scale.

Criteria C. Tract size: Measures the relative size of tracts of vegetation in the landscape. The size of any tract is a major indicator of ecological significance, and is also strongly correlated with the long-term viability of biodiversity values. Larger tracts are less susceptible to ecological edge effects and are more likely to sustain viable populations of native flora and fauna than smaller tracts.

Criteria D. Relative size of regional ecosystems: Classifies the relative size of each regional ecosystem unit within its bioregion (**D1**) and its subregion (**D2**). Remnant units are compared with all other occurrences with the same regional ecosystem. Large examples of a regional ecosystem are more significant than smaller examples of the same regional ecosystem because they are more representative of the biodiversity values particular to the regional ecosystem, are more resilient to the effects of disturbance, and constitute a significant proportion of the total area of the regional ecosystem.

Criteria F. Ecosystem diversity: Is an indicator of the number of regional ecosystems occurring within an area. An area with high ecosystem diversity will have many regional ecosystems and ecotones relative to other areas within the bioregion.

Criteria G. Context and connection: Represents the extent to which a remnant unit incorporates, borders or buffers areas such as significant wetlands, endangered ecosystems; and the degree to which it is connected to other vegetation.

A summary of the biodiversity status based upon the diagnostic criteria is provided in the following table.

Table 10: Summary of biodiversity significance based upon diagnostic criteria with respect to the AOI

Biodiversity significance	Description	Area (Ha)	% of AOI
State	Remnant contains at least 1 Vulnerable or Near Threatened species (A) & Nat. Threatened Ecol. Community (B1)	49.69	0.69
State	Remnant contains at least one Of Concern RE (B1) & Nat. Threatened Ecol. Community (B1)	170.08	2.36
Regional	Remnant contains at least 1 Vulnerable or Near Threatened species (A)	297.04	4.11
Regional	Remnant contains at least one Of Concern RE (B1)	24.52	0.34
Local or Other Values	Refer to diagnostic data for additional information	1,787.11	24.75

Assessment of diagnostic criteria with respect to the AOI

The following table reflects an assessment of the individual diagnostic criteria noted above in regards to the AOI.

Table 11: Assessment of individual diagnostic criteria with respect to the AOI

Diagnostic Criteria	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
A: Habitat for EVNT Taxa			346.7	4.8	1,451.58	20.1	530.12	7.3
B1: Ecosystem Value (Bioregion)	219.75	3.0	24.52	0.3	1,842.09	25.5		
B2: Ecosystem Value (Subregion)					2,086.36	28.9		
C: Tract Size			695.57	9.6	635.1	8.8	755.69	10.5
D1: Relative RE Size (Bioregion)							2,086.36	28.9
D2: Relative RE Size (Subregion)							2,086.36	28.9
F: Ecosystem Diversity	40.49	0.6	770.08	10.7	1,160.05	16.1	115.74	1.6
G: Context and Connection	182.92	2.5	467.75	6.5	1,377.66	19.1	58.03	0.8

Other Essential Criteria

Other essential criteria (also known as expert panel criteria) are based on non-uniform information sources and which may rely more upon expert opinion than on quantitative data. These criteria are used to provide a "second-cut" determination of biodiversity significance, which is then combined with the diagnostic criteria for an overall assessment of relative biodiversity significance. A summary of the biodiversity status based upon the other essential criteria is provided in the following table.

Table 12: Summary of biodiversity significance based upon other essential criteria with respect to the AOI

Biodiversity significance	Description	Area (Ha)	% of AOI
State	Remnant contains Special Biodiversity Values (view Expert Panel data for further information) (I)	709.9	9.83
Regional	Remnant contains Special Biodiversity Values (view Expert Panel data for further information) (I)	0.32	0.0
Regional	Remnant forms part of a bioregional corridor (J)	95.17	1.32
Local	Remnant contains Special Biodiversity Values (view Expert Panel data for further information) (I)	10.56	0.15

A description of each of the other essential criteria and associated assessment in regards to the AOI is provided in the following sections.

Criteria H. Essential and general habitat for priority taxa: Priority taxa are those which are at risk or of management concern, taxa of scientific interest as relictual (ancient or primitive), endemic taxa or locally significant populations (such as a flying fox camp or heronry), highly specialised taxa whose habitat requirements are complex and distributions are not well correlated with any particular regional ecosystem, taxa important for maintaining genetic diversity (such as complex spatial patterns of genetic variation, geographic range limits, highly disjunct populations), taxa critical for management or monitoring of biodiversity (functionally important or ecological indicators), or economic and culturally important taxa.

Criteria I. Special biodiversity values: areas with special biodiversity values are important because they contain multiple taxa in a unique ecological and often highly biodiverse environment. Areas with special biodiversity values can include the following:

- Ia - centres of endemism - areas where concentrations of taxa are endemic to a bioregion or subregion are found.
- Ib - wildlife refugia (Morton *et al*. 1995), for example, islands, mound springs, caves, wetlands, gorges, mountain ranges and topographic isolates, ecological refuges, refuges from exotic animals, and refuges from clearing. The latter may include large areas that are not suitable for clearing because of land suitability/capability.
- Ic - areas with concentrations of disjunct populations.
- Id - areas with concentrations of taxa at the limits of their geographic ranges.
- Ie - areas with high species richness.
- If - areas with concentrations of relictual populations (ancient and primitive taxa).
- Ig - areas containing REs with distinct variation in species composition associated with geomorphology and other environmental variables.
- Ih - an artificial waterbody or managed/manipulated wetland considered by the panel/s to be of ecological significance.
- Ii - areas with a high density of hollow-bearing trees that provide habitat for animals.
- Ij - breeding or roosting sites used by a significant number of individuals.
- Ik - climate change refuge.

The following table identifies the value and extent area of the Other Essential Criteria H and I within the AOI.

Table 13: Relative importance of expert panel criteria (H and I) used to access overall biodiversity significance with respect to the AOI

Expert Panel	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
H: Core Habitat Priority Taxa								
Ia: Centres of Endemism								
Ib: Wildlife Refugia	709.92	9.8	0.32		10.55	0.1		
Ic: Disjunct Populations								

Expert Panel	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
Id: Limits of Geographic Ranges								
Ie: High Species Richness								
If: Relictual Populations								
Ig: Variation in Species Composition								
Ih: Artificial Wetland								
Ii: Hollow Bearing Trees								
Ij: Breeding or Roosting Site	30.51	0.4						
Ik: Climate Refugia								

NB. Whilst biodiversity values associated with Criteria I may be present within the site (refer to tables 12 and 15), for the New England Tableland and Central Queensland Coast BPAs, area and % area figures associated with Criteria Ia through to Ij cannot be listed in the table above (due to slight variations in data formats between BPAs).

Criteria J. Corridors: areas identified under this criterion qualify either because they are existing vegetated corridors important for contiguity, or cleared areas that could serve this purpose if revegetated. Some examples of corridors include riparian habitats, transport corridors and "stepping stones".

Bioregional and subregional conservation corridors have been identified in the more developed bioregions of Queensland through the BPAs, using an intensive process involving expert panels. Map 3 displays the location of corridors as identified under the Statewide Corridor network. The Statewide Corridor network incorporates BPA derived corridors and for bioregions where no BPA has been assessed yet, corridors derived under other planning processes. *Note: as a result of updating and developing a statewide network, the alignment of corridors may differ slightly in some instances when compared to those used in individual BPAs.*

The functions of these corridors are:

- **Terrestrial** Bioregional corridors, in conjunction with large tracts of remnant vegetation, maintain ecological and evolutionary processes at a landscape scale, by:

  • Maintaining long term evolutionary/genetic processes that allow the natural change in distributions of species and connectivity between populations of species over long periods of time;

  • Maintaining landscape/ecosystems processes associated with geological, altitudinal and climatic gradients, to allow for ecological responses to climate change;

  • Maintaining large scale seasonal/migratory species processes and movement of fauna;

  • Maximising connectivity between large tracts/patches of remnant vegetation;

  • Identifying key areas for rehabilitation and offsets; and

- **Riparian** Bioregional Corridors also maintain and encourage connectivity of riparian and associated ecosystems.

The location of the corridors is determined by the following principles:

- Terrestrial

  • Complement riparian landscape corridors (i.e. minimise overlap and maximise connectivity);

  • Follow major watershed/catchment and/or coastal boundaries;

  • Incorporate major altitudinal/geological/climatic gradients;

  • Include and maximise connectivity between large tracts/patches of remnant vegetation;

• Include and maximise connectivity between remnant vegetation in good condition; and

- Riparian

• Located on the major river or creek systems within the bioregion in question.

The total extent of remnant vegetation triggered as being of "State", "Regional" or "Local" significance due to the presence of an overlying BPA derived terrestrial or riparian corridor within the AOI, is provided in the following table. For further information on how remnant vegetation is triggered due to the presence of an overlying BPA derived corridor, refer to the relevant landscape BPA expert panel report(s).

Table 14: Extent of triggered remnant vegetation due to the presence of BPA derived corridors with respect to the AOI

Biodiversity Significance	Area (Ha)	% of AOI
State	0.0	0.0
Regional	95.17	1.32
Local	0.0	0.0

NB: area figures associated with the extent of corridor triggered remnant vegetation are only available for those bioregions where a BPA has been undertaken.

Refer to **Map 3** for further information.

Threatening process/condition (Criteria K) - areas identified by experts under this criterion may be used to amend (upgrade or downgrade) biodiversity significance arising from the "first-cut" analysis. The condition of remnant vegetation is affected by threatening processes such as weeds, ferals, grazing and burning regime, selective timber harvesting/removal, salinity, soil erosion, and climate change.

Assessment of Criteria K with respect to the AOI is not currently included in the "Biodiversity and Conservation Values" report, as it has not been applied to the majority of Queensland due to data/information limitations and availability.

Special Area Decisions

Expert panel derived "Special Area Decisions" are used to assign values to Other Essential Criteria. The specific decisions which relate to the AOI in question are listed in the table below.

Table 15: Expert panel decisions for assigning levels of biodiversity significance with respect to the AOI

Decision Number	Description	Panel Recommended Significance	Criteria Values
brbn_l_62	Taunton Scientific Reserve	State	Ib (refugia): VH
brbs_l_18b	None	None	None
brbs_l_47	Regionally significant natural palustrine & lacustrine wetlands	Regional	Ib (refugia): H
brbs_l_48	Locally significant natural palustrine & lacustrine wetlands	Local	Ib (refugia): M
brbs_l_49	Gilgai Remnants	State	Ib (refugia): VH; Ij (aggregation site):VH

Expert panel decision descriptions:

brbn_l_62

Taunton National Park (Scientific) acts as a refugia within a heavily modified landscape. The park was established primarily for the purpose of protecting the endangered bridled nailtail wallaby Onychogalea fraenata. Dispersal of individuals in time to suitable habitat to the south will rely on retaining connectivity from the park, particularly along the creeks Five Mile, Duckworth, Walton, Iguana, Stanley, Charlevue, Spectacle, Lagoon and Wild Horse (not captured in the spatial implementation).

Other known conservation significant fauna which occur or have been recorded within the park are golden-tailed gecko Strophurus taenicauda, brigalow scaly-foot Paradelma orientalis, ornamental snake Denisonia maculata, speckled warbler Chthonicola sagittata, koala Phascolarctos cinereus and squatter pigeon Geophaps s. scripta. Representatives from six of the Australian snake families are also found in the reserve.

With respect to flora, 12 regional ecosystems are present including endangered brigalow communities. More than 190 species of flora have been recorded, of which at least 4 are threatened - Solanum elachophyllum, Solanum adenophorum, Dichanthium setosum and Cerbera dumicola.

brbs_l_18b

None

brbs_l_47

The panel considered that relatively natural palustrine and lacustrine wetlands and waterbodies within the Brigalow Belt bioregion act as important refugia, especially during periods of drought.

Whilst State significant wetlands are captured under Criterion B1, the panel agreed that all such natural wetland complexes with a combined area of greater than or equal to 5ha in size should be classed as being of at least Regional significance.

Refer to brbn_l_92 for the northern BRB implementation of this decision.

brbs_l_48

The panel considered that relatively natural palustrine and lacustrine wetlands and waterbodies within the Brigalow Belt bioregion act as important refugia, especially during periods of drought.

Whilst State significant wetlands are captured under Criterion B1, and regionally significant wetlands under the decision brbn_l_47, the panel agreed that all remaining relatively natural wetland complexes of less than 5ha in size be classed as being of at least local significance.

Refer to brbn_l_93 for the northern BRB implementation of this decision.

brbs_l_49

The gilgai wetland systems in the Brigalow Belt tend to be dominated by acacia and casuarina (mostly brigalow Acacia harpophylla and belah Casuarina cristata). Melaleuca, Corymbia and Eucalyptus species are also common along with Astrebla or Dichanthium spp. grassland. Gilgai systems are widespread and some are in good condition while others are largely cleared. The range of threatened wildlife present may use inundated gilgai as a water source at some stage of their life or are closely associated with the cracking clay soil habitat and wetlands.

Gilgai reptiles include the death adder Acanthophis antarcticus, De Vis' banded snake Denisonia devisi and ornamental snake D. maculata. Amphibians that use gilgai include salmon striped frog Limnodynastes salmini, scarlet-sided pobblebonk L. terraereginae and striped burrowing frog Cyclorana alboguttata. Other fauna which may use gilgai habitat at various times include bridled nailtail wallaby Onychogalea fraenata, black-striped wallaby Macropus dorsalis and the glossy black cockatoo Calyptorhynchus lathami.

Refer to brbn_l_75 for the northern BRB implementation of this decision.

Aquatic Conservation Assessments

Introduction

The Aquatic Biodiversity Assessment and Mapping Method or AquaBAMM (Clayton *et al.* 2006), was developed to assess conservation values of wetlands in queensland, and may also have application in broader geographical contexts. It is a comprehensive method that uses available data, including data resulting from expert opinion, to identify relative wetland conservation/ecological values within a specified study area (usually a catchment). The product of applying this method is an Aquatic Conservation Assessment (ACA) for the study area.

An ACA using AquaBAMM is non-social, non-economic and identifies the conservation/ecological values of wetlands at a user-defined scale. It provides a robust and objective conservation assessment using criteria, indicators and measures that are founded upon a large body of national and international literature. The criteria, each of which may have variable numbers of indicators and measures, are naturalness (aquatic), naturalness (catchment), diversity and richness, threatened species and ecosystems, priority species and ecosystems, special features, connectivity and representativeness. An ACA using AquaBAMM is a powerful decision support tool that is easily updated and simply interrogated through a geographic information system (GIS).

Where they have been conducted, ACAs can provide a source of baseline wetland conservation/ecological information to support natural resource management and planning processes. They are useful as an independent product or as an important foundation upon which a variety of additional environmental and socio-economic elements can be added and considered (i.e. an early input to broader 'triple-bottom-line' decision-making processes). An ACA can have application in:

- determining priorities for protection, regulation or rehabilitation of wetlands and other aquatic ecosystems
- on-ground investment in wetlands and other aquatic ecosystems
- contributing to impact assessment of large-scale development (e.g. dams)
- water resource and strategic regional planning prcesses

For a detailed explanation of the methodology please refer to the summary and expert panel reports relevant to the ACA utilised in this assessment. These reports can be accessed at Wetland *Info*:

http://wetlandinfo.des.qld.gov.au/wetlands/assessment/assessment-methods/aca

The GIS results can be downloaded from the Queensland Spatial Catalogue at:

http://qspatial.information.qld.gov.au/geoportal/

Explanation of Criteria

Under the AquaBAMM, eight criteria are assessed to derive an overall conservation value. Similar to the Biodiversity Assessment and Mapping Methodology, the criteria may be primarily diagnostic (quantitative) or primarily expert opinion (qualitative) in nature. The following sections provide a brief description of each of the 8 criteria.

Criteria 1. Naturalness - Aquatic: This attribute reflects the extent to which a wetland's (riverine, non-riverine, estuarine) aquatic state of naturalness is affected through relevant influencing indicators which include: presence of exotic flora and fauna; presence of aquatic communities; degree of habitat modification and degree of hydrological modification.

Criteria 2. Naturalness - Catchment: The naturalness of the terrestrial systems of a catchment can have an influence on many wetland characteristics including: natural ecological processes e.g. nutrient cycling, riparian vegetation, water chemistry, and flow. The indicators utilised to assess this criterion include: presence of exotic flora and/or fauna; riparian, catchment and flow modification.

Criteria 3. Naturalness - Diversity and Richness: This criterion is common to many ecological assessment methods and can include both physical and biological features. It includes such indicators as species richness, riparian ecosystem richness and geomorphological diversity.

Criteria 4. Threatened Species and Ecosystems: This criterion evaluates ecological rarity characteristics of a wetland. This includes both species rarity and rarity of communities / assemblages. The communities and assemblages are best represented by regional ecosystems. Species rarity is determined by NCA and EPBC status with Endangered, Vulnerable or Near-threatened species being included in the evaluation. Ecosystem rarity is determined by regional ecosystem biodiversity status i.e. Endangered, Of Concern, or Not of Concern.

Criteria 5. Priority Species and Ecosystems: Priority flora and fauna species lists are expert panel derived. These are aquatic, semi-aquatic and riparian species which exhibit at least 1 particular trait in order to be eligible for consideration. For

flora species the traits included:

- It forms significant macrophyte beds (in shallow or deep water).
- It is an important food source.
- It is important/critical habitat.
- It is implicated in spawning or reproduction for other fauna and/or flora species.
- It is at its distributional limit or is a disjunct population.
- It provides stream bank or bed stabilisation or has soil binding properties.
- It is a small population and subject to threatening processes.

Fauna species are included if they meet at least one of the following traits:

- It is endemic to the study area (>75 per cent of its distribution is in the study area/catchment).
- It has experienced, or is suspected of experiencing, a serious population decline.
- It has experienced a significant reduction in its distribution and has a naturally restricted distribution in the study area/catchment.
- It is currently a small population and threatened by loss of habitat.
- It is a significant disjunct population.
- It is a migratory species (other than birds).
- A significant proportion of the breeding population (>one per cent for waterbirds, >75 per cent other species) occurs in the waterbody (see Ramsar criterion 6 for waterbirds).
- Limit of species range.

See the individual expert panel reports for the priority species traits specific to an ACA.

Criteria 6. Special Features: Special features are areas identified by flora, fauna and ecology expert panels which exhibit characteristics beyond those identified in other criteria and which the expert panels consider to be of the highest ecological importance. Special feature traits can relate to, but are not solely restricted to geomorphic features, unique ecological processes, presence of unique or distinct habitat, presence of unique or special hydrological regimes e.g. spring-fed streams. Special features are rated on a 1 - 4 scale (4 being the highest).

Criteria 7. Connectivity: This criterion is based on the concept that appropriately connected aquatic ecosystems are healthy and resilient, with maximum potential biodiversity and delivery of ecosystem services.

Criteria 8. Representativeness: This criterion applies primarily to non-riverine assessments, evaluates the rarity and uniqueness of a wetland type in relation to specific geographic areas. Rarity is determined by the degree of wetland protection within "protected Areas" estate or within an area subject to the *Fisheries Act 1994*, *Coastal Protection and Management Act 1995*, or *Marine Parks Act 2004*. Wetland uniqueness evaluates the relative abundance and size of a wetland or wetland management group within geographic areas such as catchment and subcatchment.

Riverine Wetlands

Riverine wetlands are all wetlands and deepwater habitats within a channel. The channels are naturally or artificially created, periodically or continuously contain moving water, or connecting two bodies of standing water. AquaBAMM, when applied to riverine wetlands uses a discrete spatial unit termed subsections. A subsection can be considered as an area which encompasses discrete homogeneous stream sections in terms of their natural attributes (i.e. physical, chemical, biological and utilitarian values) and natural resources. Thus in an ACA, an aquatic conservation significance score is calculated for each subsection and applies to all streams within a subsection, rather than individual streams as such.

Please note, the area figures provided in Tables 16 and 17, are derived using the extent of riverine subsections within the AOI. Refer to **Map 5** for further information. A summary of the conservation significance of riverine wetlands within the AOI is provided in the following table.

Table 16: Overall level/s of riverine aquatic conservation significance

Aquatic conservation significance (riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0

Aquatic conservation significance (riverine wetlands)	Area (Ha)	% of AOI
High	0.0	0.0
Medium	7,219.57	100.0
Low	0.0	0.0
Very Low	0.0	0.0

The individual aquatic conservation criteria ratings for riverine wetlands within the AOI are listed below.

Table 17: Level/s of riverine aquatic conservation significance based on selected criteria

Criteria	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
1. Naturalness aquatic					1,273.24	17.6	5,946.33	82.4
2. Naturalness catchment	2.53		7,217.04	100.0				
3. Diversity and richness	1,273.24	17.6	2,074.17	28.7	3,872.16	53.6		
4. Threatened species and ecosystems			7,219.57	100.0				
5. Priority species and ecosystems	7,217.04	100.0						
6. Special features								
7. Connectivity			5,946.33	82.4	1,273.24	17.6		
8. Representative-ness								

The table below lists and describes the relevant expert panel decisions used to assign conservation significance values to riverine wetlands within the AOI.

Table 18: Expert panel decisions for assigning overall levels of riverine aquatic conservation significance

Decision number	Special feature	Catchment	Criteria/Indicator/Measure	Conservation rating (1-4)
(No Records)				

4 is the highest rating/value

Expert panel decision descriptions:

(No Records)

Non-riverine Wetlands

Non-riverine wetlands include both lacustrine and palustrine wetlands, however, do not currently incorporate estuarine, marine or subterranean wetland types. A summary of the conservation significance of non-riverine wetlands within the AOI is provided in the following table. Refer to **Map 6** for further information.

Table 19: Overall level/s of non-riverine aquatic conservation significance

Aquatic conservation significance (non-riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0
High	0.0	0.0
Medium	10.88	0.15
Low	0.0	0.0
Very Low	0.0	0.0

The following table provides an assessment of non-riverine wetlands within the AOI and associated aquatic conservation criteria values.

Table 20: Level/s of non-riverine aquatic conservation significance based on selected criteria

Criteria	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
1. Naturalness aquatic	4.68	0.1			6.19	0.1		
2. Naturalness catchment					10.87	0.2		
3. Diversity and richness			6.8	0.1	3.75	0.1	0.32	
4. Threatened species and ecosystems	2.43		4.37	0.1				
5. Priority species and ecosystems			10.87	0.2				
6. Special features								
7. Connectivity								
8. Representative-ness					6.8	0.1		

The table below lists and describes the relevant expert panel decisions used to assign conservation significance values to non-riverine wetlands within the AOI.

Table 21: Expert panel decisions for assigning overall levels of non-riverine aquatic conservation significance.

Decision number	Special feature	Catchment	Criteria/Indicator/Measure	Conservation rating (1-4)
ma_nr_fl_02	Regional ecosystems 8.3.4 & 11.3.27	Mackenzie	5.2.1	3

4 is the highest rating/value

Expert panel decision descriptions:

ma_nr_fl_02

These regional ecosystems contain significant habitat values that are under threat from threatening processes such as physical alteration/ destruction and invasion by **hymenachne**.

Note: This priority ecosystem decision applies to the following catchments: Calliope, Comet, Dawson, Fitzroy, Isaac, Mackenzie, Misc Other Islands, Nogoa, O'Connell, Pioneer, Plane, Proserpine, Shoalwater, Styx and Waterpark.

Threatened and Priority Species

Introduction

This chapter contains a list of threatened and priority flora and/or fauna species that have been recorded on, or within 4km of the Assessment Area.

The information presented in this chapter with respect to species presence is derived from compiled databases developed primarily for the purpose of BPAs and ACAs. Data is collated from a number of sources and is updated periodically.

It is important to note that the list of species provided in this report, may differ when compared to other reports generated from other sources such as the State government's WildNet, Herbrecs or the federal government's EPBC database for a number of reasons.

Records for threatened and priority species are filtered and checked based on a number of rules including:

- Taxonomic nomenclature - current scientific names and status,
- Location - cross-check co-ordinates with location description,
- Taxon by location - requires good knowledge of the taxon and history of the record,
- Duplicate records - identify and remove,
- Expert panels - check records and provide new records,
- Flora cultivated records excluded,
- Use precise records less than or equal to 2000m,
- Use recent records greater than or equal to 1975 animals, greater than or equal to 1950 plants.

Threatened Species

Threatened species are those species classified as "Endangered" or "Vulnerable" under the *Environment Protection and Biodiversity Conservation Act 1999* or "Endangered", "Vulnerable" or "Near threatened" under the *Nature Conservation Act 1992*.

The following threatened species have been recorded on, or within approximately 4km of the AOI.

Table 22: Threatened species recorded on, or within 4km of the AOI

Species	Common name	NCA status	EPBC status	Back on Track rank	Migratory species*	Wetland species**	Identified flora/fauna
Cerbera dumicola		NT		Low			FL
Geophaps scripta scripta	Squatter Pigeon (southern subsp.)	V	V	Medium			FA
Onychogalea fraenata	Bridled Nailtail Wallaby	E	E	Critical			FA
Solanum elachophyllum		E		Medium			FL

NB. Please note that the threatened species listed in this section are based upon the most recently compiled DES internal state-wide threatened species dataset. This dataset may contain additional records that were not originally available for inclusion in the relevant individual BPAs and ACAs.

**JAMBA - Japan-Australia Migratory Bird Agreement; CAMBA - China-Australia Migratory Bird Agreement; ROKAMBA - Republic of Korea-Australia Migratory Bird Agreement; CMS - Convention on the Conservation of Migratory Species*.

***Y - wetland indicator species*.

BPA Priority Species

A list of BPA priority species that have been recorded on, or within approximately 4km of the AOI is contained in the following table.

Table 23: Priority species recorded on, or within 4km of the AOI

(no results)

NB. Please note that the list of priority species is based on those species identified in the BPAs, however records for these species may be more recent than the originals used. furthermore, the BPA priority species databases are updated from time to time. At each update, the taxonomic details for all species are amended as necessary to reflect current taxonomic name and/or status changes.

ACA Priority Species

A list of ACA priority species used in riverine and non-riverine ACAs that have been recorded on, or within approximately 4km of the AOI are contained in the following tables.

Table 24: Priority species recorded on, or within 4 km of the AOI - riverine

Species	Common name	Back on Track rank	Identified flora/fauna
Eucalyptus camaldulensis			FL
Eucalyptus tereticornis			FL
Lomandra longifolia			FL

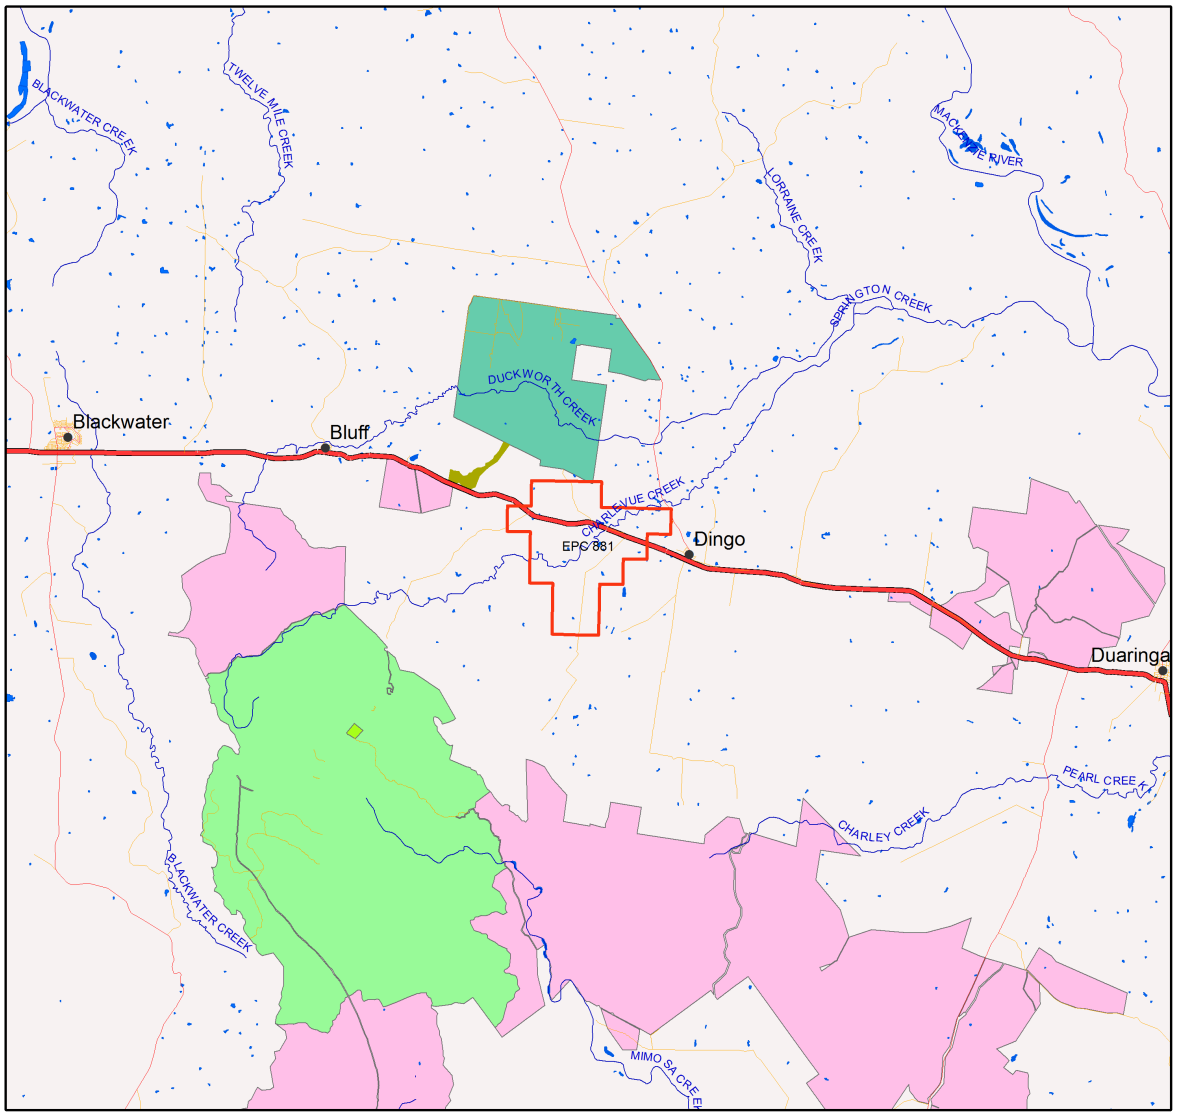

Table 25: Priority species recorded on, or within 4 km of the AOI - non-riverine

Species	Common name	Back on Track rank	Identified flora/fauna
Eucalyptus tereticornis			FL

NB. Please note that the priority species records used in the above two tables are comprised of those adopted for the released individual ACAs. The ACA riverine and non-riverine priority species databases are updated from time to time to reflect new release of ACAs. At each update, the taxonomic details for all ACAs records are amended as necessary to reflect current taxonomic name and/or status changes.

WetlandMaps Report

For selected area of interest

Current as at 06/06/2019

Environmental Reports - General Information

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is ot present within the Area of Interest(AOI) (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no matters of interest have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Important Note to User

Information presented in this report is based upon the mapping of water bodies and wetland regional ecosystems across Queensland. The Queensland wetland mapping was produced using existing information including water body mapping derived from Landsat satellite imagery, regional ecosystem mapping, topographic data, and a springs database. The result is a consistent wetland map for the whole of Queensland.

Ancillary data, such as higher resolution imagery (for example SPOT and aerial photographs), other vegetation and wetland mapping, geology, soil and land system mapping was also used in attributing and assessing the derived Queensland Wetlands Program wetland mapping products.

The wetland mapping was done in accordance with a detailed peer reviewed methodology which included quality assurance measures for all steps in the process. For more detailed information on how the Queensland Wetlands Program wetland mapping was produced, please see the Wetland Mapping and Classification Methodology.

Disclaimer

The State of Queensland, as represented by this department, gives no warranty in relation to the data (including without limitation, accuracy, reliability, completeness or fitness for a particular purpose) hosted on this website.

The user accepts sole responsibility and risk associated with the use and results of department data hosted on this website, irrespective of the purpose to which such use or results are applied. It is recommended that users consider independently verifying any information obtained from this website.

To the maximum extent permitted by applicable law, in no event shall the department be liable for any special, incidental, indirect, or consequential loss whatsoever (including, but not limited to, damages for loss of profits or confidential or other information, for business interruption, for personal injury, for loss of privacy, for failure to meet any duty including of good faith or of reasonable care, for negligence, for any other pecuniary or other loss whatsoever including, without limitation, legal costs on a solicitor own client basis) arising out of, or in any way related to, the use of or inability to use the data.

Summary Information

The following table provides an overview of the area of interest.

Table 1. Area of interest details

Size (ha)	133,776.49
Local Government(s)	Central Highlands Regional
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda, Isaac - Comet Downs
Catchment(s)	Fitzroy
Drainage sub-basin	Mackenzie River, Dawson River, Comet River

NRM Regions

The following NRM region(s) are in the area of interest:

Fitzroy Basin Association

Water Resource Plan Boundaries

The following Water Resource Plan(s) are in the area of interest:

Fitzroy Basin

Great Artesian Basin and Other Regional Aquifers

Learn more about how Wetlands are mapped in Queensland:

Queensland Wetlands Mapping Definitions

Wetlands are areas of permanent or periodic/intermittent inundation, with water that is static or flowing fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed 6 metres. To be a wetland the area must have one or more of the following attributes:

- at least periodically the land supports plants or animals that are adapted to and dependent on living in wet conditions for at least part of their life cycle, or
- the substratum is predominantly undrained soils that are saturated, flooded or ponded long enough to develop anaerobic conditions in the upper layers, or
- the substratum is not soil and is saturated with water, or covered by water at some time.

Examples under this definition **include**:

- those areas shown as a river, stream, creek, swamp, lake, marsh, waterhole, wetland, billabong, pool or spring on the latest Sunmap 1:25,000, 1:50,000, 1:100,000 or 1:250,000 topographic map
- areas defined as wetlands on local or regional maps prepared with the aim of mapping wetlands
- wetland regional ecosystems (REs) as defined by the Queensland Herbarium (Environmental Protection Agency 2005a)
- areas containing recognised hydrophytes as provided by the Queensland Herbarium
- saturated parts of the riparian zone
- artificial wetlands such as farm dams
- water bodies not connected to rivers or flowing water such as billabongs and rock pools.

Examples under this definition **exclude**:

- areas that may be covered by water but are not wetlands according to the definition
- floodplains that are intermittently covered by flowing water but do not meet the hydrophytes and soil criteria
- riparian zone above the saturation level.

Wetland Systems

Riverine wetlands are all wetlands and deepwater habitats within a channel. The channels are naturally or artificially created, periodically or continuously contain moving water, or connecting two bodies of standing water.

Palustrine wetlands are primarily vegetated non-channel environments of less than 8 hectares. They include billabongs, swamps, bogs, springs, soaks etc, and have more than 30% emergent vegetation.

Lacustrine wetlands are large, open, water-dominated systems (for example, lakes) larger than 8ha. This definition also applies to modified systems (for example, dams), which are similar to lacustrine systems (for example, deep, standing or slow-moving waters).

Marine wetlands include the area of ocean from the coastline or estuary, extending to the jurisdictional limits of Queensland waters (3 nautical mile limit). This definition differs from that in Ramsar, as it includes waters deeper than 6m below the lowest astronomical tide.

Estuarine wetlands are those with oceanic water sometimes diluted with freshwater run-off from the land.

Subterranean wetlands are wetlands occurring below the surface of the ground and that are fed by groundwater i.e. caves and aquifers. These wetlands provide water to groundwater dependent ecosystems.

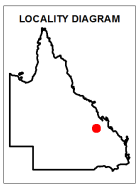
Wetland habitat types in the AOI. Total area: 11468.08ha

Wetland Class	Habitat type	Area (ha)
None	Coastal/ Sub-coastal floodplain tree swamps (Melaleuca and Eucalypt)	8578.24
Riverine	Riverine	1931.53
None	Coastal/ Sub-Coastal non-floodplain tree swamps (Melaleuca and Eucalypt)	530.79
Lacustrine	Artificial/ highly modified wetlands (dams, ring tanks, irrigation channel	149.53
Palustrine	Coastal/ Sub-coastal floodplain tree swamps (Melaleuca and Eucalypt)	121.24
Palustrine	Coastal/ Sub-Coastal non-floodplain tree swamps (Melaleuca and Eucalypt)	110.62
Palustrine	Coastal/ Sub-coastal floodplain grass, sedge and herb swamps	46.13

Queensland wetland habitat typology: Major wetland habitat types for wetland conceptual models and wetland management profiles

Wetland name	Conceptual model	Wetland profile
Mangrove Wetlands	Not developed	Mangrove Wetlands
Saltmarsh Wetlands	Not developed	Saltmarsh Wetlands
Coastal and subcoastal saline swamps of all substrates, water regimes, topographic types and vegetation communities	Coastal and subcoastal saline swamps	Coastal grass-sedge wetlands
Coastal and subcoastal non-floodplain tree swamps (Melaleuca and Eucalypt) of all substrates and water regimes	Coastal and subcoastal non-floodplain tree swamps - melaleuca and eucalypt	Coastal and subcoastal tree swamps
Coastal and subcoastal non-floodplain wet heath swamps of all substrates and water regimes	Coastal and subcoastal non-floodplain wet heath swamps	Coastal and subcoastal wet heath swamps
Coastal and subcoastal non-floodplain grass, sedge and herb swamps of all substrates and water regimes	Coastal and subcoastal non-floodplain grass, sedge and herb swamps	Coastal grass-sedge wetlands
Coastal and subcoastal spring swamps of all substrates, water types, water regimes and vegetation communities	Coastal and subcoastal spring swamps	Great Artesian Basin spring wetlands
Coastal and subcoastal floodplain tree swamps - melaleuca and eucalypt of all substrates and water regimes	Coastal and subcoastal floodplain tree swamps - melaleuca and eucalypt	Coastal and subcoastal tree swamps
Coastal and subcoastal floodplain wet heath swamps of all substrates and water regimes	Coastal and subcoastal floodplain wet heath swamps	Coastal and subcoastal wet heath swamps
Coastal and subcoastal floodplain, grass, sedge herb swamps of all substrates and water regimes	Coastal and subcoastal floodplain grass, sedge, herb swamps	Coastal grass-sedge wetlands
Coastal and subcoastal tree swamps - palm of all substrates, topographic types and water regimes	Coastal and subcoastal floodplain tree swamps - palm	Coastal Palm Swamps
Coastal and subcoastal Floodplain Lakes of all substrates, water types and water regimes	Coastal and subcoastal Floodplain Lakes	Coastal and subcoastal floodplain lakes and non-floodplain soil lakes
Coastal and subcoastal non-floodplain rock lakes of all water types and water regimes	Coastal and subcoastal non-floodplain rock lakes	Coastal and subcoastal non-floodplain rock lakes



Wetland name	Conceptual model	Wetland profile
Coastal and subcoastal non-floodplain sand lakes (window) of all water types and water regimes	Coastal and subcoastal non-floodplain sand lakes - window	Coastal non-floodplain sand lakes
Coastal and subcoastal non-floodplain sand lakes (perched) of all water types and water regimes	Coastal and subcoastal non-floodplain sand lakes - perched	Coastal non-floodplain sand lakes
Coastal and subcoastal non-floodplain soil lakes of all water types and water regimes	Coastal and subcoastal non-floodplain soil lakes	Coastal and subcoastal floodplain lakes and non-floodplain soil lakes
Arid and semi-arid saline swamps of all substrates, water regimes, topographic types and vegetation communities	Arid and semi-arid saline swamps	Semi-arid swamps
Arid and semi-arid fresh tree swamps of all substrates, and water regimes and topographic types	Arid and semi-arid tree swamps	Arid swamps Semi-Arid swamps
Arid and semi-arid lignum swamps of all substrates, and water regimes and topographic types	Arid and semi-arid lignum swamps	Arid swamps Semi-Arid swamps
Arid and semi-arid grass, sedge, herb swamps of all substrates, water regimes and topographic types	Arid and semi-arid grass, sedge, herb swamps	Arid swamps Semi-Arid swamps
Arid and semi-arid fresh non-floodplain tree swamps of all substrates and water regimes	Arid and semi-arid non-floodplain tree swamps	Arid swamps Semi-Arid swamps
Arid and semi-arid fresh non-floodplain lignum swamps of all substrates and water regimes	Arid and semi-arid non-floodplain lignum swamps	Arid swamps Semi-Arid swamps
Arid and semi-arid fresh non-floodplain grass, sedge, herb swamps of all substrates and water regimes	Arid and semi-arid non-floodplain grass, sedge, herb swamps	Arid swamps Semi-Arid swamps
Arid and semi-arid, non-floodplain swamps - springs of all substrates, water regimes and vegetation communities	Arid and semi-arid spring swamps	Great Artesian Basin spring wetlands
Arid and semi-arid, saline lakes of all substrates, topographic types and water regimes	Arid and semi-arid saline lakes	Arid and semi-arid lakes
Arid and semi-arid, floodplain lakes of all, substrates and water regimes	Arid and semi-arid floodplain lakes	Arid and semi-arid lakes
Arid and semi-arid, non-floodplain Lakes of all substrates and water regimes	Arid and semi-arid non-floodplain lakes	Arid and semi-arid lakes
Arid/ semi-arid, non-floodplain (clay pans) lakes of all substrates and water regimes	Arid and semi-arid fresh non-floodplain lakes (clay pans)	Arid and semi-arid lakes
Arid and semi-arid, Permanent Lakes permanently inundated lakes of all substrates, water types, topographic types and vegetation communities	Arid and semi-arid permanent lakes	Arid and semi-arid lakes

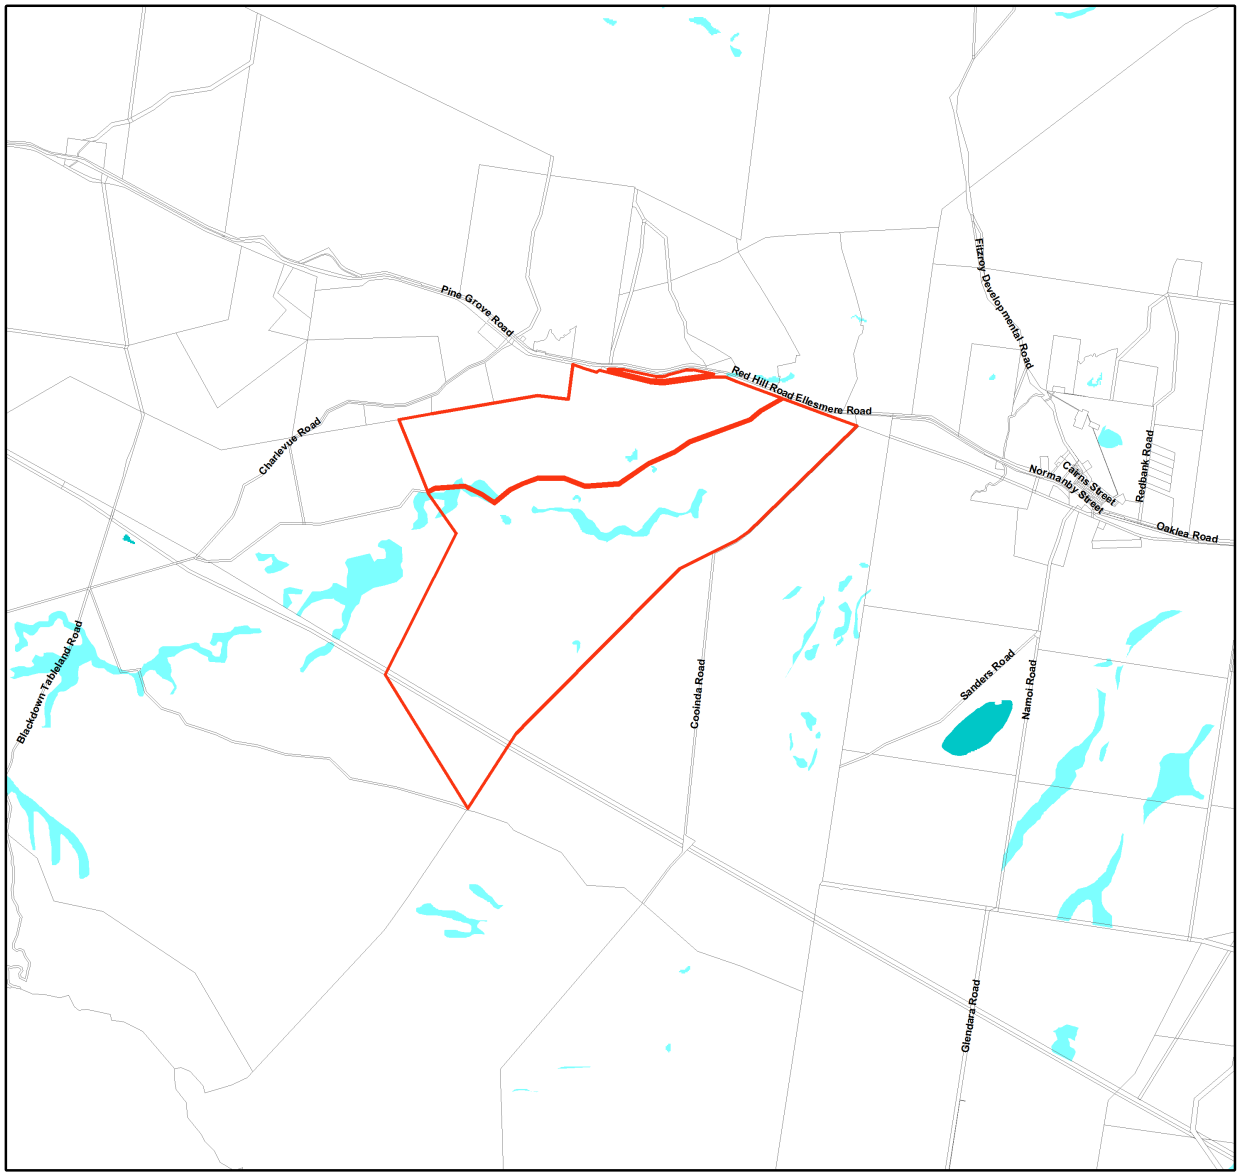
Note:
This map shows the location of wetland protection areas which are defined under the Environmental Protection Regulation 2008. Within wetland protection areas, certain types of development involving high impact earthworks are made assessable under Schedule 3 of the Sustainable Planning Regulation 2009.

The Department of State Development, Manufacturing, Infrastructure and Planning is the State Assessment Referral Agency (SARA) under Schedule 7 of the Sustainable Planning Regulation 2009 for assessable development involving high impact earthworks within wetland protection areas. The Department of Environment and Science is a technical agency.

The policy outcome and assessment criteria for assessing these applications are described in the State Development Assessment Provisions (SDAP) *Module 11: Wetlands and wild rivers.*

This map is produced at a scale relevant to the size of the lot on plan identified and should be printed at A4 size in portrait orientation. Consideration of the effects of mapped scale is necessary when interpreting data at a large scale.



For further information or assistance with interpretation of this product, please contact the Department of Environment and Science, email planning.support@des.qld.gov.au.

Note:
This map shows the location of wetlands on the Map of Referable Wetlands which are defined under the Environmental Protection Regulation 2008.

Wetlands are assessed for ecological significance using the environmental values for wetlands in section 81A of the Environmental Protection Regulation 2008. Wetlands are considered either High Ecological Significance (HES) or of General Ecological Significance (GES) for the purposes of the environmental values.

This map is produced at a scale relevant to the size of the lot on plan identified and should be printed at A4 size in portrait orientation. Consideration of the effects of mapped scale is necessary when interpreting data at a large scale.

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or area of interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "central coordinates" option, the resulting assessment area encompasses an area extending for a 2km radius from the input coordinates.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 1994). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no matters of interest have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Important Note to User

Information presented in this report is based upon the Queensland Herbarium's Regional Ecosystem framework. The Biodiversity Status has been used to depict the extent of "Endangered", "Of Concern" and "No Concern at Present" regional ecosystems in all cases, rather than the classes used for the purposes of the *Vegetation Management Act 1999* (VMA). Mapping and figures presented in this document reflect the Queensland Herbarium's Remnant and Pre-clearing Regional Ecosystem Datasets, and not the certified mapping used for the purpose of the VMA.

For matters relevant to vegetation management under the VMA, please refer to the Department of Natural Resources, Mines and Energy website

https://www.dnrme.qld.gov.au/

Please direct queries about these reports to: Queensland.Herbarium@dsiti.qld.gov.au

Disclaimer

Whilst every care is taken to ensure the accuracy of the information provided in this report, the Queensland Government makes no representations or warranties about its accuracy, reliability, completeness, or suitability, for any particular purpose and disclaims all responsibility and all liability (including without limitation, liability in negligence) for all expenses, losses, damages (including indirect or consequential damage) and costs which the user may incur as a consequence of the information being inaccurate or incomplete in any way and for any reason.

Summary Information

The following table provides an overview of the AOI with respect to selected topographic and environmental themes. Refer to **Map 1** for locality information.

Table 1: Area of interest details: epc: 881

Size (ha)	7,219.57
Local Government(s)	Central Highlands Regional
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda
Catchment(s)	Fitzroy

The table below summarizes the extent of remnant vegetation classed as "Endangered", "Of concern" and "No concern at present" regional ecosystems classified by Biodiversity Status within the area of interest (AOI).

Table 2: Summary table, biodiversity status of regional ecosystems within the AOI

Biodiversity Status	Area (Ha)	% of AOI
Endangered	6.41	0.09
Of concern	237.45	3.29
No concern at present	1,842.10	25.52
Total remnant vegetation	2,085.96	28.89

Refer to **Map 2** for further information.

Regional Ecosystems

1. Introduction

Regional ecosystems are vegetation communities in a bioregion that are consistently associated with particular combinations of geology, landform and soil (Sattler and Williams 1999). Descriptions of Queensland's Regional ecosystems are available online from the Regional Ecosystem Description Database (REDD). Descriptions are compiled from a broad range of information sources including vegetation, land system and geology survey and mapping and detailed vegetation site data. The regional ecosystem classification and descriptions are reviewed as new information becomes available. A number of vegetation communities may form a single regional ecosystem and are usually distinguished by differences in dominant species, frequently in the shrub or ground layers and are denoted by a letter following the regional ecosystem code (e.g. a, b, c). Vegetation communities and regional ecosystems are amalgamated into a higher level classification of broad vegetation groups (BVGs).

A published methodology for survey and mapping of regional ecosystems across Queensland (Neldner et al 2017) provides further details on regional ecosystem concepts and terminology.

This report provides information on the type, status, and extent of vegetation communities, regional ecosystems and broad vegetation groups present within a user specified area of interest. Please note, for the purpose of this report, the Biodiversity Status is used. This report has not been developed for application of the *Vegetation Management Act 1999* (VMA). Additionally, information generated in this report has been derived from the Queensland Herbarium's Regional Ecosystem Mapping, and not the regulated mapping certified for the purposes of the VMA. If your interest/matter relates to regional ecosystems and the VMA, users should refer to the Department of Natural Resources, Mines and Energy website.

https://www.dnrme.qld.gov.au/

With respect to the Queensland Biodiversity Status,

"Endangered" regional ecosystems are described as those where:

- remnant vegetation is less than 10 per cent of its pre-clearing extent across the bioregion; or 10-30% of its pre-clearing extent remains and the remnant vegetation is less than 10,000 hectares, or
- less than 10 per cent of its pre-clearing extent remains unaffected by severe degradation and/or biodiversity loss*, or
- 10-30 per cent of its pre-clearing extent remains unaffected by severe degradation and/or biodiversity loss and the remnant vegetation is less than 10,000 hectares; or
- it is a rare** regional ecosystem subject to a threatening process.***

"Of concern" regional ecosystems are described as those where:

- the degradation criteria listed above for 'Endangered' regional ecosystems are not met and,
- remnant vegetation is 10-30 per cent of its pre-clearing extent across the bioregion; or more than 20 per cent of its pre-clearing extent remains and the remnant extent is less than 10,000 hectares, or
- 10-30 percent of its pre-clearing extent remains unaffected by moderate degradation and/or biodiversity loss.****

and "No concern at present" regional ecosystems are described as those where:

- remnant vegetation is over 30 per cent of its pre-clearing extent across the bioregion, and the remnant area is greater than 10,000 hectares, and
- the degradation criteria listed above for 'Endangered' or 'Of concern' regional ecosystems are not met.

**Severe degradation and/or biodiversity loss is defined as: floristic and/or faunal diversity is greatly reduced but unlikely to recover within the next 50 years even with the removal of threatening processes; or soil surface is severely degraded, for example, by loss of A horizon, surface expression of salinity; surface compaction, loss of organic matter or sheet erosion.*

***Rare regional ecosystem: pre-clearing extent (1000 ha); or patch size (100 ha and of limited total extent across its range).*

****Threatening processes are those that are reducing or will reduce the biodiversity and ecological integrity of a regional ecosystem. For example, clearing, weed invasion, fragmentation, inappropriate fire regime or grazing pressure, or infrastructure development.*

*****Moderate degradation and/or biodiversity loss is defined as: floristic and/or faunal diversity is greatly reduced but unlikely to recover within the next 20 years even with the removal of threatening processes; or soil surface is moderately degraded.*

2. Remnant Regional Ecosystems

The following table identifies the remnant regional ecosystems and vegetation communities mapped within the AOI and provides their short descriptions, Biodiversity Status, and remnant extent within the selected AOI. Please note, where heterogeneous vegetated patches (mixed patches of remnant vegetation mapped as containing multiple regional ecosystems) occur within the AOI, they have been split and listed as individual regional ecosystems (or vegetation communities where present) for the purposes of the table below. In such instances, associated area figures have been generated based upon the estimated proportion of each regional ecosystem (or vegetation community) predicted to be present within the larger mixed patch.

Table 3: Remnant regional ecosystems, description and status within the AOI

Regional Ecosystem	Short Description	BD Status	Area (Ha)	% of AOI
11.3.1	Acacia harpophylla and/or Casuarina cristata open forest on alluvial plains	Endangered	6.41	0.09
11.3.2	Eucalyptus populnea woodland on alluvial plains	Of concern	125.33	1.74
11.3.25	Eucalyptus tereticornis or E. camaldulensis woodland fringing drainage lines	Of concern	112.12	1.55
11.5.2	Eucalyptus crebra, Corymbia spp., with E. moluccana woodland on lower slopes of Cainozoic sand plains and/or remnant surfaces	No concern at present	1,004.51	13.91
11.5.9b	Eucalyptus crebra and other Eucalyptus spp. and Corymbia spp. woodland on Cainozoic sand plains and/or remnant surfaces	No concern at present	142.87	1.98
11.7.2	Acacia spp. woodland on Cainozoic lateritic duricrust. Scarp retreat zone	No concern at present	694.73	9.62
non-rem	None	None	5,133.61	71.11

Refer to **Map 2** for further information. **Map 3** also provides a visual estimate of the distribution of regional ecosystems present before clearing.

Table 4 provides further information in regards to the remnant regional ecosystems present within the SOI. Specifically, the extent of remnant vegetation remaining within the bioregion, the 1:1,000,000 broad vegetation group (BVG) classification, whether the regional ecosystem is identified as a wetland, and extent of representation in Queensland's Protected Area Estate. For a description of the vegetation communities within the AOI and classified according to the 1:1,000,000 BVG, refer to **Table 6**.

Table 4: Remnant regional ecosystems within the AOI, additional information

Regional Ecosystem	Remnant Extent	BVG (1 Million)	Wetland	Representation in protected estate
11.3.1	Pre-clearing 783000 ha; Remnant 2015 80000 ha	25a	None	High
11.3.2	Pre-clearing 1936000 ha; Remnant 2015 514000 ha	17a	Contains palustrine wetland (e.g. in swales).	Low
11.3.25	Pre-clearing 791000 ha; Remnant 2015 513000 ha	16a	Riverine wetland or fringing riverine wetland.	Low
11.5.2	Pre-clearing 360000 ha; Remnant 2015 190000 ha	18b	None	Low

Regional Ecosystem	Remnant Extent	BVG (1 Million)	Wetland	Representation in protected estate
11.5.9b	Pre-clearing 364000 ha; Remnant 2015 237000 ha	18b	None	Low
11.7.2	Pre-clearing 565000 ha; Remnant 2015 367000 ha	24a	None	Low
non-rem	None	None	None	None

Representation in Protected Area Estate: High greater than 10% of pre-clearing extent is represented; Medium 4 - 10% is represented; Low less than 4% is represented, No representation.

The distribution of mapped wetland systems within the area of interest is displayed in **Map 6**.

The following table lists known special values associated with a regional ecosystem type.

Table 5: Remnant regional ecosystems within the AOI, special values

Regional Ecosystem	Special Values
11.3.1	Habitat for threatened fauna species including painted honeyeater, Grantiella picta particularly in subregion 35 (Oliver et al. 2003).
11.3.2	Habitat for threatened flora species Homopholis belsonii.
11.3.25	Shown to be associated with a high fauna species richness in the Taroom area (Venz et al. 2002). Within parts of the Fitzroy catchment, this RE is known habitat for the threatened freshwater turtle Rheodytes leukops. Known to be important habitat for other riparian freshwater turtle species.
11.5.2	None
11.5.9b	None
11.7.2	Habitat for threatened plant species including Acacia wardellii.
non-rem	None

3. Remnant Regional Ecosystems by Broad Vegetation Group

BVGs are a higher-level grouping of vegetation communities. Queensland encompasses a wide variety of landscapes across temperate, wet and dry tropics and semi-arid climatic zones. BVGs provide an overview of vegetation communities across the state or a bioregion and allow comparison with other states. There are three levels of BVGs which reflect the approximate scale at which they are designed to be used: the 1:5,000,000 (national), 1:2,000,000 (state) and 1:1,000,000 (regional) scales.

A comprehensive description of BVGs is available at:

https://publications.qld.gov.au/dataset/redd/resource/

The following table provides a description of the 1:1,000,000 BVGs present and their associated extent within the AOI.

Table 6: Broad vegetation groups (1 million) within the AOI

BVG (1 Million)	Description	Area (Ha)	% of AOI
None	None	5,133.61	71.11

BVG (1 Million)	Description	Area (Ha)	% of AOI
16a	Open forest and woodlands dominated by Eucalyptus camaldulensis (river red gum) (or E. tereticornis (blue gum)) and/or E. coolabah (coolabah) (or E. microtheca (coolabah)) fringing drainage lines. Associated species may include Melaleuca spp., Corymbia tessellaris (carbeen), Angophora spp., Casuarina cunninghamiana (riveroak). Does not include alluvial areas dominated by herb and grasslands or alluvial plains that are not flooded. (land zone 3) (MGD, BRB, GUP, CHC, MUL, DEU, EIU, NWH, SEQ, [NET, WET]) (All bioregions except CYP and CQC)	112.12	1.55
17a	Woodlands dominated by Eucalyptus populnea (poplar box) (or E. brownii (Reid River box)) on alluvium, sand plains and footslopes of hills and ranges. (land zones 3, 5, 10, 9, 4, 11, 12, [8]) (BRB, MUL, DEU, MUL, EIU)	125.33	1.74
18b	Woodlands dominated Eucalyptus crebra (sens. lat.) (narrow-leaved red ironbark) frequently with Corymbia spp. or Callitris spp. on flat to undulating plains. (land zones 5, 3) (BRB, DEU, EIU, GUP, CYP)	1,147.37	15.89
24a	Low woodlands to tall shrublands dominated by Acacia spp. on residuals. Species include A. shirleyi (lancewood), A. catenulata (bendee), A. microsperma (bowyakka), A. clivicola, A. sibirica, A. rhodoxylon (rosewood) and A. leptostachya (Townsville wattle). (land zones 7, 10, 5, 12, 11, [9, 3]) (MUL, CHC, BRB, GUP, EIU, MGD, DEU, NWH, [CYP])	694.73	9.62
25a	Open forests to woodlands dominated by Acacia harpophylla (brigalow) sometimes with Casuarina cristata (belah) on heavy clay soils. Includes areas co-dominated with A. cambagei (gidgee) and/or emergent eucalypts (land zones 4, 9, 3, 11, 7, 12, [5, 8]) (BRB, MUL, MGD, DEU, [SEQ])	6.41	0.09

Refer to **Map 4** for further information. **Map 5** also provides a representation of the distribution of vegetation communities as per the 1:5,000,000 BVG believed to be present prior to European settlement.

4. Technical and BioCondition Benchmark Descriptions

Technical descriptions provide a detailed description of the full range in structure and floristic composition of regional ecosystems (e.g. 11.3.1) and their component vegetation communities (e.g. 11.3.1a, 11.3.1b). See:

http://www.qld.gov.au/environment/plants-animals/plants/ecosystems/technical-descriptions/

The descriptions are compiled using site survey data from the Queensland Herbarium's CORVEG database. Distribution maps, representative images (if available) and the pre-clearing and remnant extent (hectares) of each vegetation community derived from the regional ecosystem mapping data are included. The technical descriptions should be used in conjunction with the fields from the regional ecosystem description database (REDD) for a full description of the regional ecosystem.

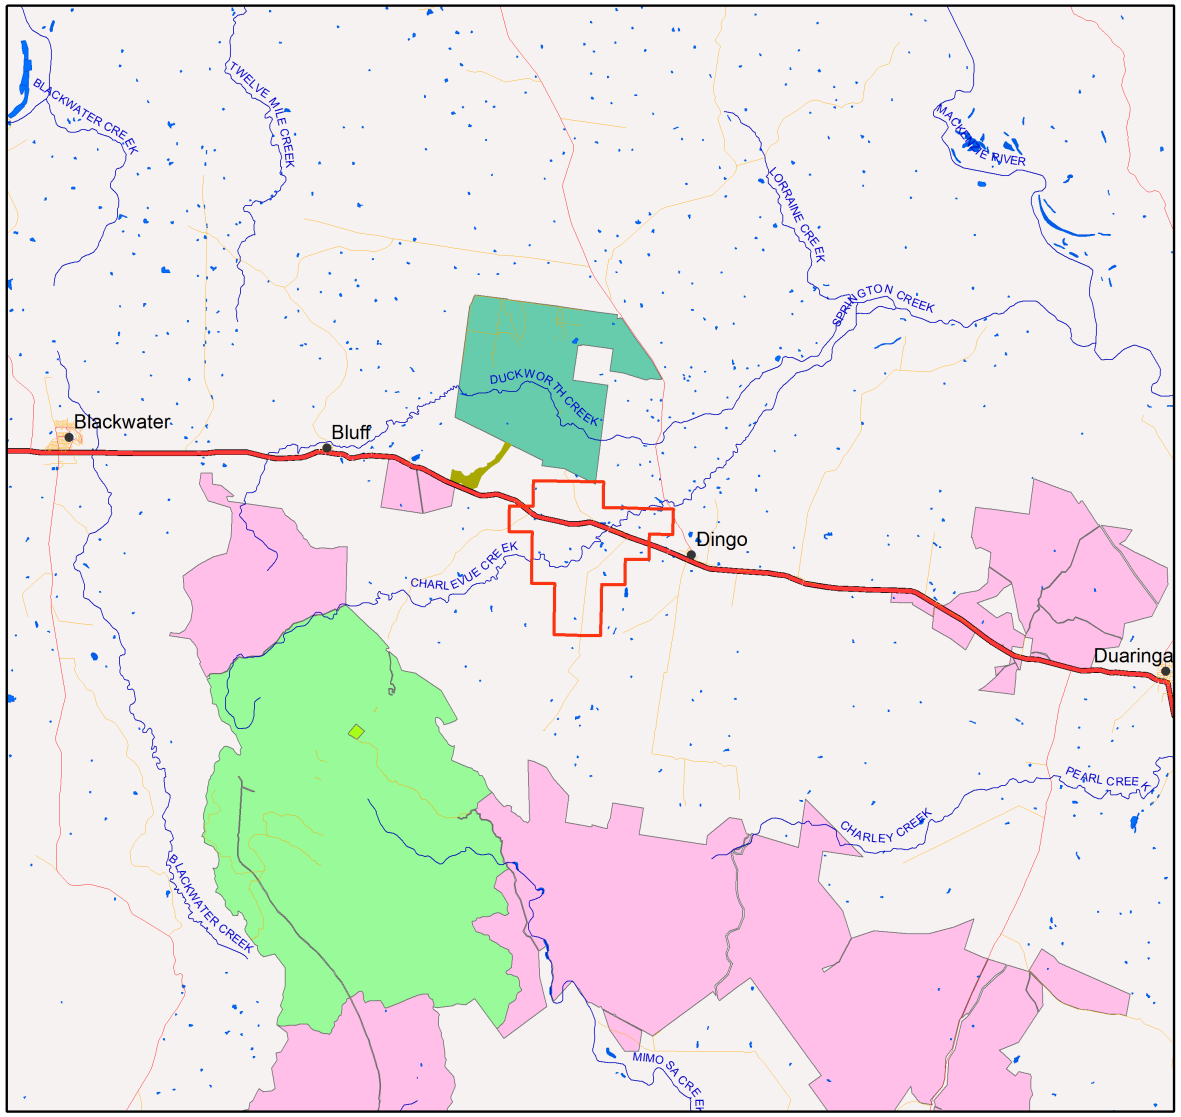
Technical descriptions include data on canopy height, canopy cover and native plant species composition of the predominant layer, which are attributes relevant to assessment of the remnant status of vegetation under the *Vegetation Management Act 1999*. However, as technical descriptions reflect the full range in structure and floristic composition across the climatic, natural disturbance and geographic range of the regional ecosystem, local reference sites should be used for remnant assessment where possible (Neldner et al. 2012 (PDF)* section 3.3.1 of:

https://publications.qld.gov.au/dataset/redd/resource/

The technical descriptions are subject to review and are updated as additional data becomes available.

When conducting a BioCondition assessment, these technical descriptions should be used in conjunction with BioCondition benchmarks for the specific regional ecosystem, or component vegetation community.

http://www.qld.gov.au/environment/plants-animals/biodiversity/benchmarks/



Benchmarks are based on a combination of quantitative and qualitative information and should be used as a guide only. Benchmarks are specific to one regional ecosystem vegetation community, however, the natural variability in structure and floristic composition under a range of climatic and natural disturbance regimes has been considered throughout the geographic extent of the regional ecosystem. Local reference sites should be used for this spatial and temporal (seasonal and annual) variability.

Table 7: List of remnant regional ecosystems within the AOI for which technical and biocondition benchmark descriptions are available

Regional ecosystems mapped as within the AOI	Technical Descriptions	Biocondition Benchmarks
11.3.1	Available	Available
11.3.2	Available	Available
11.3.25	Not currently available	Available

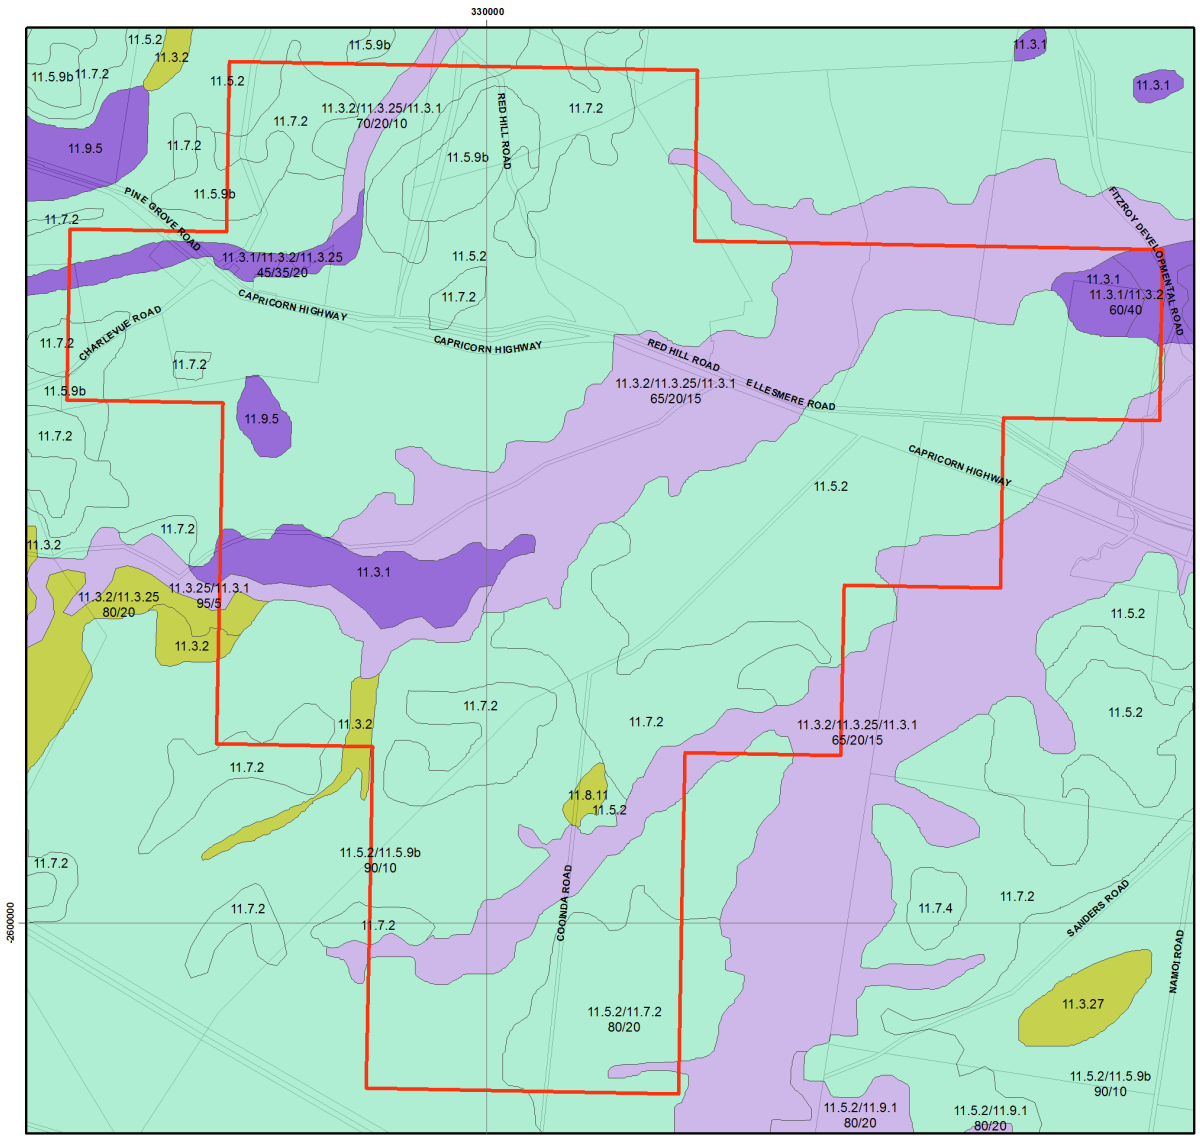
Regional ecosystem mapping over the majority of Queensland is produced at a scale of 1:100,000. At this scale, the minimum remnant polygon area is 5 hectares or minimum remnant width of 75 metres. Regional ecosystem linework reproduced at a scale greater than 1:100,000, except in designated areas, should be used as a guide only. The precision of polygon boundaries or positional accuracy of linework is 100 metres.

Regional ecosystems are defined as vegetation communities in a bioregion that are consistently associated with a particular combination of geology, landform and soil. The polygons are labelled by regional ecosystem (RE); where more than one RE occurs, the percentage of each is labelled. The label consists of 3 components: bioregion, land zone, and vegetation community – the dominant canopy species. e.g.: RE 12.3.3. Descriptions of REs are found online. Use the search term "Regional Ecosystem Framework".



Regional ecosystem mapping at 1:100,000 map scale is derived from the following sources: 1:80,000 B&W 1960's aerial photography, Landsat TM imagery, geology, soils, land systems data, field survey and historical records.

Remnant woody vegetation is defined as vegetation that has not been cleared or vegetation that has been cleared but where the dominant canopy has >70% of the height and >50% of the cover relative to the undisturbed height and cover of that stratum and is dominated by species characteristic of the vegetation's undisturbed canopy.

Non-remnant vegetation includes regrowth and disturbed native vegetation.

Accuracy information: The positional accuracy of wetland data mapped at a scale of 1:100,000 is +/-100m with a minimum polygon size of 5ha or 75m wide for linear features, except for areas along the east coa st which are mapped at the 1:50,000 scale with a positional accuracy of +/-50m, with a minimum polygon size of 1ha or 35m wide for linear features. Wetlands smaller than 1ha are not delineated on the wetland data. Consideration of the effects of mapped scale is necessary when interpret ing data at a larger scale, e.g. 1:25,000. For property assessment, digital linework should be used as a guide only. The extent of wetlands depicted on this map is based on rectified 2013 Landsat ETM+ imagery supplied by Statewide Landcover and Trees Study (SLATS), Department of Environment and Science. The extent of water bodies is based on the maximum extent of inundation derived from available Landsat imagery up to and including the 2013 imagery.

Vegetation Management Act 1999 - Extract from the essential habitat database

Essential habitat is required for assessment under the:

- State Development Assessment Provisions - State Code 16: Native vegetation clearing which sets out the matters of interest to the state for development assessment under the *Planning Act 2016*; and
- Accepted development vegetation clearing codes made under the *Vegetation Management Act 1999*

Essential habitat for one or more of the following species is found on and within 1.1 km of the identified subject lot/s on the accompanying essential habitat map.

This report identifies essential habitat in Category A, B and Category C areas.

The numeric labels on the essential habitat map can be cross referenced with the database below to determine which essential habitat factors might exist for a particular species.

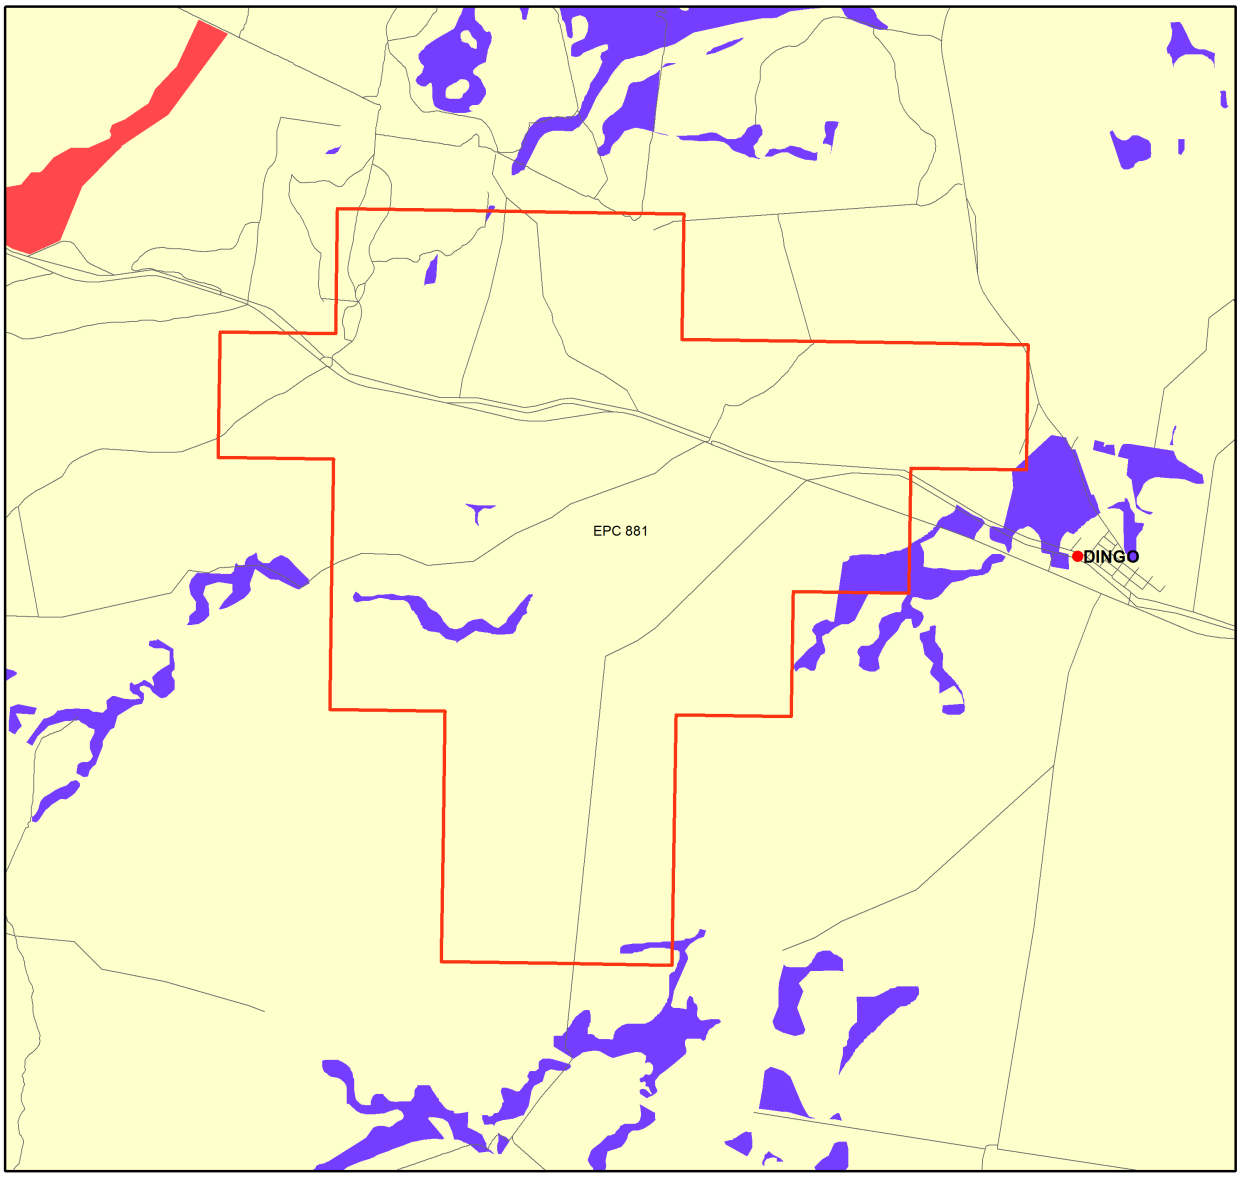
Essential habitat is compiled from a combination of species habitat models and buffered species records.

The Department of Natural Resources, Mines and Energy website (http://www.dnrme.qld.gov.au) has more information on how the layer is applied under the State Development Assessment Provisions - State Code 16: Native vegetation clearing and the *Vegetation Management Act 1999*.

Regional ecosystem is a mandatory essential habitat factor, unless otherwise stated.

Essential habitat, for protected wildlife, means a category A area, a category B area or category C area shown on the regulated vegetation management map-

1) that has at least 3 essential habitat factors for the protected wildlife that must include any essential habitat factors that are stated as mandatory for the protected wildlife in the essential habitat database; or



2) in which the protected wildlife, at any stage of its life cycle, is located.

Protected wildlife includes endangered, vulnerable or near-threatened native wildlife prescribed under the *Nature Conservation Act 1992*.

Essential habitat in Category A and/or Category B and/or Category C

Label	Scientific Name	Common Name	NCA Status	Vegetation Community	Altitude	Soils	Position in Landscape
1785	Geophaps scripta scripta	squatter pigeon (southern subsp.)	V	Dry eucalypt woodland (including poplar box, spotted gum, yellow box, acacia and callitris), with sparse short grass, often on sandy areas near to permanent water; grassy eucalypt woodlands. Nest on ground near or under grass tussock, log or low bush.	None	None	Gravelly ridges, traprock and river flats.

Label	Regional Ecosystem (mandatory unless otherwise specified)

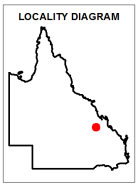
ENVIRONMENTALLY SENSITIVE AREAS - Mining Activities

- Selected Exploration Permit Coal (EPC)



CATEGORY A
- National Parks
- Conservation Parks
- Forest Reserves
- Wet Tropics World Heritage Area
- Great Barrier Reef Marine Park Area
- Marine Parks other than General Use Zones

CATEGORY B
- World Heritage Areas
- Queensland Heritage Register Places
- Ramsar Sites
- Cultural Heritage Registered Areas and DLA's other than Stanbroke
- Special Forestry Areas
- Fish Habitat Areas
- Koala Plan
- Coordinated Conservation Areas
- Endangered Regional Ecosystems (Biodiversity Status)
- General Use Zones of Marine Parks
- Marine Plants

CATEGORY C
- Nature Refuges
- Resources Reserve
- State Forests
- Timber Reserves
- Declared Catchment Areas
- Declared Irrigation Areas
- Drainage Areas
- River Improvement Areas
- Stanbroke DLA
- Coastal Management District
- Dams and Weirs

OTHERS
- Towns
- Roads
- Repealed Wild River Nominated Waterways
- Repealed Wild River Preservation Areas
- Repealed Wild River High Preservation Areas
- Mahogany Glider Habitat
- Directory of Important Wetlands
- Queensland

This product is projected into GDA 1994 MGA Zone 55

Information presented on this product is distributed by the Queensland Government as an information source only. While every care is taken to ensure the accuracy of this data, The State of Queensland makes no statements, representations or warranties about the accuracy, reliability, completeness or suitability of any information contained in this product.

The State of Queensland disclaims all responsibility for information contained in this product and all liability (including without limitation, liability in negligence) for all expenses, losses, damages and costs you may incur as a result of the information being inaccurate or ncomplete in any way for any reason.

External contributors (non-government parties) of the data for this product are: Great Barrier Reef Marine Park Authority

Regional ecosystem mapping (remnant biodiversity status) may incorporate amendments, resulting from property level assessments, to the release version of the mapping available on QSpatial.

NOTE TO USER: Themes presented in this map are indicative only. Field survey may be required to verify the 'true' spatial extent and value. Not all environmentally sensitive areas are presented in this map. A user should refer to the particular circumstances relevant to their situation to assess the 'completeness' of themes provided.

The user should note that some boundaries and indicated values are ambient and may change over time (e.g. regional ecosystem boundaries and conservation status, watercourse mapping etc).

The user should be aware that due to multiple overlapping themes/ layers present, some themes/layers may be obscured by others. Ordering in the Legend does not accurately reflect the order by which themes/layers are displayed.

Environmental Reports

Matters of State Environmental Significance

For the selected area of interest
epc: 881

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or area of interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "central coordinates" option, the resulting assessment area encompasses an area extending for a 2km radius from the point of interest.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 1994). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no values have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Please direct queries about these reports to: Planning.Support@des.qld.gov.au

Disclaimer

Whilst every care is taken to ensure the accuracy of the information provided in this report, the Queensland Government makes no representations or warranties about its accuracy, reliability, completeness, or suitability, for any particular purpose and disclaims all responsibility and all liability (including without limitation, liability in negligence) for all expenses, losses, damages (including indirect or consequential damage) and costs which the user may incur as a consequence of the information being inaccurate or incomplete in any way and for any reason.

Assessment Area Details

The following table provides an overview of the area of interest (AOI) with respect to selected topographic and environmental values.

Table 1: Summary table, details for AOI epc: 881

Size (ha)	7,219.57
Local Government(s)	Central Highlands Regional
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda
Catchment(s)	Fitzroy

Matters of State Environmental Significance (MSES)

MSES Categories

Queensland's State Planning Policy (SPP) includes a biodiversity State interest that states:

'The sustainable, long-term conservation of biodiversity is supported. Significant impacts on matters of national or state environmental significance are avoided, or where this cannot be reasonably achieved; impacts are minimised and residual impacts offset.'

The MSES mapping product is a guide to assist planning and development assessment decision-making. Its primary purpose is to support implementation of the SPP biodiversity policy. While it supports the SPP, the mapping does not replace the regulatory mapping or environmental values specifically called up under other laws or regulations. Similarly, the SPP biodiversity policy does not override or replace specific requirements of other Acts or regulations.

The SPP defines matters of state environmental significance as:

- Protected areas (including all classes of protected area except coordinated conservation areas) under the *Nature Conservation Act 1992* ;

- Marine parks and land within a 'marine national park', 'conservation park', 'scientific research', 'preservation' or 'buffer' zone under the *Marine Parks Act 2004* ;

- Areas within declared fish habitat areas that are management A areas or management B areas under the Fisheries Regulation 2008;

- Threatened wildlife under the *Nature Conservation Act 1992* and special least concern animals under the Nature Conservation (Wildlife) Regulation 2006;

- Regulated vegetation under the *Vegetation Management Act 1999* that is:

    • Category B areas on the regulated vegetation management map, that are 'endangered' or 'of concern' regional ecosystems;

    • Category C areas on the regulated vegetation management map that are 'endangered' or 'of concern' regional ecosystems;

    • Category R areas on the regulated vegetation management map;

    • Regional ecosystems that intersect with watercourses identified on the vegetation management watercourse and drainage feature map;

    • Regional ecosystems that intersect with wetlands identified on the vegetation management wetlands map;

- Strategic Environmental Areas under the *Regional Planning Interests Act 2014* ;

- Wetlands in a wetland protection area of wetlands of high ecological significance shown on the Map of Referable Wetlands under the Environmental Protection Regulation 2008;

- Wetlands and watercourses in high ecological value waters defined in the Environmental Protection (Water) Policy 2009, schedule 2;

- Legally secured offset areas.

MSES Values Present

The MSES values that are present in the area of interest are summarised in the table below:

Table 2: Summary of MSES present within the AOI

1a Protected Areas- estates	2.94 ha	0.0%
1b Protected Areas- nature refuges	0.0 ha	0.0 %
2 State Marine Parks- highly protected zones	0.0 ha	0.0 %
3 Fish habitat areas (A and B areas)	0.0 ha	0.0 %
4 Strategic Environmental Areas (SEA)	0.0 ha	0.0 %
5 High Ecological Significance wetlands on the map of Referable Wetlands	0.0 ha	0.0 %
6a High Ecological Value (HEV) wetlands	0.0 ha	0.0 %
6b High Ecological Value (HEV) waterways **	0.0 km	Not applicable
7 Threatened species and Iconic species	0.0 ha	0.0 %
8a Regulated Vegetation - Endangered/Of concern in Category B (remnant)	248.85 ha	3.4%
8b Regulated Vegetation - Endangered/Of concern in Category C (regrowth)	3.69 ha	0.1%
8c Regulated Vegetation - Category R (GBR riverine regrowth)	19.17 ha	0.3%
8d Regulated Vegetation - Essential habitat	384.78 ha	5.3%
8e Regulated Vegetation - intersecting a watercourse **	81.4 km	Not applicable
8f Regulated Vegetation - within 100m of a Vegetation Management Wetland	0.0 ha	0.0 %
9a Legally secured offset areas- offset register areas	0.0 ha	0.0 %
9b Legally secured offset areas- vegetation offsets through a Property Map of Assessable Vegetation	0.0 ha	0.0 %

Additional Information with Respect to MSES Values Present

MSES - State Conservation Areas

1a. Protected Areas - estates

LOTPLAN	Estate name
25HT655	Taunton National Park (Scientific)

1b. Protected Areas - nature refuges

(no results)

2. State Marine Parks - highly protected zones

(no results)

3. Fish habitat areas (A and B areas)

(no results)

Refer to **Map 1 - MSES - State Conservation Areas** for an overview of the relevant MSES.

MSES - Wetlands and Waterways

4. Strategic Environmental Areas (SEA)

(no results)

5. High Ecological Significance wetlands on the Map of Referable Wetlands

(no results)

6a. High Ecological Value (HEV) waters - wetlands

(no results)

6b. High Ecological Value (HEV) waters - waterways

(no results)

Refer to **Map 2 - MSES - Wetlands and Waterways** for an overview of the relevant MSES.

MSES - Species

7. Threatened wildlife and special least concern animal

(no results)

Threatened and special least concern species records

(no results)

Note: The Threatened and Special Least Concern Animal (7) layer originates from the previous MSES version (4.1, dated at 2014). The layer does not represent all currently listed species and is subject to review.

**Nature Conservation Act 1992 (NCA) Status- Endangered (E), Vulnerable (V) or Special Least Concern Animal (SL). Environment Protection and Biodiversity Conservation Act 1999 (EPBC) status: Critically Endangered (CE) Endangered (E), Vulnerable (V)*

To request a species list for an area, or search for a species profile, access Wildlife Online at:
https://www.qld.gov.au/environment/plants-animals/species-list/

Refer to **Map 3 - MSES - Species** for an overview of the relevant MSES.

MSES - Regulated Vegetation

8a. Regulated Vegetation - Endangered/Of concern in Category B (remnant)

Regional ecosystem	Vegetation management polygon	Vegetation management status
11.3.2/11.3.25	O-dom	rem_oc
11.3.2/11.3.25/11.3.1	E-subdom	rem_end
11.3.2	O-dom	rem_oc
11.3.25/11.3.1	E-subdom	rem_end

8b. Regulated Vegetation - Endangered/Of concern in Category C (regrowth)

Regional ecosystem	Vegetation management polygon	Vegetation management status
11.3.2/11.3.25	O-dom	hvr_oc
11.3.1/11.3.2/11.3.25	E-dom	hvr_end

For further information relating to regional ecosystems in general, go to:
https://www.qld.gov.au/environment/plants-animals/plants/ecosystems/
For a more detailed description of a particular regional ecosystem, access the regional ecosystem search page at:
https://environment.ehp.qld.gov.au/regional-ecosystems/

8c. Regulated Vegetation - Category R (GBR riverine regrowth)

Regulated vegetation map category	Map number	RVM rule
R	8750	4

8d. Regulated Vegetation - Essential habitat

Values are present

8e. Regulated Vegetation - intersecting a watercourse**

A vegetation management watercourse is mapped as present

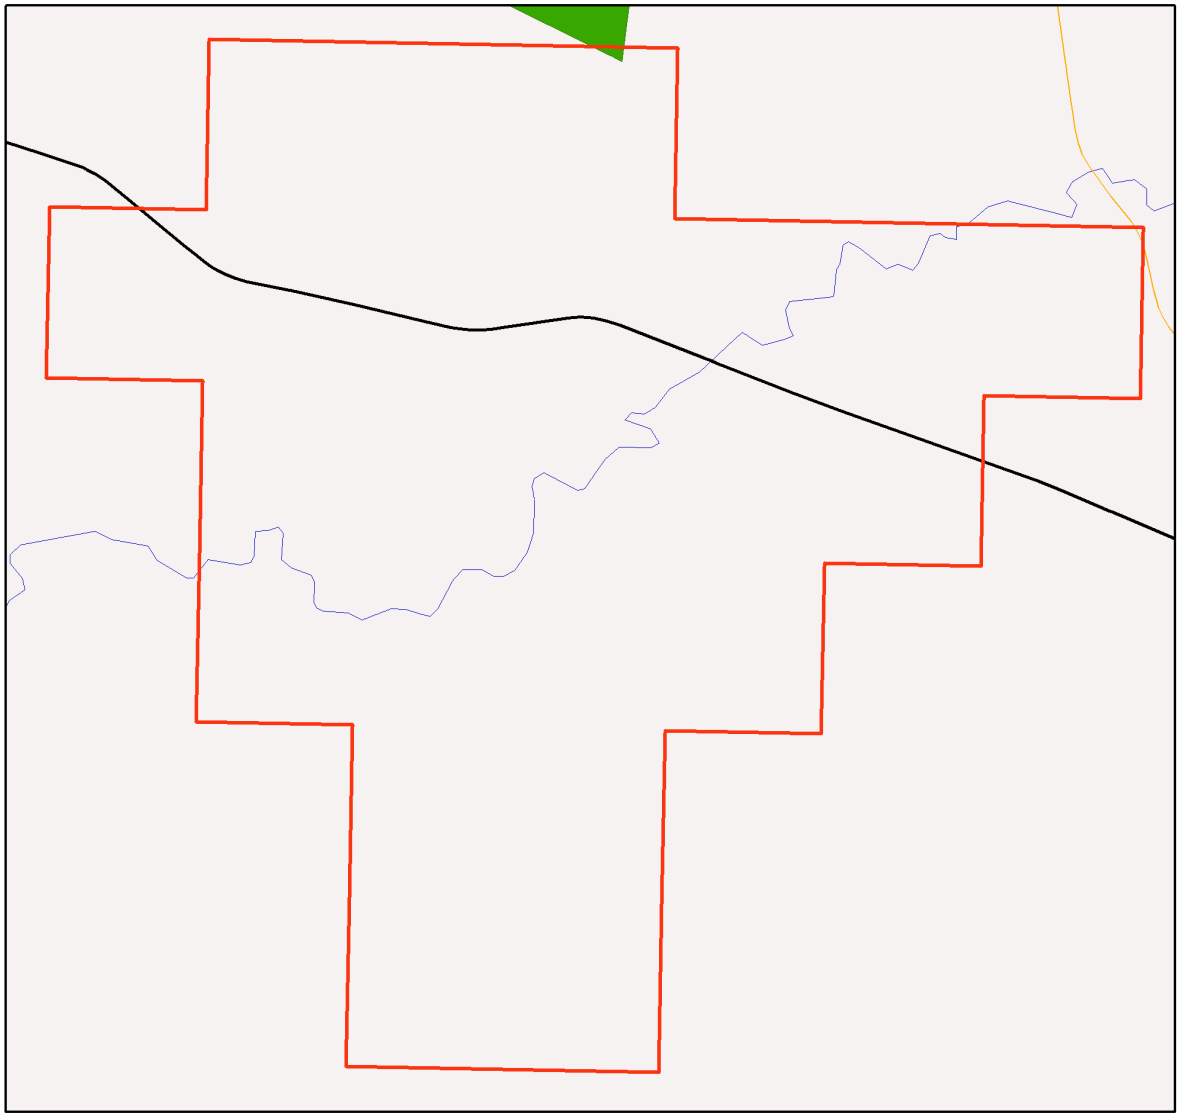
8f. Regulated Vegetation - within 100m of a Vegetation Management wetland

Not applicable

Refer to **Map 4 - MSES - Regulated Vegetation** for an overview of the relevant MSES.

MSES - Offsets

9a. Legally secured offset areas - offset register areas



(no results)

9b. Legally secured offset areas - vegetation offsets through a Property Map of Assessable Vegetation

(no results)

Refer to **Map 5 - MSES - Offset Areas** for an overview of the relevant MSES.

Appendices

Appendix 1 - Matters of State Environmental Significance (MSES) methodology

MSES mapping is a regional-scale representation of the definition for MSES under the State Planning Policy (SPP). The compiled MSES mapping product is a guide to assist planning and development assessment decision-making. Its primary purpose is to support implementation of the SPP biodiversity policy. While it supports the SPP, the mapping does not replace the regulatory mapping or environmental values specifically called up under other laws or regulations. Similarly, the SPP biodiversity policy does not override or replace specific requirements of other Acts or regulations.

The Queensland Government's "Method for mapping - matters of state environmental significance for use in land use planning and development assessment" can be downloaded from:

http://www.ehp.qld.gov.au/land/natural-resource/method-mapping-mses.html .

Appendix 2 - Source Data

The datasets listed below are available on request from:

http://qldspatial.information.qld.gov.au/catalogue/custom/index.page

- Matters of State environmental significance

Note: MSES mapping is not based on new or unique data. The primary mapping product draws data from a number of underlying environment databases and geo-referenced information sources. MSES mapping is a versioned product that is updated generally on a twice-yearly basis to incorporate the changes to underlying data sources. Several components of MSES mapping made for the current version may differ from the current underlying data sources. To ensure accuracy, or proper representation of MSES values, it is strongly recommended that users refer to the underlying data sources and review the current definition of MSES in the State Planning Policy, before applying the MSES mapping.

Individual MSES layers can be attributed to the following source data available at QSpatial:

MSES layers	**current QSpatial data (http://qspatial.ingormation.qld.gov.au)**
Protected Areas-Estates and Nature Refuges	- Protected areas of Queensland - Nature Refuges - Queensland
Marine Park-Highly Protected Zones	Moreton Bay marine park zoning 2008
Fish Habitat Areas	Queensland fish habitat areas
Strategic Environmental Areas-designated	Regional Planning Interests Act - Strategic Environmental Areas
HES wetlands	Map of Referable Wetland - wetland layers: - Wetland management area wetlands - Wetland protection area wetlands
wetlands in HEV waters	HEV waters: - EPP Water (multiple locations) intent for waters Source Wetlands: - Queensland Wetland Mapping (Current version 4, 2015) Source Watercourses: - Vegetation management watercourse and drainage feature map (1:100000 and 1:250000) - latest version 1.4
Wildlife habitat (threatened and special least concern)	-WildNet database species records - habitat suitability models (various)
VMA regulated regional ecosystems	Vegetation management regional ecosystem and remnant map - latest version 8.0
VMA Essential Habitat	Vegetation management - essential habitat map - latest version 4.41
VMA Wetlands	Vegetation management wetlands map - latest version 2.41
Legally secured offsets	Vegetation Management Act property maps of assessable vegetation. For offset register data-contact DES
Regulated Vegetation Map	Vegetation management - regulated vegetation management map - latest version 1.41

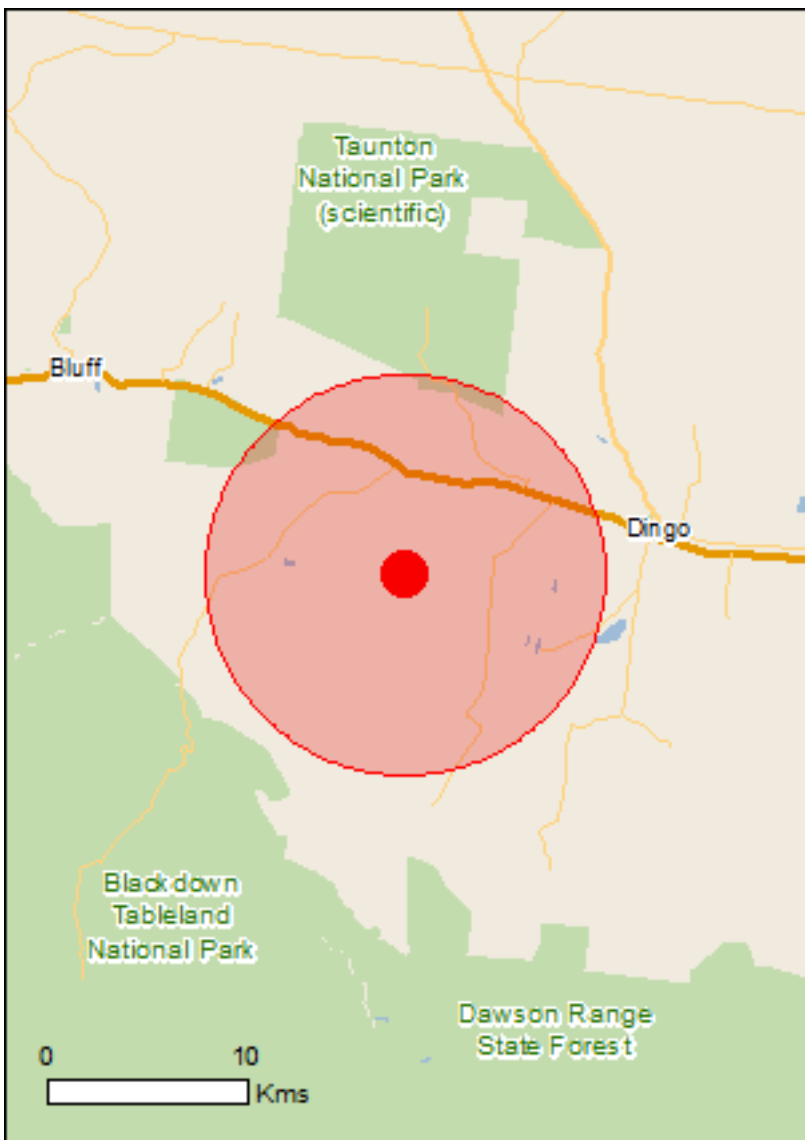
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.



Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 03/06/19 10:44:27

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	3
Listed Threatened Species:	25
Listed Migratory Species:	12

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	18
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	2
Regional Forest Agreements:	None
Invasive Species:	21
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Brigalow (Acacia harpophylla dominant and co-dominant)	Endangered	Community known to occur within area
Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	Endangered	Community may occur within area
Weeping Myall Woodlands	Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Geophaps scripta scripta Squatter Pigeon (southern) [64440]	Vulnerable	Species or species habitat known to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Neochmia ruficauda ruficauda Star Finch (eastern), Star Finch (southern) [26027]	Endangered	Species or species habitat likely to occur within area
Poephila cincta cincta Southern Black-throated Finch [64447]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species habitat may occur within area
Fish		
Maccullochella peelii Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Mammals		

Name	Status	Type of Presence
Chalinolobus dwyeri Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat may occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Nyctophilus corbeni Corben's Long-eared Bat, South-eastern Long-eared Bat [83395]	Vulnerable	Species or species habitat may occur within area
Onychogalea fraenata Bridled Nail-tail Wallaby, Bridled Nailtail Wallaby [239]	Endangered	Species or species habitat known to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat likely to occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT) Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat likely to occur within area
Plants		
Cadellia pentastylis Ooline [9828]	Vulnerable	Species or species habitat likely to occur within area
Dichanthium setosum bluegrass [14159]	Vulnerable	Species or species habitat likely to occur within area
Logania diffusa [24159]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat likely to occur within area
Denisonia maculata Ornamental Snake [1193]	Vulnerable	Species or species habitat may occur within area
Egernia rugosa Yakka Skink [1420]	Vulnerable	Species or species habitat may occur within area
Elseya albagula Southern Snapping Turtle, White-throated Snapping Turtle [81648]	Critically Endangered	Species or species habitat likely to occur within area
Furina dunmalli Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Rheodytes leukops Fitzroy River Turtle, Fitzroy Tortoise, Fitzroy Turtle, White-eyed River Diver [1761]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		

Name	Threatened	Type of Presence
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Cuculus optatus		
Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area
Monarcha melanopsis		
Black-faced Monarch [609]		Species or species habitat likely to occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca		
Satin Flycatcher [612]		Species or species habitat may occur within area
Rhipidura rufifrons		
Rufous Fantail [592]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Gallinago hardwickii		
Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Anseranas semipalmata		
Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur

Name	Threatened	Type of Presence within area
[Ardea alba](#) Great Egret, White Egret [59541]		Species or species habitat likely to occur within area
[Ardea ibis](#) Cattle Egret [59542]		Species or species habitat may occur within area
[Calidris acuminata](#) Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
[Calidris ferruginea](#) Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
[Calidris melanotos](#) Pectoral Sandpiper [858]		Species or species habitat may occur within area
[Chrysococcyx osculans](#) Black-eared Cuckoo [705]		Species or species habitat likely to occur within area
[Gallinago hardwickii](#) Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area
[Haliaeetus leucogaster](#) White-bellied Sea-Eagle [943]		Species or species habitat likely to occur within area
[Merops ornatus](#) Rainbow Bee-eater [670]		Species or species habitat may occur within area
[Monarcha melanopsis](#) Black-faced Monarch [609]		Species or species habitat likely to occur within area
[Motacilla flava](#) Yellow Wagtail [644]		Species or species habitat may occur within area
[Myiagra cyanoleuca](#) Satin Flycatcher [612]		Species or species habitat may occur within area
[Pandion haliaetus](#) Osprey [952]		Species or species habitat likely to occur within area
[Rhipidura rufifrons](#) Rufous Fantail [592]		Species or species habitat may occur within area
[Rostratula benghalensis (sensu lato)](#) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Extra Information

State and Territory Reserves [Resource Information]

Name	State
Taunton	QLD
Wallaby Lane	QLD

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Acacia nilotica subsp. indica Prickly Acacia [6196]		Species or species habitat may occur within area
Cryptostegia grandiflora Rubber Vine, Rubbervine, India Rubber Vine, India Rubbervine, Palay Rubbervine, Purple Allamanda [18913]		Species or species habitat likely to occur within area
Jatropha gossypifolia Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Parthenium hysterophorus Parthenium Weed, Bitter Weed, Carrot Grass, False Ragweed [19566]		Species or species habitat likely to occur within area
Vachellia nilotica Prickly Acacia, Blackthorn, Prickly Mimosa, Black Piquant, Babul [84351]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	4
Listed Threatened Species:	28
Listed Migratory Species:	15

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	21
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	4
Regional Forest Agreements:	None
Invasive Species:	21
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Matters of National Environmental Significance

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Brigalow (Acacia harpophylla dominant and co-dominant)	Endangered	Community known to occur within area
Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	Endangered	Community may occur within area
Natural Grasslands of the Queensland Central Highlands and northern Fitzroy Basin	Endangered	Community likely to occur within area
Weeping Myall Woodlands	Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Geophaps scripta scripta Squatter Pigeon (southern) [64440]	Vulnerable	Species or species habitat known to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Neochmia ruficauda ruficauda Star Finch (eastern), Star Finch (southern) [26027]	Endangered	Species or species habitat likely to occur within area
Poephila cincta cincta Southern Black-throated Finch [64447]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species habitat likely to occur within area
Fish		
Maccullochella peelii Murray Cod [66633]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Mammals		
Chalinolobus dwyeri Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat likely to occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Nyctophilus corbeni Corben's Long-eared Bat, South-eastern Long-eared Bat [83395]	Vulnerable	Species or species habitat may occur within area
Onychogalea fraenata Bridled Nail-tail Wallaby, Bridled Nailtail Wallaby [239]	Endangered	Species or species habitat known to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat known to occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT) Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Plants		
Cadellia pentastylis Ooline [9828]	Vulnerable	Species or species habitat likely to occur within area
Daviesia discolor [3567]	Vulnerable	Species or species habitat likely to occur within area
Dichanthium setosum bluegrass [14159]	Vulnerable	Species or species habitat likely to occur within area
Homoranthus decumbens a shrub [55186]	Endangered	Species or species habitat may occur within area
Logania diffusa [24159]	Vulnerable	Species or species habitat likely to occur within area
Macrozamia platyrhachis cycad [3412]	Endangered	Species or species habitat likely to occur within area
Reptiles		
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat known to occur within area
Denisonia maculata Ornamental Snake [1193]	Vulnerable	Species or species habitat known to occur within area
Egernia rugosa Yakka Skink [1420]	Vulnerable	Species or species habitat known to occur within area
Elseya albagula Southern Snapping Turtle, White-throated Snapping Turtle [81648]	Critically Endangered	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Furina dunmalli		
Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Rheodytes leukops		
Fitzroy River Turtle, Fitzroy Tortoise, Fitzroy Turtle, White-eyed River Diver [1761]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Marine Species		
Crocodylus porosus		
Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Cuculus optatus		
Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area
Hirundapus caudacutus		
White-throated Needletail [682]		Species or species habitat known to occur within area
Monarcha melanopsis		
Black-faced Monarch [609]		Species or species habitat likely to occur within area
Monarcha trivirgatus		
Spectacled Monarch [610]		Species or species habitat may occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca		
Satin Flycatcher [612]		Species or species habitat may occur within area
Rhipidura rufifrons		
Rufous Fantail [592]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Gallinago hardwickii		
Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Pandion haliaetus		
Osprey [952]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Anseranas semipalmata		
Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba		
Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis		
Cattle Egret [59542]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Chrysococcyx osculans		
Black-eared Cuckoo [705]		Species or species habitat likely to occur within area
Gallinago hardwickii		
Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Haliaeetus leucogaster		
White-bellied Sea-Eagle [943]		Species or species habitat likely to occur within area
Hirundapus caudacutus		
White-throated Needletail [682]		Species or species habitat known to occur within area
Merops ornatus		
Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis		
Black-faced Monarch [609]		Species or species habitat likely to occur within area
Monarcha trivirgatus		
Spectacled Monarch [610]		Species or species habitat may occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca		
Satin Flycatcher [612]		Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat likely to occur within area
Rhipidura rufifrons		
Rufous Fantail [592]		Species or species habitat may occur within area
Rostratula benghalensis (sensu lato)		
Painted Snipe [889]	Endangered*	Species or species habitat may occur within area
Reptiles		
Crocodylus porosus		
Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area

Ghungalu	QLD
Taunton	QLD
Wallaby Lane	QLD

Invasive Species	[Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia		
Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus		
House Sparrow [405]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Acacia nilotica subsp. indica Prickly Acacia [6196]		Species or species habitat may occur within area
Cryptostegia grandiflora Rubber Vine, Rubbervine, India Rubber Vine, India Rubbervine, Palay Rubbervine, Purple Allamanda [18913]		Species or species habitat likely to occur within area
Jatropha gossypifolia Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Parthenium hysterophorus Parthenium Weed, Bitter Weed, Carrot Grass, False Ragweed [19566]		Species or species habitat likely to occur within area
Vachellia nilotica Prickly Acacia, Blackthorn, Prickly Mimosa, Black Piquant, Babul [84351]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

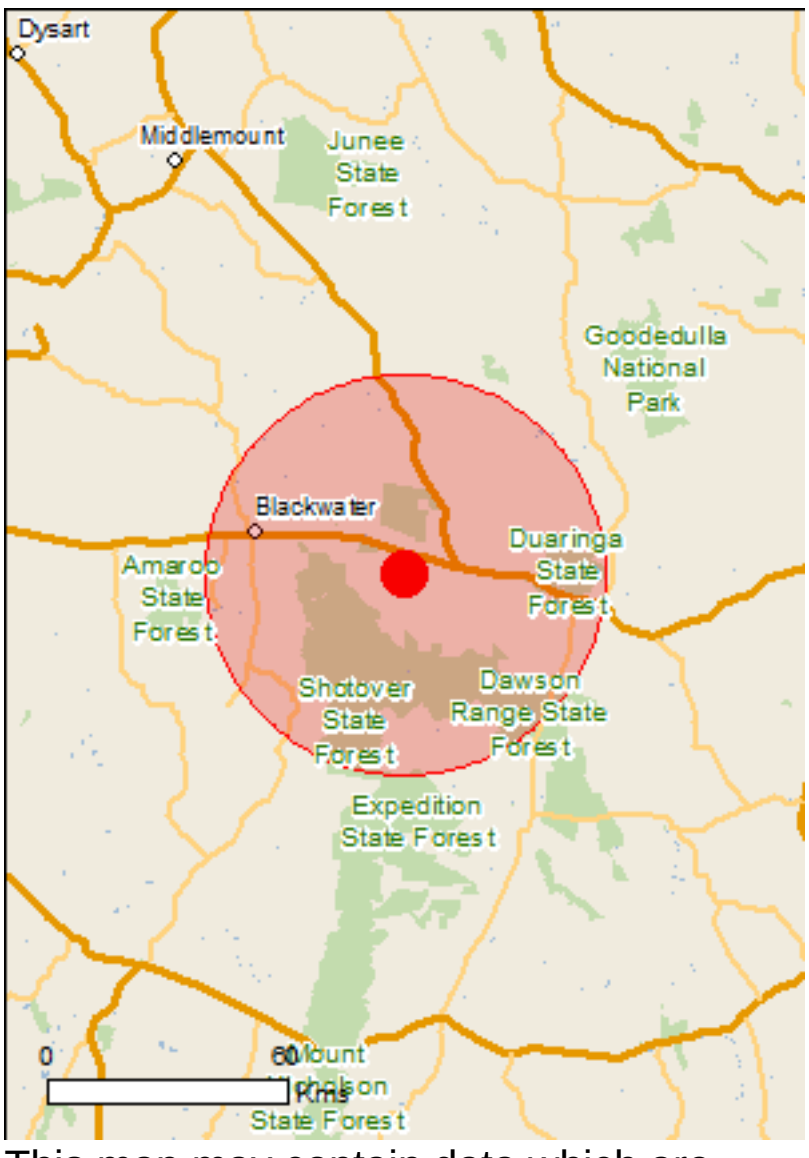
EPBC Act Protected Matters Report

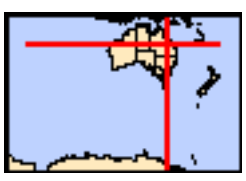
This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.



Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 03/06/19 09:45:56



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	5
Listed Threatened Species:	39
Listed Migratory Species:	16

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	1
Commonwealth Heritage Places:	None
Listed Marine Species:	22
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	5
Regional Forest Agreements:	None
Invasive Species:	27
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Matters of National Environmental Significance

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Brigalow (Acacia harpophylla dominant and co-dominant)	Endangered	Community known to occur within area
Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	Endangered	Community may occur within area
Natural Grasslands of the Queensland Central Highlands and northern Fitzroy Basin	Endangered	Community likely to occur within area
Semi-evergreen vine thickets of the Brigalow Belt (North and South) and Nandewar Bioregions	Endangered	Community likely to occur within area
Weeping Myall Woodlands	Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Geophaps scripta scripta Squatter Pigeon (southern) [64440]	Vulnerable	Species or species habitat known to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Neochmia ruficauda ruficauda Star Finch (eastern), Star Finch (southern) [26027]	Endangered	Species or species habitat likely to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Poephila cincta cincta Southern Black-throated Finch [64447]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Fish		
Maccullochella peelii		
Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Mammals		
Chalinolobus dwyeri		
Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat likely to occur within area
Dasyurus hallucatus		
Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Macroderma gigas		
Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Nyctophilus corbeni		
Corben's Long-eared Bat, South-eastern Long-eared Bat [83395]	Vulnerable	Species or species habitat may occur within area
Onychogalea fraenata		
Bridled Nail-tail Wallaby, Bridled Nailtail Wallaby [239]	Endangered	Species or species habitat known to occur within area
Petauroides volans		
Greater Glider [254]	Vulnerable	Species or species habitat known to occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT)		
Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Pteropus poliocephalus		
Grey-headed Flying-fox [186]	Vulnerable	Foraging, feeding or related behaviour may occur within area
Plants		
Acacia grandifolia		
[3566]	Vulnerable	Species or species habitat known to occur within area
Aristida annua		
[17906]	Vulnerable	Species or species habitat likely to occur within area
Bertya opponens		
[13792]	Vulnerable	Species or species habitat likely to occur within area
Cadellia pentastylis		
Ooline [9828]	Vulnerable	Species or species habitat likely to occur within area
Cycas ophiolitica		
[55797]	Endangered	Species or species habitat likely to occur within area
Daviesia discolor		
[3567]	Vulnerable	Species or species habitat likely to occur within area
Dichanthium queenslandicum		
King Blue-grass [5481]	Endangered	Species or species habitat may occur within area
Dichanthium setosum		
bluegrass [14159]	Vulnerable	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Eucalyptus raveretiana Black Ironbox [16344]	Vulnerable	Species or species habitat likely to occur within area
Homoranthus decumbens a shrub [55186]	Endangered	Species or species habitat known to occur within area
Logania diffusa [24159]	Vulnerable	Species or species habitat likely to occur within area
Macrozamia platyrhachis cycad [3412]	Endangered	Species or species habitat likely to occur within area
Phaius australis Lesser Swamp-orchid [5872]	Endangered	Species or species habitat known to occur within area
Solanum dissectum [75720]	Endangered	Species or species habitat known to occur within area
Solanum johnsonianum [84820]	Endangered	Species or species habitat may occur within area
Reptiles		
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat known to occur within area
Denisonia maculata Ornamental Snake [1193]	Vulnerable	Species or species habitat known to occur within area
Egernia rugosa Yakka Skink [1420]	Vulnerable	Species or species habitat known to occur within area
Elseya albagula Southern Snapping Turtle, White-throated Snapping Turtle [81648]	Critically Endangered	Species or species habitat known to occur within area
Furina dunmalli Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Rheodytes leukops Fitzroy River Turtle, Fitzroy Tortoise, Fitzroy Turtle, White-eyed River Diver [1761]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Marine Species		
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Hirundapus caudacutus		
White-throated Needletail [682]		Species or species habitat known to occur within area
Monarcha melanopsis		
Black-faced Monarch [609]		Species or species habitat likely to occur within area
Monarcha trivirgatus		
Spectacled Monarch [610]		Species or species habitat may occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca		
Satin Flycatcher [612]		Species or species habitat may occur within area
Rhipidura rufifrons		
Rufous Fantail [592]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]		Species or species habitat likely to occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Gallinago hardwickii		
Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

animals	mammals	Pseudocheiridae	*Petauroides volans volans*	southern greater glider		V	V	1
animals	reptiles	Diplodactylidae	*Strophurus taenicauda*	golden-tailed gecko		NT		2
plants	Equisetopsida	Apocynaceae	*Cerbera dumicola*			NT		2/2
plants	Equisetopsida	Orchidaceae	*Corunastylis pedersonii*			V		1/1
plants	Equisetopsida	Solanaceae	*Solanum elachophyllum*			E		1

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

Suite 5a, 1 Swann Road
TARINGA Qld 4068

Dear Caitlin

The botanical specimens received by the Queensland Herbarium on 11 April 2019 have been identified as:

DWI 6	**Eragrostis trichophora*
DWR 4	*Ammannia multiflora*
DWR 4	*Cyperus difformis*
DA 12	*Lobelia concolor*
DWR 4	*Glinus lotoides*
DA 15	*Arundinella nepalensis*
DWR 6	*Murdannia graminea*
DAR 1	*Arundinella nepalensis*
DAI 5	**Indigofera tinctoria*

*Naturalised, non-native species

There is a charge of $228.80 (2 hrs @ $114.40 per hr incl GST) for these identifications.

You can contribute to Queensland's biodiversity information by submitting this/these plant identification(s) and associated information to the Atlas of Living Australia using the 'Report a sighting' template at (https://www.ala.org.au/)

Yours sincerely

G.P.Guymer
Director

1 Introduction

1.1 Background

The Gemini Project is a greenfield, open-cut metallurgical coal mine project, which will produce pulverised coal injection (PCI) coal and coking coal for export to the international steel making industry. The Project will be developed and managed by Magnetic South Pty Ltd, a private Australian based company which was founded in 2006. The executive team of Magnetic South has some 60 years' experience in the development and operation of metallurgical coal assets and agribusiness in central Queensland.

The Project is located in the Bowen Basin, approximately 110 km east of Emerald and 125 km southwest of Rockhampton, in central Queensland. Blackwater, a larger town serving mines in the region, is located approximately 34 km to the west.

An application for a site-specific environmental authority was submitted by Magnetic South on 23 October 2019 (application reference number APP0043095). The administering authority considered the EA application, and issued Magnetic South with an information request on 31 January 2020. Magnetic South provided a response to this information request in December 2020, accompanied by a revision to the EA Application Supporting Information document.

A notification of change for the Project was submitted to DES in Jan 2021, notifying of changes to the project layout in response to landholder consultation.

The minor revisions to the Project layout include the following:

- Relocation of the camp and associated infrastructure to the south of the Capricorn Highway, on Lot 4 on RP801280 and Lot 1 on HT424, to be accessed via the main mine access road.
- Removal of the Train Load Out Facility (TLO) access road from the Redrock Park Property to an alternate location further to the east.

An application to amend the ML surface area has also recently been made, to reflect the change in infrastructure location described in the EA application. The revised conceptual project layout, showing the updated camp location, surface rights extent and the nearest sensitive receivers is provided in Figure 1.

A secondary information request was received from DES in February 2021, which included questions in relation to the traffic, air and noise quality impacts of the revised Project layout, as well as a number of additional questions in relation to groundwater, geochemistry, water quality objectives, vegetation disturbance areas, post mining land use and Pit AB geotechnical stability.

In response to the secondary information request, a revision to the Traffic Impact Assessment (Appendix A) and Noise Impact Assessment (Appendix F) has been prepared. Supplementary technical memorandums have also been provided in relation to groundwater, mine waste geochemistry, air quality and noise (Appendices B-E). The purpose of this document is to provide a response to each question, specifically addressing each of the issues raised in the secondary information request and directing the administering authority to further information contained within the additional assessments and supplementary technical memorandums, where applicable.

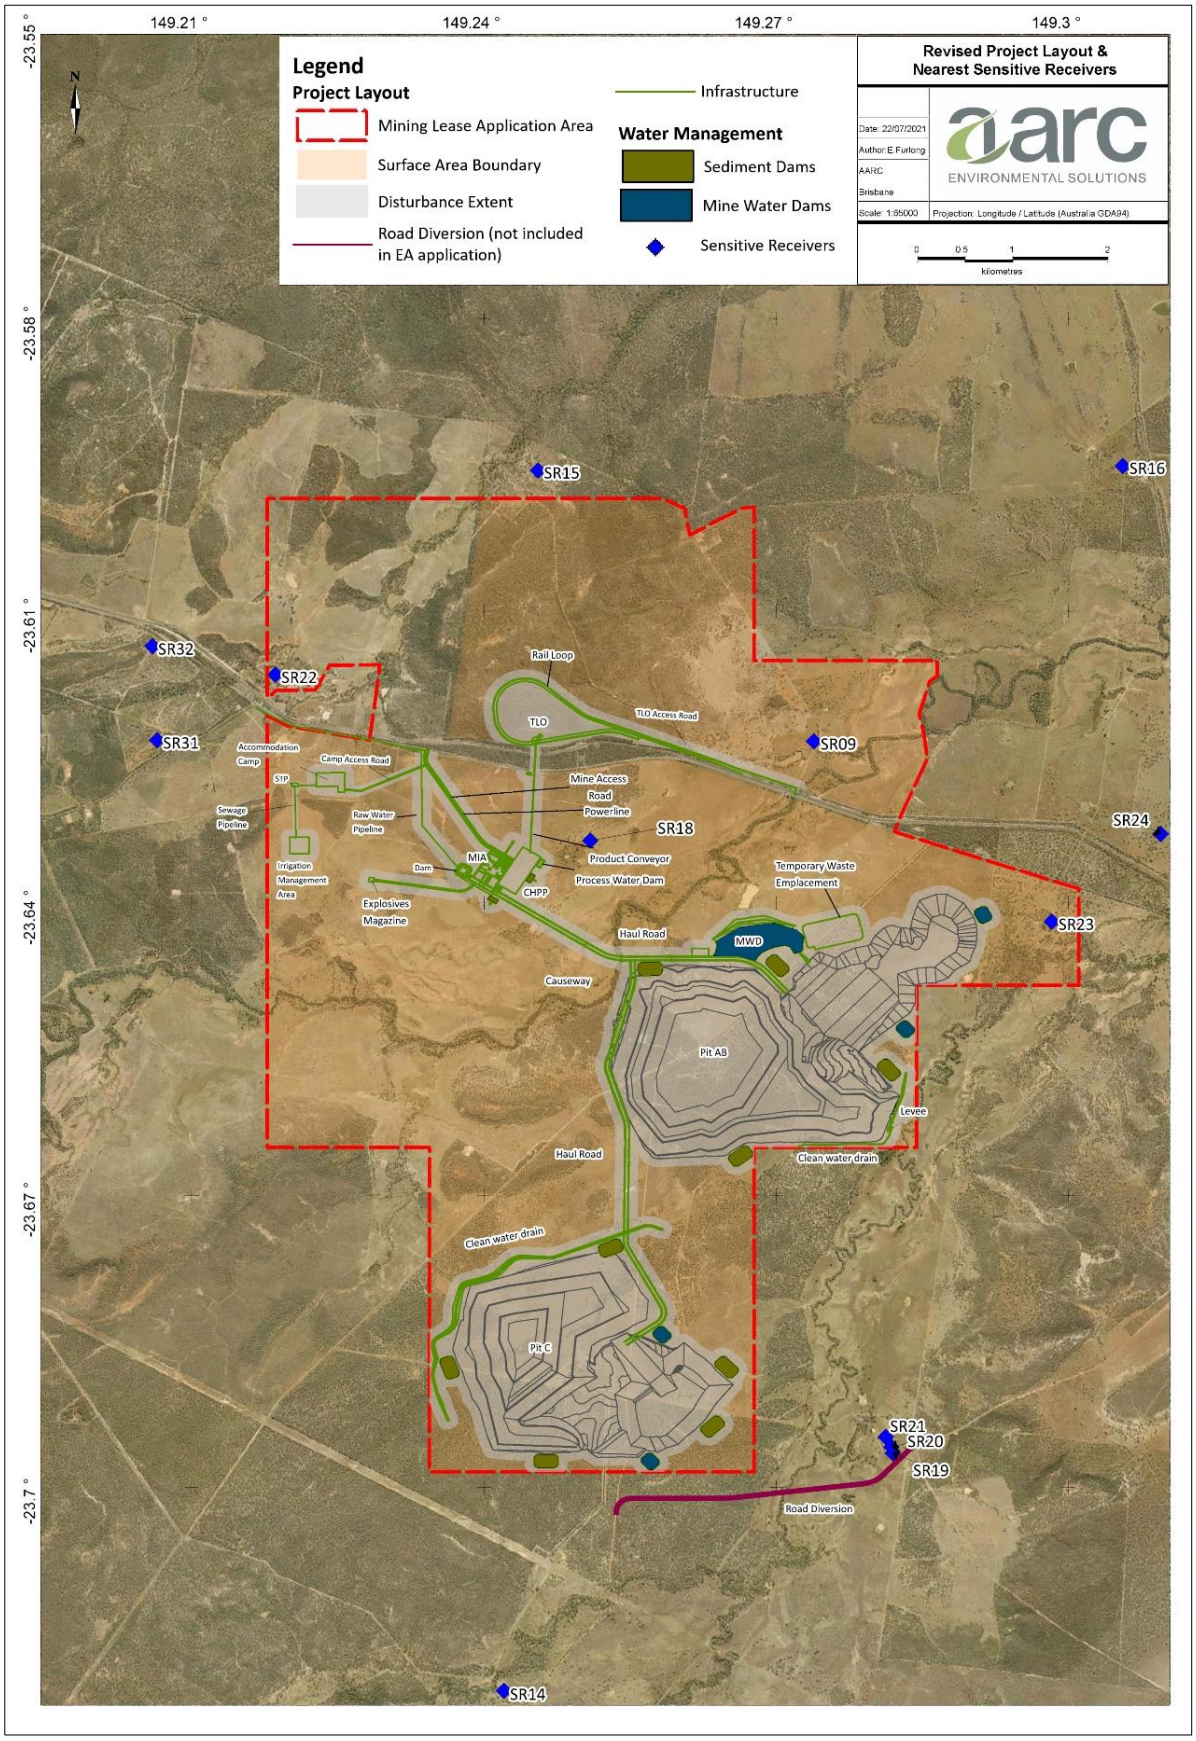

Figure 1: Revised conceptual project layout and location of adjacent sensitive receivers

2 Conceptual Project Layout

2.1 Geotechnical stability of Pit AB high wall

2.1.1 DES Comment

Figure 7 - Conceptual Layout of the Gemini Project shows that the crest of the high wall on the southern end of the Pit AB final void is proposed to extend right to a corner boundary of the tenure, MLA 700056. Table 7 states that a 100 metre buffer has been included around the perimeter of the disturbance footprint, but it is not clear if the buffer has been applied to this part of Pit AB final void area. The Revised Supporting Information does not sufficiently address information requirements, such as, the expected geotechnical stability of the final battered high wall and potential liability of high wall failure. The assessing officer's concern is that as the final landform is proposed to be so close to the tenure boundary, there is a possibility that high wall failure may cause impacts outside of the tenure boundary.

2.1.2 DES Requirement

Provide further information to justify the position of the final void for Pit AB with regard to the concerns of creating disturbance and impacts to environmental values (EVs) outside of the tenure boundary. Alternatively, provide a revised conceptual project layout that includes an appropriate buffer between the battered high wall of Pit AB final void and MLA 700056 boundary.

2.1.3 Response

2.1.3.1 Buffer around perimeter of disturbance footprint

Figure 7 in Section 3.1 of the *Revised EA Application Supporting Information* shows the conceptual project layout, including a 100m buffer within which disturbance may occur (also shown in Figure 1 of this report). The authorised disturbance areas provided in Table 7 include this 100 m buffer. The purpose of this 100 m buffer is to provide design flexibility for activities that may require disturbance beyond the original design infrastructure footprint. This 100m disturbance area has been reduced on the eastern edge of the AB Pit, due to the proximity of the mining lease (ML) boundary. The eastern edge of the AB Pit will be located approximately 50m from the edge of ML during mine operations, and the top of the final battered highwall (following backfill, regrading and rehabilitation activities) will be located approximately 15m from the edge of lease.

It was not intended that a 100 m buffer would be maintained between mining activities and the edge of the ML.

2.1.3.2 Geotechnical stability of the final battered high walls

The conceptual mine plan was based on preliminary geotechnical studies completed for the Project. The excavated eastern high wall slopes were designed to achieve a factor of safety of 1.3 during mine operations (refer to Table 1). The highwall slopes will then be flattened during rehabilitation, in order to achieve a stable post mining landform.

Geotechnical assessment of the post mining landform has now been undertaken for the Project. A final slope of 18° is proposed for the weathered upper sections of the void high walls (alluvium, Tertiary clay and weathered Permian zone) (instead of the previously described 22°). This additional geotechnical control will ensure the final void design achieves a minimum Factor of Safety of 1.5 for the entire Project. Where space is limited by proximity to the ML boundary, minor adjustments will be made in the detailed design phase of the Project, to ensure all disturbance is contained within the ML footprint both during and post-mining.

These minor changes will not result in significant changes to the mine plan layout and the location of the highwall in relation to the mining lease will remain unchanged to that which is shown in Figure 1.

It is proposed that the void design parameters summarised in Table 1 will replace previous design criteria described in Sections 4 and 5 of the *Revised EA Application Supporting Information*.

Table 1: Pit design parameters for excavated eastern highwall

Material / area	**High wall slope during mine operations to achieve SF of 1.3**	**High wall slope for final rehabilitated landform to achieve SF of 1.5**
Cenozoic soil (alluvium and Tertiary clay) (0-55m) and distinctly weathered Permian material	45° slopes with 20m batters in Cenozoic soil/distinctly weathered Permian material. A 15 m wide catch bench is proposed at the base of this horizon.	Maximum slope of 18°
Unweathered strata / coal measures	65° batters in slightly weathered/fresh coal measures. A 15 m catch bench is required every 50 m.	Maximum slope of 22°

3 Traffic and Train Load Out Facility Construction

3.1 Train Load Out Facility access

3.1.1 DES Question

An existing access road off the Capricorn Highway, Red Hill Road, is proposed to be the revised intersection and access road for the Train Load Out Facility (TLO). No detail has been provided regarding:

- existing condition of the intersection and road
- justification for its suitability for TLO construction and operation access
- whether upgrades will be necessary to make the intersection and road suitable for intended uses
- reference to a traffic impact assessment for the Capricorn Highway / Red Hill Road intersection.

The original application states, in section 3.3.4 of the supporting information, that Red Hill Road is only suitable for light vehicles but the revised section 3.3.4 and the notice of changed application state that construction equipment can be mobilised to the TLO along this access; however, no further detail has been provided about how this will be possible.

3.1.2 DES Requirement

Provide further detail and justification to demonstrate that Red Hill Road / Capricorn Highway intersection and Red Hill Road will be suitable for access to the TLO during construction and operation phases by addressing the concerns raised.

3.1.3 Response

Additional modifications have been proposed to the TLO access to address the concerns raised in the information request. A revised *Gemini Project Traffic Impact Assessment* (Cardno April 2021) (TIA) is provided in Appendix A.

3.1.3.1 TLO heavy vehicle access

To address concerns, heavy vehicle access to the TLO facility during construction is now proposed via a short temporary access track from the Capricorn Highway, to be located within the footprint of the product conveyor belt. This temporary heavy vehicle access will include a temporary level crossing over the existing rail line, to be in operation for the construction of the TLO and rail loop only, when larger volumes of materials are expected to be trucked to the site.

During operations, heavy vehicle access to the TLO is not required. Bulk materials required for maintenance will be transported to the Project via rail.

An assessment of the proposed temporary intersection with the Capricorn Highway is provided in Section 7.6 of the revised TIA. A figure showing the location of the proposed temporary access track is provided in Section 5.1.1 of the revised TIA (Appendix A).

3.1.3.2 TLO light vehicle access

Light vehicle (LV) access to the TLO during construction and operation will be via the existing Capricorn Highway / Red Hill Road intersection. An assessment of the existing road condition is provided in Section 3.1.5 of the revised TIA. It is anticipated that during peak construction and operations there will be approximately 4

light vehicle movements per day. The existing intersection is therefore considered to be suitable for the required light vehicle access requirements during construction and operations.

3.2 Traffic impacts of mine accommodation access

3.2.1 DES Question

Figure 1-1 and Figure 1-2 do not show the revised mine layout as per the notice of change application.

It is not clear what impacts the revised location of mine accommodation – which is now proposed to be accessed from the main mine access road – will have in terms of the potential increase in drive-in-drive-out traffic entering the mine access road, given that it is predicted that 80% of the operation workforce will be drive-in-drive-out on a weekly basis.

3.2.2 DES Requirement

Provide updated mine layout figures in the traffic impact assessment report. Provide a revised Appendix A: Traffic Impact Assessment to address the potential impacts of the proposed relocation of mine accommodation on traffic using the Capricorn highway and mine access intersection, as per the written notice of changed application. Alternatively, provide a justification of why the potential impact does not warrant updates to the Traffic Impact Assessment.

3.2.3 Response

The intersection impact assessment for the mine access road has been updated to include camp accommodation traffic (refer to Section 7.4 of the revised TIA (Appendix A)).

3.3 Red Hill Road / Capricorn Highway intersection traffic impacts

3.3.1 DES Question

The intersection Capricorn Highway / Red Hill Road has not been included in the assessment scope for State Intersections, and, as per the notice of changed application, this is the only proposed access road to the TLO. The written notice of change states that the road will only be used for two vehicle movements daily. It is not clear if this includes construction equipment during the TLO construction phase. Red Hill Road is directly adjacent to Charlevue Creek. Queensland Globe mapping indicates this is a watercourse with a stream order of 5 and contains Matters of State Environmental Significance (MSES) downstream. According to Figure 61 of the revised supporting information, Red Hill Road also falls within flood zone levels. However, the potential impacts to EVs related to Charlevue Creek have not been clearly addressed with regard to Red Hill Road use during construction and operation phases and contingency plans to access the TLO in case of flooding.

3.3.2 DES Requirement

Provide more information about the potential impacts to traffic of using Red Hill Road and the intersection with the Capricorn Highway, differentiating between the frequency and intensity of impact during TLO construction and operation phases and including consideration to the potential for flooding.

3.3.3 Response

An assessment of the Capricorn Highway / Red Hill Road intersection has now been included in Section 3.1.5 of the revised TIA (Appendix A). The revised TIA also included information about the frequency and intensity of traffic using the Capricorn Highway / Red Hill Road intersection during mine construction and operation (refer to Section 5.1 of the revised TIA) and an assessment of the traffic impacts of the project (Section 7.5).

It is anticipated that during both peak mine construction and operations there will be approximately 4 light vehicle movements per day. Heavy vehicle access to the TLO during construction is now proposed via an alternate temporary access. The minor increase in traffic associated with a small number of light vehicle movements is unlikely to impact environmental values outside of the existing road footprint. It is therefore not expected that there will be any impacts to downstream environmental values as a result of use of this intersection for light vehicles.

It is anticipated that on average the Red Hill Road train underpass will flood every one to two years. Should flooding occur emergency access to the TLO will be maintained via the rail level crossing or through private property via landholder agreements.

An erosion and sediment control plan (ESCP) has been prepared for the Project, which outlines the strategies to manage erosion, and the release of sediment into receiving waters, during Project construction and operations (including the potential impacts of Project traffic) (refer to section 6.1.6 of the *Gemini Project Erosion and Sediment Control Plan* (AARC 2020).

Water quality monitoring will be undertaken during mine operations (including at a location downstream of Red Hill Road in Charlevue Creek) in accordance with the *Gemini Project Receiving Environment Monitoring Program Design Document* (AARC 2020) to ensure the effectiveness of employed control measures, including the enforcement of sediment quality trigger values.

4 Groundwater

4.1 Relationship between streamflow and groundwater levels

4.1.1 DES Comment

Two downstream gauging and water quality monitoring stations are noted to have been installed on Charlevue and Springton Creeks (CC2 and SC2). It is understood that flow will be recorded continuously during a flow event. The date of installation and the data collected should be provided. These monitoring stations are considered to be important in establishing the relationship between creek flow and ground water levels.

4.1.2 DES Requirement

Provide the date of installation of the downstream flow gauging and water quality monitoring stations.

Provide the stream flow and water quality data that has been collected to date.

Collate this information with alluvial and groundwater dependent ecosystem (GDE) aquifer information to identify the relationship between streamflow and groundwater levels.

4.1.3 Response

Water gauge stations were installed at Charlevue Creek and Springton Creek on 19 November 2020.

Groundwater level data loggers have been installed in the Charlevue Creek alluvium monitoring bore (DW7076W) and Springton Creek alluvium monitoring bore (DW7292W1) since December 2018 and July 2020, respectively.

The location of existing groundwater monitoring bores and surface water gauging stations, along with identified potential GDE areas in the project area, are shown in Figure 2.

Time series plots of rainfall (derived from the SILO data drill), water level and water quality data (collected from the gauging stations and alluvium bores) are provided in Figure 3 and a summary of the key findings is provided below. A more detailed analysis is also provided in the *Response to DES Comments on the EA Submission – Gemini Project* (JBT Consulting, May 2020) (Groundwater Technical Memorandum) (Appendix B).

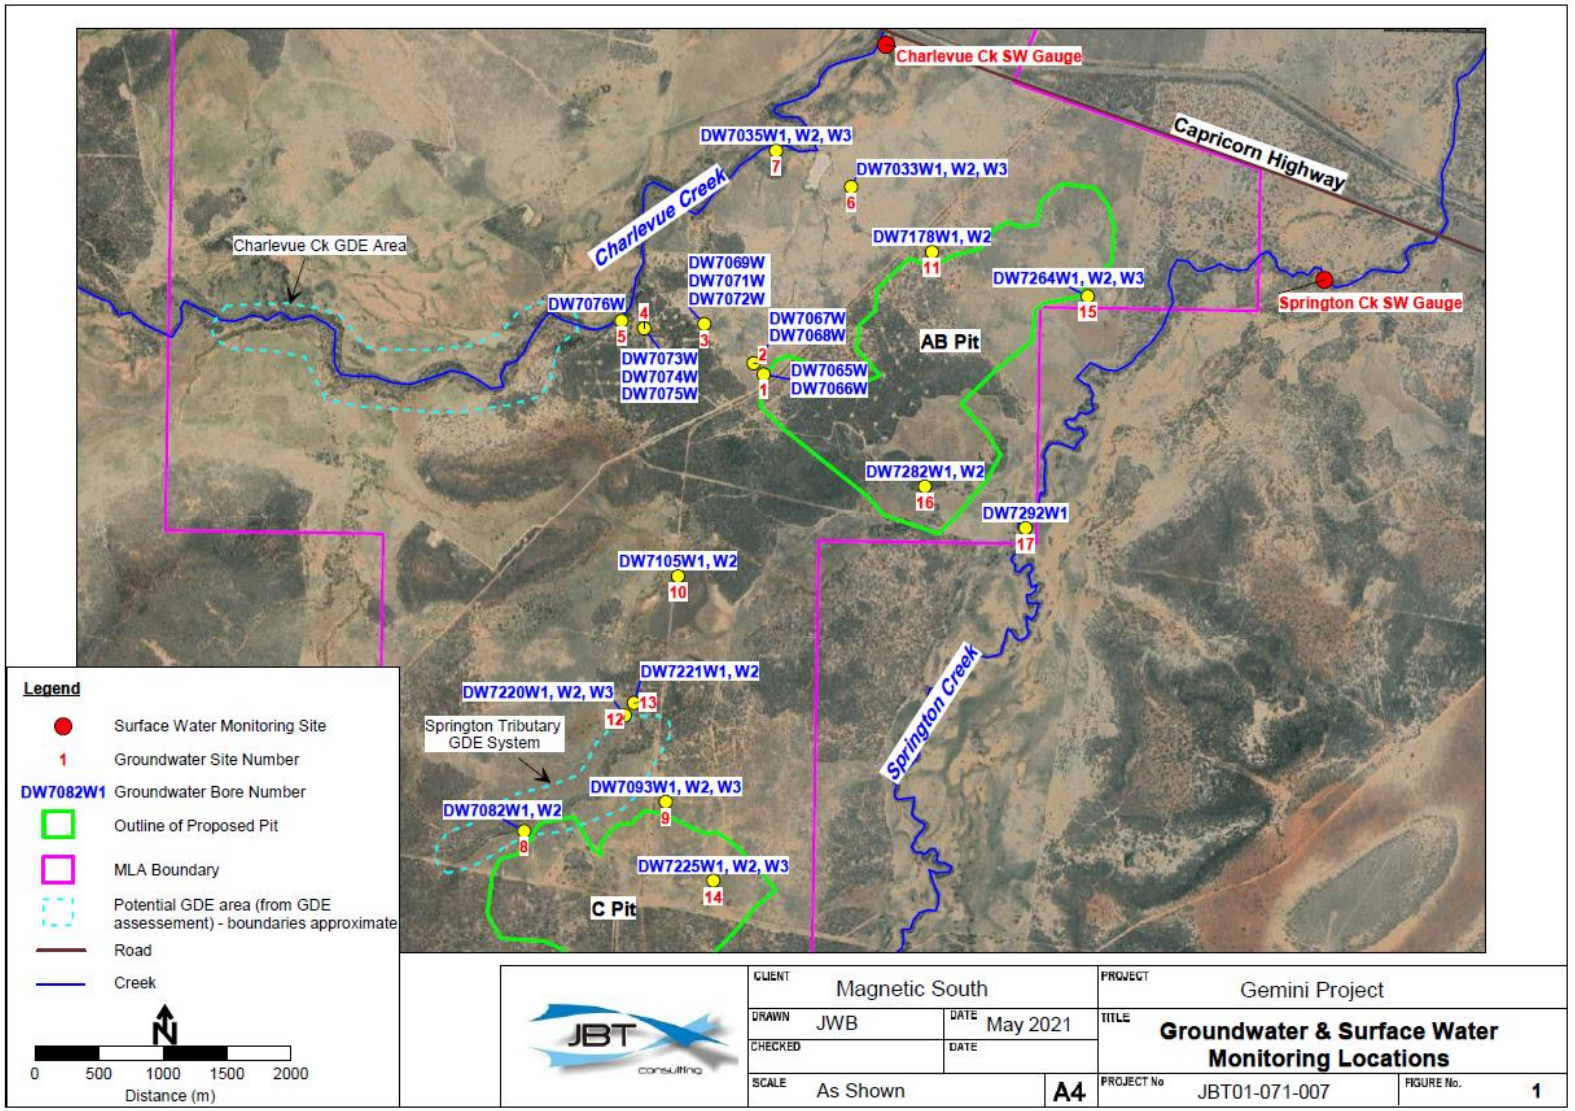

Figure 2: Location of monitoring bores and water gauge stations

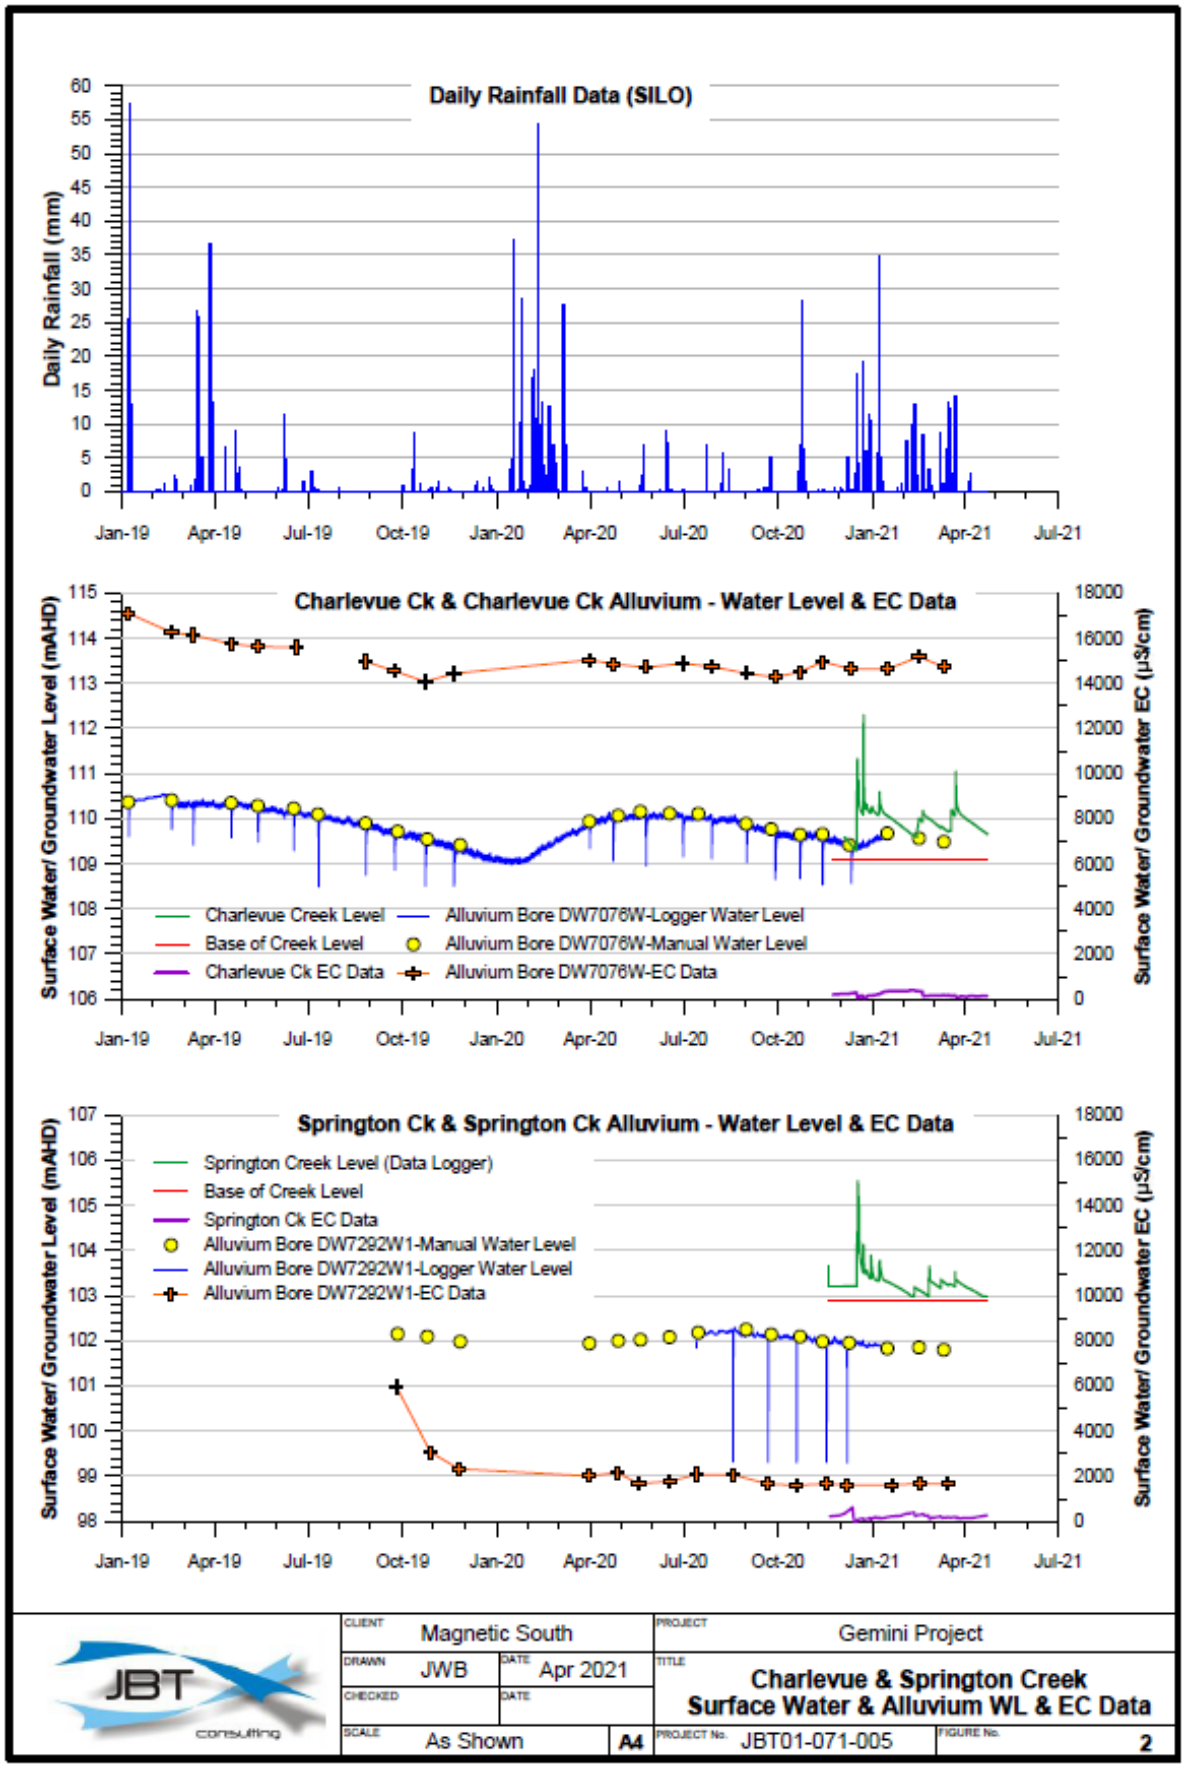

Figure 3: Alluvium and stream flow monitoring data

4.1.3.1 Charlevue Creek surface water and alluvium

The analysis of groundwater level data and stream flow data as it relates to the potential Charlevue Creek GDE (provided in Appendix B) concluded the following:

- Surface water levels in Charlevue Creek are highly reactive to rainfall, with water levels rising by more than 3 m in response to rainfall and failing relatively quickly towards the base of creek level during non-rainfall periods.
- Alluvial groundwater levels in the Charlevue Creek alluvium monitoring bore (DW7076W) are also shown to respond to high rainfall/streamflow events, rising and falling by up to 1.5 m between the wet season and dry season. Although less pronounced than the surface water reactivity to rainfall, seasonal (wet season/dry season) rise and fall in alluvial water level can be seen in the data, indicating that the alluvium is seasonally recharged by wet season streamflow events.
- The electrical conductivity (EC) of Charlevue Creek surface water is low, ranging between ~65 and 400 µS/cm. By contrast, the EC of groundwater within the Charlevue Creek alluvium at DW7076W is very high, ranging between ~14,000 to 17,000 µS/cm.
- A distinct seasonal variation in groundwater EC is not evident at DW7076W. This could indicate that a lens of fresh, low EC, low density water (from seasonal recharge) is occurring over a deeper zone of denser, higher EC groundwater. This interpretation is consistent with the findings of the *Groundwater Dependent Ecosystem Assessment* (3D Environmental 2020) (GDE Assessment), which postulates that the Charlevue Creek GDE area is supported by an unconfined, fresh alluvial aquifer perched above older Quaternary alluvium and Tertiary sediments. To further investigate this theory an additional groundwater monitoring bore could be installed within the sandy interval at this site (i.e. adjacent to bore DW7076W) and fitted with a water level/EC data logger.
- To monitor and detect future changes in the relationship between surface water flow, alluvium and the underlying groundwater units, a nested groundwater monitoring site will be designed and installed adjacent to the water gauge station prior to the commencement of mining activities, i.e:
    - Install one bore screened within the Charlevue Creek alluvium
    - Install one bore screened within underlying Tertiary strata
    - Install one bore screened within the underlying Permian strata at the shallowest depth where groundwater occurs
    - Install water level data loggers within all bores and undertake regular testing
    - Undertake hydraulic conductivity testing (i.e. slug testing) on all bores.

4.1.3.2 Springton Creek surface water and alluvium

The analysis of groundwater level data and stream flow data as it relates to the potential Springton Creek Tributary System GDE (provided in Appendix B) concluded the following:

- Streamflow response to rainfall and seasonal trends in the alluvial groundwater levels in the Springton Creek alluvium monitoring bore (DW7292W1) were similar to those described above for Charlevue Creek (although there was less variation in wet season/dry season water levels). This indicates that the Springton Creek alluvium is also seasonally recharged by wet season streamflow events.
- Springton Creek surface water EC had a similar EC range to Charlevue Creek. However, the EC of alluvial groundwater from DW7292W1 was much lower than at Charlevue Creek (generally <2,000 µS/cm).
- As with Charlevue Creek, EC levels do not appear to reduce with wet season recharge. It is therefore possible that this alluvial groundwater system is also stratified, as has been postulated above for Charlevue Creek. This is an interpretation consistent with the GDE Assessment, which indicates that the Springton Creek Tributary System GDE is supported by a seasonally variable perched aquifer.
- There are already a number of existing nested bores installed in the Tertiary and Permian groundwater in/ adjacent to the Springton Creek Tributary System GDE (DW7220, DW7221, DW7082, DW7093) (refer to Figure 2). Site DW7082 has been identified as a suitable location to install an alluvium bore, which would

provide a better understanding of the relationship between the alluvium and the underlying groundwater units in this location. This would also provide an additional impact monitoring bore for Pit C (also outlined in Section 4.3.3.3).

- To better understand the relationship between surface water and alluvium in Springton Creek an additional alluvium groundwater monitoring bore could be installed within the sandy interval at the eastern extent of the mining lease on Springton Creek. This would also provide an additional downstream / impact monitoring bore for Pit AB (also outlined in Section 4.3.3.3).
- In order to provide an upstream/reference bore for Pit C mining activities, it is also proposed to install an additional monitoring bore in the Springton Creek alluvium upstream of Pit C, prior to mining activities commencing in this area (Year 12) (also outlined in Section 4.3.3.3).

4.2 Major anions and cations

4.2.1 DES Comment

The information supporting the conclusions that have been made in relation to the limited hydraulic connectivity between the regional groundwater table and the perched aquifer that supports the GDE's (Appendix F: Groundwater Dependent Ecosystems Assessment) as well as the limited connectivity between the perched alluvium and deeper groundwater systems remain of concern to the department.

The conclusion is that it is unlikely that the project will reduce surface flows that replenish the perched GDE aquifer and that impacts of drawdown will not be propagated into the perched aquifer system, which is likely disconnected.

The proportions of major cations and anions within different monitoring bores can provide an indication of the degree of connectivity between groundwater bores. The major cations include sodium, potassium, calcium and magnesium and the major anions include chloride, sulphate, bicarbonate and carbonate.

Hydraulic conductivity has only been calculated for one (1) of the alluvial bores using the result from a single test to demonstrate that the alluvium is hydraulically isolated. Hydraulic conductivity testing should be provided to justify the conclusions drawn relating to the hydraulic conductivity of the GDE and alluvial aquifers.

The department has been unable to identify indicators/ thresholds/triggers that have been identified specifically for the purpose of protecting GDE values. While it is noted that conclusions have been drawn around the lack of connectivity between surface water, deeper groundwater and the GDE aquifers; there is little data to support the conclusions. A trigger of 2m/year has been assigned for an unconsolidated quaternary alluvial aquifer, and it is unclear how a 2m/year drawdown is believed to afford the relevant necessary protection to GDE's.

The department still considers it necessary to include indicators, thresholds and limits in drawdown that will be relevant to the protection of GDE values.

4.2.2 DES Requirement

All major anions and cations must be monitored for all bores in accordance with the current proposed monitoring regime. Produce a figure(s) that visualise the ionic chemistry of the groundwater samples, for example, a piper diagram.

Conduct adequate hydraulic conductivity testing of alluvial aquifers and include the data and results in the response. Identify and justify appropriate draw down triggers and management actions for the protection of GDE values.

4.2.3 Response

4.2.3.1 Box and whisker plots

Box and whisker plots for pH, field EC and sulphate have been produced for surface water, Quaternary alluvium, Tertiary sediments and Permian sediments, and are provided in Figures 3 - 5 of Appendix C. A summary of the relevant key findings is provided below. A more detailed analysis of these plots is provided in the Groundwater Technical Memorandum (Appendix B).

The EC ranges are highly variable, but showed the following trends:

- Surface water EC was generally relatively low, ranging from 65 to 392 µS/cm in Charlevue Creek and 1 to 615 µS/cm in Springton Creek.
- Quaternary alluvium EC was relatively high (particularly at Charlevue Creek), ranging from 14,079 µS/cm to 17,106 µS/cm at Charlevue Creek and 1,594 to 5,948 µS/cm at Springton Creek.
- Tertiary sediment EC is generally >7000 µS/cm
- Permian sediment EC is generally >10,000 µS/cm.

A number of observations were also made in relation to EC and groundwater levels in the nested bores located in/adjacent to the Springton Creek Tributary GDE area (DW7220, DW7221, DW7105) (refer to Figure 2 for locations):

- At site DW7220, both the Tertiary bore (W1) and shallow Permian bore (W2) recorded an EC of <2,000 µS/cm, which is much lower than was generally observed for these units. While the deeper Permian bore at this site (W3) had an EC range of 17,398 to 20,693 µS/cm.
- At site DW7221 the shallow Permian bore (W1) also recorded a relatively low EC ranging from 3,325 to 3,979 µS/cm. The deeper Permian bore (W2) records a higher EC range of 7,851 to 16,059 µS/cm.
- The data from these nested bores supports the theory in the GDE Assessment that the potential GDE's in this area are supported by a seasonally variable perched aquifer. This theory is further supported by the water level data collected from bores in this area, as follows:
    - Tertiary bore DW7220W1 records a water level that is approximately 16 mbgl while the deeper bores at this location record a water level of approximately 20 mbgl, indicating a potential for downward flow (i.e. recharge) at this site. The depth to groundwater at this site is considered too deep to support vegetation.
    - Tertiary bore DW7105W1 is dry, while the adjacent shallow Permian bore DW7105W2 records a water level of approximately 32 mbgl. The high EC range of the Permian bore at this location (949 to 1,367 µS/cm) indicates that recharge is occurring from the shallow groundwater system to the Permian strata at this site. The depth to groundwater at this site is also considered too deep to support vegetation.

4.2.3.2 Piper diagrams

Separate Piper diagrams for Tertiary bores, Permian Bores and surface water/Quaternary alluvium bores are provided in Figure 6 of Appendix C, as well as a combined diagram showing the data from all these water sources. A summary of the relevant key findings is provided below. A more detailed analysis of these diagrams is provided in the Groundwater Technical Memorandum (Appendix B).

- Plots for the surface water and alluvium bores are indicative of surface water recharge to the alluvial groundwater system.
- Plots for the Tertiary and Permian bores show increasing sodium and chloride with depth, indicating increased groundwater residence time (i.e. increasing salinity as groundwater moves downwards through the sediments).

- This data further supports the interpretation that the alluvium is receiving surface water recharge (as outlined in Section 4.1.3).

4.2.3.3 Conclusion

- Streamflow and alluvium water level and EC data indicates that recharge is occurring seasonally from the Springton Creek and Charlevue Creek into the adjacent alluvial groundwater.
- Salinity data presented in the box and whisker plots further supports the theory from the GDE Assessment (outlined in Section 4.1.3 above) that the potential GDE's identified in the ML are supported by a shallow seasonally variable perched aquifer systems.
- The depth to groundwater in the Springton Creek Tributary GDE area is generally considered too deep to support vegetation.
- Ongoing monitoring of major cations and anions will be included in the groundwater monitoring program for interpretive purposes, and to enhance the understanding of hydraulic isolation/connectivity between aquifer systems.

4.2.3.4 GDE drawdown triggers

Isotopic testing of groundwater samples and twig (xylem) samples taken from potential GDE areas do not demonstrate any overlap, with groundwater demonstrating much more depleted isotopic values (refer to section 4.3 of the GDE Assessment for details). However, twig samples did overlap with isotopic values of surface waters. These results indicate that trees within the identified potential GDE areas are not utilising groundwater in the regional Tertiary or alluvial aquifers, even when groundwater would be within reach of maximum rooting depth. The GDE Assessment further postulates that any groundwater usage by trees on the Project site is from fresh perched aquifers that are recharged from surface water and are disconnected from the regional aquifer. This theory is supported by the groundwater data (as discussed in Section 4.1 and 4.2 above).

It is therefore considered that if GDEs are present within the Project area, they are dependent on perched aquifers which are disconnected from the regional aquifer system.

However, to further understand the system, installation of additional monitoring bores is proposed prior to the commencement of mining activities (as detailed in Section 4.1.3).

As further data is collated and the system is better understood, specific GDE drawdown indicators/thresholds /limits will be developed if appropriate, prior to the commencement of mining activities.

4.3 Groundwater flow direction, identification of impact and reference bores

4.3.1 DES Comment

The groundwater network is representative of the groundwater units present, in that bores are located within each of the groundwater units; however, the bore locations have not been demonstrated to be representative of the directional flow of groundwater and reflect the up and down gradient for each groundwater unit. Furthermore, bore location continues to appear to be random and the spatial distribution is not well justified in terms of anticipated impacts from potential sources of contamination. Locations of reference bores should be located upgradient as opposed to just being 'distant'. The demonstration of conceptual understanding of ionic chemistry and groundwater flow direction is important to evaluate if the bore network is appropriate and representative. There does not currently appear to be an upgradient or reference bore proposed for the alluvial aquifers.

4.3.2 DES Requirement

Detailed conceptual understanding of the direction of groundwater flow needs to be demonstrated. Provide a figure illustrating ground water level contours indicating directional flow of groundwater. To demonstrate that the bore network is entirely representative of up and down gradient for each groundwater unit, produce a figure that visualises the ionic chemistry of the groundwater samples, for example, a piper diagram.

Provide justification for a lack of reference bores and up/down gradient bores for the alluvial aquifer or alternatively install the necessary bores.

4.3.3 Response

4.3.3.1 Groundwater flow direction in Tertiary sediments

A map of the elevation base of the Tertiary sediments (based on date for the site geological model) and the water level data for Tertiary sediment monitoring bores is provided in Figure 4. The Tertiary groundwater system in the ML area is shown to be intersected by a Permian ridge (shown in Grey), which separates the northern and southern parts of the mining lease. The groundwater flow direction in the Tertiary sediments in the ML area is therefore interpreted as being quite localised – moving towards the areas of lower Tertiary base elevation from areas where the preferential recharge occurs (e.g. the area around bore DW7220W1 (refer to Section 2.1.2 of Appendix B. A more detailed analysis is provided in Section 2.1.3 of Appendix B.

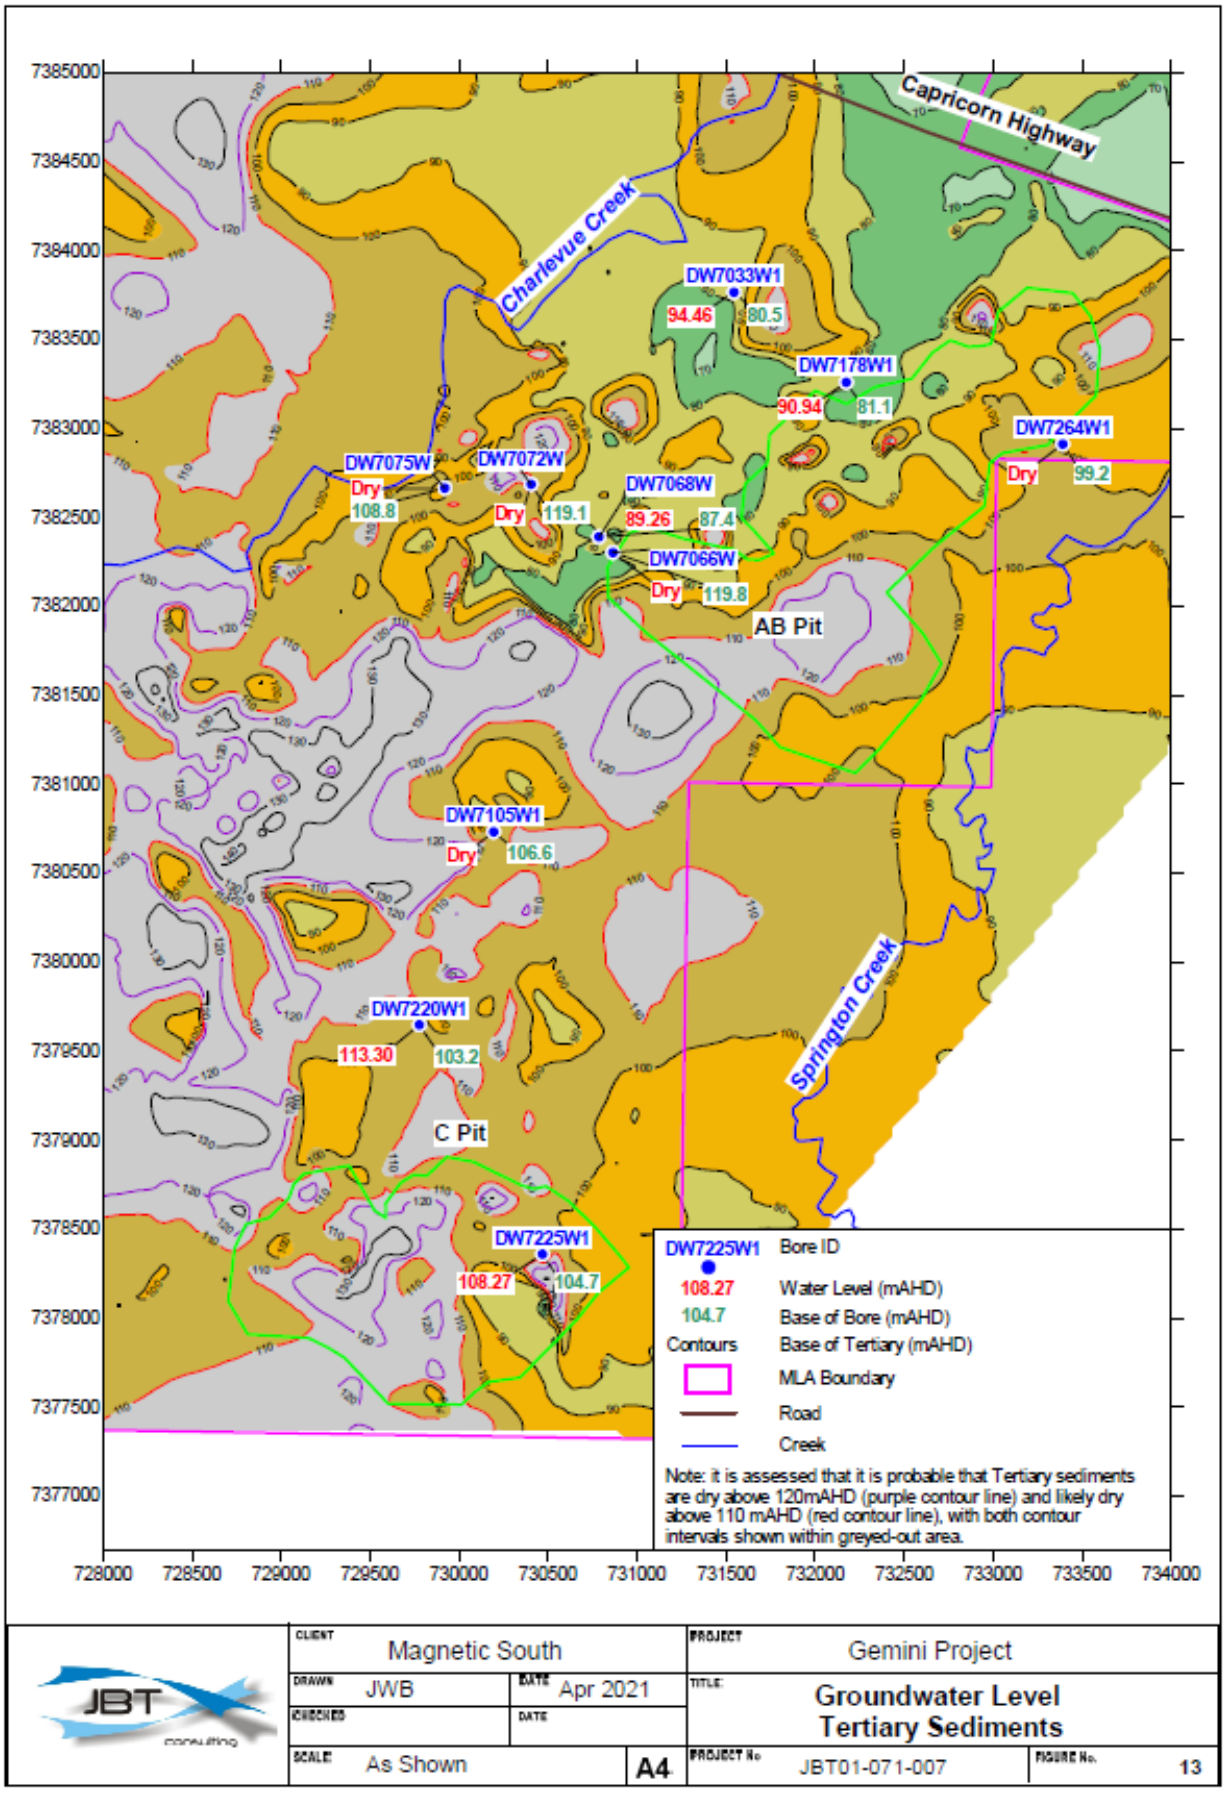

Figure 4: Groundwater level in, and base of, Tertiary sediments

4.3.3.2 Groundwater flow direction in Permian sediments

Groundwater level contours for the Permian sediments are shown in Figure 5. The data indicates that the groundwater flow direction in the Permian sediments is from the south-southwest to north-north-east.

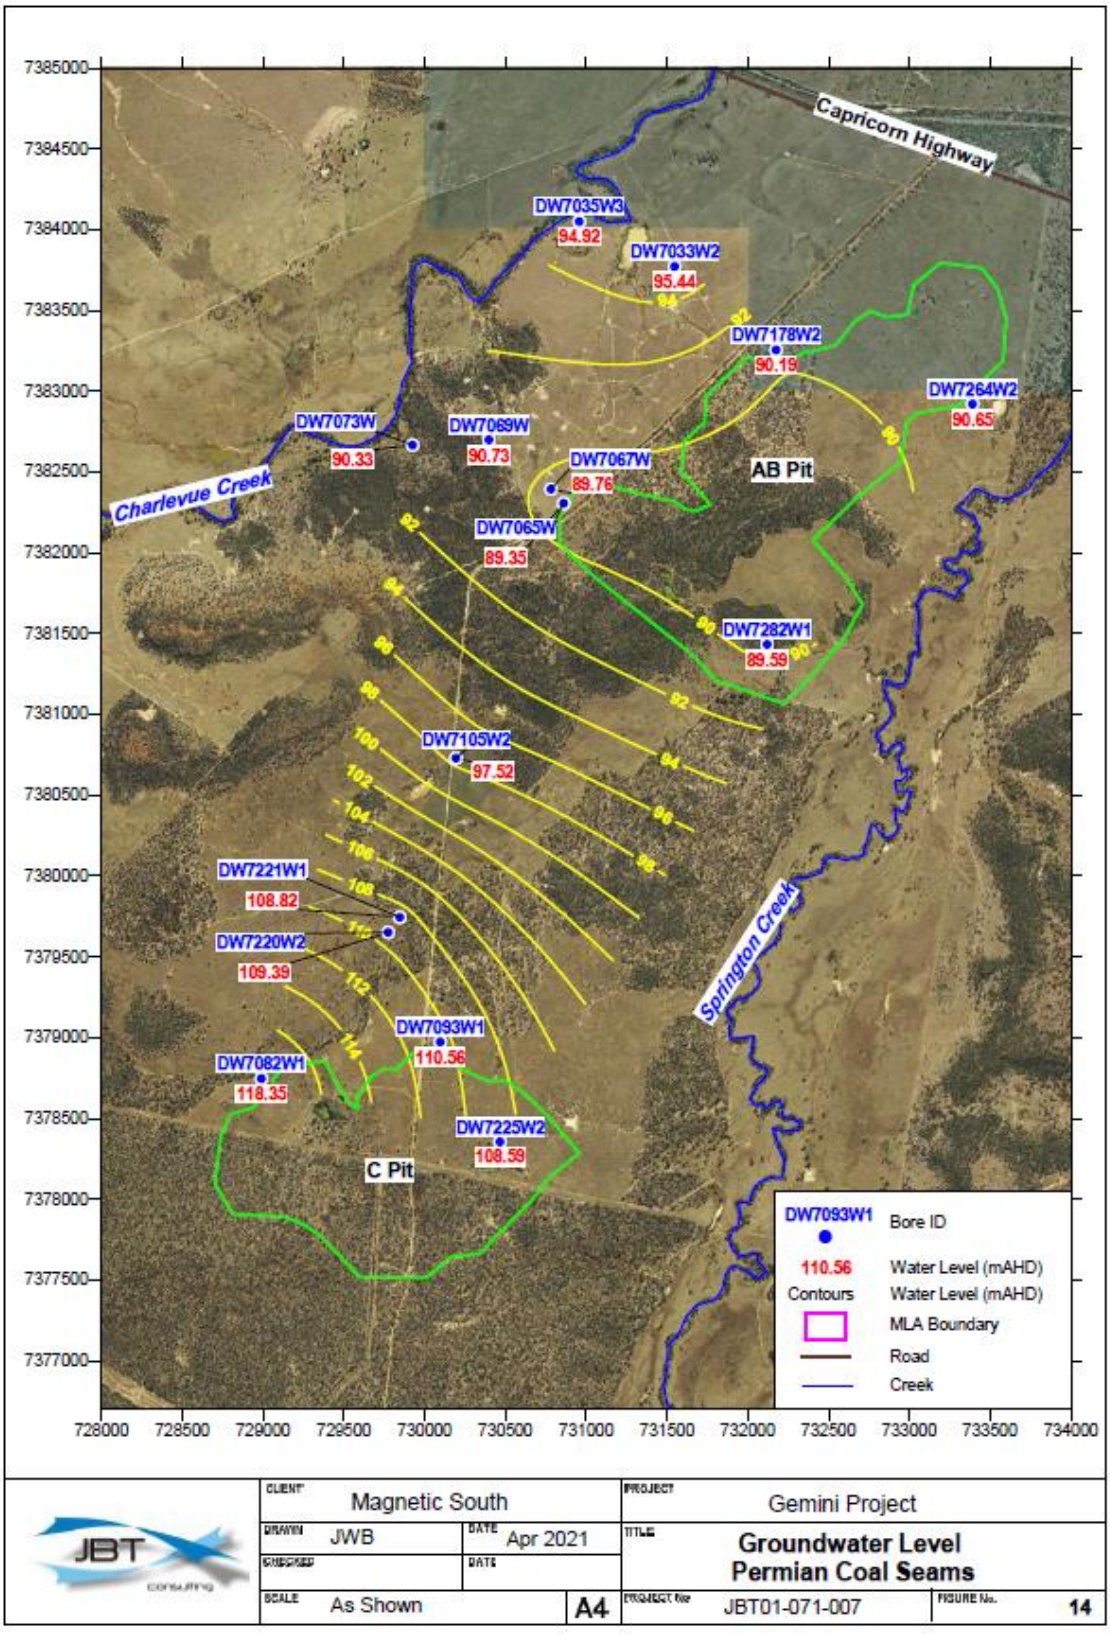

Figure 5: Groundwater level and contours in Permian coal seams

4.3.3.3 Alluvium monitoring bores

The location of existing/proposed groundwater monitoring reference/impact bores for the alluvial aquifer is shown in Table 2. The proposed new monitoring bores are to be installed prior to commencement of mining activities.

Table 2: Existing and proposed alluvial groundwater monitoring bores

	Charlevue Creek alluvium	**Springton Creek alluvium**
Upstream/reference bore	Charlevue Creek alluvium monitoring bore DW7076W Additional alluvium monitoring bore proposed to be installed (refer to Section 4.1.3.1).	Springton Creek alluvium monitoring bore DW7292W1 Additional alluvium monitoring bore proposed to be installed upstream of Pit C prior (refer to section 4.1.3.2).
Downstream/impact bore	Additional alluvium monitoring bore proposed to be installed adjacent to the water gauge station (refer to Section 4.1.3.1).	Alluvium monitoring bore proposed to be installed upstream of the water gauge station (refer to Section 4.1.3.2) Alluvium monitoring bore proposed to be installed at site DW7082 (refer to Section 4.1.3.2).

5 Geochemical Assessment of mine waste materials

5.1 Drill hole sample depth

5.1.1 DES Comment

In Section 2.1, it states, “recoverable coal will come from the Rangal coal seams but may also target the Upper Burngrove formation.” Figure A2 in Attachment A indicates that the Upper Burngrove coals seams are found at depths of approximately 175 metres (m) to 250m. However, in section 3.1, Table 3-1 indicates the maximum sample depth was 158.00 metres. It is not clear how these samples are representative of the geochemical characteristics of the Upper Burngrove Formation.

5.1.2 DES Requirement

Provide further explanation for the maximum sample depth, including justification that it is representative of geochemical characteristics and amount of potential mining waste materials expected to be encountered in the Upper Burngrove Formation given that Figure A2 identifies the coal seam presence at 175m to 250m, while the samples were taken at a shallower depth.

5.1.3 Response

The Gemini Project will target the Rangal Coal Measures (Aries, Castor and Pollux seams). It is not planned to mine coal seams in the Upper Burngrove Formation. Please refer to Section 2.1 of the *RGS Technical Memorandum: Geochemical Assessment of Mine Waste Materials* (RGS, May 2021) (Mine Waste Geochemistry Technical Memorandum) (Appendix D) for further information.

5.2 Drill hole locations

5.2.1 DES Comment

Table 3-1 in Section 3.1 of the Appendix G: Geochemical Assessment of Mining Waste Materials (RGS, Sep 2019) presents the drill hole identification (ID) numbers from which samples were taken for geochemical assessments, that is DW7002, DW7003 and DW7012. The drill hole ID numbers correspond to locations provided in Figure A3 (Attachment A) of Appendix G. Figure A3 shows that the three (3) drill holes sample sites are in the centre of MLA 700056 tenure area, in an area that is not proposed to be disturbed by activities associated with the mining project. Neither Appendix G nor the Revised Supporting Information document provide discussion of the sufficiency of the geochemical sampling sites to be representative of the characteristics of the mining waste materials likely to be encountered. It is not clear how the drill hole samples sites are representative of mining waste materials likely to be encountered for Gemini Project when the samples have been taken from outside the proposed areas for Pit AB and Pit C.

5.2.2 DES Requirement

Ensure a representative sampling regime is conducted for the assessment of geochemical properties of mining waste materials likely to be encountered. Provide a statement to justify that the chosen sampling regime sufficiently reflects the likely characteristics of mining waste materials encountered for Gemini Project, given the samples have been taken from outside the areas proposed to be disturbed by Pit AB and C.

5.2.3 Response

The three drill holes (DW7002, DW7003 and DW7012) used to collect representative samples of mining waste (spoil) materials were drilled in 2017 from an additional resource area that was targeted in early mine planning and subsequently dropped (as shown in Figure 1).

While it is acknowledged that the three drill holes are located outside the planned open pit areas, the chosen sampling regime is considered to sufficiently reflect the likely characteristics of mining waste materials encountered for the Gemini Project for the following reasons:

- Magnetic South has drilled 36 partially cored coal quality holes in the Pit AB and Pit C areas. The drilling consisted of five 150 mm large diameter (LD) cores twinned with four 100 mm cores at four sites. The major coal seams AR3, CAS, PLU1 and PLU2 were intersected in all holes as well as roof and floor samples.
- The cores were subjected to pre-treatment, washability and flotation testing on samples from both the thicker and thinner plies, and also provided sufficient coal and dilution mass to make up a simulated bulk ROM sample for bulk processing to generate product, reject and tailings material. This material was subjected to specialist handleability, thickening and dewatering test work, as well as physical, chemical, XRD and geotechnical characterization of the potentially clay rich reject and tailings.
- Results from quality testing showed very little variation between trace elements concentrations such as Sulphur, Phosphorus and Chlorine.
- The sedimentary stratigraphic profile, and overburden and interburden materials encountered at the drill hole locations DW7002, DW7003 and DW7012 is very similar to those encountered at the planned open pit areas (soil, clay, sandstone and siltstone).
- The Rangal Coal Measures are mined at a number of locations in the Bowen Basin. Mine spoil is typically very low in sulphur, has excess acid neutralising capacity (ANC) and is classified as Non-Acid Forming (NAF). These characteristics are typical of spoil characteristics at proposed and actual coal mines in close proximity to the Project such as the Walton Coal Project, Baralaba, Jellinbah and Yarrabee mines.

The three holes (DW7002, DW7003 and DW7012) are located in the same overburden and interburden strata at Pit AB and Pit C. This provides geological justification that these samples are representative of the material proposed to be mined from Pit AB and Pit C. Validation sampling will be undertaken during operations to confirm this conclusion.

6 Geochemical assessment of Coal Reject Material

6.1 Placement and encapsulation of rejects material

6.1.1 DES Comment

Regarding the expected coal reject material disposal, the Revised Supporting Information document states in Section 12.3, Table 68: "Coal rejects will be disposed of within Pit AB and Pit C and out-of-pit waste rock emplacements." Further in Section 13.4.1 and 13.4.4, respectively, it is stated: "Coal reject material will be placed where there is a lower risk of connectivity to surface water or groundwater resources." "Coal reject materials and any potentially acid forming waste rock materials identified will be selectively handled and encapsulated within waste rock emplacements and well away from the outside surface of rehabilitated landforms, where there is a low risk of connectivity to surface water or groundwater resources." Appendix H and the Revised Supporting Information document do not give clear locations of where coal reject material will be disposed of other than, generally, within the waste rock or spoil emplacements and at a depth where there is a lower risk of connectivity to surface water or groundwater resources.

Further information is required to ensure that there is sufficient capacity for the achievement of the proposed disposal requirements with respect to the proposed final landform.

6.1.2 DES Requirement

Provide a discussion of the likely position of disposed coal reject material within the out-of-pit and in-pit waste rock emplacements and demonstrate that there is sufficient capacity for proposed coal reject material disposal, including sufficient quantities of benign material to encapsulate potentially acid forming waste.

6.1.3 Response

It is estimated that less than 10 Mt of coal reject material will be generated over the life of the mine, while the volume of waste rock materials to be generated is estimated to be over 1000 Mt. The volume of coal reject material will make up a very small proportion of the total spoil materials (<1%).

It is anticipated that most coal reject materials have a relatively low risk of acid generation, while the overwhelming majority of waste rock waste samples are classified as non-acid forming, with excess acid neutralising capacity.

Reject material will be placed at least 10 m from the edge of the final spoil storage areas, such that it remains encapsulated and is not exposed near the surface of the final rehabilitated landforms/edge of void.

Ongoing sampling and geochemical testing of mining waste materials will be strategically undertaken during mine operations to verify the findings of the geochemical assessments and additional management measures will be employed where necessary to ensure reject materials are adequately neutralised.

Please refer to Section 2.3 of the Mine Waste Geochemistry Technical Memorandum (Appendix D) for further information.

6.2 Coal reject sampling methodology

6.2.1 DES Comment

Table 2.1 in Section 2.1 assigns geochemical samples to a sample number according to the coal seam (AR2, AR3, CAS, PLU1, PLU2); however, it is unclear what consideration was given to spatial variability across the coal

seams. It is noted that the samples are composite. It is not clear what influence this has on geochemical characteristics of the samples where quality may be variable across the coal seam.

6.2.2 DES Requirement

Provide a list of the coal reject drillhole ID numbers for each generated composite coal reject sample detailed in Table 2.1 of section 2.1. Provide further information on how the geochemical characteristics across a coal seam is considered in the assessment of the quality of coal reject material from each coal seam or each composite sample.

6.2.3 Response

6.2.3.1 Drill hole ID numbers contributing to each composite sample

Geochemical testing was undertaken for each of the target coal seams (Aries, Castor and Pollux). Evaluation of the anticipated geochemistry of coal reject materials requires a number of tests, including coal quality, processing methodologies and reject material geochemistry. This requires a high volume of material to be provided to the laboratory. It was therefore necessary to form composite samples for each coal seam using material from multiple drill holes. In consideration of the proportionately small volume of rejects to be produced and disposed of over the life of mine and the fact that reject waste streams will comprise a mixture of any number of coal seam waste products, the approach of composite sample testing across coal seams is considered appropriate.

Section 2.4 of the Mine Waste Geochemistry Technical Memorandum (Attachment D) provides details on which drill holes were used to form each of the composite samples.

6.2.3.2 Geochemical characteristics across coal seams

Sulphur contours plotted for the main target seams indicate that the total sulphur content of the coal seams is relatively consistent across the open pit areas. It is therefore considered that the average geochemical nature of bulk coal reject materials generated from processing the target coal seams is also likely to be consistent (although some natural variability will occur). Further detail, including figures showing total sulphur contours for the main target coal seams, is provided in Section 2.4 of the Mine Waste Geochemistry Technical Memorandum, describing coal reject sampling drill hole locations and overall representativeness.

6.2.4 DES Comment

Figure A3 provides the locations of the drill hole sites from which samples were extracted for geochemical assessment of coal rejects material. Figure A3 shows that one (1) drill hole was taken from the proposed area of Pit C (drill hole ID number DW7253C), while eight (8) where taken from the proposed area of Pit AB. Neither Appendix H nor the Revised Supporting Information document provide discussion of the sufficiency of the geochemical sampling sites to be representative of the characteristics of the mining waste materials likely to be encountered. It is not clear how the drill hole samples sites are representative of mining waste materials likely to be encountered for Gemini Project when the samples have been taken from outside the proposed areas for Pit AB and Pit C.

6.2.5 DES Requirement

Ensure a representative sampling regime is conducted for the assessment of geochemical properties of coal reject material likely to be produced. Provide a statement to justify that the chosen sampling regime sufficiently reflects the likely characteristics of coal reject material produced by the Gemini Project.

6.2.6 Response

It is acknowledged that the majority of coal reject material samples were taken from the Pit AB area.

As outlined in Section 6.2.3.2 above the average total sulphur content of the coal seams is relatively consistent across the open pit areas. The average geochemical nature of the bulk coal reject materials generated from processing the target coal seams is also likely to be relatively consistent. The coal reject samples are therefore expected to reflect the characteristics of the coal reject material at the Project. However, validation sampling and geochemical testing of mining waste materials will be undertaken during mine operations to verify the findings of the geochemical assessments. Please refer to Section 2.5 of the Mine Waste Geochemistry Technical Memorandum (Attachment D) for further detail.

7 Soils and Land Suitability

7.1 Post Mining Land Use (PMLU)

7.1.1 DES Comment

Appendix I provides pre-mining land suitability classes for grazing, which range from Class 2 to 4. It is stated that, "the majority of areas in the final landform will aim to restore a post-mining land use of grazing." However, "grazing" is not defined by a land suitability class that it will aim to achieve. Further discussion in this section describes areas that may not achieve the pre-mining land suitability class, "such as steeper outer slopes of spoil", but these areas are not referenced by a specific location.

For the mining disturbance domains that have a post-mining land use of grazing, it is unclear which areas are proposed to achieve the pre-mining land suitability class and which areas will not, and furthermore, what land suitability class for grazing they are proposed to achieve.

7.1.2 DES Requirement

Provide more detailed explanation and acceptance criteria for the post-mining land use "grazing", particularly:

- The land suitability class/es that will be achieved for areas with a post mining land-use of "grazing", including if it will return to pre-mining land suitability class or different
- If an area will have a different class to pre-mining, provide justification for how the proposed post-mining land suitability class is appropriate
- If "grazing" will achieve varying land suitability classes in the post-mining landform, provide proposed areas and locations for each class
- Given land suitability classes are assessed against limitations, provide the parameters that will demonstrate that an area has achieved the proposed post-mining land suitability class.

7.1.3 Response

The post mining cattle grazing Land Suitability Class (LSC) proposed to be achieved for each mine domain is shown in Figure 6. This was determined based on the *Land Suitability Assessment Technique* (DME 1995)), with consideration of the pre-mining LSC (refer to Figure 7 SLSA Assessment) and physical characteristics of the post mining landscape, such as topography, recreated soil profiles and the underlying substrate (e.g. mine waste).

The pre mining cattle grazing LSC that was determined for the project area is shown in Figure 7 of the *Gemini Project Soil and Land Suitability Assessment* (AARC, July 2019) (SLSA Assessment)).

The calculated area (in hectares) for each pre and post mining LSC within the project disturbance area is provided in Table 3.

Justification for the proposed post mining LSC of each Rehabilitation Area (RA) is provided in Table 4.

The parameters that will be used to demonstrate achievement of the post mining cattle grazing LSC are the same parameters which were used to assess the pre-mining land use suitability, as identified in the *Land Suitability Assessment Technique* (DME 1995): water availability, nutrient deficiency, soil physical factors, salinity, rockiness, ESP, wetness, topography, water erosion, flooding and vegetation regrowth.

Table 3: Pre and post mining cattle grazing LSC areas

Area (ha)						
	Class 2	**Class 3**	**Class 4**	**Class 5**	**Class 3/5**	**Total**
Pre-mining	63.2	1644.0	246.3	0	0	1953.5
Post-mining	0	631.5	1027.1	224.4	70.5	1953.5
Change from pre to post	-63.2	-1012.5	+780.8	+224.4	+70.5	0

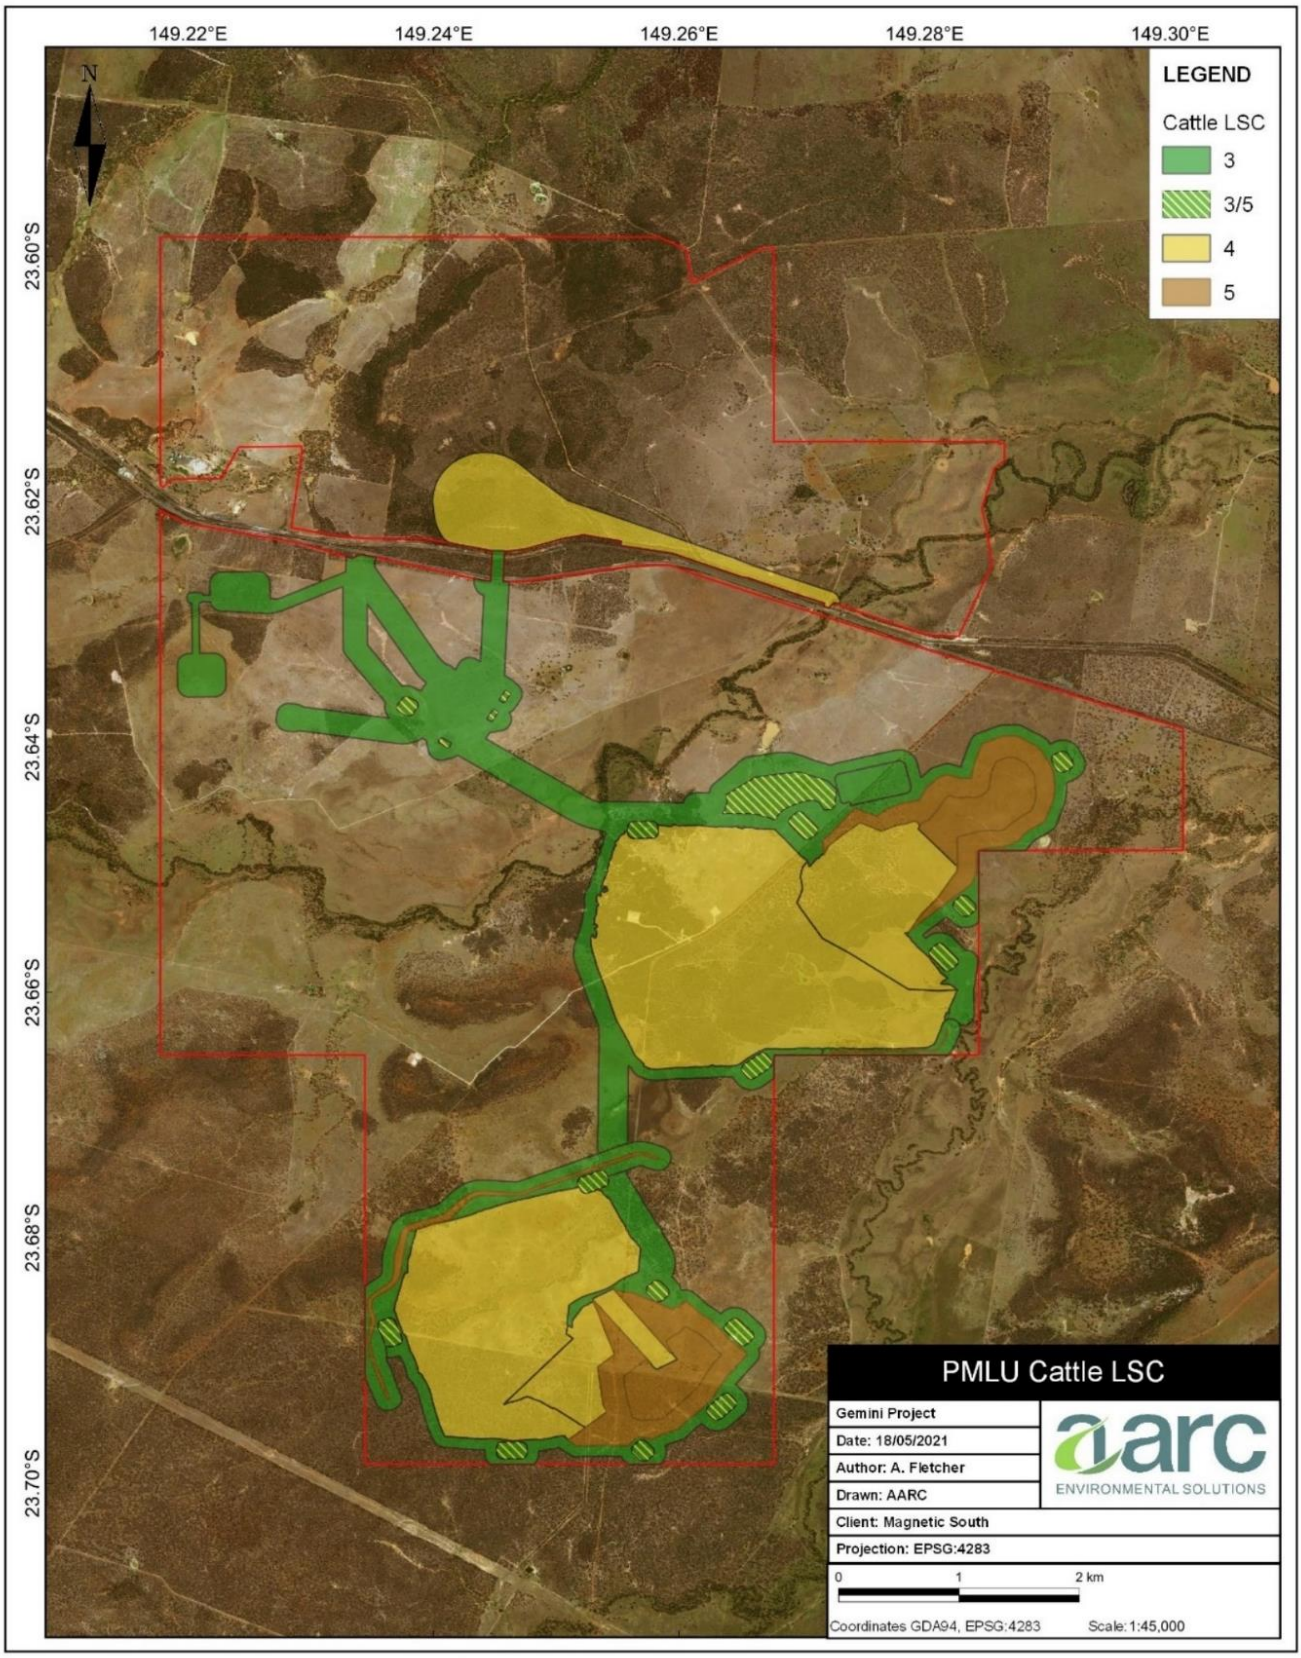

Figure 6: Proposed Post Mining Land Use (PMLU) LSC for cattle grazing

Table 4: Post mining land suitability class that will be achieved for areas with a post mining land-use of grazing

Area	Rehabilitation area description	Proposed PMLU	Pre-mining LSC (cattle grazing)	Post-mining LSC (cattle grazing)	Justification proposed post-mining LSC
RA1	Pit AB in pit and out of pit waste emplacements	Grazing	Class 3 & 4	Class 4	Slope It is planned that the final waste emplacements will have a maximum slope of approximately 6°, which is not anticipated to greatly impact the productivity for cattle grazing. However, the soil characteristics and nature of the underlying waste is anticipated to lead to increased limitations of land productivity in these areas, as outlined below. Soils The Pit AB footprint is comprised of areas with a cattle grazing LSC of 3 and 4, which are associated with the Geoffrey and Charlevue soil management units (SMUs), respectively. The Charlevue SMU has a variable pH, ranging from 5.4 (strongly acid) in the topsoil to 7.9 (moderately alkaline) in the lower subsoil. EC is medium in the surface soil (0.28-0.43 dS/m) and increases to high in the subsoil (0.46 dS/m). Chloride is considered to be high from 0.2 m depth downwards (>600 mg/kg), which can cause toxicity by interfering with plants' osmotic capacity. Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Geoffrey SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0-0.6 m) are moderately acidic, with pH gradually increasing with depth from 5.8 to 6.0. The clay B2 horizon has a pH value over two units higher (8.1) and is classified as 'moderately alkaline'. This is likely due to the increased CEC of the clay in the B2 horizon compared with the sand in the upper horizons. As such, it is expected that the recreated soil profile in this area would practically achieve a cattle grazing LSC of 4. Plant Available Water Capacity The pre-mining plant available water capacity (PAWC) for the Charlevue and Geoffrey SMUs have been assessed at 75-100mm (LSC 3). PAWC is identified as one of the limiting factors for productivity of these SMUs. It is anticipated that the chemical and physical properties of the underlying spoil material, combined with anticipated post mining soil depths, is such that the growth medium will be reduced to the top 20-40cm, effectively reducing the LSC for cattle grazing to Class 4 in this area. Erosion Risk Recreated post-mining landforms, such as in pit and out of pit spoil, will initially present an increased risk of erosion. Particularly on the slopes of the out of pit spoil dumps. Cattle grazing at a reduced intensity is therefore recommended, until such time that landforms stabilise and soil profiles further develop. This change in productivity is expected to be consistent with cattle grazing LSC 4.
	Pit C in pit and out of pit waste emplacements	Grazing	Class 3	Class 4	Slope It is planned that the final waste emplacements will have a maximum slope of approximately 6°, which is not anticipated to greatly impact the productivity for cattle grazing. However, the soil characteristics and nature of the underlying waste is anticipated to lead to increased limitations of land productivity in these areas, as outlined below. Soils The Pit C footprint is comprised of LSC3 areas, associated with the Geoffrey, Namoi and Cooinda SMUs. Plant Available Water Capacity The pre-mining plant available water capacity (PAWC) for the Geoffrey and Cooinda SMUs have been assessed at 75-100mm (LSC 3), with Namoi assessed at 100-125mm (LSC 2). PAWC is identified as one of the limiting factors for productivity of the Geoffrey and Cooinda SMUs. It is anticipated that the chemical and physical properties of the underlying spoil material, combined with anticipated post mining soil depths, is such that the growth medium will be reduced to the top 20-40cm, effectively reducing the PAWC to LSC (cattle grazing) 4 in this area. Erosion Risk Recreated post-mining landforms, such as in pit and out of pit spoil, will initially present an increased risk of erosion. Particularly on the slopes of the out of pit spoil dumps. Cattle grazing at a reduced intensity is therefore recommended, until such time that landforms stabilise and soil profiles further develop. This change in productivity is expected to be consistent with cattle grazing LSC 4.
RA2	Temporary waste rock emplacements	Grazing	Class 3	Class 3	No change to the LSC for cattle grazing is predicted.

Area	Rehabilitation area description	Proposed PMLU	Pre-mining LSC (cattle grazing)	Post-mining LSC (cattle grazing)	Justification proposed post-mining LSC
RA5	Residual void low walls	Grazing	Class 3 & 4	Class 4	Slope It is planned that the final waste emplacements will have a maximum slope of approximately 6°, which is not anticipated to greatly impact the productivity for cattle grazing. However, the soil characteristics and nature of the underlying waste is anticipated to lead to increased limitations of land productivity in these areas, as outlined below. Soils The Charlevue SMU has a variable pH, ranging from 5.4 (strongly acid) in the topsoil to 7.9 (moderately alkaline) in the lower subsoil. EC is medium in the surface soil (0.28-0.43 dS/m) and increases to high in the subsoil (0.46 dS/m). Chloride is considered to be high from 0.2 m depth downwards (>600 mg/kg), which can cause toxicity by interfering with plants' osmotic capacity. Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Geoffrey SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0-0.6 m) are moderately acidic, with pH gradually increasing with depth from 5.8 to 6.0. The clay B2 horizon has a pH value over two units higher (8.1) and is classified as 'moderately alkaline'. This is likely due to the increased CEC of the clay in the B2 horizon compared with the sand in the upper horizons. As such, it is expected that the recreated soil profile in this area would practically achieve a cattle grazing LSC of 4. Plant Available Water Capacity The pre-mining plant available water capacity (PAWC) for the Charlevue and Geoffrey SMUs have been assessed at 75-100mm (LSC 3). PAWC is identified as one of the limiting factors for productivity of these SMUs. It is anticipated that the chemical and physical properties of the underlying spoil material, combined with anticipated post mining soil depths, is such that the growth medium will be reduced to the top 20-40cm, effectively reducing the LSC (cattle grazing) to Class 4 in this area. Erosion Risk Recreated post-mining landforms, such as in pit and out of pit spoil, will initially present an increased risk of erosion. Particularly on the slopes of the out of pit spoil dumps. Cattle grazing at a reduced intensity is therefore recommended, until such time that landforms stabilise and soil profiles further develop. This change in productivity is expected to be consistent with cattle grazing LSC 4.
RA6	Clean water drains	Native vegetation	Class 3	Class 5	Clean water drains will become permanent landforms, which will incorporate geomorphic and riparian vegetation features and provide ongoing habitat and connectivity to Springton Creek.
	Other water Management Infrastructure (mine water dams, sediment dams, raw water dams)	Grazing/native vegetation	Class 2 & 3	Class 3 / Class 5	The pre-mining footprint of these areas is predominantly comprised of LSC 3 areas (associated with the Geoffrey and Namoi SMUs), with a small pocket of LSC 2 area located near the Mine infrastructure Area (associated with the Kosh SMU). If water storage facilities are identified by the post-mining landholder as of value to their future use of the land, an agreement may be is entered into to retain water storages, in which case these areas will have a post mining LSC of 5. Otherwise, they will be regraded to natural surface levels and returned to a grazing land use. It is anticipated that areas returned to a post mining land use of cattle grazing can be returned to LSC 3. Given the small area of Class 2 soils that will be stripped for the project, it is considered that the most viable and beneficial option for these soils will be to use them for mixing with other more problematic soils.
RA7	Train loadout facility (TLO)	Grazing	Class 3 &4	Class 4	Soils The TLO footprint is comprised of LSC 3 and 4 areas associated with the Geoffrey and Nigel soil management units (SMU). The area is predominantly Class 4 land. The pH within the Nigel SMU is highly variable, changing from 6.3 (slightly acid) in the topsoil to 8.5 (strongly alkaline) in the lower subsoil. EC follows a similar pattern, changing from very low between 0.0-0.3 m depth, to medium in the subsoil. CEC increases with depth from low (6.8 meq/100g) to moderate (17.4 meq/100g), likely due to the increased clay content in the subsoil layers. It is therefore anticipated that this area can returned to a post mining cattle grazing LSC of 4.
	Mine infrastructure areas (CHPP, camp, STP, effluent irrigation area, roads).	Grazing	Class 2 & 3	Class 3	Soils The majority of these areas have a cattle grazing LSC of 3 (associated with the Geoffrey SMU), with an area of cattle grazing LSC 2 in the road and effluent irrigation area footprints, associated with Kosh and Normanby SMUs. As described above, the pH for the Geoffrey SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0-0.6 m) are moderately acidic, with pH gradually increasing with depth from 5.8 to 6.0. The clay B2 horizon has a pH value over two units higher (8.1) and is classified as 'moderately alkaline'. This is likely due to the increased CEC of the clay in the B2 horizon compared with the sand in the upper horizons. As these infrastructure areas will remain relatively flat, consistent with the surrounding landscape, it is anticipated these areas can be returned to post-mining cattle grazing LSC of 3. Given the small area of Class 2 soils that will be stripped for the project, it is considered that the most viable and beneficial option for these soils will be to use them for mixing with more problematic soils.

8 Terrestrial ecology and Environmental Offsets Strategy

8.1 Area of impact for prescribed environmental matters

8.1.1 DES Comment

The maximum extent of impact (ha) has been provided as a total area for all regulated vegetation that are regional ecosystems within a defined distance of a vegetation management watercourse and for connectivity areas that are regional ecosystems. It is unclear the maximum extent of impact (ha) to each regional ecosystem identification for both these prescribed matters. The draft EA conditions for impacts to prescribed environmental matters does not include reference figures associated with Table H2 to provide context about the locations of prescribed environmental matters being offset and therefore, it is unclear the locations within the project area they are located.

8.1.2 DES Requirement

As per the mining guideline for Model Mining Conditions (ESR/2016/1936, Version 6.02, Effective 07 Mar 17) for Impacts to Prescribed Environmental Matters, provide the location of impact and area (ha) of maximum extent of impact for each regional ecosystem (RE) within the prescribed environmental matters for regulated vegetation and connectivity areas. For the location of impact, multiple figures that reference only the areas of the prescribed environmental matters that are being impacted by the resource activity, is preferable.

8.1.3 Response

A revised Table H2 has been prepared providing a breakdown of the area of each regional ecosystem (RE) for each of the Prescribed Environmental Matters (Table 5).

Table 5: Significant Residual Impacts to Prescribed Environmental Matters

Prescribed Environmental Matter	Description		Maximum Extent of Impact (ha)		Figure
Regulated Vegetation	Of concern regional ecosystem	RE 11.3.2	2.57		Figure 7
	Regional ecosystems within a defined distance of a vegetation management watercourse	RE 11.5.2	31.01	58.32	Figure 8
		RE 11.3.2	0.59		
		RE 11.7.2	17.82		
		RE 11.3.25	8.9		
Connectivity Areas		RE 11.3.2	3.15	710.7	Figure 9
		RE 11.3.25	21.85

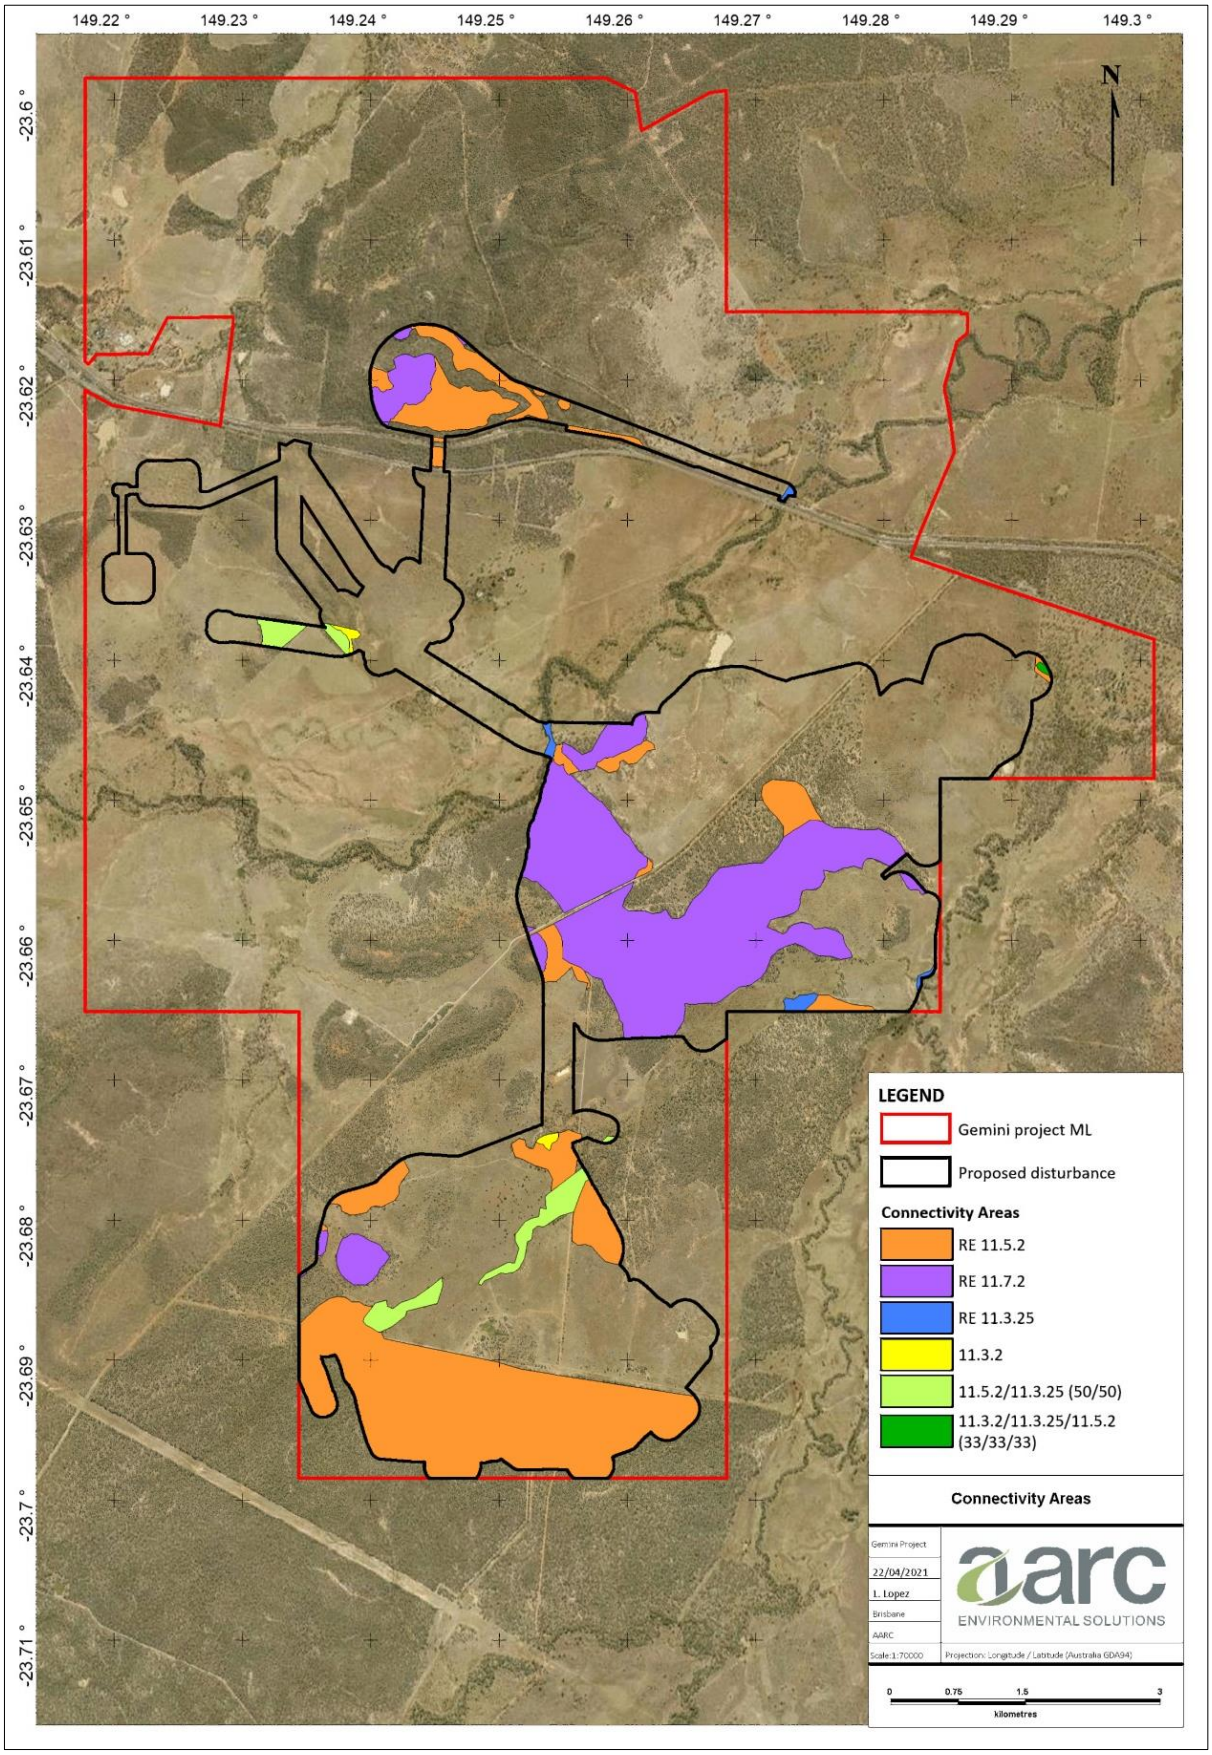

Figure 9: Connectivity Areas

9 Aquatic ecology

9.1 Environmental Values for water quality

9.1.1 DES Comment

Section 4.1 states: "EHP identifies ten EVs in the Mackenzie River (2013b) sub- basin. Two of these are deemed relevant for the waters surrounding the study area: 1. protection of aquatic ecosystem values; and 2. suitability for stock watering." Discussion about the other eight (8) EVs for waters listed in the Environmental Protection (Water) Policy 2009 has not been addressed to provide sufficient explanation for why only two (2 EVs are relevant. Please also note, the original application for Gemini Project was submitted on 23 October 2019. Environmental Protection (Water) Policy 2009 was superseded by Environmental Protection (Water and Wetland Biodiversity) Policy 2019 (EPP Water 2019) on 1 September 2019. Section 6 of the EPP Water 2019 defines eleven (11) EVs for waters to be enhanced and protected.

9.1.2 DES Requirement

Ensure references to subordinate legislation are current for the time of original submission of the EA application for Gemini Project. Address all EVs for waters providing justification for why they may or may not be relevant.

9.1.3 Response

Section 7.2.3 of the application is to be removed and replaced with the following:

In accordance with section 6 and Schedule 1 of the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* (EPP (Water)), environmental values (EVs) and water quality objectives (WQOs) for the Mackenzie River Sub-basin area are those described in the *Mackenzie River Sub-basin Environmental Values and Water Quality Objectives* document (DES 2011) (Mackenzie River WQOs document). Charlevue Creek and Springton Creek form part of the basin's southern tributaries.

EVs ascribed to the southern tributaries of the Mackenzie River Sub-basin are:

- Protection of aquatic ecosystems (moderately disturbed)
- Suitability for farm supply and use
- Suitability for stock water
- Suitability for human consumption of aquatic foods
- Suitability for primary contact recreation
- Suitability for secondary contact recreation
- Suitability for visual recreation
- Suitability for drinking water
- Suitability for industrial use
- Cultural and spiritual values

A list of WQOs for the environmental values described above is provided in the *Mackenzie River WQOs document*.

10 Air Quality and Greenhouse Gases

10.1 Ambient air quality monitoring data

10.1.1 DES Comment

It is noted from Section 3.3.3.2.1 of Appendix L that air quality data from Department of Environment and Science (the department) monitoring station in Blackwater has been used to provide ambient background concentrations. Section 9.2.3.1 of Revised Supporting Information states that data from the department's monitoring station in Blackwater adequately accounts for potential cumulative contributions from surrounding industry, including Bluff Coal Mine. Bluff Coal Mine is 12 kilometres (km) from Gemini Project. Blackwater is located a further 23km west of Bluff Coal Mine, i.e., a total of 35 km from Gemini Project. Ambient background concentrations measured at Blackwater would, therefore, not be representative of the ambient air quality at Gemini, which is a lot closer to Bluff, for example, than Bluff is to Blackwater. Gemini Project is also located in a different direction from Bluff than Blackwater, and therefore, ambient air quality as influenced by prevailing winds, for example, would be quite different.

Section 9.2.3.1 also states that Bluff Coal Mine is currently in care and maintenance with no certainty of return to operations. Therefore, it is not clear if air quality modelling for Gemini Project has accounted for the worst case scenario which assumes Bluff Coal Mine is operating at full capacity at the same time as Gemini Project.

10.1.2 DES Requirement

Explain how Blackwater monitoring data is expected to adequately account for the potential contributions to existing air quality and adequately represent cumulative impacts to air quality in the assessment model, with particular reference to Bluff Coal Mine.

10.1.3 Response

An explanation for how the Blackwater monitoring data adequately accounts for potential contributions to air quality, and adequately represent cumulative impacts to air quality in the assessment model, is provided below. Refer to Item 1 in the *Response to Further Information Request: Gemini Project: Air Quality and Greenhouse Gas Assessment* (Katestone, May 2021) (Air Quality Technical Memorandum) (Appendix E)) for further detail.

10.1.3.1 Period of data available for analysis

DES commenced monitoring PM10 and PM2.5 at Bluff in November 2020. Consequently, there is insufficient data available from DES's Bluff monitoring station to adequately characterise air quality. The Bluff Coal Mine is currently in care and maintenance with no certainty of return to operation.

At the time of the current Air Quality and Greenhouse Gas Assessment (Katestone, Dec 2020) (AQGGA), DES's Blackwater monitoring station was the closest monitoring station to the Project which had more than 12 months of PM10 and PM2.5 data available for analysis.

10.1.3.2 Proximity to other mines

The Blackwater monitoring station is located approximately 35 km west of the project and is surrounded by five mines located between 6km and 18km from the station, with three of the mines located within 11km. Those three mines are estimated to have emitted 21,242 tonnes of PM10 to air for the 2019/2010 based on NPI reporting.

The Bluff monitoring station is located within 1km of the Bluff Coal Mine. There are no other mines located within 11km of the Bluff monitoring station. The Gemini Project has only one mine within 11km and that is the Bluff Coal Mine, located 11km to the west. The Bluff Coal Mine was estimated to have emitted 1,098 tonnes of PM10 to air for the 2019/2020 reporting period.

10.1.3.3 Wind direction

The Bluff Coal Mine is located approximately 11km to the west of the Project site. As detailed in Appendix A of the AQGGA and shown in Figure 10 and Figure 11 of this report, the meteorological data for the Gemini Project illustrates that winds occur infrequently from the west (less than 8% of the time).

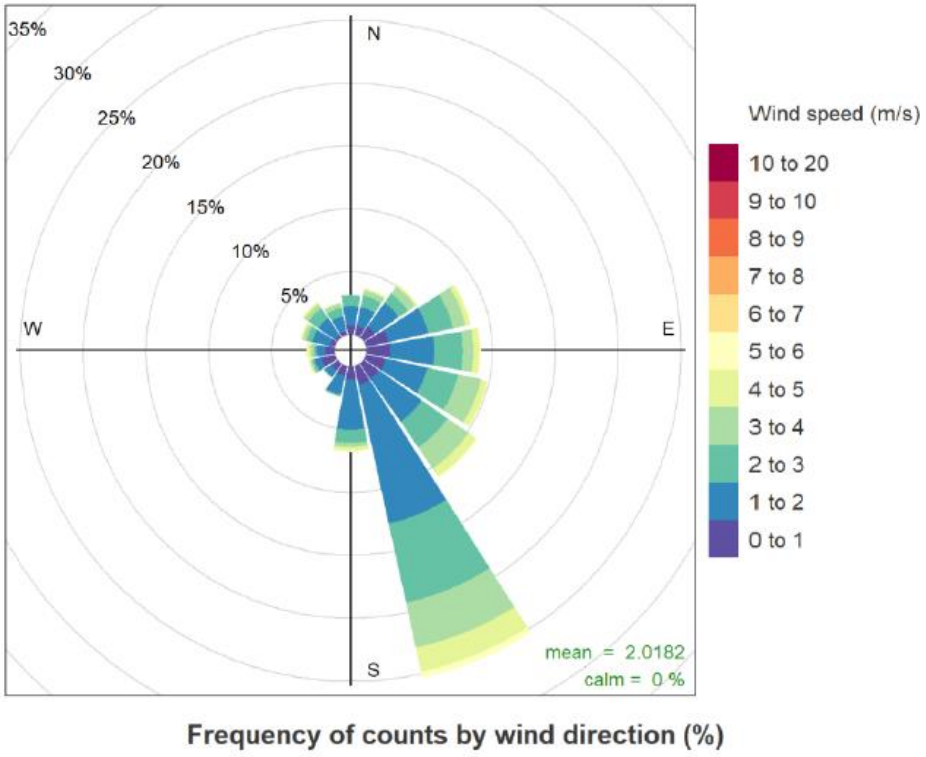

Figure 10: Annual distribution of winds at the Project site predicted by TAPM/CALMET

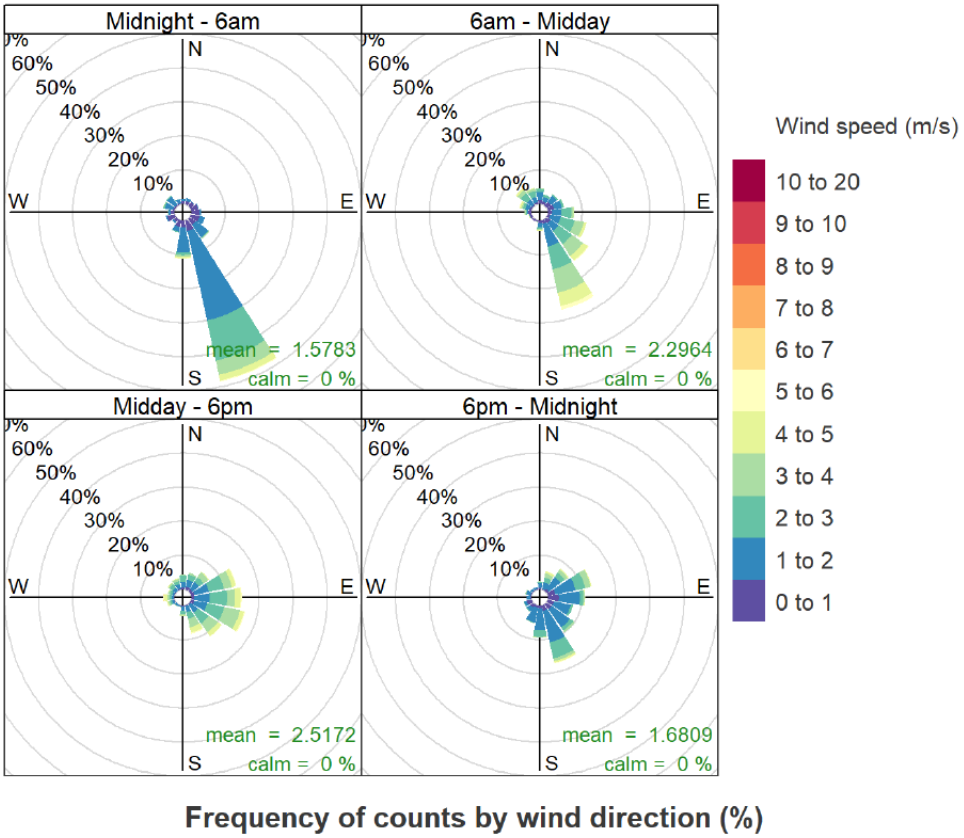

Figure 11: Seasonal distribution of winds at the Project site predicted by TAPM/CALMET

10.1.3.4 Summary

In summary, DES's Blackwater monitoring station is expected to adequately account for the potential contribution from the Bluff Coal mine on sensitive receptors near to the Gemini Project for the following reasons:

- There are three mines located within 11km of Blackwater monitoring station, which are closer than the Bluff Coal Mine is to the Gemini Project.
- The emissions to air from those mines are estimated to be 20 times higher than the emissions from the Bluff Coal Mine.
- Given the low frequency of the winds from the west and distance from Bluff Coal mine to the Gemini Project, it is unlikely that Bluff Coal mine will contribute significantly to dust at the sensitive receptors surrounding the Gemini Project.

10.2 Impact of revised mine camp location

10.2.1 DES Comment

The list of main activities (included in Section 2 and Table 7 in Section 3.4.4) associated with Gemini Project does not include "workers' accommodation and associated infrastructure (camp access road, sewage treatment plant, sewage pipeline and effluent irrigation management area)" as proposed by the written notice of changed application and the revised conceptual mine layout. Furthermore, workers' accommodation and associated infrastructure was not included as key dust-generating activities for Gemini Project (Section 3.4.1). It is noted that these activities were not considered as a source in air quality modelling and assessment in the original EA application submission. However, given the changed application,

it is not clear how the revised mine layout has the potential to impact the EVs of air at nearby sensitive receptors.

10.2.2 DES Requirement

Provide justification for why workers' accommodation and associated infrastructure, which includes camp access road, sewage treatment plant, sewage pipeline and effluent irrigation management area, has been excluded as sources from the air quality modelling and assessment. Demonstrate how the EVs of air will be enhanced or protected given the change to the conceptual mine layout.

10.2.3 Response

The AQGGA completed in December 2020 was undertaken using the revised mine layout (as shown in Figure 2 of the AQGGA). There have been no subsequent changes to the conceptual mine layout.

In response to this information request, further assessment has been undertaken to justify why the workers accommodation and associated infrastructure (camp access road, sewage treatment plant, sewage pipeline and effluent irrigation management area) have not been included in the air quality model (refer to Item 2 in in the Air Quality Technical Memorandum) (Appendix E)). The assessment deemed these sources too insignificant to be able to differentiate in the model. A summary of the key findings of the assessment is provided below.

10.2.3.1 Camp and access road

The workers accommodation camp is now located to the northwest corner of the ML, south of the highway. As shown in Figure 1 the nearest sensitive receivers (SR) to the revised mine camp location are SR22, SR31 and SR32. The revised camp location is approximately 1km south of sensitive receiver SR22, 1.5km east of sensitive receiver SR31 and 2km south east of SR32.

The camp access road to the workers' accommodation and to the mine infrastructure area will be sealed.

Traffic projections indicate that during peak operations there will be 122 trips per day when light vehicles will travel from the highway to the workers' accommodation camp, which is a distance of 0.45km, and five trips per day when the mine bus transports workers from the accommodation camp to the mine infrastructure area, which is a distance of 1.65km.

Emissions of TSP, PM10 and PM2.5 are estimated to be 0.23g/s, 0.04g/s and 0.01g/s, respectively. This is negligible, being less than 0.3% of emissions generated from the mining operations. Inclusion of these emissions would not change the outcome of the assessment.

10.2.3.2 Sewage Treatment Plant and effluent irrigation management area

The proposed STP and the effluent irrigation area are located approximately 1.5km east of sensitive receiver SR31, 2.1km south east of SR32 and 750m south of SR22.

It is estimated that during operation, up to 140 workers may be accommodated on site, and during construction up to 280 workers may be accommodated on site. The STP will be designed for a 280 EP maximum capacity (56,000 L/day). The STP will be a modular containerised design with very low odour emissions, designed in accordance with AS/NZS 1546.1:2008. This is conventional technology that is widely deployed throughout Queensland with minimal odour issues.

The following management measures will be implemented to manage aerosol drift, odour nuisance and potential impacts to human health as a result of effluent irrigation activities:

- Irrigation volumes have been designed to prevent surface run-off.
- Irrigation will cease in significant rainfall events when there is the risk of surface runoff.

- Spray drift control (low-throw sprinklers - 180º inward throw).
- Irrigation will be restricted when wind direction is not favourable, or temperature inversions present.
- Suitable wet weather storage (3 days) is to be provided in tanks, to prevent potential overflow events.

Given the STP design, proximity to nearest receptors and management measures to be put in place, it is not anticipated that there will be any impacts associated with aerosol drift and odour nuisance at the nearest sensitive receivers.

10.3 Impact to sensitive receivers SR31 and SR32

10.3.1 DES Comment

Table 2 lists sensitive receptors surrounding the project. The property name for SR31 and SR32 is “unknown”. It is not clear if the revised conceptual mine layout affects and alters the impacts to air quality at these sensitive receptors from the original application.

10.3.2 DES Requirement

Provide more information about SR31 and SR32 and the potential impacts to air at these locations given the change to the conceptual mine layout.

10.3.3 Response

SR31 and SR32 are private homesteads located on Lot 1RP61678, shown in Queensland Globe as being the ‘Dunbea’ property. As outlined in Section 10.2, given the distance of the revised camp accommodation and associated infrastructure from these receptors, and the controls to be implemented (road sealing, STP design and effluent irrigation management measures), the assessment predicts no adverse impact on environmental values at these sensitive receivers.

10.4 Emission quantities over years of mine

10.4.1 DES Comment

Table 7 presents the list of activities that will create dust emissions and provides estimates of the quantity (kg/year) of emissions that will be produced during mine operational year 2, 5 and 15. However, it is not clear how this data has been applied to conclusions of the air quality assessment.

10.4.2 DES Requirement

Provide a summary or conclusion that interprets the data in Table 7 to help provide understanding of how the emission quantities differ between years of mine operation and explain what might cause differences.

10.4.3 Response

Table 7 of the AQGGA presents the emissions to air (kg/year) of TSP, PM10 and PM2.5 per year for each mining activity (for example blasting, drilling, hauling of ROM, wind erosion). The emission rates of TSP, PM10 and PM2.5 for each activity are proportional to the activity rate for each year (as summarised in Appendix D of the AQGGA. For example, emissions of TSP from haul trucks are proportional to vehicle kilometres travelled. In Year 2 91,440 vehicle kilometres are travelled within 6 months to transport ROM coal from the pit to the CHPP, whereas in Year 15 289,108 vehicle kilometres are travelled over 12 months. The

haul distance in Year 15 is 1.6 times higher than in Year 2 when taking into account period over which the haulage is undertaken. This is reflected in the emission rates in that for Year 15 it is estimated that 365,959 kg/year of TSP is emitted due to ROM coal haul compared to Year 2 where it is estimated 231,494 kg/year of TSP is emitted.

It can be seen from Table 7 of the AQGGA that overall emissions of dust are highest in Year 15. This is predominately due to emissions associated with ROM haulage and overburden haulage as well as wind erosion of rehabilitation areas. In Year 15, haul distances are the longest due to location of the pit relative to the CHPP and dumps (refer to Appendix D Table B1 of the AQGGA). In Year 15, the area assigned for rehabilitation is the greatest due to it being the year when there is the most land available for rehabilitation (refer to Appendix D Table B1 of the AQGGA).

10.5 Meteorological data used in modelling

10.5.1 DES Comment

The Air Pollution Model (TAPM) was configured using meteorological data from 2016. Configuring TAPM based on one year of historical 24-hourly data is acceptable if that year represents the worst case scenario.

10.5.2 DES Requirement

Explain and demonstrate that meteorological data from 1 January 2016 to 31 December 2016 represents the worst case meteorological conditions, very low rainfall and strong windy conditions, compared to 5 years of hourly site meteorological data.

10.5.3 Response

Meteorological modelling was conducted using the TAPM/CALMET modelling approach (refer to Appendix A of the AQGGA). This was conducted in accordance with standard industry practice.

In terms of “worst case”, the AQGGA assesses the worst-case in terms of emissions of dust to air from the proposed mining activities. For meteorology, strong wind conditions do not necessarily correlate with worst case impacts from a mining activity. For example, strong winds may give rise to dust lift off, but strong winds also help disperse the dust. Very light to calm winds on the other hand can result in elevated dust concentrations due to poor mixing and dispersion of emissions sources such as haul dust. It is important that the meteorological data that is used for the site is representative of average conditions for dust assessments.

The year 2016 was chosen as the most recent year at the time of the commencement of the assessment. Notwithstanding this, an analysis of five years of meteorological data from the Bureau of Meteorology’s station at Blackwater has been conducted. Figure 11 presents annual windroses for 2015 to 2020. Wind frequencies including the frequency of strong winds are consistent between the years. There is very little difference in average wind speeds. Therefore, the choice of 2016 as the meteorological year is adequate.

The regulatory emission estimation techniques cannot account for the effect of rainfall on dust emissions. The emissions model uses average material moisture contents. Whilst the dispersion model can characterise the effect of rainfall to reduce dust levels in the atmosphere (wet deposition), it has been conservatively assumed that rainfall does not remove dust from the atmosphere. This results in higher predicted dust levels rather than lower.

Therefore, the choice of a year with high or low rainfall does not affect the outcomes of this assessment.

11 Noise

11.1 Impact of revised mine camp location

11.1.1 DES Comment

The list of main activities associated with Gemini Project does not include "workers' accommodation and associated infrastructure (camp access road, sewage treatment plant, sewage pipeline and effluent irrigation management area)" as proposed by the written notice of changed application and the revised conceptual mine layout. It is noted that these activities were not considered as a source in noise quality modelling and assessment in the original EA application submission. However, given the changed application, it is not clear how the revised mine layout has the potential to impact the EVs of noise at nearby sensitive receptors.

11.1.2 DES Requirement

Provide justification for why workers' accommodation and associated infrastructure, which includes camp access road, sewage treatment plant, sewage pipeline and effluent irrigation management area, has been excluded as sources from the noise modelling and assessment. Demonstrate how the EVs of noise will be enhanced or protected given the change to the conceptual mine layout.

11.1.3 Response

In response to the secondary information request, a revision to the Noise Impact Assessment (NIA) has been prepared (Appendix F), which includes the workers' accommodation and associated infrastructure. As outlined in Table 1.1 of the revised NIA the following noise sources have been added:

- Vehicles on camp access road
- Air-conditioning units and people talking at the camp
- Sewerage Treatment Plant (STP)
- Pumping at the irrigation management area.

Details of the additional modelled noise source data is provided in Table 6.2 and 6.3 of the revised NIA (Appendix F).

Inclusion of these additional noise sources did not result in any new exceedances of criteria. However, there were slight increases to the predicted noise outcomes at the nearest sensitive receivers. Exceedances for night-time scenarios N1 and N2 at SR10 in Mine Year 8 increased slightly from 38dBA to 39dB, (refer to Table 6.7 of the revised NIA). There were also slight increases at other sensitive receivers, but as the increase was minimal (less 0.5dB) no other updates were required for Tables 6.6 – 6.8 of the NIA.

A number of operational scenarios have previously been modelled to demonstrate that changes to mining operations (i.e. reduction in the number of machines in operation) can be implemented to prevent exceedances and ensure that compliance can be achieved at all sensitive receivers. Mitigation measures previously proposed for SR10 in Mine Year 8 were already more than sufficient to ensure night-time compliance at this location. Updates to the modelled mitigation measures were therefore not required. However, to achieve night-time compliance at SR10 and SR22 in Year 2, modelling indicate an additional 2 trucks may need to be temporarily shut down during high risk conditions in order to achieve compliance (refer to Table 8.1 of the revised NIA). It should be noted that the scenarios presented in Table 8.1 should be considered examples only, and other acoustically equivalent scenarios may be developed.

As outlined in section 8.4 of the NIA, real time noise monitoring will be undertaken at the most noise affected receptors (i.e. SR10 and SR22) prior to mining commencing. A noise monitoring survey will be then conducted at the commencement of operations to verify noise emissions for the Project and the level of noise impact at sensitive receptors. Real time noise monitoring will be implemented throughout mine operations to track noise trends, develop appropriate mitigation strategies and react to potential noise exceedances, should they occur.

11.2 Sensitive receivers SR31 and SR32

11.2.1 DES Comment

Table 2.1 lists sensitive receptors surrounding the project. The real property description for SR31 and SR32 is not provided. It is not clear if the revised conceptual mine layout affects and alters the impacts to noise at these sensitive receptors from the original application.

11.2.2 DES Requirement

Provide more information about SR31 and SR32 and the potential impacts to the EVs of noise at these locations given the change to the conceptual mine layout.

11.2.3 Response

SR31 and SR32 are private homesteads on Lot 1 on RP61678. An assessment of the noise impact at these sensitive receivers, including the camp and associated infrastructure, has been included in the revised NIA. Refer also to Section 11.1.3.

µS/cm	microSiemens per centimetre

1.0 INTRODUCTION

AARC Environmental Solutions (AARC) was commissioned by Magnetic South Pty Ltd (Magnetic South; the Proponent) to prepare an environmental authority (EA) application for the Gemini Project (the Project). This report provides the supporting information to be considered as part of the EA Application to the Department of Environment and Science (DES) in consideration of Sections 125 and 126A of the *Environmental Protection Act 1994* (EP Act).

This document provides a description of the Project, environmentally relevant activities (ERAs), environmental values (EVs), potential impacts of the ERAs on the identified EVs, and mitigation measures and management commitments.

1.1 THE PROPONENT

The Proponent for the Gemini Project is:

Magnetic South Pty Ltd

Suite 302, Level 3, 102 Adelaide Street, Brisbane, Queensland, 4000

ABN: 95 122 465 749

ACN: 122 465 749

Magnetic South is a private Australian based company which was founded in 2006. The executive team of Magnetic South has some 60 years' experience in the development and operation of metallurgical coal assets and agribusiness in central Queensland.

Magnetic South is the registered entity proposing to carry out the Project, and all permits and licences are held and will be issued to that entity.

1.2 ENVIRONMENTAL IMPACT STATEMENT TRIGGERS

The proposed EA Application does not trigger the requirement for an Environmental Impact Statement (EIS) under the EP Act. The Project does not propose any petroleum or coal seam gas activities. EIS triggers for a new application for mining activities are summarised below in Table 1.

1.3 CONTENT OF SUPPORTING INFORMATION

In accordance with Section 125 and 126A of the EP Act, this document includes the information described in Table 2.

1.4 ENVIRONMENTALLY RELEVANT ACTIVITIES

ERAs include resource activities or specific agricultural activities or other activities as defined by the EP Act. Current prescribed ERAs and resource activities are specified in Schedules 2 and 3, respectively, of the *Environmental Protection Regulation 2019* (EP Regulation). The Project will include the resource activity of "mining black coal" as well as the ancillary activities outlined in Table 3 which require approval as part of the EA Application.

1.5 NOTIFIABLE ACTIVITIES

Notifiable activities are activities that have the potential to cause land contamination. The notifiable activities listed under Schedule 3 of the EP Act relevant to the Project are provided in Table 4.

Table 1 EIS Trigger Criteria

EIS Trigger	Yes / No
For greenfield (new) mine proposals	
Would the application involve the removal of two million tonnes per year or more of run-of-mine (ROM) ore or coal?	**No.** The Gemini Project is proposing the removal of up to 1.9 Mtpa of ROM coal, averaging 1.8 Mtpa over the production life of the Project.
Would the application involve the removal of one million tonnes per year or more of ROM ore or coal on or under a floodplain or in a coastal hazard area?	**No.** The Gemini Project is not proposing the removal of 1 Mtpa or more of ROM coal under a floodplain as defined by the *Water Act 2000*.The Gemini Project is not located in a coastal hazard area.
Would the application involve the introduction of a novel or unproven resource extraction process, technology or activity?	**No.** The Gemini Project is proposing a traditional truck and shovel operation, and proven processing approach.

Table 2 EP Act Requirements for Supporting Information

Component	Relevant Section
Section 125 – Requirements for applications generally	
Description of all environmentally relevant activities for the application.	Section 1.4 and Table 3
Description of any development permit under the Planning Act, or State Development Area approval under the State Development Act required for carrying out the environmentally relevant activities for the application.	No approvals are required under the *Planning Act 2016* or *State Development and Public Works Organisation Act 1971*.
Description of the land on which each activity will be carried out.	Section 5.0
Assessment of the likely impact of each relevant activity on environmental values, including: • a description of the environmental values likely to be affected by each relevant activity; • details of any emissions or releases likely to be generated by each relevant activity; • a description of the risk and likely magnitude of impacts on the environmental values; • details of the management practices proposed to be implemented to prevent or minimise adverse impacts; and • details of how the land, the subject of the application will be rehabilitated after each relevant activity ceases.	EVs, emissions or releases, risk and magnitude of impacts, and proposed management practices are detailed within each 'environmental' section. This constitutes Section 5.0 through to Section 13.0. Section 4.0
Description of the proposed measures for minimising and managing waste generated by each relevant activity.	Section 12.5 and Section 12.7
Details of any site management plan that relates to the application.	Details of relevant management plans are covered in the *Mitigation Measures, Management and Monitoring* subsection of each 'environmental' section (Section 5.0 through to Section 13.0).
Section 126A – Requirements for site-specific applications – particular resource projects and resource activities	
Any proposed exercise of underground water rights during the period in which resource activities will be carried out under the relevant tenure.	Section 8.3
The areas in which underground water rights are proposed to be exercised.	Pit AB and Pit C mining areas as specified in the conceptual layout (Figure 7) and mine stage plans (Figure 23 through to Figure 32).
For each aquifer affected, or likely to be affected, by the exercise of underground water rights: • a description of the aquifer; • an analysis of the movement of underground water to and from the aquifer, including how the aquifer interacts with other aquifers and surface water; • a description of the area of the aquifer where the water level is predicted to decline because of the exercise of underground water rights; and • the predicted quantities of water to be taken or interfered with because of the exercise of underground water rights during the period in which resource activities are carried out.	Section 8.2.1 Section 8.2.4 and Figure 71 Section 6.3.1 and Section 6.4.1 Section 8.3.3, Figure 74 and Figure 75 Table 12 and Table 13.
The environmental values that will, or may, be affected by the exercise of underground water rights and the nature and extent of the impacts on the environmental values.	Section 8.2 Section 8.3.3 and Section 8.3.4
Any impacts on the quality of groundwater that will, or may, happen because of the exercise of underground water rights during or after the period in which resource activities are carried out.	Section 8.3.3
Strategies for avoiding, mitigating or managing the predicted impacts on the environmental values or the impacts on the quality of groundwater.	Section 8.4

Table 3 Applicable ERAs for the Project

Environmentally Relevant Activity	Description
Schedule 2 (Prescribed ERAs)	
8 (1) (c) Chemical storage	Chemical storage (the relevant activity) consists of storing more than 500 m^3 of class C1 or C2 combustible liquids under AS1940 or dangerous goods class 3. Threshold 3) Storing more than 500 m^3 of chemicals of class C1 or C2 combustible liquids under AS1940 or dangerous goods class 3 under subsection (1)(c). *Aggregate Environmental Score: 85*
31 (1) Mineral processing	Mineral processing (the relevant activity) consists of processing, in a year, a total of 1,000t or more of coke or mineral products. Threshold 2) Processing, in a year, the following quantities of mineral products, other than coke (b) more than 100,000 t. *Aggregate Environmental Score: 280*
33 (1) Crushing, milling, grinding or screening	Crushing, milling, grinding or screening (the relevant activity) consists of crushing, grinding, milling or screening more than 5,000 t of material in a year. Threshold Crushing, grinding, milling or screening more than 5,000 t of material in a year. *Aggregate Environmental Score: no score*
60 (1)(ii)(A) Waste disposal	Waste disposal (the relevant activity) consists of operating a facility for disposing of general waste and a quantity of limited regulated waste that is no more than 10% of the total amount of waste received at the facility in a year. Threshold 2) Operating a facility for disposing of, in a year, (h) more than 200,000 t. *Aggregate Environmental Score: 107*
63 (1)(b)(i) Sewage treatment	Sewage treatment (the relevant activity) consists of operating 1 or more sewage treatment works at a site that have a total daily peak design capacity of at least 21EP. Threshold 1) Operating sewage treatment works, other than no-release works, with a total daily peak design capacity of (b) more than 100 but not more than 1500 EP (i) if treated effluent is discharged from the works to an infiltration trench or through an irrigation scheme. *Aggregate Environmental Score: 27*
Schedule 3 (Resource Activity)	
13 Mining black coal	*Aggregate Environmental Score: 128*

Table 4 Notifiable Activities For the Project

Notifiable Activities	Description
Schedule 3	
1 Abrasive Blasting	Carrying out abrasive blast cleaning (other than cleaning carried out in fully enclosed booths) or disposing of abrasive blasting material.
7 Chemical Storage	Storing more than 10 t of chemicals (other than compressed or liquefied gases) that are dangerous goods under the dangerous goods code.
15 Explosives production or storage	Operating an explosives factory under the *Explosives Act 1999.*
24 Mine Wastes	a) storing hazardous mine or exploration wastes, including, for example, tailing dams, overburden or waste rock dumps containing hazardous contaminants; or b) exploring for, or mining or process, minerals in a way that exposes faces, or releases groundwater, containing hazardous contaminants.
29 Petroleum Product or Oil Storage	Storing petroleum products or oil: a) in underground tanks with more than 200 litre (L) capacity; or b) in above ground tanks with: I. for petroleum products or oil in class 3 in packaging groups 1 and 2 of the dangerous goods code – more than 2,500 L capacity; or II. for petroleum products or oil in class 3 in packaging groups 3 of the dangerous goods code – more than 5,000 L capacity; or III. for petroleum products that are combustible liquids in class C1 or C2 in *Australian Standard AS1940 The storage and handling of flammable and combustible liquids* published by Standards Australia – more than 25,000 L capacity.
37 Waste Storage, treatment of disposal	Storing, treating, reprocessing or disposing of waste prescribed under a regulation to be regulated waste for this item (other than at the place it is generated), including operating a nightsoil disposal site or sewage treatment plant where the site or plant has a design capacity that is more than the equivalent of 50,000 persons having sludge drying beds or on-site disposal facilities.

2.0 PROJECT LOCATION, SETTING AND TENURE

2.1 LOCATION AND SETTING

The Project is situated within the Bowen Basin, approximately 110 km east of Emerald and 125 km southwest of Rockhampton, in central Queensland (Figure 1). Blackwater, a larger town serving mines in the region, is located approximately 34 km to the west (Figure 1). The small rural townships of Bluff and Dingo are located approximately 15 km west and 3 km east of the Project, respectively (Figure 1).

The Project is located within the Central Highlands Regional Council (CHRC) local government area (LGA), which covers approximately 60,000 km^2 and supports a population of more than 30,000 residents living in Arcadia Valley, Bauhinia, Blackwater, Bluff, Capella, Comet, Dingo, Duaringa, Emerald, Rolleston, Sapphire Gemfields, Springsure and Tieri.

Nearby mining operations include Bluff PCI Project (approximately 12 km to the west), Yarrabee Coal Mine (approximately 34 km to the northwest), Jellinbah Mine (approximately 32 km to the northwest), Curragh Coal Mine (approximately 33 km to the northwest), and the Blackwater Mine (approximately 36 km to the southwest) (Figure 2). It is noted the Bluff Mine is currently in care and maintenance with no certainty of return to operations.

Taunton National Park is situated to the north of the Project's mining lease application (MLA) area, whilst Walton State Forest is approximately 6 km to the west and Blackdown Tablelands National Park is located approximately 9 km to the southwest of the MLA (Figure 2).

The Capricorn Highway, which is a state-controlled road, links Rockhampton with western Queensland (Figure 1). Capricorn Highway traverses the MLA and links the townships of Bluff and Dingo (Figure 2). The Aurizon Blackwater Rail System (Blackwater Railway) tracks along the northern side of the Capricorn Highway (Figure 1 and Figure 2). A stock route (ID: 413CENT) tracks alongside the Capricorn Highway and is currently open but classified as minor and unused.

Publicly gazetted roads including Sanders, Namoi, Charlevue, Cooinda, Red Hill, Normanby and Ellesmere roads provide local access (Figure 2).

The topography of the MLA varies from flat to gently undulating, with elevations ranging between approximately 120-150 metres in Australian Height Datum (mAHD). The MLA and surrounds are currently used for low intensity cattle grazing and resource exploration activities. Land ownership in the vicinity of the Project is described in Section 2.3.2. It is Magnetic South's intention that the land continue to be used for agricultural purposes until such time that it is required for Project construction and/or operation. Land not required for mining activities will continue to be utilised for agricultural purposes throughout the life of the Project.

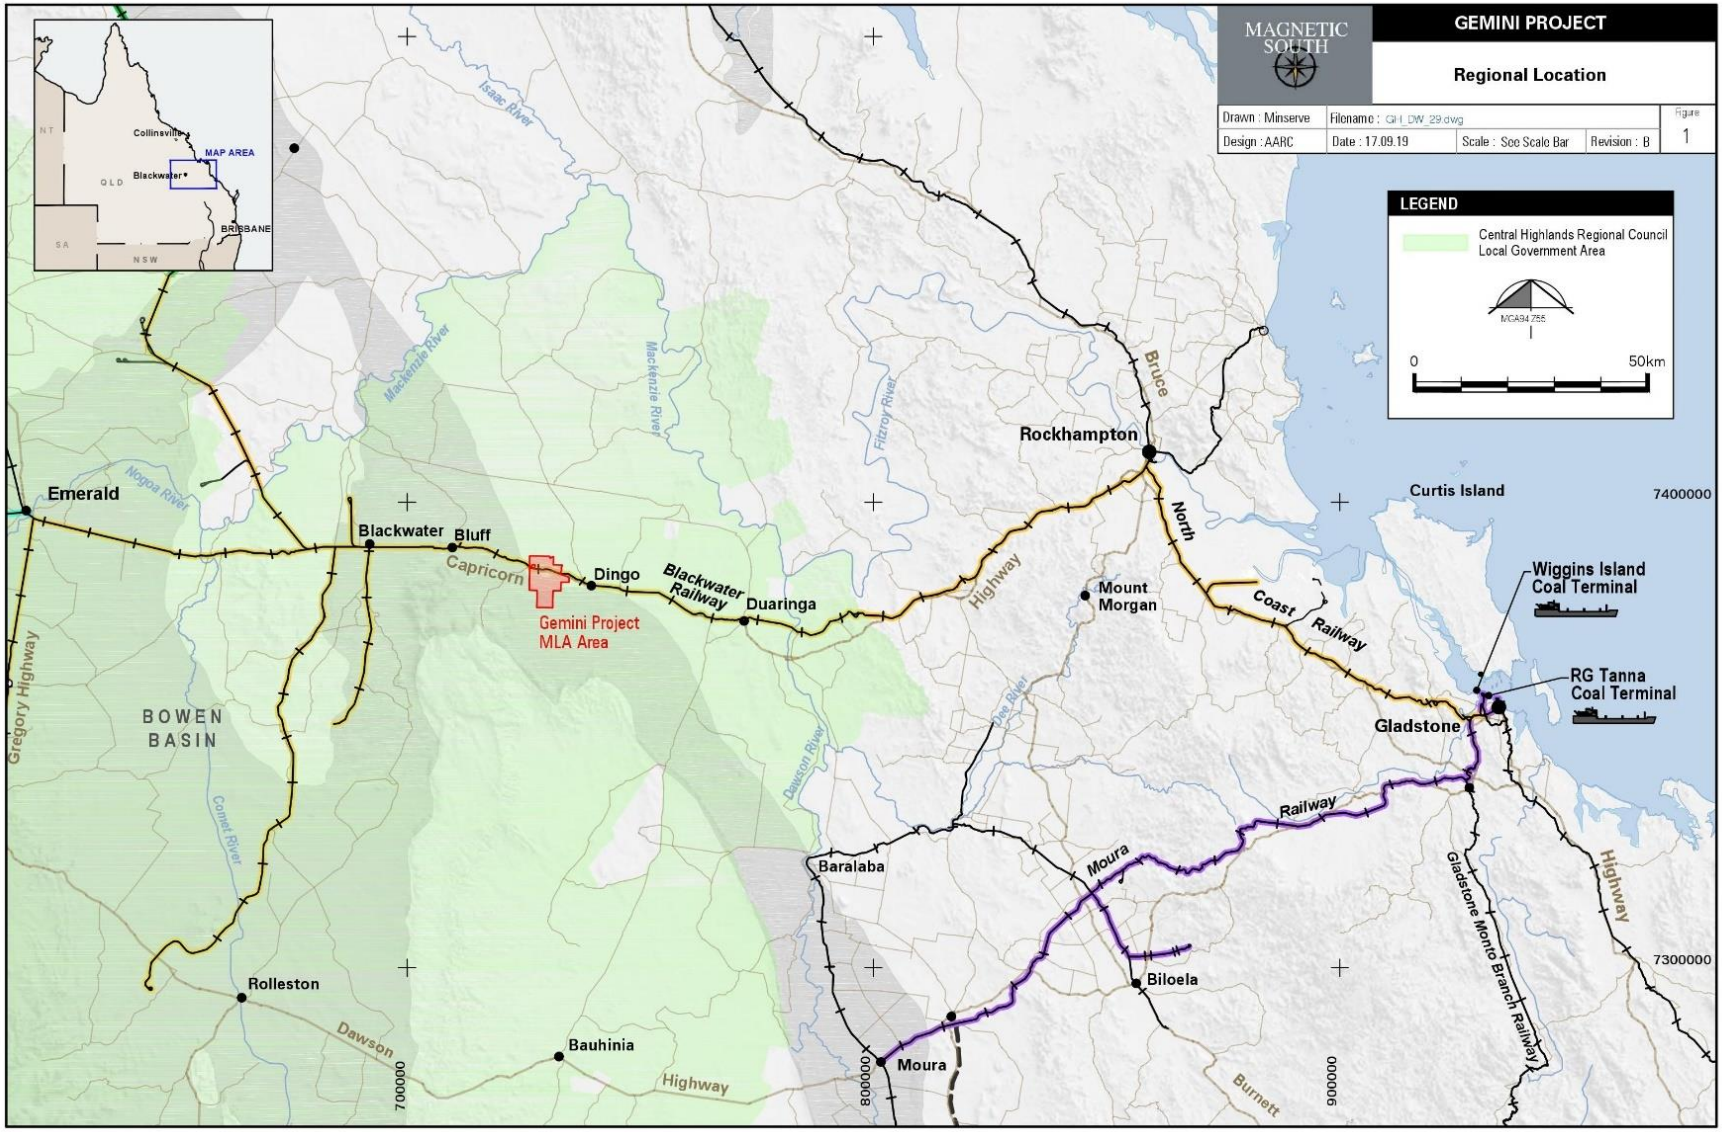

Figure 1 Regional Location

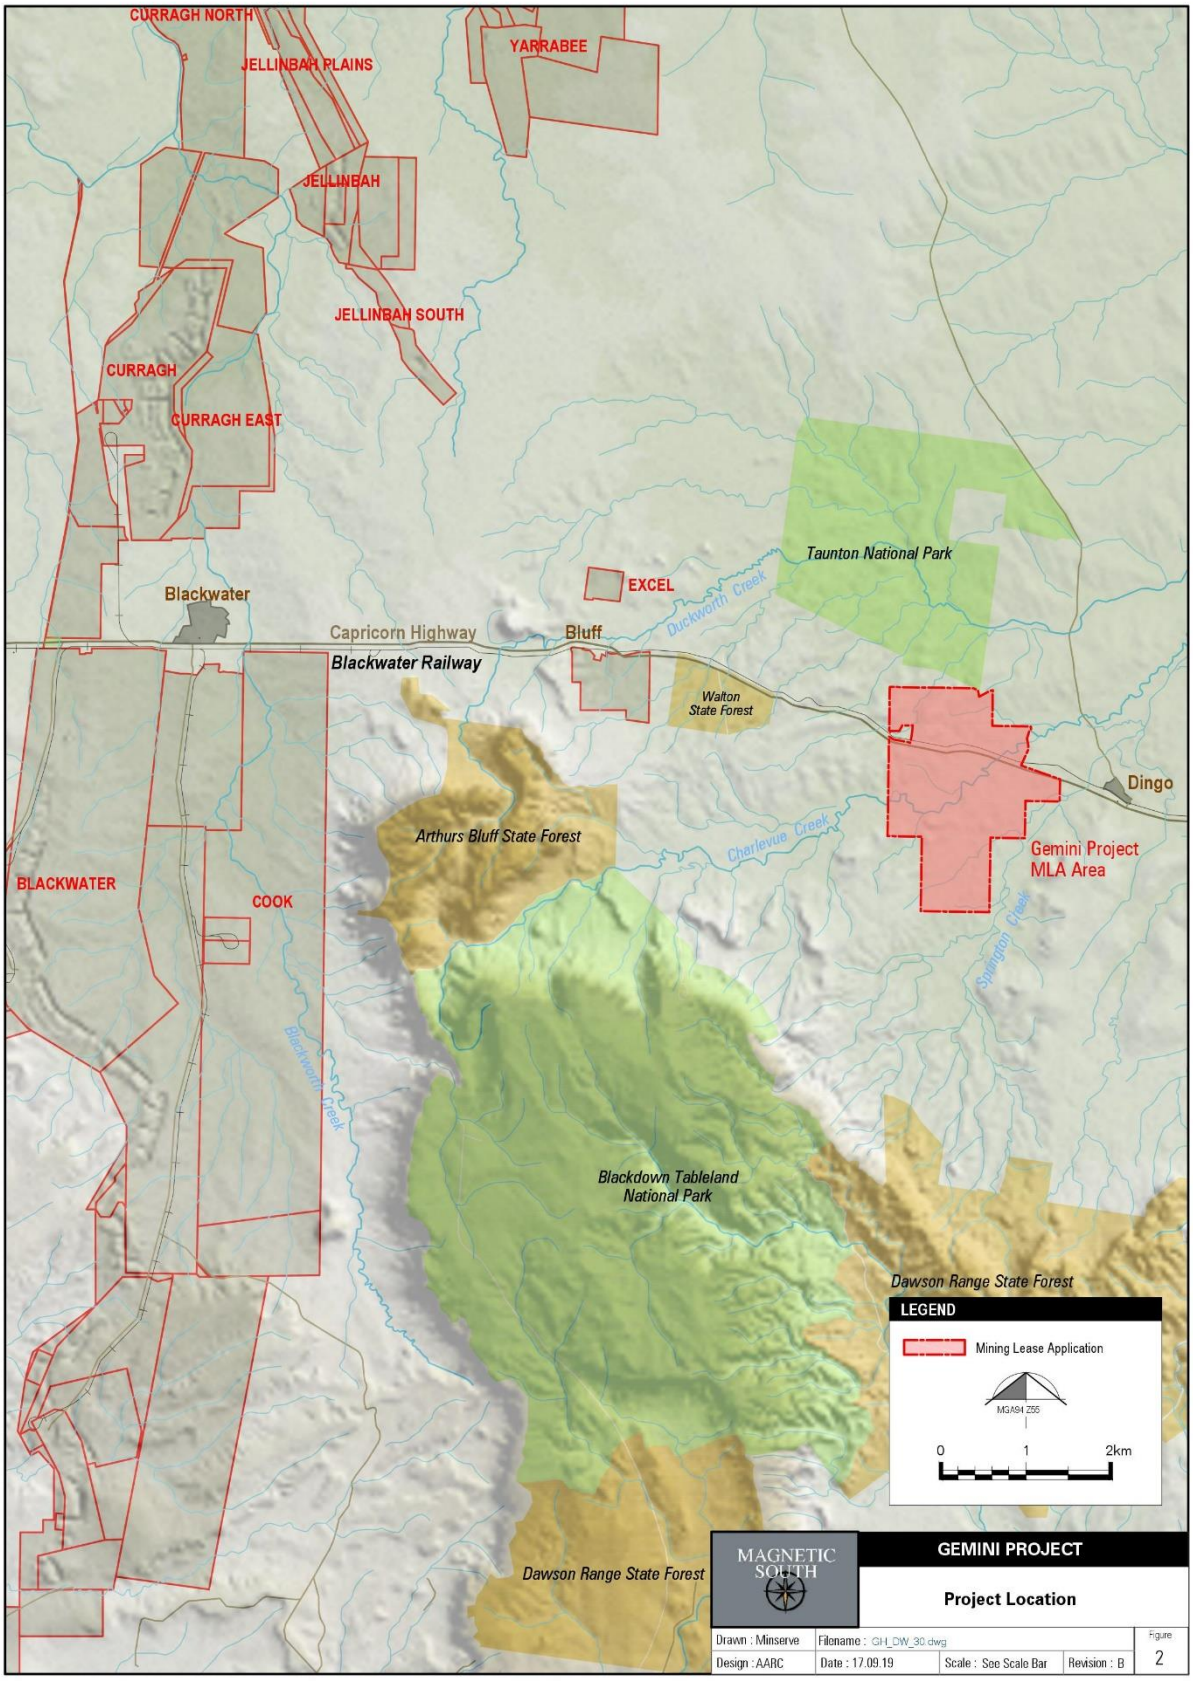

Figure 2 Project Location

2.2 LOCAL METEOROLOGICAL CONDITIONS

The Project area has a climate classification of 'subtropical' (moderately dry winter) using the Bureau of Meteorology's (BoM) modified Köppen climate classification system. The local region experiences a subtropical climate characterised by high variability seasonal rainfall subject to cyclic wet summer and dry winter seasons, with variable temperature and evaporation. Predominantly wind blows from the southeast and east in the region.

Local meteorological conditions have been compiled using data from the Scientific Information for Land Owners (SILO) Data Drill. The Data Drill accesses grids of climate data available from surrounding BoM point observations and then creates interpolated climate values for the requested location. The SILO climate data was obtained for coordinates that correspond to the approximate centre of the Project MLA. The data has been utilised to produce a climatograph for the Project (Figure 3).

The mean annual rainfall for the Project region is approximately 655 mm with average annual (pan) evaporation of 2,024 mm which exceeds rainfall for every month of the year (Table 5). Rainfall is highly seasonal, with November to March generally accepted as the 'wet season' and rainfall during this time accounting for approximately 68% of the region's total yearly rainfall. The 'dry season' usually occurs from April through to October with monthly rainfall totals below 45 mm consistently throughout this period. The rainfall data for this region is consistent with the Köppen classification of 'subtropical' (moderately dry winter).

The hottest months typically occur between October and March while the coolest months occur between May and September. The highest mean maximum temperature typically occurs in January (33.8°C) and the lowest mean minimum temperature in July (7.7°C).

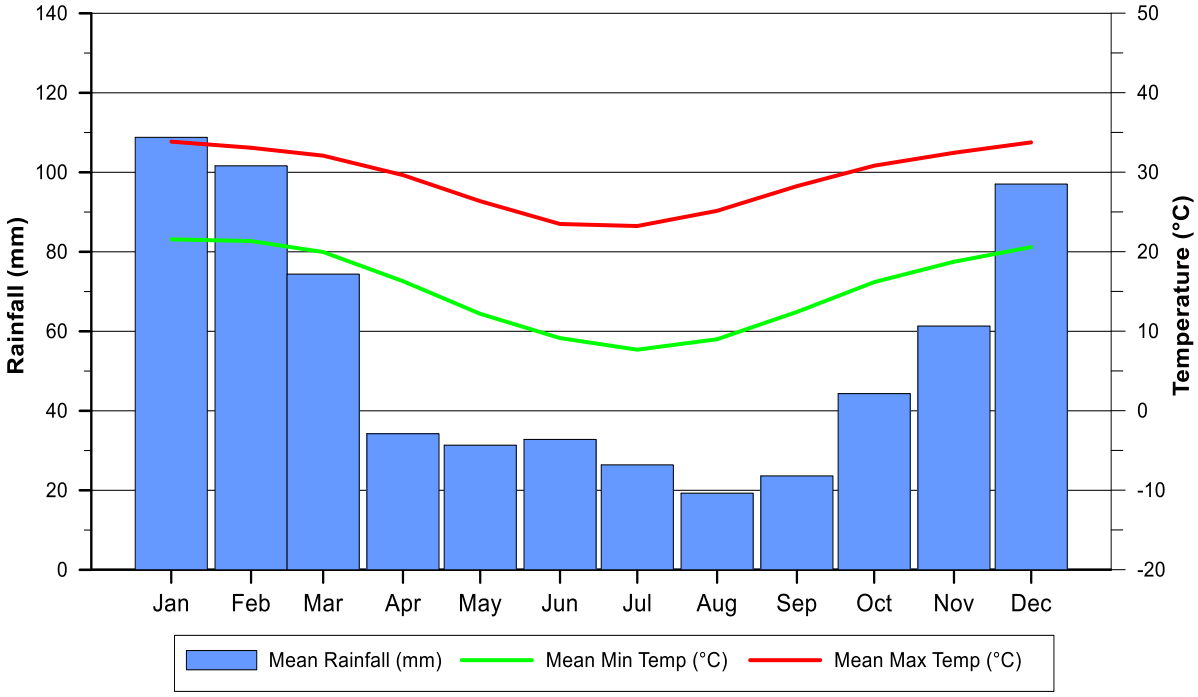

Figure 3 Climatograph

Table 5 Average Monthly Rainfall and Evaporation

Month	Average Rainfall (mm)	Average Evaporation (mm)
January	108.8	229.6
February	101.6	186.4
March	74.4	185.1
April	34.2	150.8
May	31.3	117.7
June	32.8	93.5
July	26.4	101.2
August	19.3	129.9
September	23.6	164.2
October	44.3	207.6
November	61.3	220.2
December	97	237.8
Total	**655.2**	**2,024.1**

2.3 TENURE AND LAND OWNERSHIP

2.3.1 Tenure

The Project is located entirely within the MLA, which is within exploration permit for coal (EPC) 881 held by Magnetic South (Figure 4). The surface rights held by Magnetic South within the MLA are also shown on Figure 4.

Petroleum tenements overlapping the MLA and surrounds include authority to prospect (ATP) 758, ATP 806 and potential commercial area (PCA) 163, PCA 165, and PCA 166 (Figure 5). All of the petroleum tenements are held by OME Resources Australia Pty Ltd, a subsidiary of Queensland Gas Company (QGC). Magnetic South and OME Resources Australia Pty Ltd are parties to a co-development agreement.

Other tenements proximal to the MLA include EPC 960 and mineral development licence (MDL) 505 held by Walton Coal Pty Ltd, EPC 769 held by Peabody Capricorn Pty Ltd, and EPC 1859 held by Area Coal Pty Ltd (Figure 4).

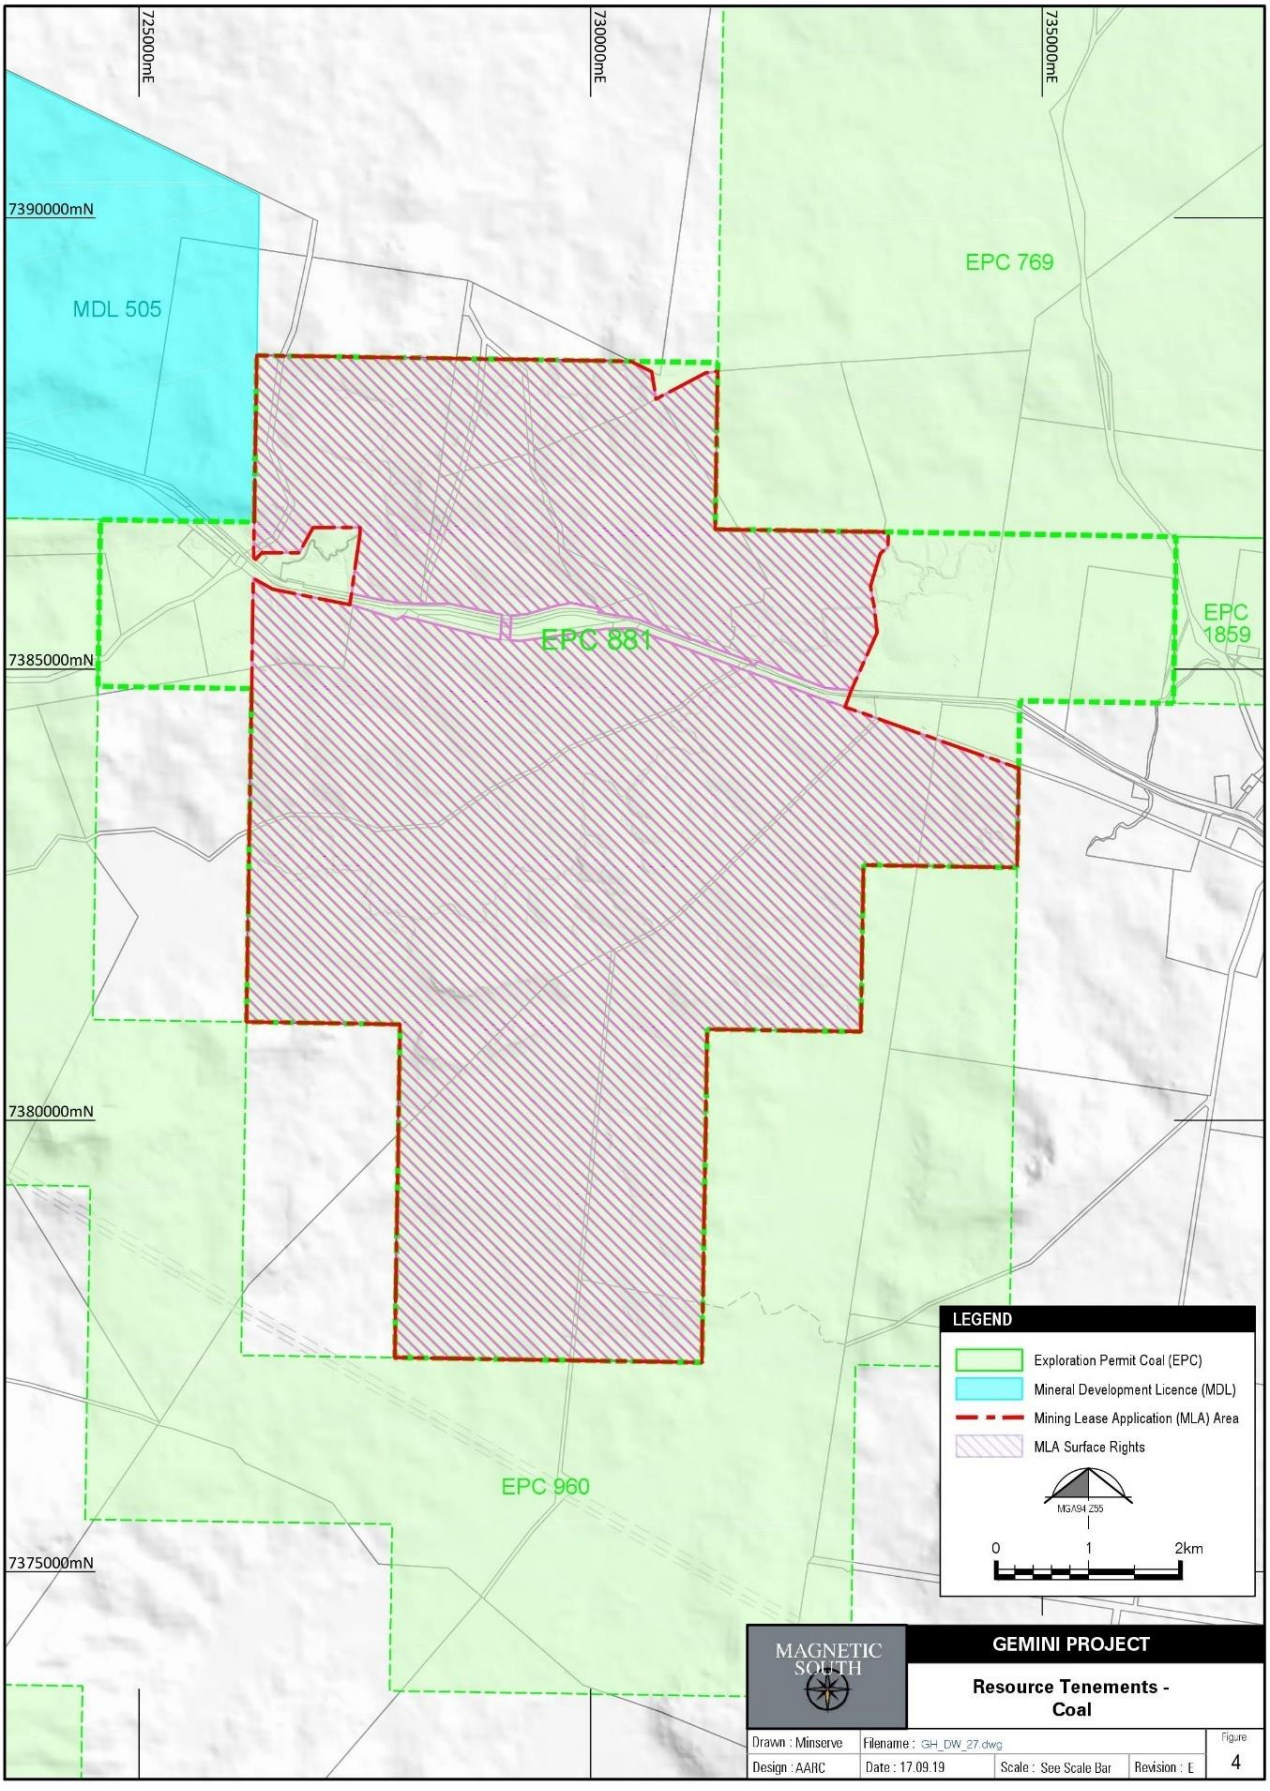

Figure 4 Resource Tenements – Coal

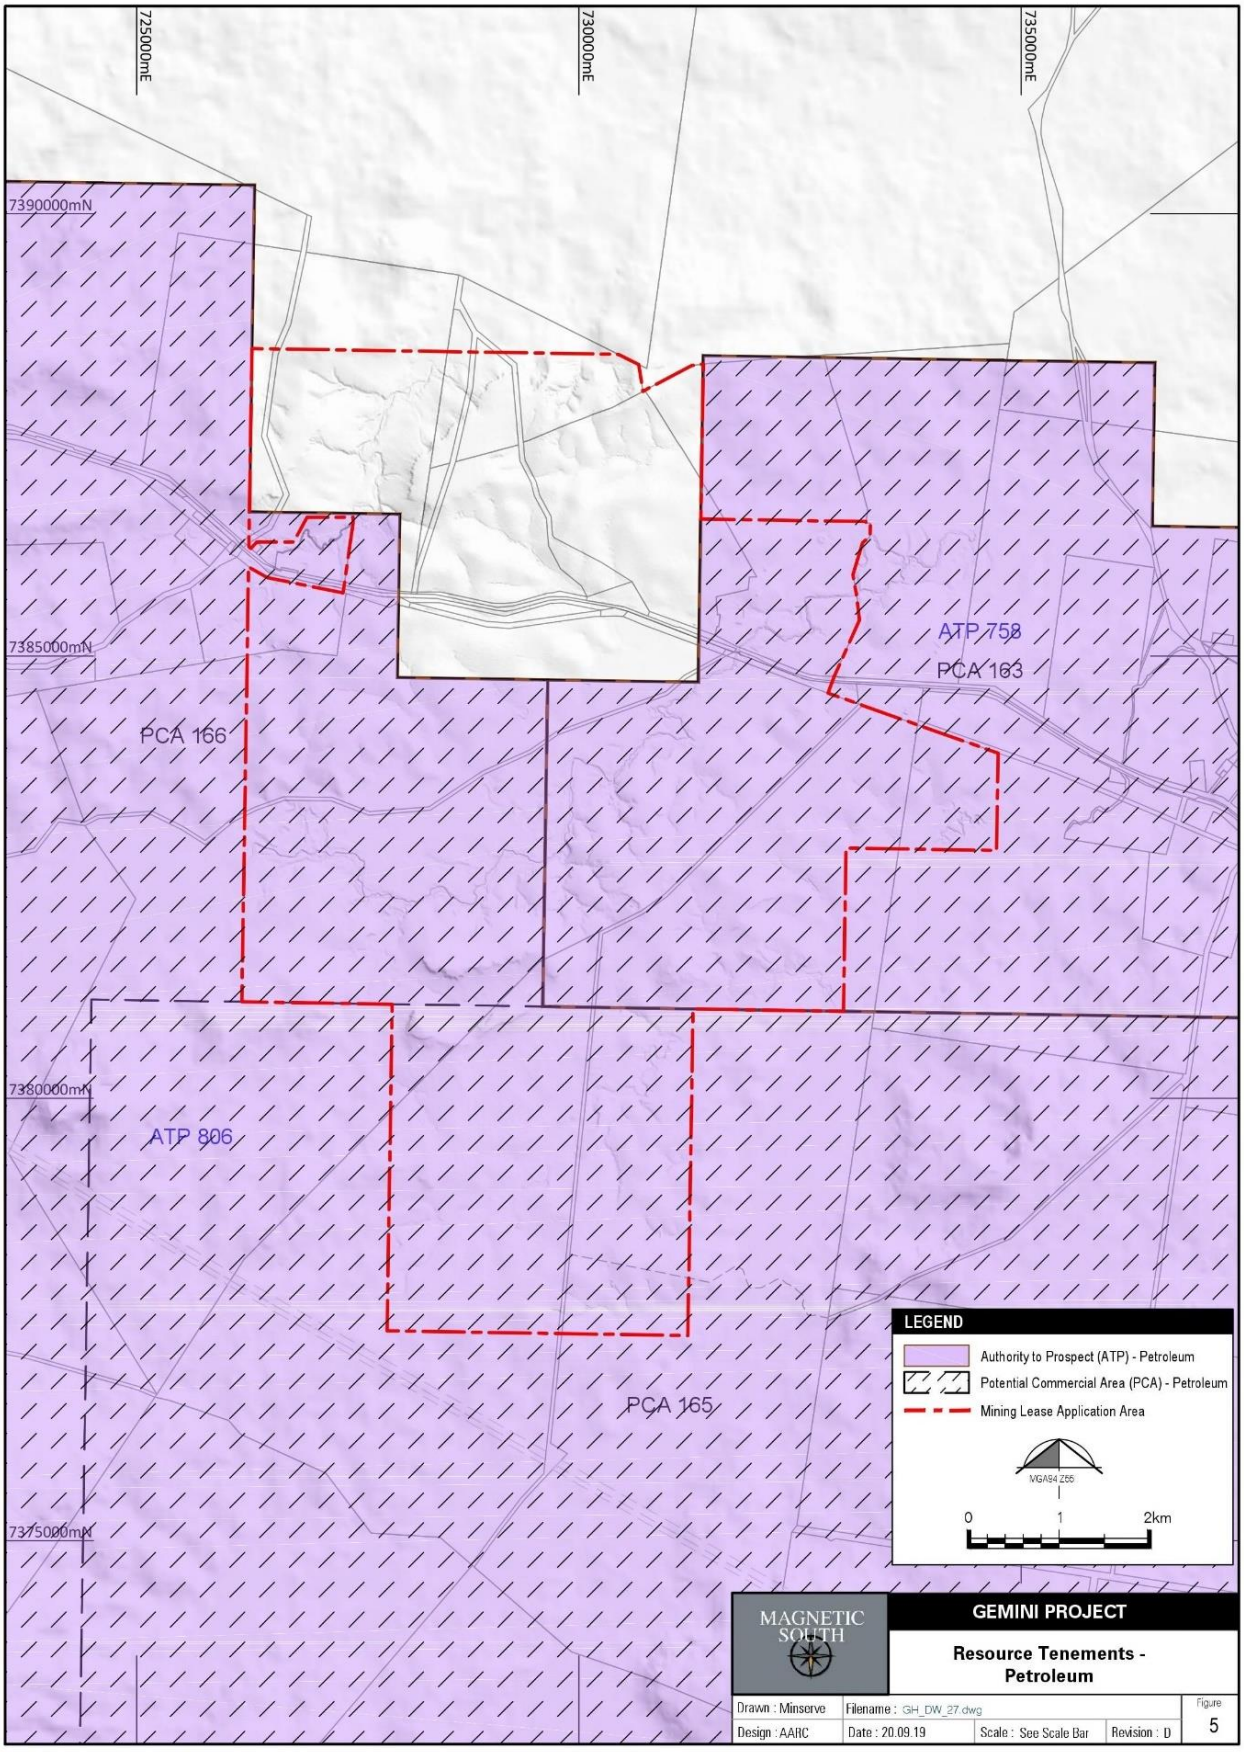

Figure 5 Resource Tenements – Petroleum

2.3.2 Land Ownership

The subject land within the MLA is held as freehold, leasehold or road reserve. Land ownership within the MLA is outlined in Table 6 and shown in Figure 6.

The Project's infrastructure is located on Lot 1 on Plan HT424 (freehold), Lot 2 on Plan HT138 (leasehold), Lot 100 on Plan RP882349 (freehold), and Lot 1 on Plan RP904099.

A number of publicly gazetted road reserves occur within the MLA; including the Capricorn Highway. The Blackwater Railway occurs within leasehold land along the northern side of the Capricorn Highway.

Consultation with private landholders within the MLA has been conducted by Magnetic South and discussions continue in relation to consent.

Table 6 Land Ownership

Registered Owner/s	Lot / Plan	Tenure	Property Name

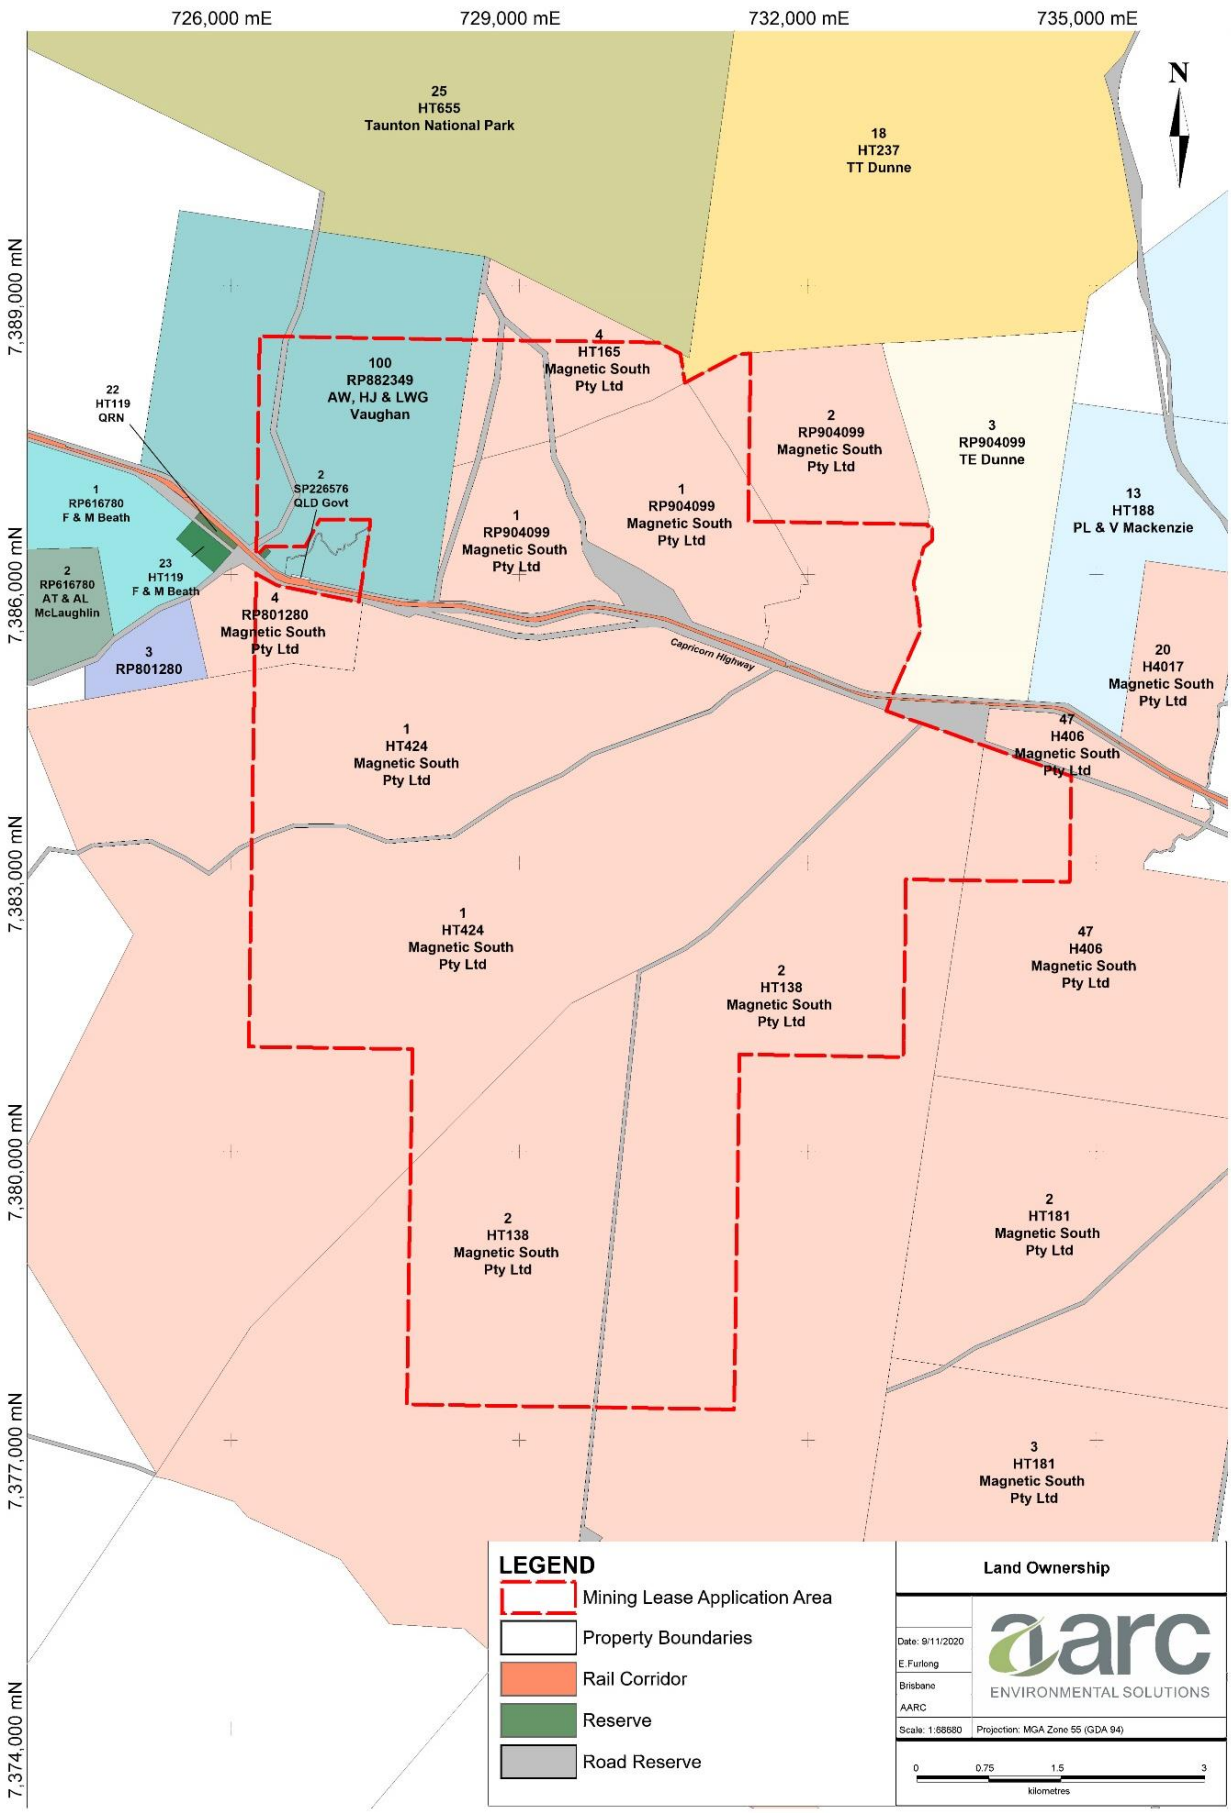

Figure 6 Land Ownership

3.0 PROJECT DESCRIPTION

3.1 PROJECT OVERVIEW

The Gemini Project is a greenfield, open-cut metallurgical coal mine producing pulverised coal injection (PCI) coal and coking coal for export to the international steel making industry.

The Project is located in the Bowen Basin, a well-established coal mining area with existing transport infrastructure. The Project will bring benefits to the local community, region, Queensland and the Commonwealth through direct employment opportunities, royalties and taxes. The Project will also utilise the services of regional suppliers of rail, power, water, communications, contractors, service providers and local businesses, which will have a positive economic impact beyond direct employment.

The Project term is anticipated to be 37 years from grant of the mining lease (ML); with this term including initial construction, mine operation and rehabilitation activities.

Mine construction activities are scheduled to commence in July 2021; subject to granting of the Project ML and EA. It is anticipated that it will take approximately six months to establish the necessary infrastructure to commence overburden removal and 18 months to commence coal production.

The main activities associated with the Project include:

- exploration activities continuing in order to support mine planning;
- development of a mine infrastructure area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, wash bay, laydown area, sewage, effluent and liquid waste storage, and a helipad;
- construction and operation of a coal handling and preparation plant (CHPP) and coal handling facilities adjacent to the MIA, including run-of-mine (ROM) coal and product coal stockpiles and rejects bin/overflow (coarse and fine rejects);
- construction and operation of a surface conveyor from the product stockpiles to a train load out (TLO) facility and rail loop connecting to the Blackwater Railway to transport product coal to coal terminals at Gladstone for export.
- construction of an accommodation facility, sewage treatment plant and effluent irrigation area within the northwest bounds of the MLA;
- construction of access roads from the Capricorn Highway to the MIA, and from the Capricorn Highway to the TLO facility;
- installation of a raw water supply pipeline to connect to the Blackwater Pipeline network;
- construction of a 66 kV transmission line and switching/substation to connect to the existing regional network;
- other associated minor infrastructure, plant, equipment and activities;
- development of mine areas (open-cut pits) and out-of-pit waste rock emplacements;
- drilling and blasting of competent waste material;

- mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers);
- mining up to 1.9 Mtpa ROM coal (average of 1.8 Mtpa) for a construction/production period of approximately 20 years;
- progressive placement of waste rock in:
    - emplacements, adjacent to and near the open-cut voids; and
    - mine voids, behind the advancing open-cut mining operations;
- progressive rehabilitation of waste rock emplacement areas and mined voids;
- progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works; material will be sourced from local quarries where required);
- disposal of CHPP rejects (coarse and fine rejects) in out-of-pit spoil dumps, and in-pit behind the mining void;
- progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access;
- development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, diversions and drains.

Existing local and regional infrastructure, facilities and services would be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

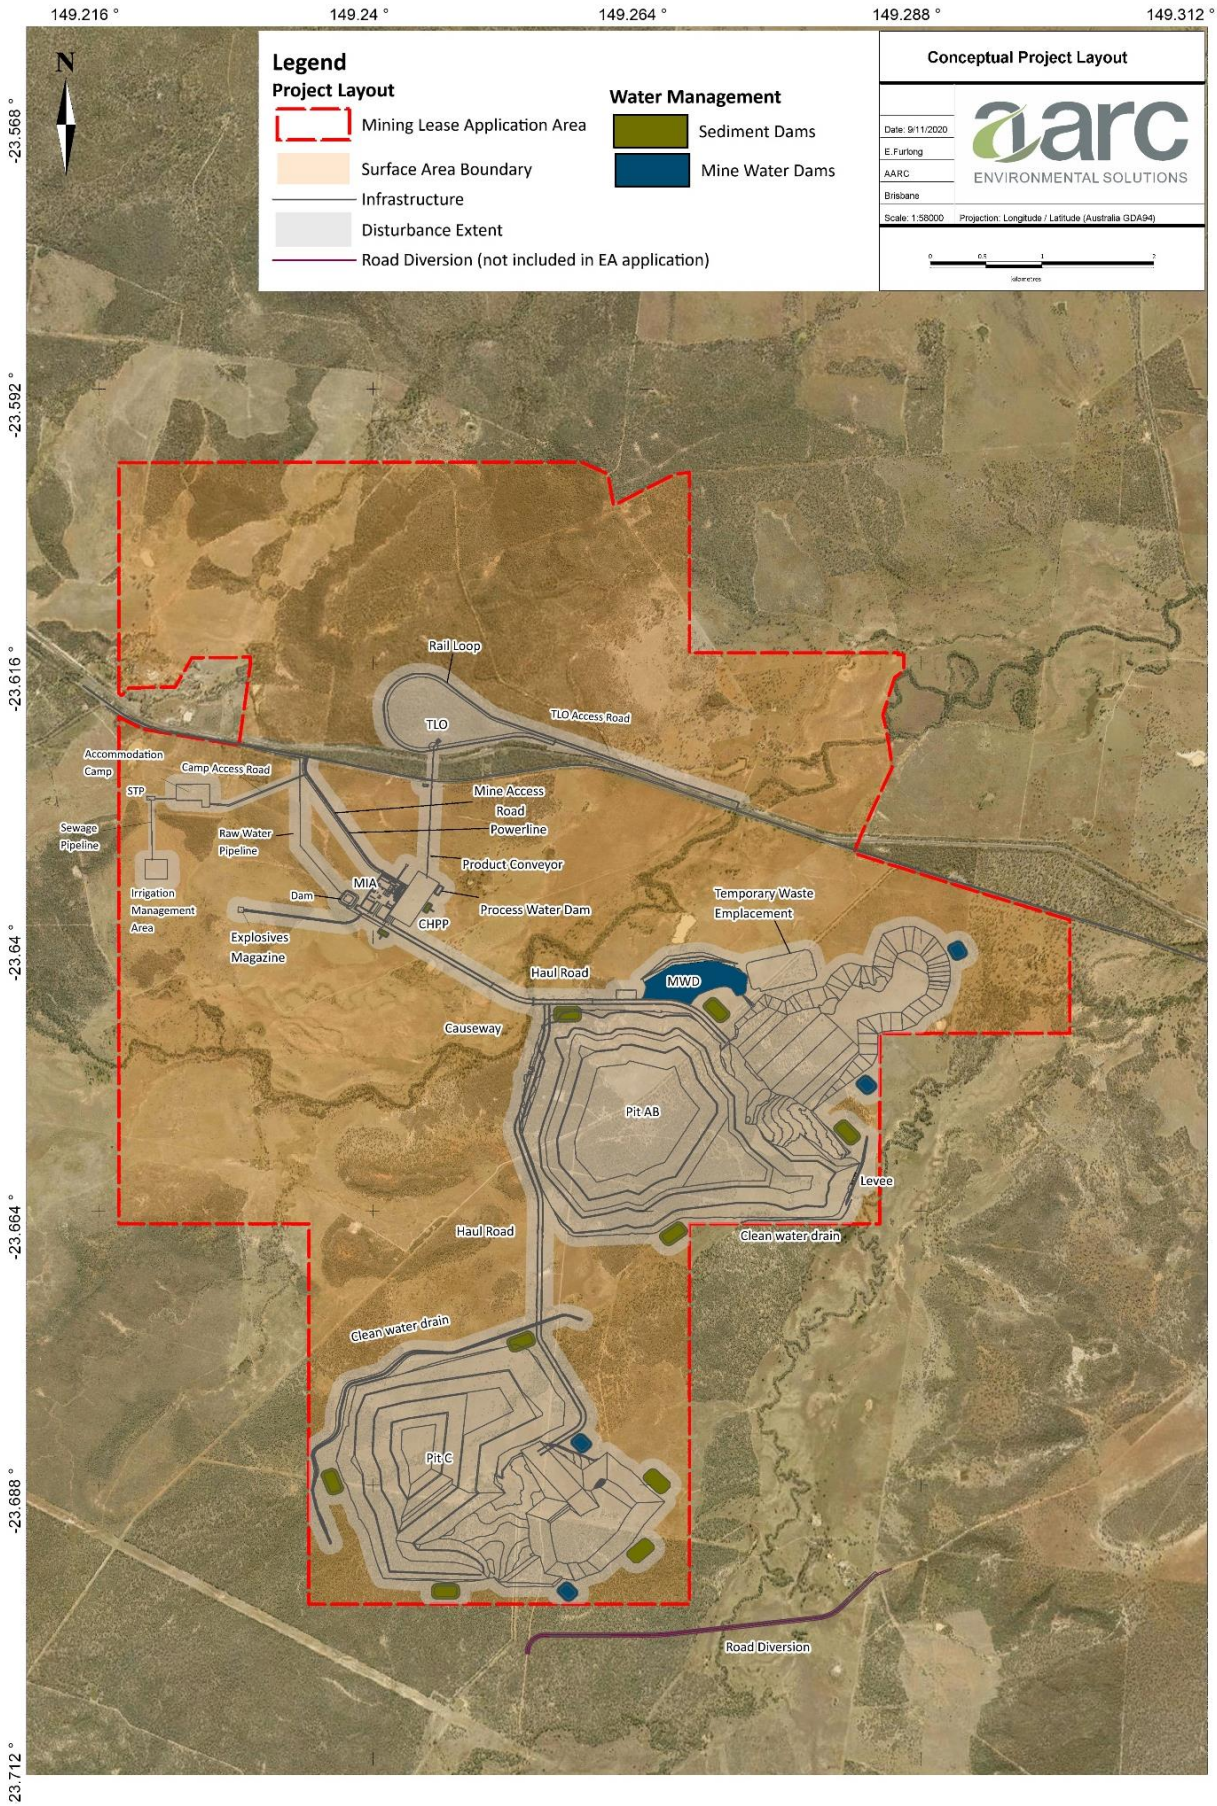

Figure 7 **Conceptual Layout - Gemini Project**

3.2 PROJECT DISTURBANCE AREA

A conceptual Project layout is provided in Figure 7 which represents the total area disturbed by mine operations only and does not equate to the disturbance footprint at any one point in time. Open-cut mining areas will be developed and rehabilitated progressively. The total disturbance footprint for the Project is 1,953.50 ha which incorporates all mining and infrastructure components as described in Table 7.

Table 7 Total Disturbance Area

Proposed Disturbance	Approximate Area (ha)
In-pit and out-of-pit waste emplacements, including dry rejects disposal areas	722.4
Temporary waste emplacements	17.5
Residual void lakes	76.5
Residual void high walls	133.1
Residual void low walls	187.2
Water management infrastructure1	85
Mine infrastructure areas	731.8
Total	**1,953.5**

* Infrastructure disturbance area includes a 100 m buffer around the perimeter of the disturbance footprint.

3.3 CONSTRUCTION

Proposed infrastructure and other development activities for the Project during the construction phase will include:

- mine access road from the Capricorn Highway to the MIA, associated Capricorn Highway intersection, site access security infrastructure and car parking at the MIA;
- MIA;
- explosives magazine;
- CHPP and associated coal handling infrastructure;
- TLO facility and access road;
- haul road to Pit AB including a low-level causeway across Charlevue Creek;
- construction of the haul road to Pit C (anticipated to commence in Year 11 of the Project); and
- accommodation facility and camp access road adjoining the mine access road.

These infrastructure components are described in Section 3.3.1 through to Section 3.3.5.

Water management infrastructure for the Project will include a temporary flood protection levee, clean water diversions for drainage features, mine water dams, sediment dams, raw water dam and process water dam. The water management components are described in Section 3.4.3.

Supporting infrastructure required for the Project includes an electrical power transmission line (refer Section 3.5.1) and raw water supply pipeline (refer Section 3.5.2).

Site preparation will include the clearance of vegetation, topsoil removal and stockpiling, bulk earthworks and temporary drainage works. Initial site preparation works will be focused on the rail infrastructure, mine access road, MIA, CHPP, accommodation facilities and haul road. Site clearance will be staged throughout the construction phases on an "as needs" basis to coincide with infrastructure installation and development to minimise the extent and duration of disturbance.

Quarry materials will be sourced from onsite deposits, where available, for use as road base, select fill, rail ballast, rock protection, and other construction materials. It is expected that waste rock from pit excavation will provide the majority of construction and bulk fill materials, however, some material may also be sourced from the onsite Project disturbance footprint or from quarries in the region.

The majority of infrastructure components (e.g., CHPP, buildings, pipelines, etc.) will be manufactured offsite and transported to site for assembly and installation.

3.3.1 Mine Access Road

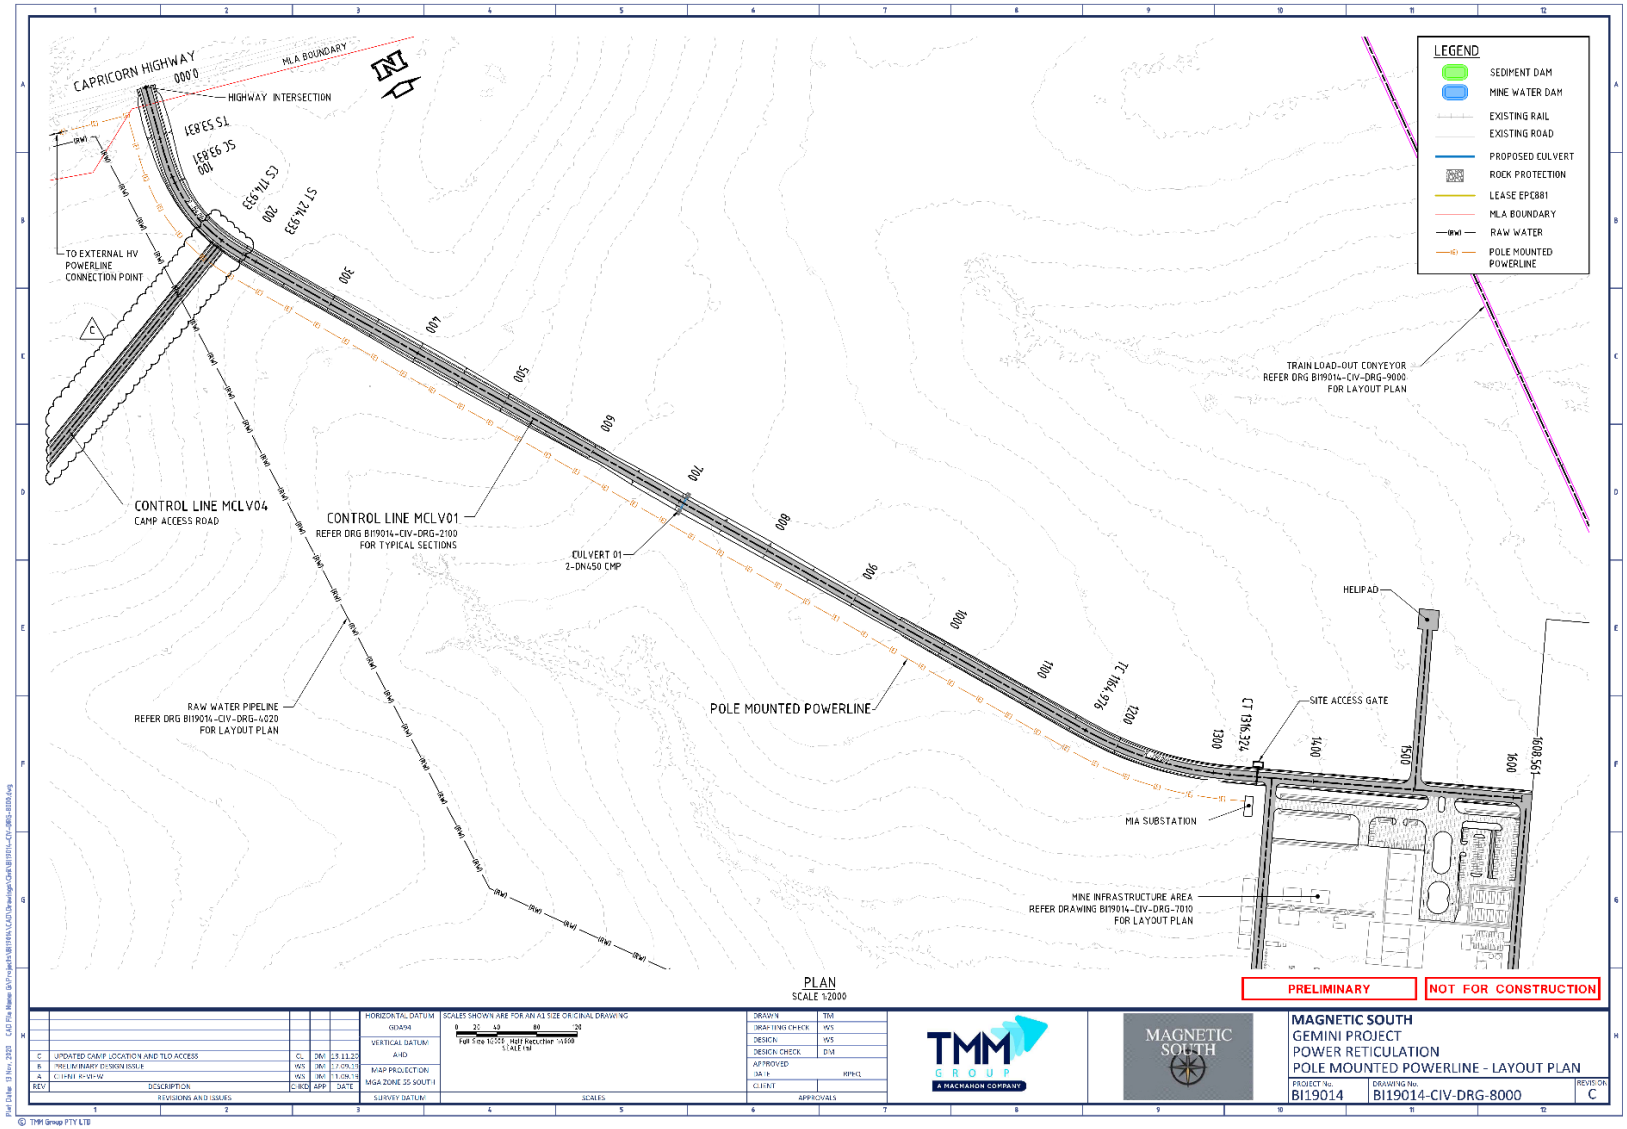
Vehicle access for mine personnel, contractors, suppliers and deliveries to the Project will be via a new mine access road from the Capricorn Highway. The concept design of the mine access road is shown in Figure 8. The proposed mine access road intersection will be located approximately 2.7 km east of the Capricorn Highway/Charlevue Road intersection. The concept design of the proposed intersection is shown in Figure 9. The design includes an auxiliary left turn treatment – short turn lane and a channelised right turn treatment with reduced length of right turn slots, which has been designed in accordance with the *Guide to Road Design Part 4A: Unsignalised and Signalised Intersections* (Austroads Ltd 2017).

The mine access road intersection will be sealed, while the remainder of the mine access road to the MIA will be unsealed. Just beyond the mine access road intersection, access to the accommodation facilities will occur via an adjoining camp access road to the west of the MIA. A *Traffic Impact Assessment* (Cardno 2019) has been prepared for the Project and is included as Appendix A.

A MIA will be constructed in the northwest of the MLA (Figure 7). An indicative layout of the MIA is shown in Figure 10. A security gate will be established at the entrance to the mine on the mine access road (Figure 10) to prevent inadvertent access to the mine site operations. The security gate will be positioned to direct visitors to the MIA and associated car park (Figure 10).

The MIA will include the mine offices, bathhouse, crib rooms, warehouses and storage areas, workshops, potable water storage, fuel storage and refuelling facilities, sewage, effluent and liquid waste storage, tyre bay, laydown area, Go-line, wash bay, and other associated amenities (Figure 10).

Personnel, visitors and deliveries will access the MIA and associated mine offices via the mine access road. Access from the MIA to the mining operations is via internal light vehicle access roads and the mine haul roads.



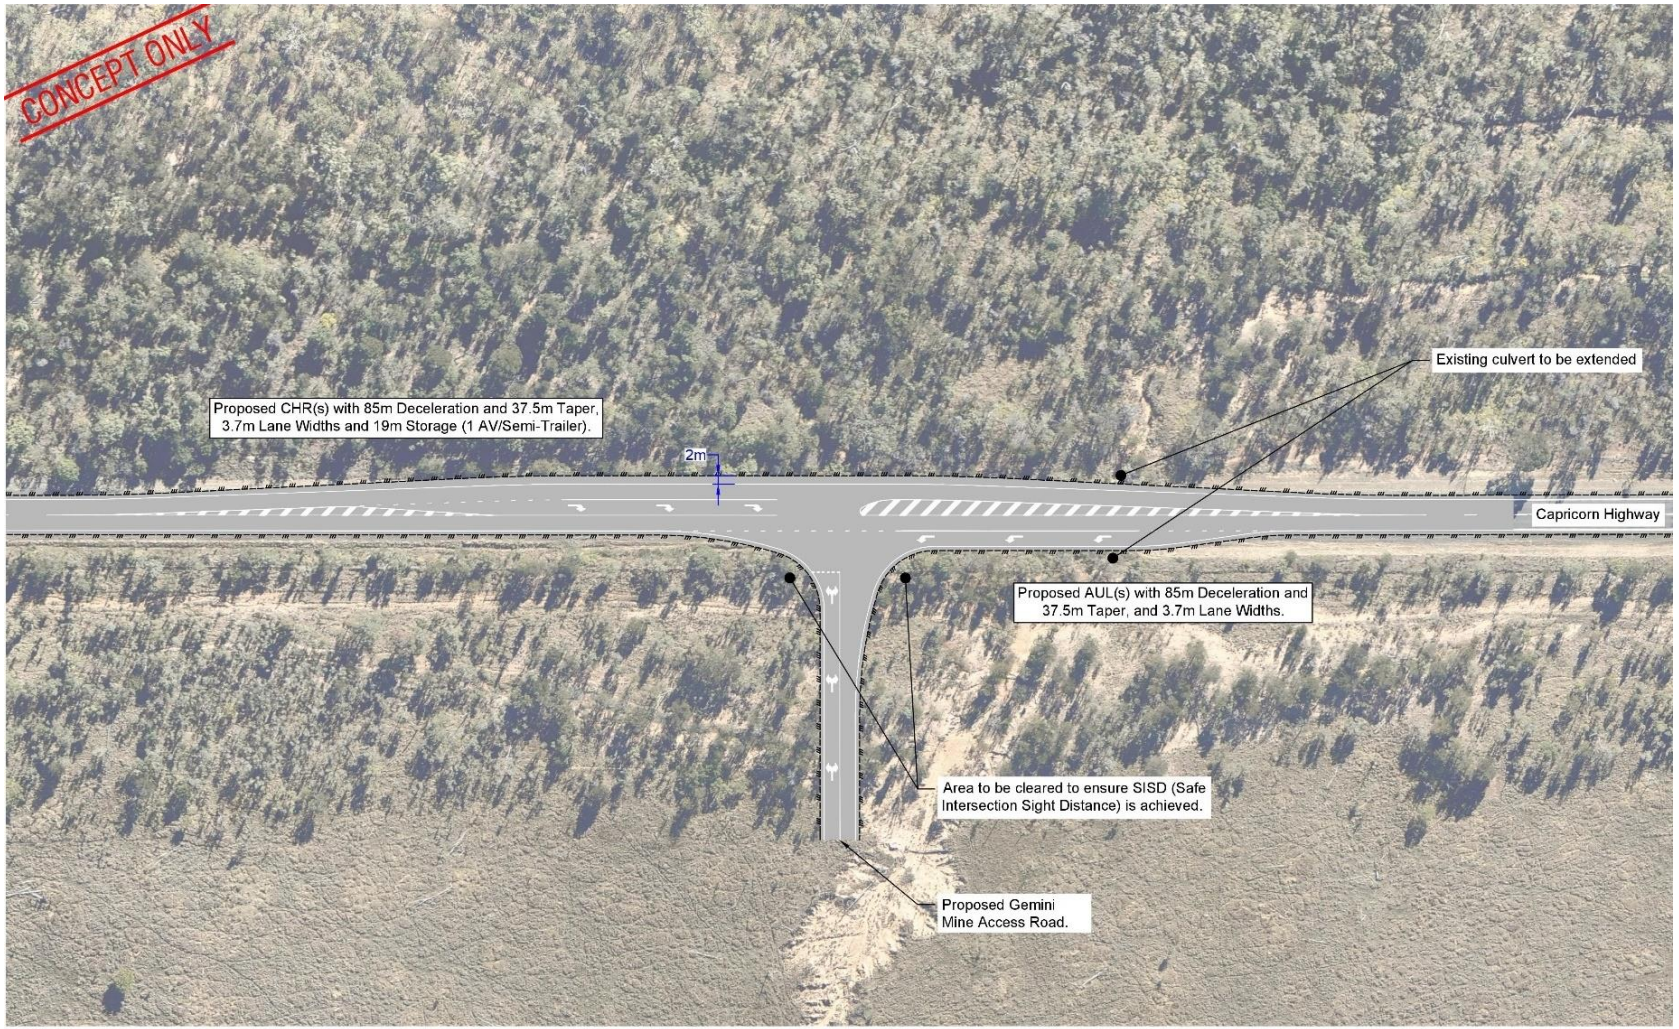


Figure 8 Conceptual Design - Mine Access Road

Safe Intersection Sight Distance (SISD)			
Westbound		Eastbound	
Required	Achieved	Required	Achieved
285m	350m+	285m	350m+

Figure 9 Conceptual Design - Mine Access Road Intersection

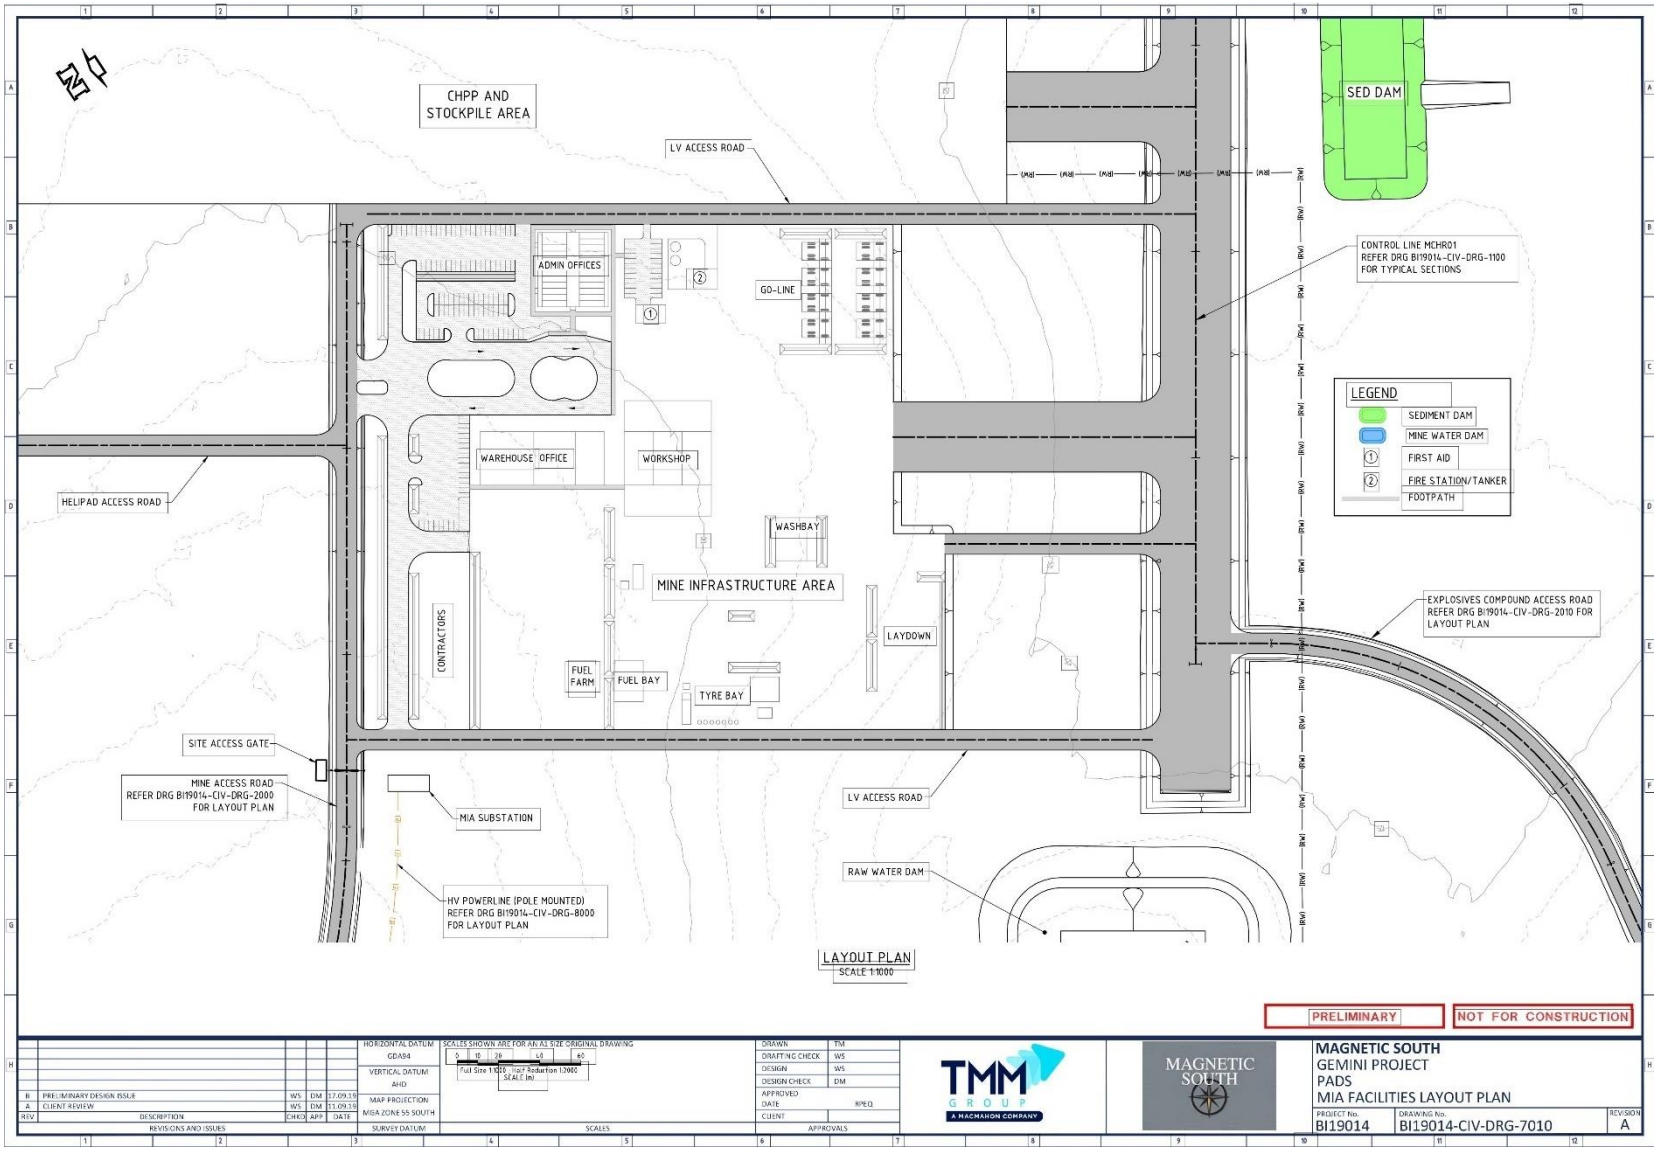

Figure 10 Conceptual Layout - MIA

3.3.2 Explosives Storage

An explosives compound will be established to the west of the MIA (Figure 7 and Figure 11). Explosives magazines will be fenced, signed and maintained in accordance with *AS2187.2-2006: Explosives – Storage and use (Part 2: Use of explosives).*

3.3.3 CHPP, Stockpiles and Overland Conveyor

A CHPP and associated coal handling facilities will be constructed adjacent to the MIA (Figure 7 and Figure 11) and will include:

- CHPP;
- ROM coal stockpile;
- product stockpile;
- rejects bin and overflow (coarse and fine rejects); and
- coal handling facilities including an overland conveyor to transport product coal to the TLO.

It is anticipated that construction of the CHPP and associated coal handling facilities will take approximately 18 months. The CHPP will operate 24 hours per day, 7 days a week.

Product coal will be direct fed to the train loading bin by conveyor from the product coal stockpile adjacent to the CHPP. The conveyor will be constructed to pass over both the Capricorn Highway and the Blackwater Railway (Figure 12). Concept design of the Capricorn Highway conveyor crossing is shown in Figure 13, and the Blackwater Railway conveyor crossing in Figure 14.

3.3.4 Train Load Out Facility and Access Road

A TLO facility comprising a rail spur, rail loop and train loading bin will be constructed adjacent to the Blackwater Railway (Figure 7). The rail spur and loop will be approximately 6 km in length and will connect to the Blackwater Railway west of the existing Charlevue Creek rail bridge.

Access to the TLO facility will utilise an existing access road off the Capricorn Highway via Red Hill Road at Lot 2 on Plan RP904099 (Figure 7). The TLO access road is unsealed and runs beneath the rail bridge proximal to Charlevue Creek and will continue around the perimeter of the TLO rail loop. This access road will be used for TLO construction activities and for operations.

3.3.5 Haul Roads

The alignment of the haul roads from the MIA to Pit AB and Pit C is shown in Figure 7. Construction of the haul road to Pit C is anticipated to commence in Year 11 of the Project.

The haul road to Pit AB will include a causeway to cross Charlevue Creek. The causeway will be designed for a 1 in 2-year rainfall event, with the capacity to carry a 540 t class excavator on a float.

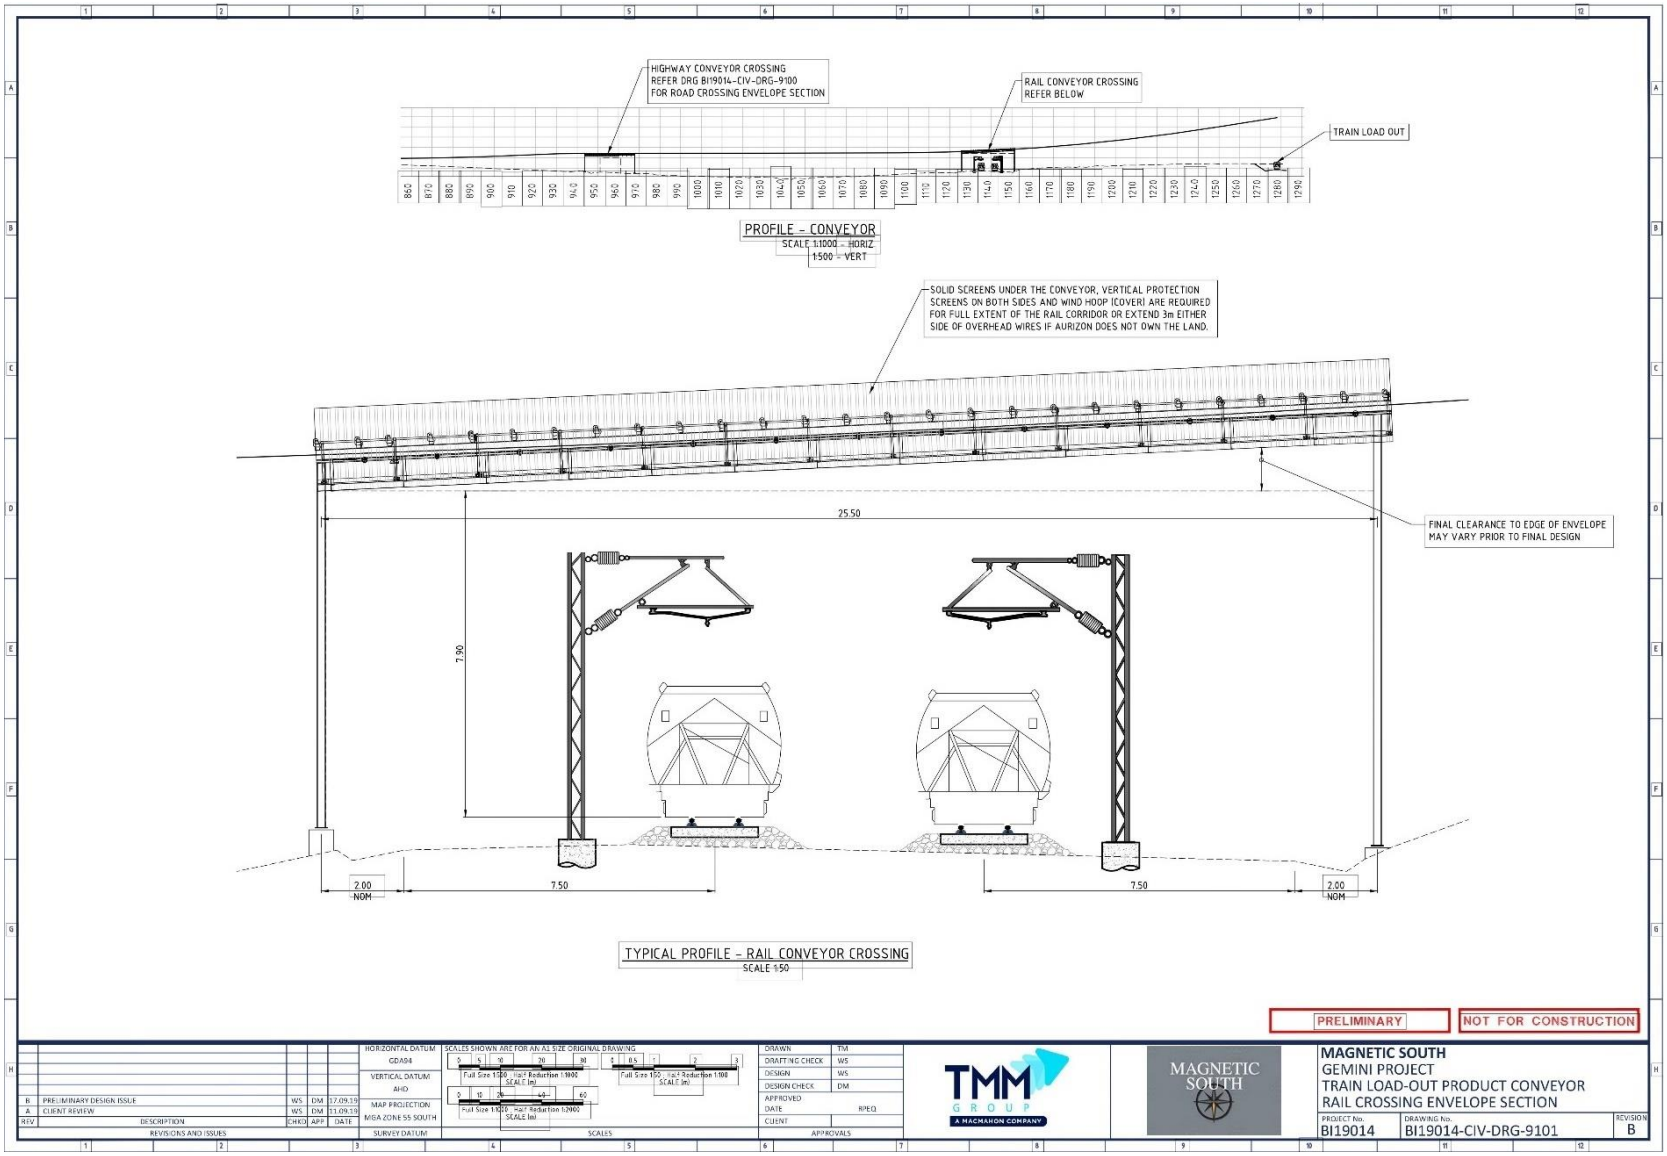

Figure 14 Conceptual Design - Conveyor Crossing (Blackwater Railway)

3.4 SITE WATER MANAGEMENT

3.4.1 Water Management Principles

The 'Site Water Management System' (SWMS) for the Gemini Project is based on the following key principles:

- divert clean catchment water around mining works to the extent practicable;
- use/recycle lesser quality water in preference to higher quality water;
- use potentially contaminated water in preference to imported raw water or uncontaminated water;
- release water from site only in accordance with the conditions of the EA, such that the released water will not significantly impact on the values of the receiving waters or downstream properties;
- manage water storages and transfers within the site in order to:
    - maximise onsite storage to meet reasonably anticipated periods of wet and dry weather; and
    - minimise disruption to mining operations.

3.4.2 Site Water Management System

For the purpose of site water management, site water has been classified into the types shown in Table 8 on the basis of the likely water quality characteristics.

The proposed strategy for the management of surface water at the Project is based on the separation of water from different sources based on anticipated water quality.

A conceptual SWMS was developed for the Project by WRM Water and Environment Pty Ltd (WRM) as a part of the *Surface Water Assessment* (WRM 2020b) (Appendix B). On the basis of the expected runoff and groundwater inflow quality, the SWMS separates water into two segregated management systems:

1. **Mine affected water (MAW) system:** will manage runoff and seepage from the mine pits, CHPP, coal stockpiles, and MIA. This is a closed system designed to prevent releases of MAW to the environment.
2. **Sediment water system:** runoff from overburden dumps will be managed under an *Erosion and Sediment Control Plan* (ESCP) which is to be implemented throughout the Project, such that sediment generated and transported by runoff will be settled in a sediment dam. As overburden runoff quality is expected to be relatively benign (refer Section 13.0), the sediment dams will potentially discharge directly into the environment (after the settlement of suspended sediment), and as such, will not affect the mine water balance. However, the water balance assessment has assumed sediment dams will be pumped back to the CHPP for reuse.

Clean water flows from undisturbed areas are generally diverted around the areas of disturbance. A raw water supply pipeline is proposed to supply all site water requirements prior to dam construction, and supplement site water supplies throughout the life of the Project. Raw water will be delivered to a

dedicated raw water dam (located adjacent to the MIA), which will also intercept clean water from its local upstream catchment.

A site water balance model has been developed by WRM (2020b) to determine the most appropriate design of the SWMS. The site water balance forms the basis of impact assessment and infrastructure design for the site. Details of the site water balance are provided in Section 3.4.5.

A schematic of the integrated SWMS configuration for the Project is shown in Figure 15.

Table 8 Site Water Types

Water Type	Definition
Mine affected water	In accordance with the *Model mining conditions* (DES 2017e), MAW means the following types of water: i) pit water, tailings dam water, processing plant water; ii) water contaminated by a mining activity which would have been an ERA under Schedule 2 of the EP Regulation if it had not formed part of the mining activity; iii) rainfall runoff which has been in contact with any areas disturbed by mining activities which have not yet been rehabilitated, excluding rainfall runoff discharging through release points associated with erosion and sediment control structures that have been installed in accordance with the standards and requirements of an ESCP to manage such runoff, provided that this water has not been mixed with pit water, tailings dam water, processing plant water or workshop water; iv) groundwater which has been in contact with any areas disturbed by mining activities which have not yet been rehabilitated; v) groundwater from the mine dewatering activities; vi) a mix of MAW (under any of paragraphs i to v) and other water.
Sediment water	Surface water runoff from areas that are disturbed by mining operations (including out-of-pit waste rock emplacements). This runoff does not come into contact with coal or other carbonaceous material and may contain high sediment loads but does not contain elevated level of other water quality parameters (e.g., electrical conductivity (EC), pH, metals, metalloids, non-metals). This runoff must be managed to ensure adequate sediment removal prior to release to receiving waters.
Clean catchment water	Surface runoff from areas unaffected by mining operations. Clean catchment water includes runoff from undisturbed areas and fully rehabilitated areas.
Raw water	Untreated water, generally from an external water supply, that has not been contaminated by mining activities.
Potable water	Treated water suitable for human consumption.

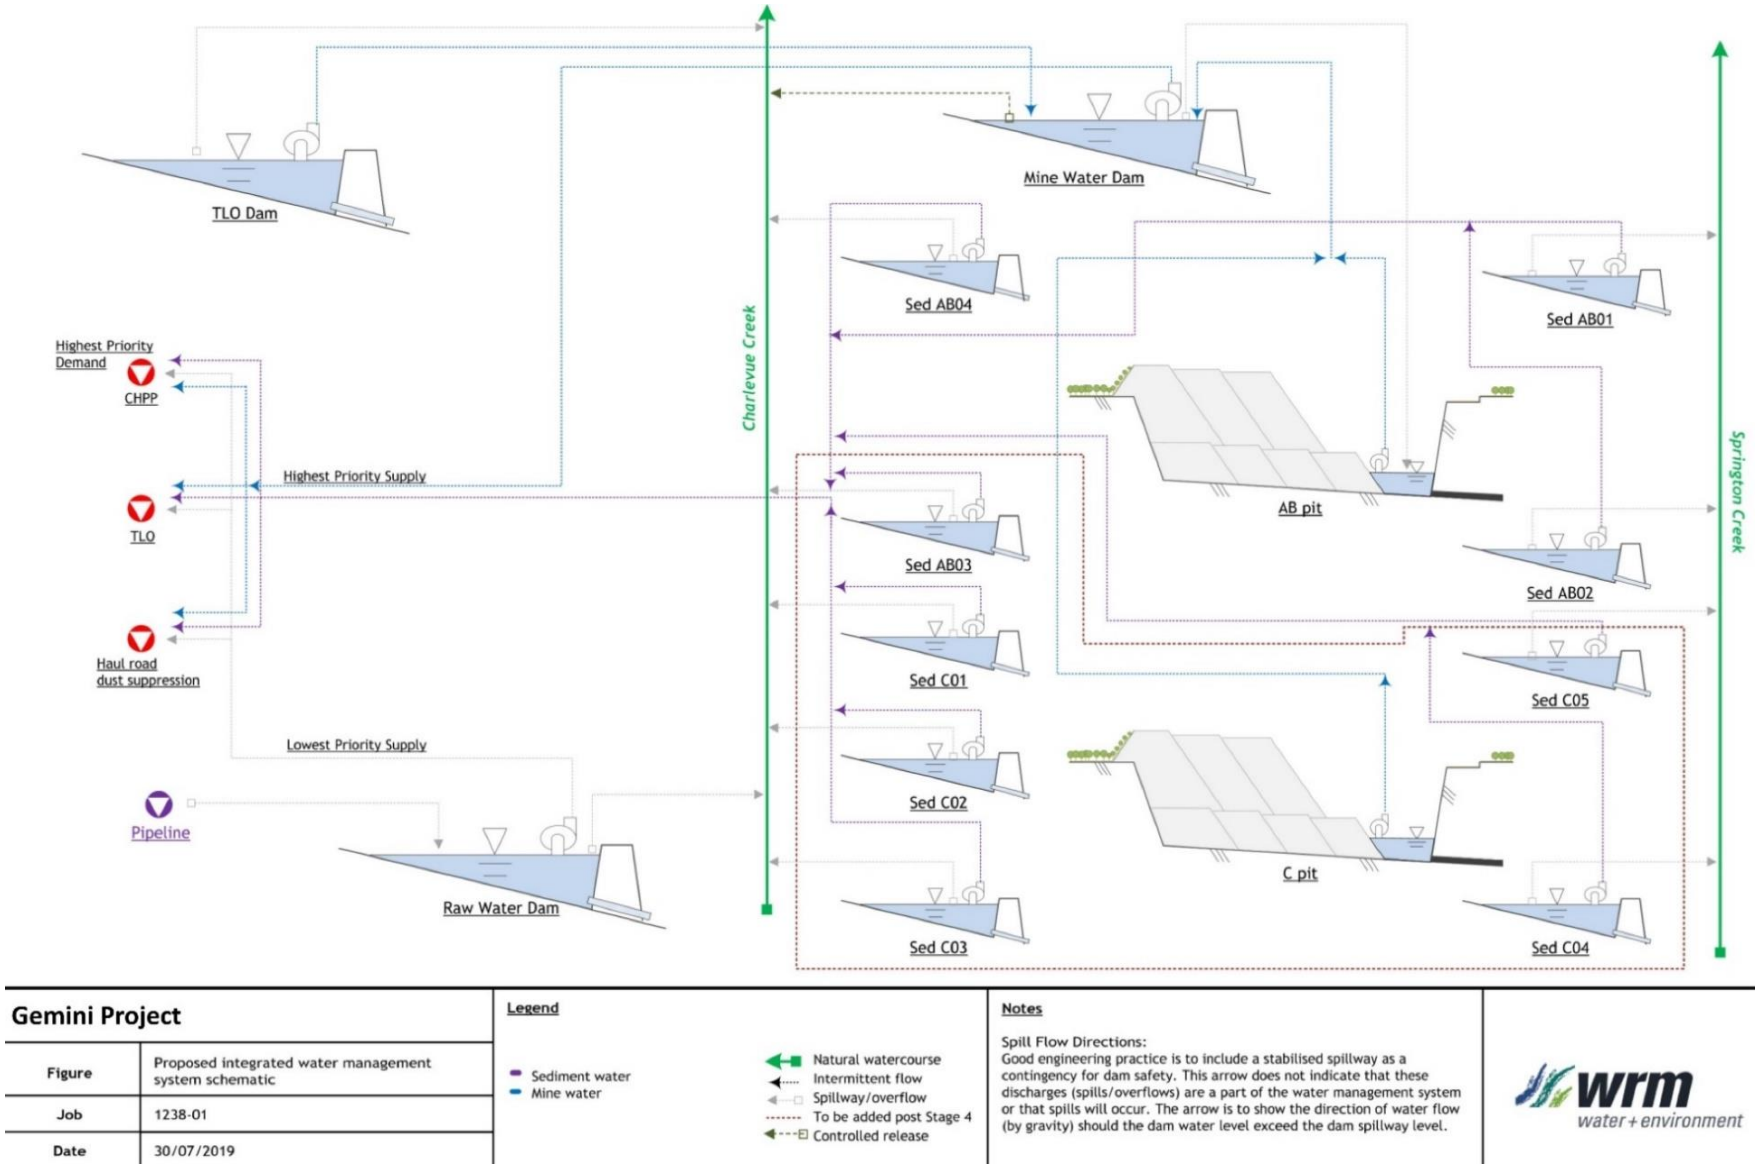

Figure 15 Proposed Integrated SWMS Schematic

3.4.3 Water Management Infrastructure

The SWMS consists of infrastructure to provide catchment separation and manage water quality and quantity onsite. Infrastructure for the Project's SWMS includes:

- temporary flood protection levee to protect Pit AB from potential flood waters;
- clean water drains to divert runoff from undisturbed catchments around areas disturbed by mining activities;
- sediment water drains to divert water from waste rock emplacements, and areas yet to be rehabilitated;
- sediment water dams to store water from waste rock emplacements and allow settlement of sediment loads before discharging treated water or recycling back to the CHPP;
- mine water drains to divert water from MIA, CHPP and coal stockpile areas into the MAW system; and
- mine water dams to store water pumped out of the pit, and collect water from the MIA, CHPP and coal stockpile areas.

Figure 7 provides a schematic layout of proposed water management infrastructure for the Project.

3.4.3.1 Temporary Flood Protection Levee

A temporary flood levee designed to provide protection from a 0.1% annual exceedance probability (AEP) flood event will be constructed adjacent to Pit AB (Figure 7). The levee will be required to reduce the risk of ingress of clean floodwaters into operational areas where they may become contaminated with possible adverse impact on water management operations and containment performance. The levee will be constructed prior to the commencement of waste stripping within Pit AB.

The levee will be a 'regulated structure' and will be designed, constructed and decommissioned in accordance with the '*Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933)*' and *'Structures which are dams or levees constructed as part of environmentally relevant activities (ESR/2016/1934)*'. The design height of the levee ranges from 1.21 m to 2.37 m, determined by the modelled flood height, plus 0.5 m freeboard. A plan and longitudinal section of the levee is provided in Figure 16, with a typical cross-section provided in Figure 21. The levee will be reinforced by in-pit rock dumps as mining progresses.

These levee structures would be temporary, required only until the final overburden profile is achieved and the associated permanent drainage systems commissioned. The final voids are located and designed such that they are not inundated by flooding in the probable maximum flood. Accordingly, no flood levee will be required to prevent inundation of the final void. The levee constructed to protect the operational pit would not be required post-mining and therefore has been designed to form part of the rehabilitated dump.

3.4.3.2 Clean Water Drains

The Project will require two sections of a 'drainage feature' (as determined under the *Water Act 2000* (Water Act) to be diverted around surface disturbance areas associated with Pit AB and Pit C (Figure 7). This will allow the runoff from undisturbed upslope catchments to flow around the operations, minimising the impact on the downstream environment, while also minimising the potential volume of

water captured into the MAW system. The drainage feature is a tributary of Springton Creek and is not considered to be a 'watercourse' as defined by the Water Act.

The engineered drainage features will be required throughout operations at each mine pit and will become permanent features at mine closure.

Runoff and seepage from the mine pits will be contained within the MAW system. The mine pits and MAW dams are located such that it would not be possible for this MAW water to enter the engineered drainage features.

The overburden dumps will be initially placed within the levees, and (in accordance with the erosion and sediment control plan) sediment-laden runoff would be directed to sediment dams via drains designed to prevent overflow into the engineered drainage features.

As the final overburden dump profile is developed, a series of contour drains would direct runoff away from the engineered drainage structures and to sediment dams. Overflows to "engineered 'drainage features'" would only occur after treatment in a sediment dam.

The preliminary channel designs included in the assessment have the following design features:

- Pit AB:
    - compound trapezoidal channel shape:
        - 1m deep low flow channel with 5 m base width;
        - Base width of high flow channel 15 m;
        - side slopes 1V in 3H;
    - longitudinal slope: 0.4% (the existing channel has a slope of approximately 0.3%);
    - design 1 in 50 AEP depths are up to 3.7 m, and peak velocities range up to 2.5 m/s;
- Pit C:
    - compound trapezoidal channel shape:
        - 1m deep low flow channel with 4 m base width;
        - width of high flow channel 15 m;
        - side slopes 1V in 3H;
    - longitudinal slope varies between 0.25% and 0.4%; and
    - design 1 in 50 AEP depths are up to 1.3 m, and peak velocities range between 1.0 m/s and 2.0 m/s.

A plan and longitudinal section of the channels is provided in Figure 17 (Pit AB) and Figure 18 to Figure 20 (Pit C), with a typical cross-section provided in Figure 21.

While the engineered drainage channels themselves would not be regulated structures, they are designed to ensure they do not interfere with the functioning of the levees in the design flood event (for example by inducing scour which could affect the integrity of the levee).

Based on the flood model results, flow velocities in the Pit AB drainage feature would generally be non-erosive, however, there may be a requirement for scour protection near the channel outlet where velocities are highest.

The permanent channels will be designed to be self-sustaining features of the local surface water environment. It is therefore proposed that the design of the drains will take into account key design principles and requirements for the functionality of permanent diversions, including for operations, maintenance, monitoring and revegetation.

Magnetic South will investigate the potential to realign the proposed diversion further south at mine closure to improve the geomorphological characteristics and reduce the need for erosion protection.

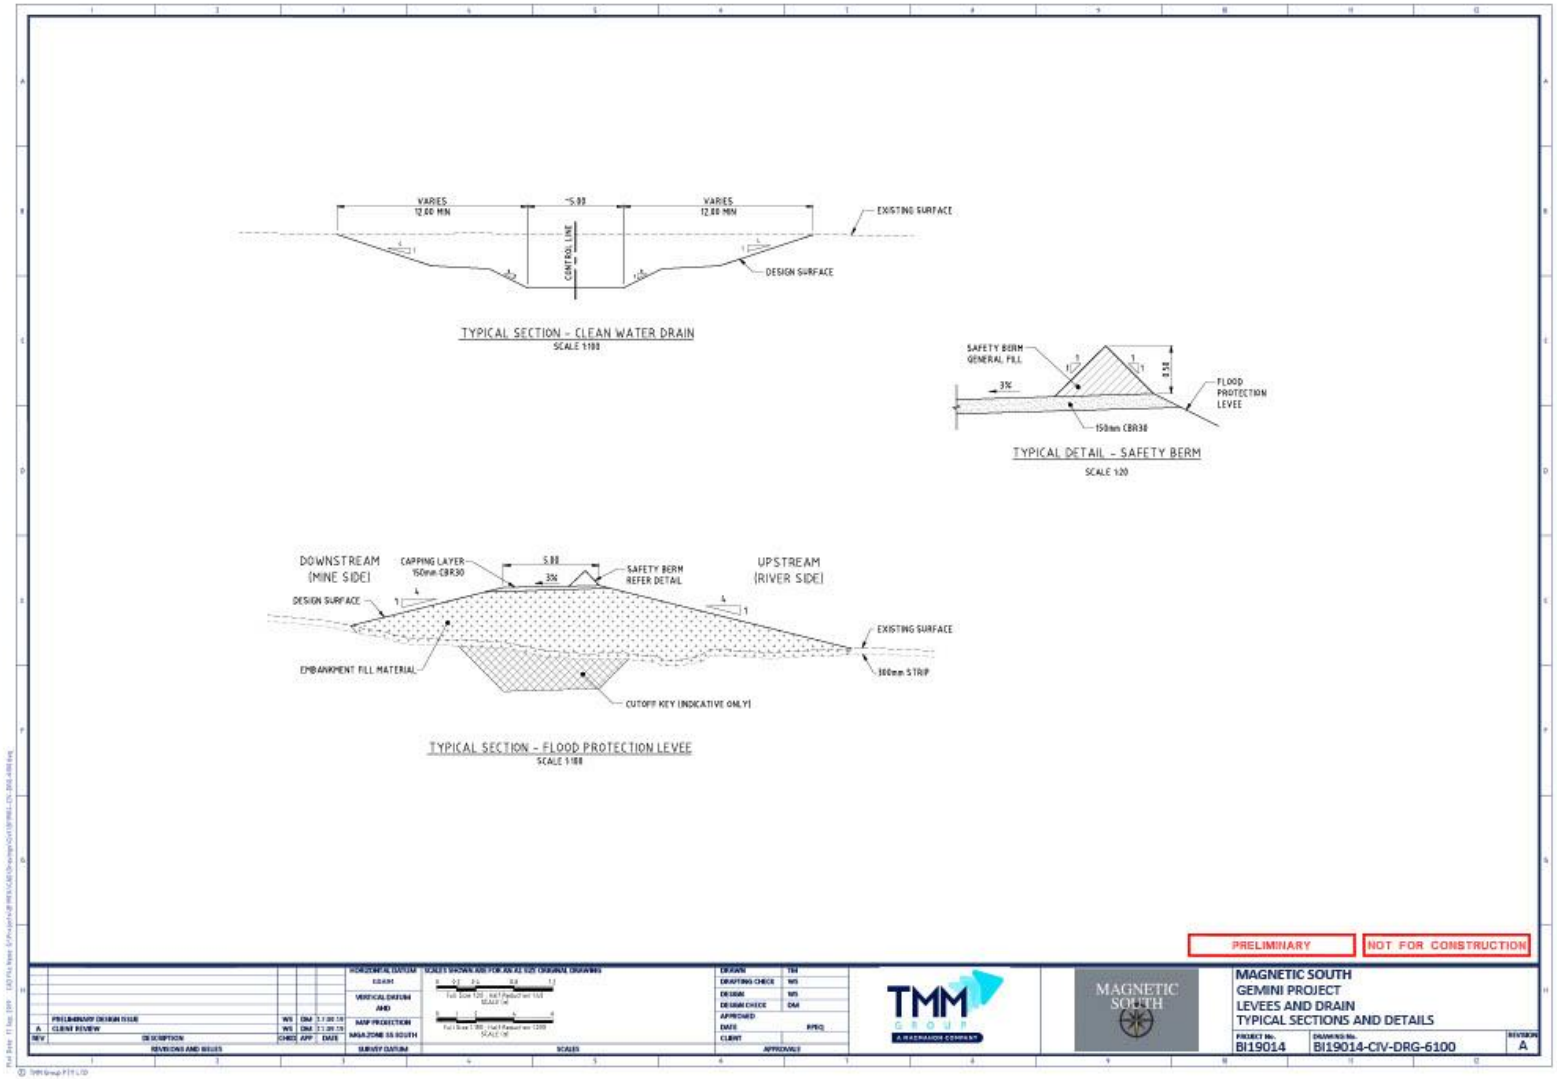

Figure 21 **Levees and Drains - Typical Sections and Details**

3.4.3.3 Water Storages

Water storages will include mine water dams, sediment dams, raw water dam, and process water dam. All storages will be located such that they are above the 0.1% AEP flood level.

All water storage dams, structures and facilities will be designed, constructed and managed in accordance with the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016).

Water collected in sediment dams will be captured and retained for reuse on-site and/or controlled release off-site to the receiving environment in accordance with *Model water conditions for coal mines in the Fitzroy basin [ESR/2015/1561]* (EHP 2013a).

Process Water Dam

Water is used in the CHPP for the sizing and removal of waste material. Water recovered from the CHPP during processing will be recycled through a closed loop circuit whereby any wastewater from the CHPP is temporarily stored in the process water dam and reused in the CHPP.

Mine Water Dams

Water that accumulates in the pits will be transferred to contained water storages (i.e., mine water dams) for beneficial use (i.e., dust suppression and/or CHPP water supply). Pit AB will be used as a supplementary mine water storage after commencement of mining in Pit C. A number of small staging dams may be used to collect water pumped from the mine pits before transferring to the mine water dam. These ancillary dams are designed to overtop back into the pits. The main mine water dam is located to the north of Pit AB and offsite discharge of mine water will be avoided by operating below a maximum operating level and directing emergency overflows from the mine water dam via a spillway to the Pit AB.

MIA dams will capture and contain runoff from the MIA and coal stockpiles. Oil/water separators are proposed for vehicle wash and workshop areas to treat hydrocarbon contaminated runoff prior to capture. These dams will be sized to ensure full containment of MIA and coal stockpile runoff.

A series of sediment traps and small drainage dams will be used to capture washdown and overflow from trains and sumps before it is directed to the TLO dam. Water collected in this small dam will be pumped to the mine water dam.

Haul Road Dams

Two small dams will be used to manage runoff from disturbed catchments. One dam (between Pit AB and Pit C) will be used to contain runoff from the Pit C haul road, while the other dam will be used to collect runoff from the haul road on the western side of Charlevue Creek.

Raw Water Dam

A raw water dam will be located adjacent to the MIA (Figure 7 and Figure 11) and will be sized to hold approximately 50 megalitres (Ml). The raw water dam will store water transported to site via the raw water pipeline from Blackwater, described in Section 3.5.2.

Sediment Dams

Sediment dams will be constructed to contain runoff from the waste rock emplacements and haul roads. The sediment dams allow for gravity settling of sediment prior to re-use of the water onsite or release

offsite. The sediment dams will be designed and operated in accordance with *Best Practice Erosion and Sediment Control* (IECA Australasia 2008) and the Department of Environment and Heritage Protection guideline for *Stormwater and environmentally relevant activities [ESR/2015/1653]* (DES 2017f). A consequence category assessment will be undertaken by a suitably qualified person during the final design process. However, sediment dams are unlikely to have a significant consequence category due to their locality from the floodplain, climate modelling and the preliminary design parameters.

The sediment dams have been sized as follows:

- water storage capacity 0.1% AEP 24-hour storm event with an adopted volumetric event runoff coefficient for disturbed catchments of 0.5;
- *total sediment basin volume = settling zone capacity + sediment storage volume.*
  The sediment storage volume is the portion of the basin storage volume that progressively fills with sediment until the basin is de-silted; and
- *solids storage volume = 25% of water storage volume.*

If required, water captured in sediment dams will be pumped back into the MAW system.

Table 9 summarises the sediment dam design criteria in accordance with the abovementioned guidelines.

The sediment dams will be maintained until the vegetation within the catchment area of the sediment dams is successfully established; and whereby surface water runoff achieves similar water quality characteristics to background sites of areas undisturbed by mining activities. Sediment dams may be maintained during rehabilitation to augment site water requirements.

Table 9 Gemini Project Sediment Dam Design

Storage	Catchment Areas (ha)	10-year 24-hour Water Storage capacity (ML)	Solids Storage Volume (ML)	Total Storage Capacity (ML)
AB01	146.1	105.9	26.5	132

3.4.4 Preliminary Consequence Category Assessment

3.4.4.1 Consequence Assessment – Dams

A consequence assessment has been completed for the dams making up the proposed water management system, in accordance with the *Manual for assessing consequence categories and hydraulic performance of structures* (DES 2016) (the Manual). Details of the assessment protocols and criteria are provided in the *Surface Water Assessment* (WRM 2020b), with results of the assessment summarised in Table 10.

Table 10 Summary of Consequence Assessment - Dams

	Main Water Dam	CHPP and MIA Dams	Raw Water Dam	Sediment Dams
Failure to contain - seepage				
Harm to humans	L	L	L	L

Requires lining (unless detailed groundwater investigation indicates risks are low)	Y	Y	N	N

L = Low consequence
S = Significant consequence
*DSA for Mine Water Dam – no DSA required if spills are directed to the Mine Pit via an appropriately robust overflow system (the Mine Pit provides the DSA)

3.4.4.2 Consequence Assessment – Levee

A consequence assessment has also been completed for the proposed levee protecting the mine pit from flood inundation. The Manual includes specific considerations for the assessment of levee. Details of the assessment protocols and criteria are provided in the *Surface Water Assessment* (WRM 2020b), with results of the assessment summarised in Table 11.

3.4.5 Site Water Balance Model

The operating life mine stage plans were used to determine progressive catchment areas and land use types for each mine water storage. These 'snapshots' of mine operations were adopted for the site water balance modelling. OPSIM, a computer-based operational simulation model was used to assess the dynamics of the mine water balance under conditions of varying rainfall and catchment conditions throughout the development of the Project, based on the SWMS described in Section 3.4.2. The model

was configured to simulate the operations of all major components of the water management system. Detailed water balance modelling methodology is provided in Appendix B.

Water Demand

Water demands calculated for the operational life include CHPP coal washing and conveyor dust suppression, haul road dust suppression, and TLO dust suppression demands. The estimated annual demands (WRM 2020b) (Appendix B) considered the Project from the basis of full production levels (Project Year 2). Year 1 demands are estimated based on construction activities only; including infrastructure establishment and early works on Pit AB excavation. The CHPP and TLO will not be processing coal to contribute to water demand, with the only Project water demand during Year 1 would be dust suppression for construction activities. Site water demands are summarised in Table 12.

Groundwater Inflows

As indicated, there will be small 'pumpable' inflows of groundwater to mining pits at the end of operations. Current active pits do not indicate any groundwater inflows. Groundwater inflows to the pits have been assumed to increase in a linear manner over time.

Groundwater inflows were estimated in the *Groundwater Impact Assessment* (JBT 2019), which is discussed further in Section 8.0 and attached as Appendix C. The estimates provided by JBT (2019) are based on net inflows to the pit after evaporation losses from the pit faces and the entrained moisture losses due to mining.

Groundwater inflows are expected to increase over time and eventually the net inflow would exceed the total site water demand. Water is therefore expected to accumulate in the mine water dam over the long term. The relatively large capacity of the mine water dam has been provided specifically for this purpose.

The net inflow rates adopted for the site waster balance model are provided in Table 12.

Overall Water Balance

The overall average annual site water balance is summarised in Table 13. The results demonstrate the adaptive capacity of the SWMS to changing mine stages and climatic variability.

Over the life of the Project, the results of the site water balance indicate that small volumes of external water supply will be required at each stage of the Project, with the exception of Stage 1 (first four years of Project). Haul road dust suppression forms the greatest demand for water on the site, while the greatest loss of water is caused by evaporation.

Total average inflows increase steadily during the first three stages (13 years) of the Project from approximately 1,000 Ml/a to approximately 1,500 Ml/a. A larger increase is evident in Stages 4 and 5, with the commencement of Pit C adding a greater runoff catchment area which increases total average inflows to around 2,300 Ml/a over the final five years of the Project.

Total average outflows, steadily increase over the operational life of the Project from approximately 1,000 Ml/a to approximately 2,000 Ml/a.

The model of the SWMS has been configured to ensure MAW is contained within the system. Hence, the modelled results show no spills of MAW from the mine water dams (not including sediment dams).

When the sediment dams exceed their maximum operating volumes, sediment dams are allowed to discharge offsite. Note that sizing of the proposed sediment dams is in accordance with *Best Practice Erosion and Sediment Control* (IECA Australasia 2008).

Table 12 Summary of Site Water Demands and Expected Groundwater Inflows

Year	Demand (Ml/a)				Net Groundwater Inflow (Ml/a)
	CHPP	Haul Road	TLO	Total	
1	0.0	250.0	0.0	250.0	0.0

18	162.0	511.8	0.74	674.5	31.6
19	143.4	511.8	0.65	655.9	47.3
Total	**2,897.4**	**7,178.5**	**13.00**	**10,088.9**	**1,292.6**

External Water Supply

Site water requirements are preferentially sourced from the MAW system and supplemented as required by the sediment water system. However, in the event that both systems are not sufficient to meet operational water requirements, external raw water will be supplied by a spur pipeline from the Blackwater Pipeline (refer Section 3.5.2) and transferred to the raw water dam.

'External supply pipeline' refers to the quantity of raw water imported from external sources (i.e., SunWater) which is then transferred to the raw water dam.

Potential imported water requirements have been assessed using forecast simulation. The results show that:

1. imported water requirements from the external pipeline are highest in the early Project stages;
2. under very dry conditions, the demand could reach 500 Ml/a, but median Year 1 demand is less than 100 Ml/a; and
3. during later years, accumulated stored water in the MAW system and sediment water system is sufficient to supply demands in all but the driest years.

The external raw water supply contract will be sufficient to ensure continued operation even in the driest of years.

Table 13 Average Annual Site Water Balance

Process	Stage 1 Y1-Y4	Stage 2 Y5-Y10	Stage 3 Y11-Y13	Stage 4 Y14-Y15	Stage 5 Y16-Y18	Total
Inflows (Ml/a)

3.5 SUPPORTING INFRASTRUCTURE

3.5.1 Power Supply

Electricity supply to the region is provided by a Powerlink 275 kV/132 kV substation at Blackwater (Rangal Substation). Electricity is currently supplied to properties within the local area from a 132 kV/66 kV substation at Blackwater, as well as Ergon substations at Dingo and Bluff. Ergon Energy distributes electricity from these substations to local customers.

Power to the mine and all mining infrastructure (i.e., accommodation facilities, CHPP and MIA) will be supplied by the construction of a 66 kV transmission line and an onsite switching/substation located adjacent to the MIA. The transmission line will be connected to the regional network and be installed along the alignment of the mine access road to the MIA (Figure 8). Diesel power generation will be used for construction activities and until the transmission line is completed.

3.5.2 Water Supply

SunWater operates the Blackwater Pipeline network, which supplies water from the Bedford Weir (part of the Nogoa-Mackenzie River pipeline network) to the town of Blackwater and a number of nearby coal mines.

A spur pipeline from the Blackwater Pipeline will be constructed for the Project by SunWater with the take-off point located near the Blackwater Treatment Plant. SunWater has advised there is sufficient availability of water within the Mackenzie Nogoa River network to provide the Project's estimated water requirements, including in the driest of years. Within the MLA the water supply pipeline will be installed proximal to the mine access road corridor and connect to the raw water dam near the MIA (Figure 22).

During construction water will be required for dust suppression and civil works, as well as potable water for drinking. Water will be sourced from regional suppliers and transported to site by tanker and stored

at the MIA until the permanent supply is established. Potable water may also be supplied by truck from Blackwater.

3.5.3 Sewage

A *Land-Based Disposal Effluent Disposal Assessment* (Cardno 2020) for the Project's effluent disposal is attached as Appendix N. During both construction and operation phases, workers will generate domestic wastewater from accommodation, offices, and facilities. The wastewater will include material which is generated from the following:

- toilets (often classed as black water); and
- showers, kitchen facilities and laundry (often classed as grey water).

In accordance with the EP Regulation, wastewater has been estimated using each worker as an equivalent person (EP) with each EP generating 200 L/day. During construction, a total of 280 workers will be onsite and generate their total maximum volume of 56,000 L/day. During operations, only 140 workers will be present onsite and will generate their total maximum volume of 28,000 L/day.

All domestic wastewater will be channelled to a single sewage treatment plant (STP) located at the accommodation facilities towards the northwest of the MLA, as shown in Figure 7. The STP has been designed for a 280 EP maximum capacity (56,000 L/day). A closed wet weather storage tank will be located at the STP and designed in accordance with the *QLD Government Technical Guideline for Disposal of Effluent via Irrigation*. The closed wet weather storage tank will have a 3-day capacity of 168m^3 suitable for both construction and operations to account for times when the ground is showing signs of saturation (such as surface water pooling) during substantial rain events. The tank will have a length of 19.48m, width of 19.48m, and an overflow outlet depth of 3m.

A membrane bioreactor will be operated at the STP with an appropriately sized pump station to minimise the retention of raw sewage to less than eight hours and reduce the potential for odour and volatile organic compounds.

The treated effluent from the STP will be irrigated in a suitable irrigation management area, while the remaining sewage sludge will be removed by a licensed regulated waste contractor for offsite disposal. During the initial site preparation phase, prior to installation of the STP, all sewage will be contained at the MIA and transferred by a certified third-party contractor to an appropriately licensed regional waste disposal facility.

3.5.3.1 Irrigation Management Area

The proposed irrigation management area is located south of the Capricorn Highway towards the northwest of the MLA and is shown in Figure 7. It is located within reasonable proximity to the primary source of wastewater (accommodation facilities) and is accessible from the proposed camp access road.

The reasonably flat nature of the designated area and distance from significant watercourses is ideal for irrigation. The topography falls in a north to south direction. The irrigation area lacks any significant drainage lines / watercourses and sits on the divide between the catchment of Stanley Creek towards the north and the catchment of Charlevue Creek to the south. Two minor drainage lines off Charlevue Creek are present to the east and west of the irrigation management area. Stanley Creek and Charlevue Creek are highly ephemeral flowing only after substantial rainfall events. The management area has already been cleared and therefore contains limited ecological value.

The irrigation management area (approximately 195m x 195m, 3.8 ha) will maintain sufficient buffers from sensitive receivers such as waterways, ecosystems, and the residents/mining camp (refer to Figure 12-1 of Appendix N). The following buffer zones for the irrigation management area will be adopted in accordance with the *QLD Government Technical Guideline For Disposal of Effluent via Irrigation* to ensure environmental care and exposure to all sensitive receptors is negligible:

- natural waterways >100 m;
- residential facility or public amenities >50 m;
- domestic water bore > 250 m;
- drinking water catchment and aquatic ecosystems with high ecological value > 250 m;
- town water supply bore > 1000 m;
- groundwater bore used for potable water supply >250 m; and
- groundwater table at a depth >3 m.

A review of the Central Highlands Regional Council Flood Hazard Overlay indicates that the irrigation management area and the greater proposed mine are located a substantial distance away from Q100 floodplain based on the 1% AEP + climate change allowance. Therefore, inundation within the irrigation area is not considered to be high-risk.

Site specific soil data was unavailable from the selected irrigation management area and therefore soil characteristics have been interpolated from the Soil and *Land Suitability Assessment* (AARC 2019) (Appendix I). As a result, the irrigation management area has been characterised by the Soil Management Unit (SMU) Geoffrey which covers approximately two thirds of the mining lease (refer to Section 5.2.5). The Geoffrey SMU consists of texture contrast soils (loamy sands to sandy light clays) with soft surface conditions, associated with undulating plains and rises. The chemical and physical properties of the soil profile pH are described as moderately acidic in the upper loamy profile (5.8-6), with a sudden shift to weakly alkaline in the underlying clay profile (8.1). An increased cation exchange capacity (CEC) was observed at greater depths (0.4 – 8.8 meq / 100g) and also a general increase in salts, as is evident in the higher EC (0.004 – 0.137), chloride and sodicity in the bottom clay layer. Exchange sodium percentage (ESP) ranges from non-sodic in the upper profile (1 – 1.8%) to strongly sodic in the lower profile (22.1%).

Topsoil nutrients are generally quite limited with nitrate (3 mg/kg), phosphorous (8 mg/kg) and potassium (<200 mg/kg) below desirable levels. Boron (0.2 mg/kg) and sulphate (<10 mg/kg) are also lower than guideline recommendations for suitable plant growth medium. For extractable metals, manganese (16.0 mg/kg) and zinc (2.16 mg/kg) are within the desirable range, though iron (166 mg/kg) is elevated, and copper (<1.0 mg/kg) is below reportable levels. The nature of the soil is generally supportive of spray irrigation, though the sodicity in the lower soil profile will need to be managed to ensure the soil does not become dispersive.

3.5.3.2 Irrigation Regime

The irrigation regime will be undertaken in accordance with *AS/NZS 1547:2012 On-Site Domestic Wastewater Management.* The infrastructure required will include a STP, wet weather storage tank, closed pond, pump system, pump chamber, pipeline, flush and release valve, supply header and secondary treatment unit. The irrigation layout is illustrated in Appendix N. The pump system and pipeline will contain a separate effluent chamber with storage volume to match the electrical starting

requirements of the irrigation pump motor. The irrigation system will have a discharge capability of at least 50% more than the maximum 30-minute flow rate and capacity to withstand at least 150% of the shut-off head of the pump. The selected spray-irrigation system will evenly distribute effluent and control the droplet size, throw, and plume through the use of coarse spray heads suitable for effluent application.

Given the designated irrigation site is isolated and significant in size, management would only warrant a secondary treatment quality to contain negligible risk of human exposure, aerosol drift and odour nuisance to offsite locations. The following management measures will be implemented to ensure the limits identified in the *National Guidelines for Water Recycling* (Table 9-1, Appendix N) are achieved:

- no access during and after irrigation, until dry (1-4 hours);
- spray drift control (low-throw sprinklers - 180º inward throw);
- restricted irrigation when wind direction is not favourable, or temperature inversions present; and
- irrigation timing during the day when residents are not localised.

Magnetic South will also operate and manage an onsite septic system, which will be located at the MIA to service the office area. Waste from the septic system will be regularly pumped out and removed by a regulated waste contractor for disposal as required. Servicing or maintenance of the system will be contracted to a licensed plumber to undertake the works, as required.

Specific details and requirements regarding the sewage management system will be addressed in a *Non-Mineral Waste Management Plan* for the Project (Section 12.8.1).

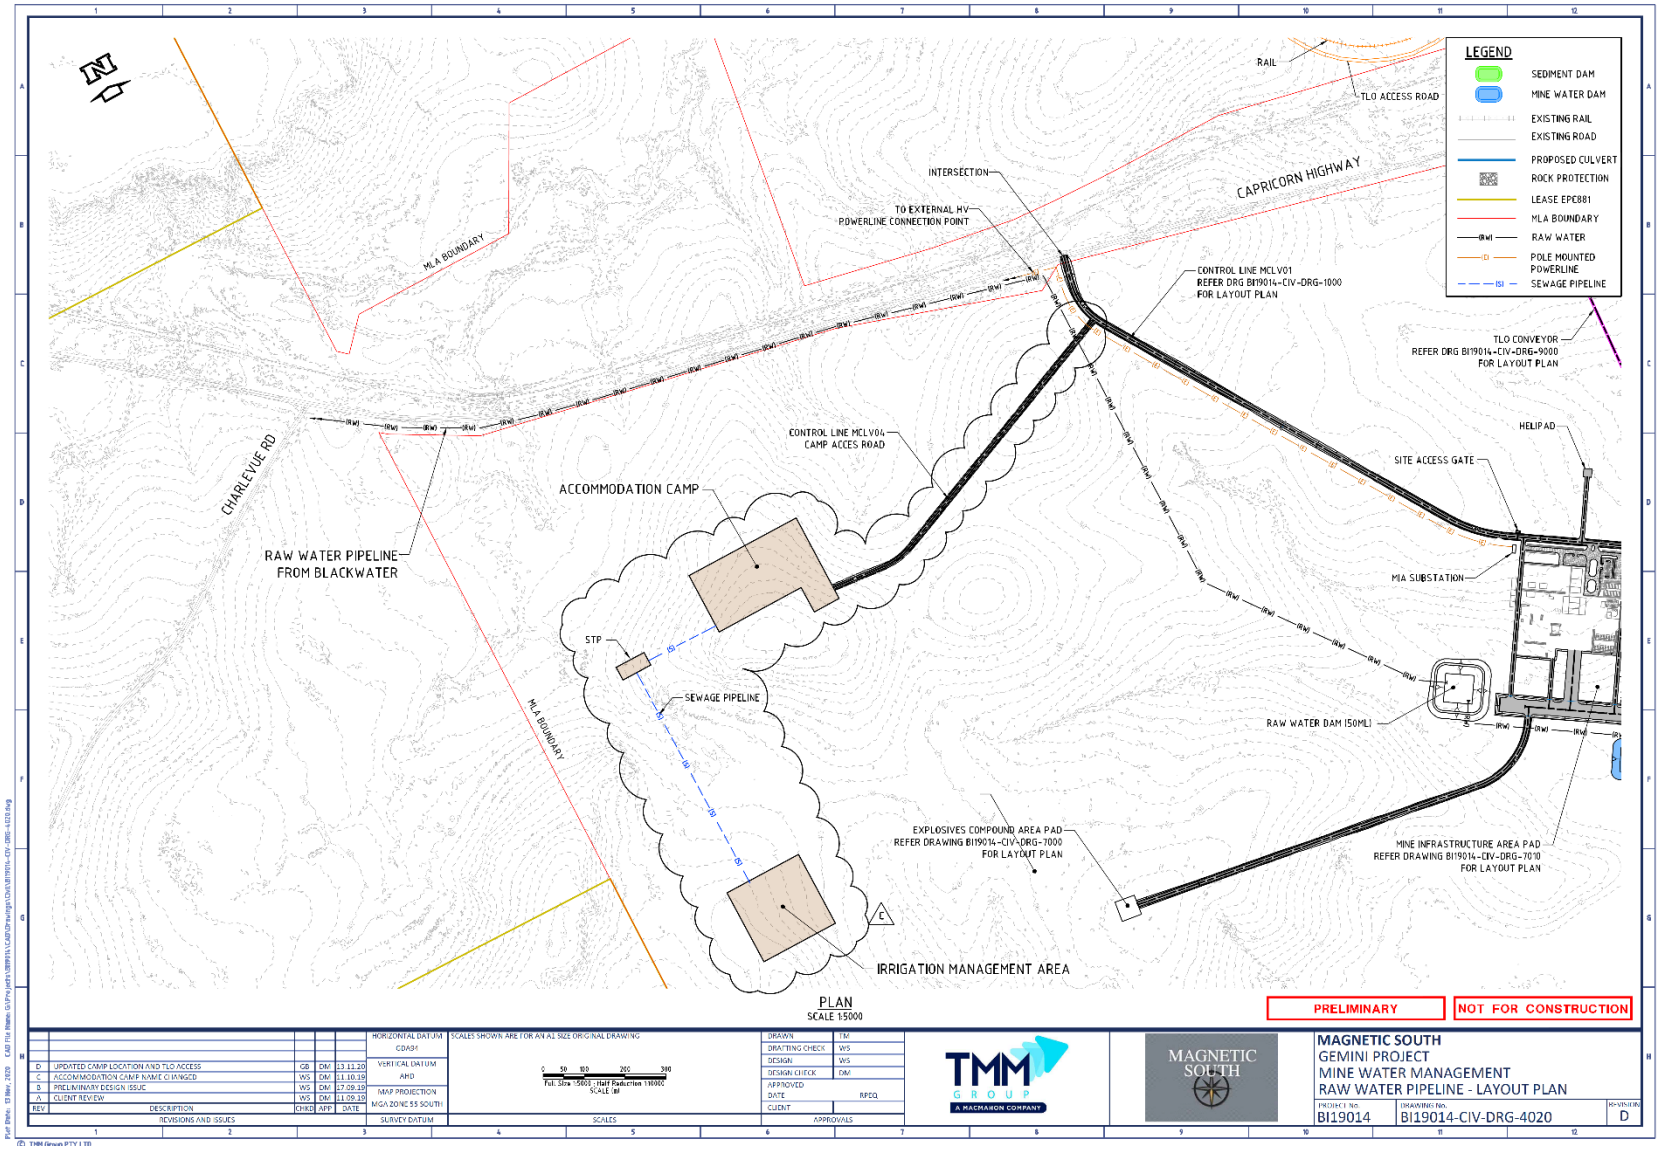

Figure 22 Conceptual Layout - Raw Water Supply Pipeline

3.5.4 Telecommunications

High speed telecommunication services are available in the region via an existing fibre optic network. Connection to this network will be undertaken utilising either microwave or fibre optic cable. A cable connection will be established in the mine access road and power supply corridor.

3.5.5 Fuel Supply

Fuels will be stored within the MIA, with additional self-bunded tanks located as required in the mining area, depending the current location of the main fleet and advancing mine face.

Fuels (including diesel) will be delivered to the Project by contractors. The transport, storage and handling of fuels (including diesel) will be undertaken in accordance with relevant legislation and guidelines.

All equipment and vehicle operators will be trained in the safe operation of the equipment (including operating procedures for the refilling and maintenance of fuel storage tanks and mine vehicles) and the relevant emergency response and spill management procedures in the event of an incident.

Regular inspection programs will be undertaken to monitor the structural integrity of fuel tanks and bunds.

3.6 MINING OPERATIONS

3.6.1 Open-cut Mining Method and Activities

The Project includes two mining areas referred to as Pit AB and Pit C. The open-cut mining areas will be mined using a conventional truck and shovel mining method with excavators and haul trucks.

Mining of Pit AB will be undertaken over a period of approximately 12 years. Out-of-pit waste rock emplacements are required until mine operations advance sufficiently to allow backfilling of the mine void. Out-of-pit waste rock emplacement for Pit AB will be conducted over a period of approximately eight years. In-pit waste rock emplacement will occur from Year 5. Following the completion of coal extraction from Pit AB, final backfilling of the Pit AB void will occur through the rehandling of out-of-pit waste rock emplacements from Year 12.

The development of Pit C is scheduled to commence in Year 12 (one year prior to the completion of mining in Pit AB) and mining will be undertaken over a period of approximately seven years. Out-of-pit waste rock emplacement will be undertaken for Pit C over a period of approximately four years. Once operations have advanced sufficiently, backfilling of the mine void will commence and continue as the mining face advances. Following the completion of coal extraction from Pit C in Year 19, final backfilling of the Pit C void will occur through the rehandling of the out-of-pit waste rock emplacement.

A summary of the open-cut mining activities is provided below.

Vegetation Clearing and Topsoil Stripping and Handling

Vegetation will be progressively cleared over the life of the Project ahead of the active mining and waste rock emplacement areas. Specific vegetation clearance procedures will be developed for the Project as described in Section 5.0.

Topsoil from disturbed areas will be stripped and stockpiled for use in rehabilitation of the final landform. Where stripped topsoils cannot be used directly for progressive rehabilitation, the topsoil will be

stockpiled separately. Specific soil management, stockpiling and re-application procedures will be developed for the Project as described in Section 4.0.

Waste Rock Management

Some weathered or friable overburden (e.g., clays and alluvium) will be pre-stripped using excavators and haul trucks, with supporting dozers.

Drilling and blasting of competent overburden and interburden material (waste rock) will be undertaken within the open-cut pit areas. Standard commercial products will be used, with the principal blasting agent being ammonium nitrate fuel oil (ANFO).

The removal of waste rock will be undertaken by excavator and haul truck, with supporting dozers to expose the underlying coal seams. The waste rock will be placed in out-of-pit waste rock emplacements, or as infill in the mine void, behind the advancing mining operations.

The permanent waste rock emplacements are located to the west of Pit AB and Pit C. The waste rock emplacements will be developed progressively during the operational life of each pit and will have a maximum elevation of approximately 190 mAHD high. As mining advances, sufficient void space will be created within the mined-out areas to enable waste rock to be placed in the in-pit waste rock emplacements.

A small temporary waste rock emplacement will also be established to the north of Pit AB. Waste material will be re-handled from each waste rock emplacement and from the temporary waste rock emplacement to backfill the final voids of each of the respective pits following the completion of coal mining activities.

ROM Coal Handling

Excavators will load the ROM coal into haul trucks for haulage to the ROM stockpile area located at the MIA. Haulage of ROM coal from Pit AB and Pit C will be conducted during day and evening hours (i.e., 7 am to 10 pm), to minimise air quality and noise impacts at sensitive receptors during the night. Noise and dust levels would be monitored for compliance management. To achieve increased Project production rate efficiencies; ROM coal haulage during night hours (i.e., 10 pm to 7 am) would be considered, providing monitoring shows that compliance can be achieved at sensitive receptors.

Landform Profiling and Rehabilitation

Re-shaping of the waste rock emplacements, re-application of topsoil and revegetation of the final landform surfaces will be undertaken progressively over the life of the Project. The rehabilitation strategy for the Project is described in Section 4.0.

3.6.2 Mine Schedule

The total quantity of coal to be mined is approximately 32 Mt ROM. The indicative mine schedule is provided in Table 14. The life of mine waste rock material handled is estimated to be approximately 475 Mbcm for the Project. The annual volumes of waste rock handled during the various mining stages of the Project are provided in Table 14.

Subject to granting of the Project ML and EA, mine construction activities are scheduled to commence in July 2021. It is anticipated that it will take approximately six months to establish the necessary infrastructure to commence overburden removal and 18 months to commence coal production.

Indicative general arrangements for various stages of the Project are shown in Figure 23 to Figure 32. The stage plans show the mine's progression over time and are based on the present schedules and production plans. The layout and mining sequence may vary from that shown to account for localised geological features, detailed engineering design, mining economics and variations in market tonnages and quality requirements.

Table 14 Indicative Mine Schedule

Year	Waste Rock (Mbcm)	ROM Coal Mined (Mtpa)	Coal Rejects (Mtpa)	Product Coal (Mtpa)[1]
Y1	13.0	0	0	0
Y2	26.1	0.9	0.83	0.07

3.6.3 ROM Coal Processing

ROM coal from the ROM stockpile area will be crushed and screened and conveyed to the CHPP for beneficiation. A portion of mined coal may be screened and crushed and bypass the CHPP, direct to the product stockpiles.

Primary sizing will break the coal down to a maximum of 250 mm diameter. Secondary and tertiary sizing will then reduce the top size coal below 50 mm diameter.

The coarse coal circuit will comprise dense medium cyclones and centrifuges to separate the coarse rejects from the washed product coal. The fine coal circuit will comprise cyclones and sieve bends, flotation cells and thickeners, and reflux classifier and screens. Product coal will be conveyed to the product stockpiles for blending to meet customer specifications. The product coal will be conveyed to the TLO facility to be loaded onto trains.

Coarse rejects will be conveyed to the rejects bin. Fine rejects and slimes will be dewatered and conveyed to the rejects bin to be combined with the coarse reject material. The combined rejects will be loaded onto trucks for placement in out of pit spoil dumps, or in-pit behind the mining void.

The conceptual materials handling flowsheet is shown in Figure 33.

3.6.4 Rail Transport and Port Operations

The PCI coal or coking coal from the Project will be transported via the Blackwater Railway to the RG Tanna Coal Terminal or Wiggins Island Export Coal in Gladstone (Figure 1) for export to the international steel making market. Both of these terminals form part of the existing Port of Gladstone.

There will be approximately four train movements per week on average, subject to train and shipping schedules.

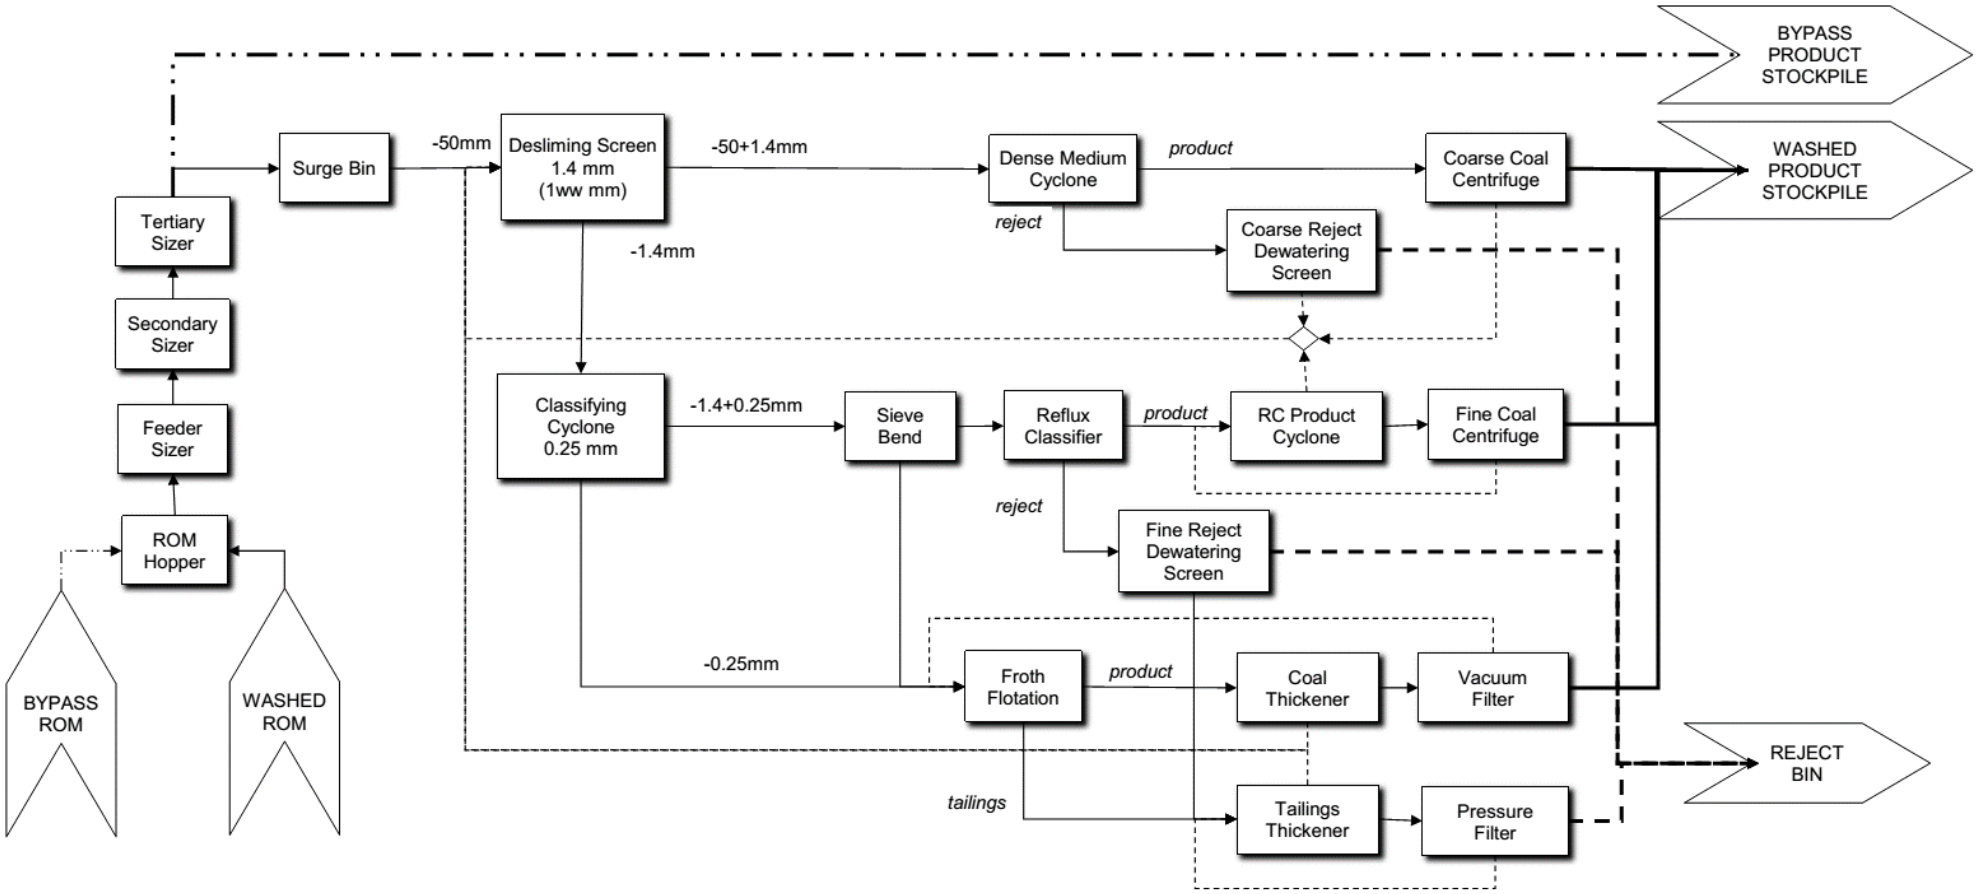

Figure 33 Conceptual Materials Handling Flowchart

3.7 EQUIPMENT FLEET

Equipment used to construct the Project will include excavators, haul trucks, dozers, drills, graders, front end loaders, cranes and water trucks. The mine fleet for the Project is forecast to vary according to the production rates and equipment requirements associated with the open-cut mining operations.

The mining equipment required for the Project includes large (540 t class) hydraulic excavators to remove the bulk of the waste rock material, supplemented by smaller 350 t and 200 t class hydraulic excavators and front-end loaders to remove interburden and partings, and to mine coal. Haul trucks will transport coal (100 t class) and waste rock (240 t class).

A fleet of ancillary equipment will be used to support the mining equipment, including dozers, graders and water trucks. Rotary drills will also be used to drill the waste rock material and coal as required.

The forecast equipment list at full development will include:

- up to four excavators;
- up to 20 haul trucks;
- up to nine dozers;
- up to two graders;
- up to four front end loaders; and
- up to two water trucks.

A small fleet of ancillary equipment will be used to service and maintain mine equipment and infrastructure and CHPP, ROM and product coal stockpiles and manage warehouse storage. This will include fuel trucks, service trucks tyre changer, forklift, mobile cranes, light trucks, loaders and light vehicles.

3.8 ROAD TRANSPORT

The Capricorn Highway traverses the MLA, providing a convenient regional link to Blackwater, Emerald and Rockhampton. As described in Section 3.3.1, an intersection with the Capricorn Highway will be constructed for the mine access road.

A number of local Council roads traverse the MLA and are located to the north and south of the Capricorn Highway. Local roads to the north of the Capricorn Highway within the MLA include Red Hill Road and Ellesmere Road.

Local roads within the MLA to the south of the Capricorn Highway include Cooinda Road and an un-named road. Cooinda Road traverses the MLA from the south and connects to the Capricorn Highway. The un-named road traverses the centre of the MLA through Lot 1 on Plan HT424 (Figure 6) and connects to the Capricorn Highway. To the east of the MLA, Sanders Road originates from Namoi Road and extends to the property boundary of Lot 2 on Plan HT138. From the property boundary, Sanders Road becomes an access track within the property and connects to Cooinda Road within the MLA. These local roads and tracks will be temporarily closed to the public for the Project.

To maintain the connection of Cooinda Road to the Capricorn Highway (via Sanders Road and Namoi Road), the access track extending from Sanders Road is proposed to be diverted. The diversion will be approximately 2 km in length and will connect onto Cooinda Road approximately 1.0-1.2 km south of its

current connection. The diversion works are located outside of the MLA and will be subject to a separate approval from the CHRC (i.e., approval is not being sought by this EA application). Notwithstanding, the approximate location of the proposed diversion is shown on Figure 7.

A *Traffic Impact Assessment* (Cardno 2019) for the Project's roads and intersections is attached as Appendix A. This assessment concluded that all proposed intersections, including the mine access intersection, successfully meet the safe intersection sight distance requirements. Modelling and analysis of the mine access intersection was conducted for a three-way priority-controlled arrangement showing that these intersections can accommodate the anticipated traffic network.

A link capacity assessment was developed for the worst-case traffic scenario anticipated in 2040. This assessment concluded that the Project's road network operates at the highest level of service under baseline traffic conditions. The status of the traffic environment with additional Project related traffic is described as "*stable flow where drivers still have reasonable freedom to select their desired speed and to manoeuvre within the traffic stream*".

The overall impacts to the existing traffic network are not expected to be significant based on an increase in mobilisation of Project vehicles on local and State roads.

3.9 WORKFORCE

Employment opportunities that will be generated by the Project include:

- peak construction workforce of up to 260 personnel; including approximately 230 persons servicing the mine development and 30 persons servicing the rail development; and
- peak operations workforce of up to 330 personnel.

The construction workforce roster will typically be 12-hour day shifts, on a 10 days on and four days off rotation. The majority of work will be conducted during the day; however, some construction activities may require night work. For these activities continuous 24-hour activities may be undertaken, scheduled over two 12-hour shifts in a 24-hour cycle.

The operational workforce roster will be 12-hour day/night shifts, on a seven days on and seven days off rotation. The senior management and technical staff roster will be 10-hour day shifts, on a five days on and two days off rotation.

3.10 WORKFORCE ACCOMMODATION

During site preparation and construction, temporary accommodation would be available for non-resident workers within the local region in towns such as Blackwater, Dingo and Bluff and in the accommodation facility, once constructed. The accommodation facility will be constructed towards the northwest of the MLA and will have capacity to accommodate up to 280 persons, but under normal conditions will only be occupied by up to 140 persons. Access to the accommodation facility will occur off the mine access road just beyond the intersection off the Capricorn Highway.

It is anticipated that 80% of the operational workforce will be drive-in-drive-out from the surrounding region, staying at the accommodation facility and bussed to site daily. The remaining 20% of the workforce would reside locally in Dingo, Bluff or Blackwater, with daily light vehicle travel to site and carpooling where practicable.

4.0 REHABILITATION AND CLOSURE

4.1 LEGISLATIVE FRAMEWORK

4.1.1 Environmental Protection Act 1994

In Queensland, mine rehabilitation is required under the EP Act. Amendments to the EP Act in late 2018 implemented key elements of the State Government's *Mined Land Rehabilitation Policy* (State of Queensland 2018) which intends to ensure that land disturbed by mining activities is rehabilitated to a safe and stable landform that does not cause environmental harm and is able to sustain an approved post-mining land use (PMLU).

A key component of the amended Act is the requirement (clause 125 (1)(n)) for a site-specific application for a mining activity related to a ML to be accompanied by a proposed *Progressive Rehabilitation and Closure Plan* (PRCP) complying with Division 3 of Part 2 of Chapter 5. Under this Division, a PRCP must include a PRCP schedule providing rehabilitation milestones for each proposed PMLU, and management milestones for each non-use management area (NUMA) proposed; as well as stating when each milestone is to be achieved. In accordance with the *Environmental Protection (Rehabilitation Reform) Amendment Regulation 2019*, the PRCP start date is 1 November 2019.

The timing of the EA application for the Gemini Project means that it is a transitional project under the amended EP Act. If the EA application is approved, a transition notice from the regulator will be issued to the holder, requiring transition into the PRCP framework. Where practical this rehabilitation and closure section has been prepared to provide information that will ultimately be required in the PRCP.

4.1.2 Mineral and Energy Resources (Financial Provisioning) Act 2018

The *Mineral and Energy Resources (Financial Provisioning) Act 2018* (MERFP Act) was assented to on 30th November 2018 and, apart from amending the EP Act to implement key elements of the *Mined Land Rehabilitation Policy* (State of Queensland 2018), introduces a new financial provisioning scheme, and changes the method for estimating the rehabilitation cost for a resource activity. The new financial provisioning scheme:

- provides for holders of an EA for a resource activity, to pay financial provision contributions to a scheme fund, or provide a surety;
- provides a way to manage the financial risk to the State, as well as the State's costs and expenses, where a resource activity EA holder does not comply with their obligations in relation to rehabilitation; and
- provides a source of funds to the State, for the rehabilitation and/or remediation of lands impacted by abandoned mines, as well as for research contributing to the rehabilitation of land on which resource activities have been carried out.

In accordance with Section 297 of the EP Act, it will be a condition of a resource activity EA that the holder must not carry out a resource activity unless an estimated rehabilitation cost (ERC) decision is in effect and the holder has made the relevant contribution to the scheme fund. Given this, it is anticipated that at the time of issue of an EA for the Project, the proponent will determine the ERC and apply to DES for an ERC decision for the resource activity in accordance with Section 298 of the EP Act.

4.1.3 Policies, Subordinate Legislation and Guidelines

As outlined in Section 4.1.1, the *Mined Land Rehabilitation Policy* (State of Queensland 2018) is the principal and current policy relevant to mine land rehabilitation.

At the time of writing, the following relevant subordinate legislation and guidelines were available:

- *Guideline (Resource Activities): Rehabilitation requirements for mining resource activities [ESR/2016/1875]* (DES 2014a).

The EP Act is supported by the EP Regulation.

4.2 KEY INFLUENCING ECOSYSTEM PROCESSES AND FUNCTIONS

4.2.1 Climate

Rehabilitation methods, particularly surface preparation activities, revegetation species selection, and revegetation timing need to consider the climatic aspects of the region.

The climate of the Project area is characterised as semi-arid with hot humid summers and dry mild winters. Temperatures range between 15°C and 30°C, with mean daily maximum temperatures ranging between 24°C in June and 34°C in January; and mean minimum temperatures ranging between 8°C in July and 22°C in January. The average annual rainfall is 655 mm and evaporation typically exceeds 2,040 mm per annum.

The climatic aspects of the Project site of most relevance to rehabilitation outcomes and erosional impacts can be summarised as:

- **Rainfall:** records depict a typical wet season between November and March of each year, approximately coinciding with the hotter summer months. Figure 34 highlights the significant variation of wet year average rainfall that exists in the region.

- **Evaporation:** average evaporation rates are typically three times greater than the average annual rainfall which, with the variation in annual rainfall commonly experienced is indicative that significant moisture stress can regularly occur, with a consequent potential impact on revegetation success rates and/or failure events.

- **Rainfall intensity:** the central Queensland area can experience high intensity rainfall events. Analysis of BoM 2016 Design Rainfall Data System indicates that short (less than five-minute) duration, high intensity storms of greater than 100 mm per hour would be expected in the Bluff area of central Queensland typically once or twice each year (BoM 2019a).

4.2.2 Landscape, Landform and Hydrology

The Project area is described as gently undulating with elevations ranging between 120-150 mAHD. The physiography of the area is characterised by a dissected tableland having a general relief variation of about 80 m with slopes within the MLA area well less than 5°. The topography of the Project is representative of the surrounding region. The viewscape, some 15-18 km distant to the southwest and west respectively is to the elevated Blackdown Tableland National Park and Arthurs Bluff State Forest which rise approximately 450 m above the elevation of the Project site. There is little relief to the north and east with the land falling gently toward the Mackenzie River valley.

The landscape is influenced by the presence of Charlevue Creek which bisects the MLA from west to east and Springton Creek which flows alongside the southeast boundary of the MLA. The associated

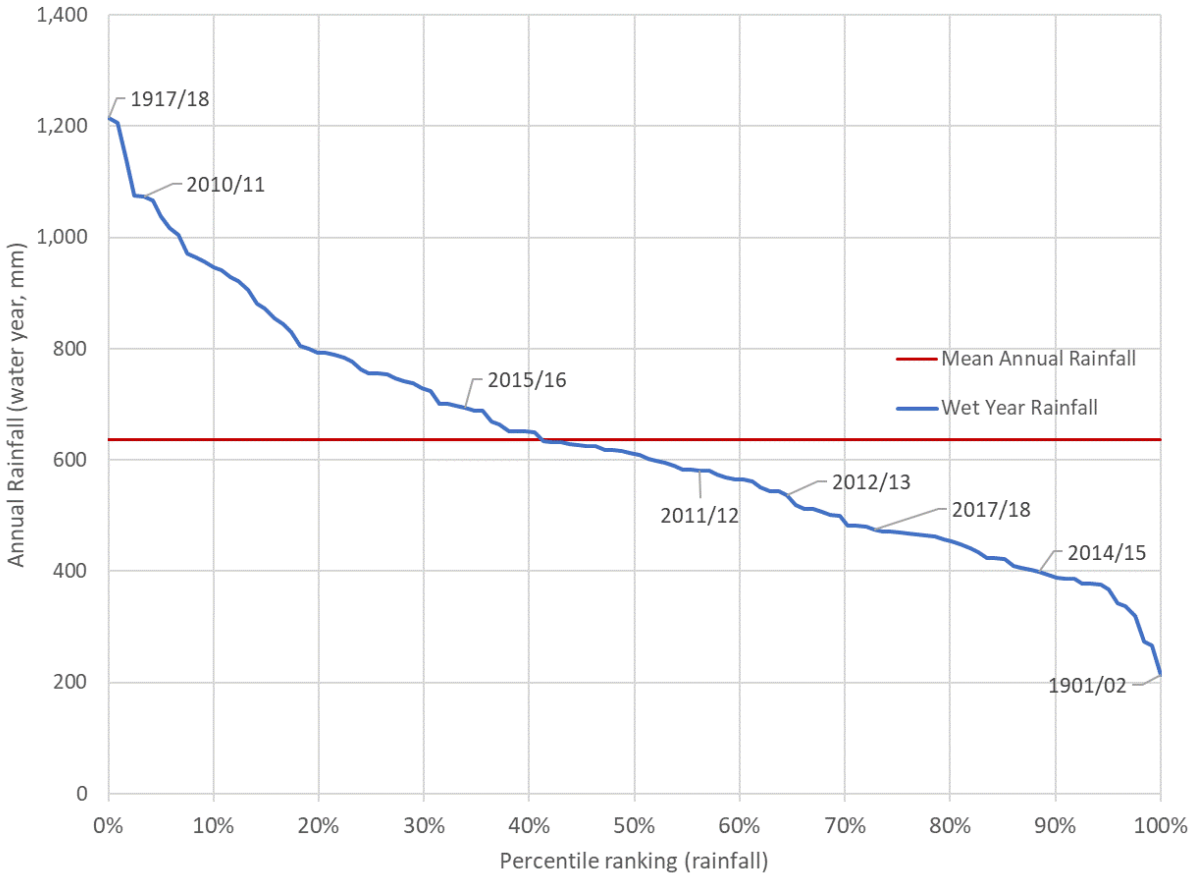

Figure 34 Percentile Ranking of Water Years

floodplains of these two watercourses result in localised lower elevations within the surrounding landscape.

The Project lies within the Mackenzie River sub-catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River catchment. The major water body associated with the Project site is Charlevue Creek. This creek begins within the boundaries of Blackdown Tablelands National Park, flowing to the northeast before joining Springton Creek. Springton Creek flows to the Fitzroy River eventually reaching the Pacific Ocean approximately 46 km north of Gladstone. A significantly smaller tributary, Stanley Creek crosses the northwest corner of the MLA boundary eventually converging with Springton Creek downstream of the MLA. Minor associated tributaries, dams and drainage features also exist across the site.

4.2.3 Spoil Geochemistry

A detailed *Geochemical Assessment of Mining Waste Materials* associated with the Project was undertaken by RGS Environmental Pty Ltd (RGS 2019) (Appendix G). Geochemical test work undertaken was based on industry recognised procedures for the geochemical characterisation and assessment of mine materials. Seventy samples representative of the main overburden, inter-burden and potential coal reject materials likely to be encountered during development of the Project were assessed.

Samples were subjected to a range of static and kinetic geochemical tests to assess the presence and degree of environmental risk from the oxidation of reactive sulphides, the potential for acid generation, and leaching of soluble metals/metalloids and salts. While these geochemical risks were determined to

be low, the assessment recommended the placement of any carbonaceous mining waste material in locations not near the surface or outer batters of waste rock emplacements.

The assessment identified that while most mining materials would be amenable to revegetation, they are likely to be susceptible to dispersion and erosion and may require amelioration for example, through the addition of gypsum and fertiliser. The assessment recommended additional testing of materials and field trials to assist in determining the most appropriate management options to ensure effective rehabilitation.

Geochemistry is discussed in further detail in Section 13.0.

4.2.4 Topsoil Resources

SMUs are detailed within Section 5.2.5. In general, the surface soils to be reclaimed for use in rehabilitation topsoiling activities are of variable pH (between 4.6 and 8), very low to medium salinity, non-sodic (with the exception of the Charlevue SMU), and of very low to high fertility (based on CEC analysis results). The majority of topsoil reclaimed will originate from the Geoffrey SMU which, while not dispersive in the A horizon, has a sandy texture and low nutrient status and may require amelioration to ensure successful revegetation.

A practical topsoil stripping depth of 30 cm has been adopted to capture the entire seed bank, although shallower topsoil stripping depths are recommended where soil chemistry changes occur at less than 30 cm below surface. Subsoil stripping depths are also provided to demarcate the subsoils of a suitable chemical nature for reuse in rehabilitation where desirable (Table 15).

The volume of topsoil and subsoil that can be reclaimed across the disturbance footprint has been calculated using the disturbance area and recommended stripping depth for topsoils and subsoils (refer Table 15). The assessment of soil and land suitability concluded that the topsoils within the disturbance area from Charlevue and Nigel are not suitable for use in rehabilitation activities due to soil limiting properties and have been excluded from the calculation of topsoil reserves (Appendix I).

The volume of topsoil able to be reclaimed across the disturbance footprint of the Project site is 4,953,748 m^3. In addition, 3,832,237 m^3 of subsoil material may also be reclaimed to supplement the topsoil resource. Based on a recommended minimum topsoil respreading depth of 0.3 m, approximately 5,231,820 m^3 of soil will be required for rehabilitation efforts over the life of the Project.

Generally, only topsoil from the A horizon/shallow B horizon will be stripped. Where subsoils are required to supplement topsoil resources, subsoils with high clay content and low erosivity risk will be preferentially selected. A review of the available SMUs has identified James and Barry as having preferred subsoils.

Delineation of topsoils and subsoils during stripping and stockpiling is proposed to prevent dilution of the seedbank. It is recommended that subsoils are placed below topsoil during rehabilitation to increase germination, provide a suitable medium for root development and to aid in water storage within the soil profile. Mixing of topsoils and subsoils is also possible at a recommended ratio of 2:1 but may lead to additional nutrient and seed input requirements to successfully establish vegetation.

Topsoil and subsoil volumes available for use in rehabilitation activities will be maintained in a topsoil inventory in accordance with a *Topsoil Management Plan* to be developed upon approval of the EA conditions and prior to the commencement of construction activities (refer to Section 4.4.2).

Soils are discussed in further detail in Section 5.0.

Table 15 Estimated Topsoil Volumes Available for Rehabilitation

* soil properties limit plant growth and are unsuitable for use in revegetation activities

4.2.5 Terrestrial Ecology

The Project area falls within the Brigalow Belt bioregion, characterised by brigalow (*Acacia harpophylla*) woodland but presenting other vegetation such as semi evergreen vine thickets, dry eucalypt woodlands and native Bluegrass (*Dichanthium sp.*) grasslands. Due to the size of Brigalow Belt bioregion, it covers a broad climatic gradient as well as a diversity of soils and topography. As a result of agricultural and development activities, most of the relatively undisturbed areas are confined to the rugged parts of the landscape.

Consistent with the surrounding country, the MLA is predominantly non-remnant and subject to low intensity cattle grazing. Remnant vegetation includes patches of eucalypt woodland within riparian areas and on flat plains. These communities are mapped as riverine wetlands where they are associated with a major watercourse or floodplain. *Acacia sp.* closed woodlands are present on higher ground. The Project proposes clearing of 720 ha of remnant vegetation over the life of the Project.

Five weeds of national significance (WoNS) and/or restricted invasive species (RIS) under the *Biosecurity Act 2014* (Biosecurity Act) (DAF 2018a) were identified on the MLA. The near threatened plant species *Cerbera dumicola* was identified in two rocky areas to the central west of the MLA. Impacts to these populations were avoided in the Project design.

Four fauna species of conservation significance; the southern squatter pigeon (*Geophaps scripta scripta*), the greater glider (*Petauroides volans*) and the short-beaked echidna (*Tachyglossus aculeatus*) and the rufous fantail (*Rhipidura rufifrons*) were identified on the Project. The rufous fantail (*Rhipidura rufifrons*) is a listed migratory bird species under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). All fauna species are regionally abundant, having been recorded

outside of the study area on numerous occasions. Ample equivalent or improved habitat is available for these species in the surrounding area. The Project proposes no significant impact to the species.

Flora, fauna and aquatic ecological systems are discussed in further detail in Section 6.0.

4.2.6 Current Land Use and Land Suitability

Under the CHRC 2016 planning scheme, the land within the Project boundary is mapped as 'rural'. This zone provides for various rural uses, opportunities for non-rural uses compatible with agriculture and the environmental features and landscape of the areas, and the protection and/or management of significant natural resources and processes related to primary production. The current use is best described as low intensity cattle grazing and resource exploration activities.

SMUs are detailed at Section 5.2.5 along with a determination of land suitability for cattle grazing (refer Section 5.2.6). The land suitability assessment identified grazing land suitability within the Project area as being of Classes 2, 3 and 4 as detailed in Table 16.

Table 16 Land Suitability Assessment

Land Suitability Class	Area Occupied	Description
Class 2	1,080.5 ha (17.49%)	Suitable land with minor limitations which either reduce production or require more than the simple management practices of Class 1 land to maintain economic production.
Class 3	4,338 ha (70.20%)	Suitable land with moderate limitations which either further lower production or require more than those management practices of Class 2 land to maintain economic production.
Class 4	750.84 ha (12.31%)	Marginal land, which is presently considered unsuitable due to severe limitations. The long-term significance of these limitations on the proposed land use is unknown or not quantified. The use of this land is dependent upon undertaking additional studies to determine whether the effect of the limitations can be reduced to achieve sustained economic production.

4.3 REHABILITATION OBJECTIVES

The overarching objective of mined land rehabilitation for the Gemini Project is to conform to the State government policy of returning disturbed lands to a safe and stable landform that does not cause environmental harm and is able to sustain an approved PMLU.

PMLUs for the mine were developed based on pre-mining land suitability, landholder/stakeholder preferences, technical studies and the existing land use and environmental values of the surrounding landscape. Magnetic South is an active member in the local community and is responsible for managing an extensive area of local cattle grazing land. Community consultation has been undertaken by Magnetic South over the past two years and has covered all relevant aspects of mine operations and closure. This Consultation included, but was not limited to:

- underlying landholders;
- surrounding community members with an interest in the Project;
- the Gaangalu Nation People;

- local council representatives; and
- state government representatives.

A meeting was held with members of the Central Highlands Regional Council on the 26 November 2019. Options for rehabilitation and final land uses were specifically addressed in this discussion. The continuation of grazing interests was a key outcome of the consultation, incorporated into the development of PMLUs.

Further consultation will be undertaken as part of the ongoing consultation strategy for the Project, including in the development phase of the PRCP. Local knowledge of graziers is highly valued by Magnetic South in all aspects of land management and is seen as essential for ensuring successful and sustainable rehabilitation of the Gemini Project.

4.3.1 Rehabilitation Areas

The disturbance areas identified in the final site design have been divided into rehabilitation areas, which have a common PMLU and rehabilitation methodology, these include:

- RA1: in-pit and out-of-pit waste emplacements, including dry rejects disposal areas;
- RA2: temporary waste emplacements;
- RA3: residual void lakes;
- RA4: residual void high walls;
- RA5: residual void low walls;
- RA6: water management infrastructure; and
- RA7: mine infrastructure areas.

These rehabilitation areas are shown below in Figure 35.

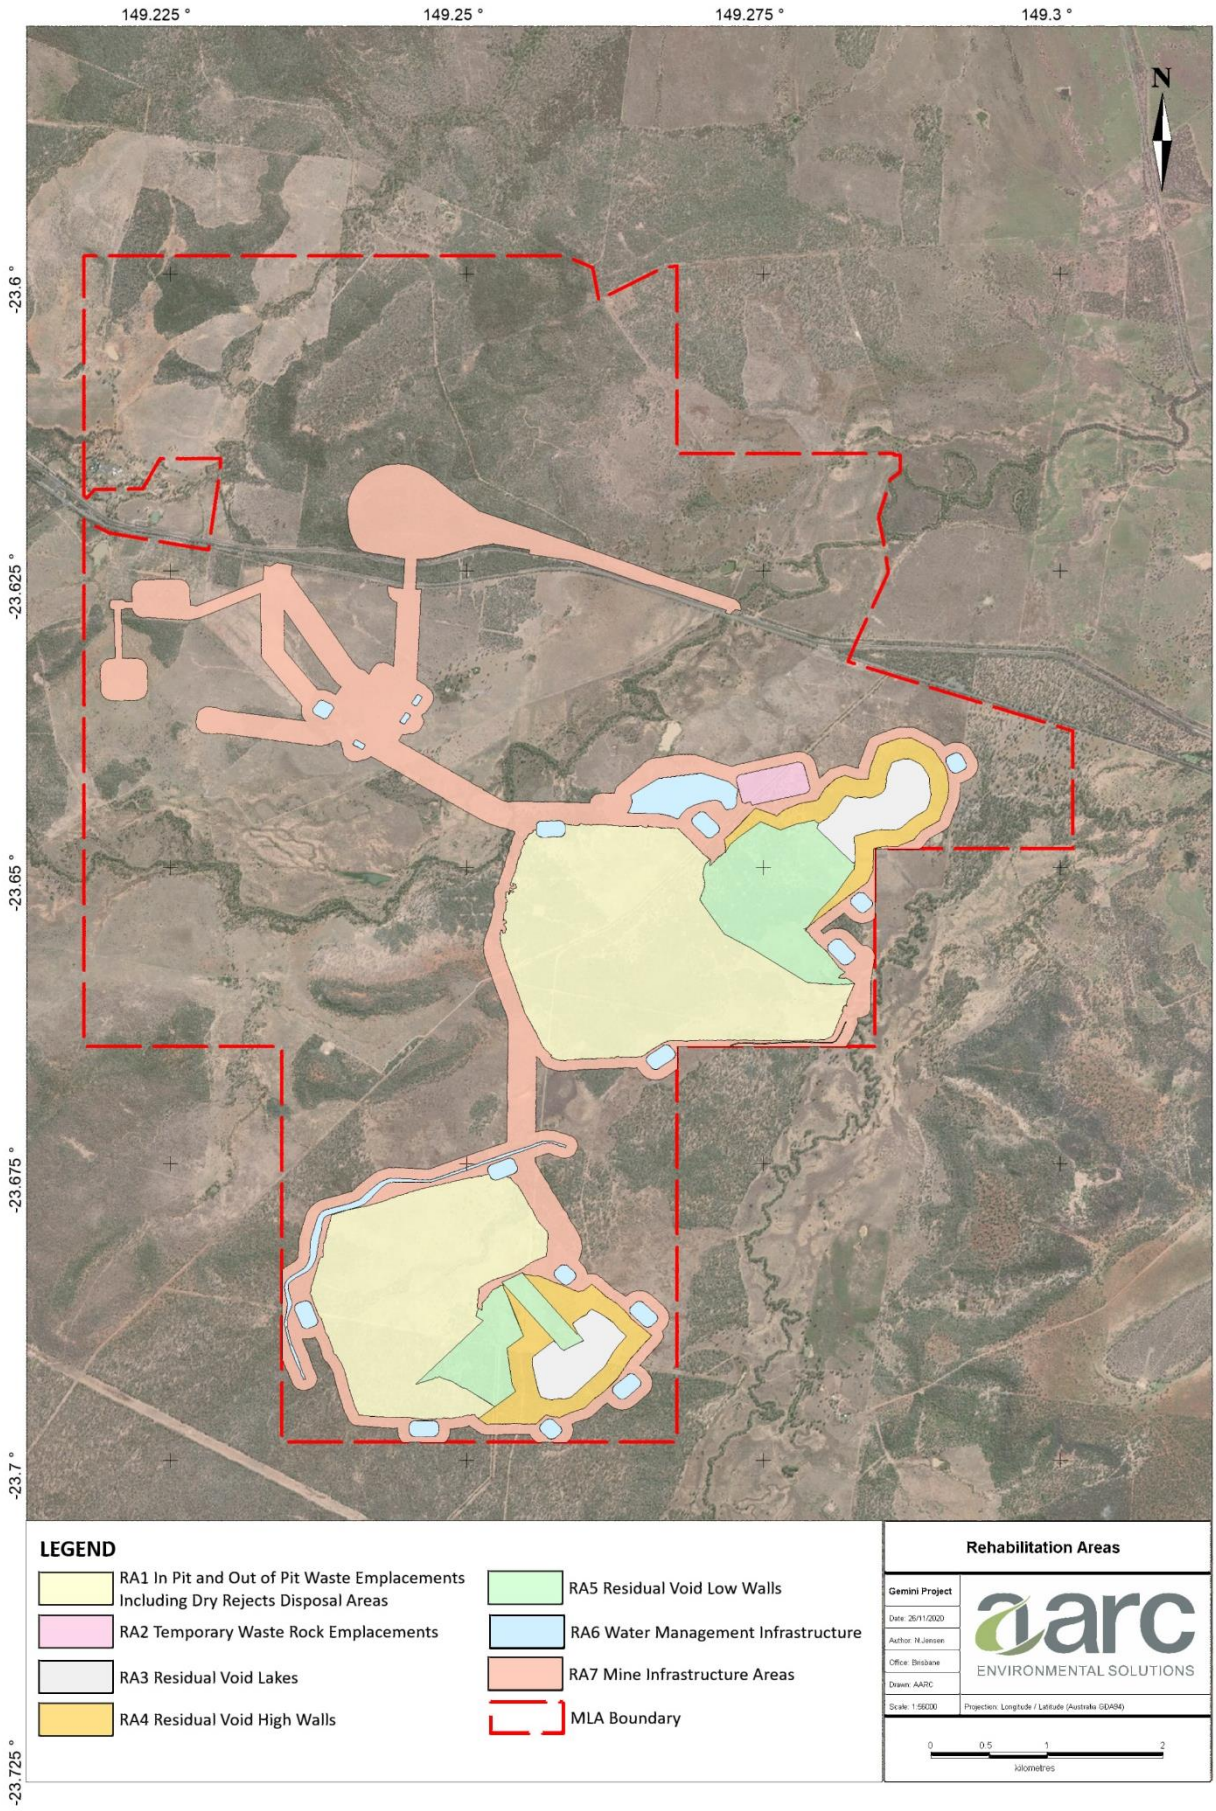

Figure 35 **Rehabilitation Areas**

4.3.2 Post-mining Land Use

In the short term, Project activities will disturb and alter the current land use of low intensity cattle grazing. The overarching objective is to return the majority of disturbed land to future landowners with a land use capacity conforming to existing local government planning instruments, and that enables a sustainable future value to be derived. Areas disturbed by mining activities will largely be returned to a grazing landscape, with the introduction of some areas of native ecosystem habitat suitable for native flora and fauna. These PMLUs have been determined based on pre-mining land suitability, landholder/stakeholder preferences, and the existing land use and environmental values of the surrounding landscape.

The development of the rehabilitation strategy for the Project has been informed by the rehabilitation hierarchy. Minimisation of disturbance has been a focus of design phase mine planning work, and a key land use objective being reinstatement of a land use at least equivalent or compatible to that existing previously. Given the existing land use of the area, reinstatement of grazing as a PMLU will be adopted for all areas apart from the proposed residual voids and any retained water management or other infrastructure where the latter supports accepted PMLUs and/or adds to the economic value of the land to be relinquished. With appropriate management of the higher sodicity topsoils identified, it is anticipated that rehabilitated landforms will be capable of sustaining improved and native pastures equivalent to those currently existing.

Two residual voids will remain post-mining and are anticipated to accumulate water over time to an equilibrium water level. The pit lakes and surrounding highwalls are proposed to support a PMLU of fauna habitat comprised of the water body itself and its surrounding inwardly draining slopes which will be rehabilitated to sustain a native ecosystem able to support native fauna. The air/waterbody interface is expected to support a range of waterborne and flying insects, as well as avifauna and various bat and microbat species. The waterbody itself is expected to support a range of freshwater aquatic plants and invertebrates in shallower edge areas and over time transition to brackish water species as water quality changes. Rehabilitated low wall slopes will be capable of supporting a grazing land use and native flora and fauna. The proposed PMLU for each of the rehabilitation areas is summarised below in Table 17 and shown in Figure 36.

Table 17 Nominated PMLUs

Rehabilitation Area	Post-mining Land Use	Approximate Footprint Area (ha)	Approximate Proportion of Total Disturbance
RA1: In-pit and out-of-pit waste emplacements, including dry rejects disposal areas	Grazing	722.4	37%
RA2: Temporary waste emplacements	Grazing	17.5	1%
RA3: Residual void lakes	Fauna habitat	76.5	4%
RA4: Residual void high walls	Native vegetation supporting fauna habitat	133.1	7%
RA5: Residual void low walls	Grazing	187.2	9%
RA6: Water management infrastructure[1]	Grazing/native vegetation	85	4%
RA7: Mine infrastructure areas[1]	Grazing	731.8	38%

Notes: 1 Where not retained under a landholder agreement allocating infrastructure responsibility.

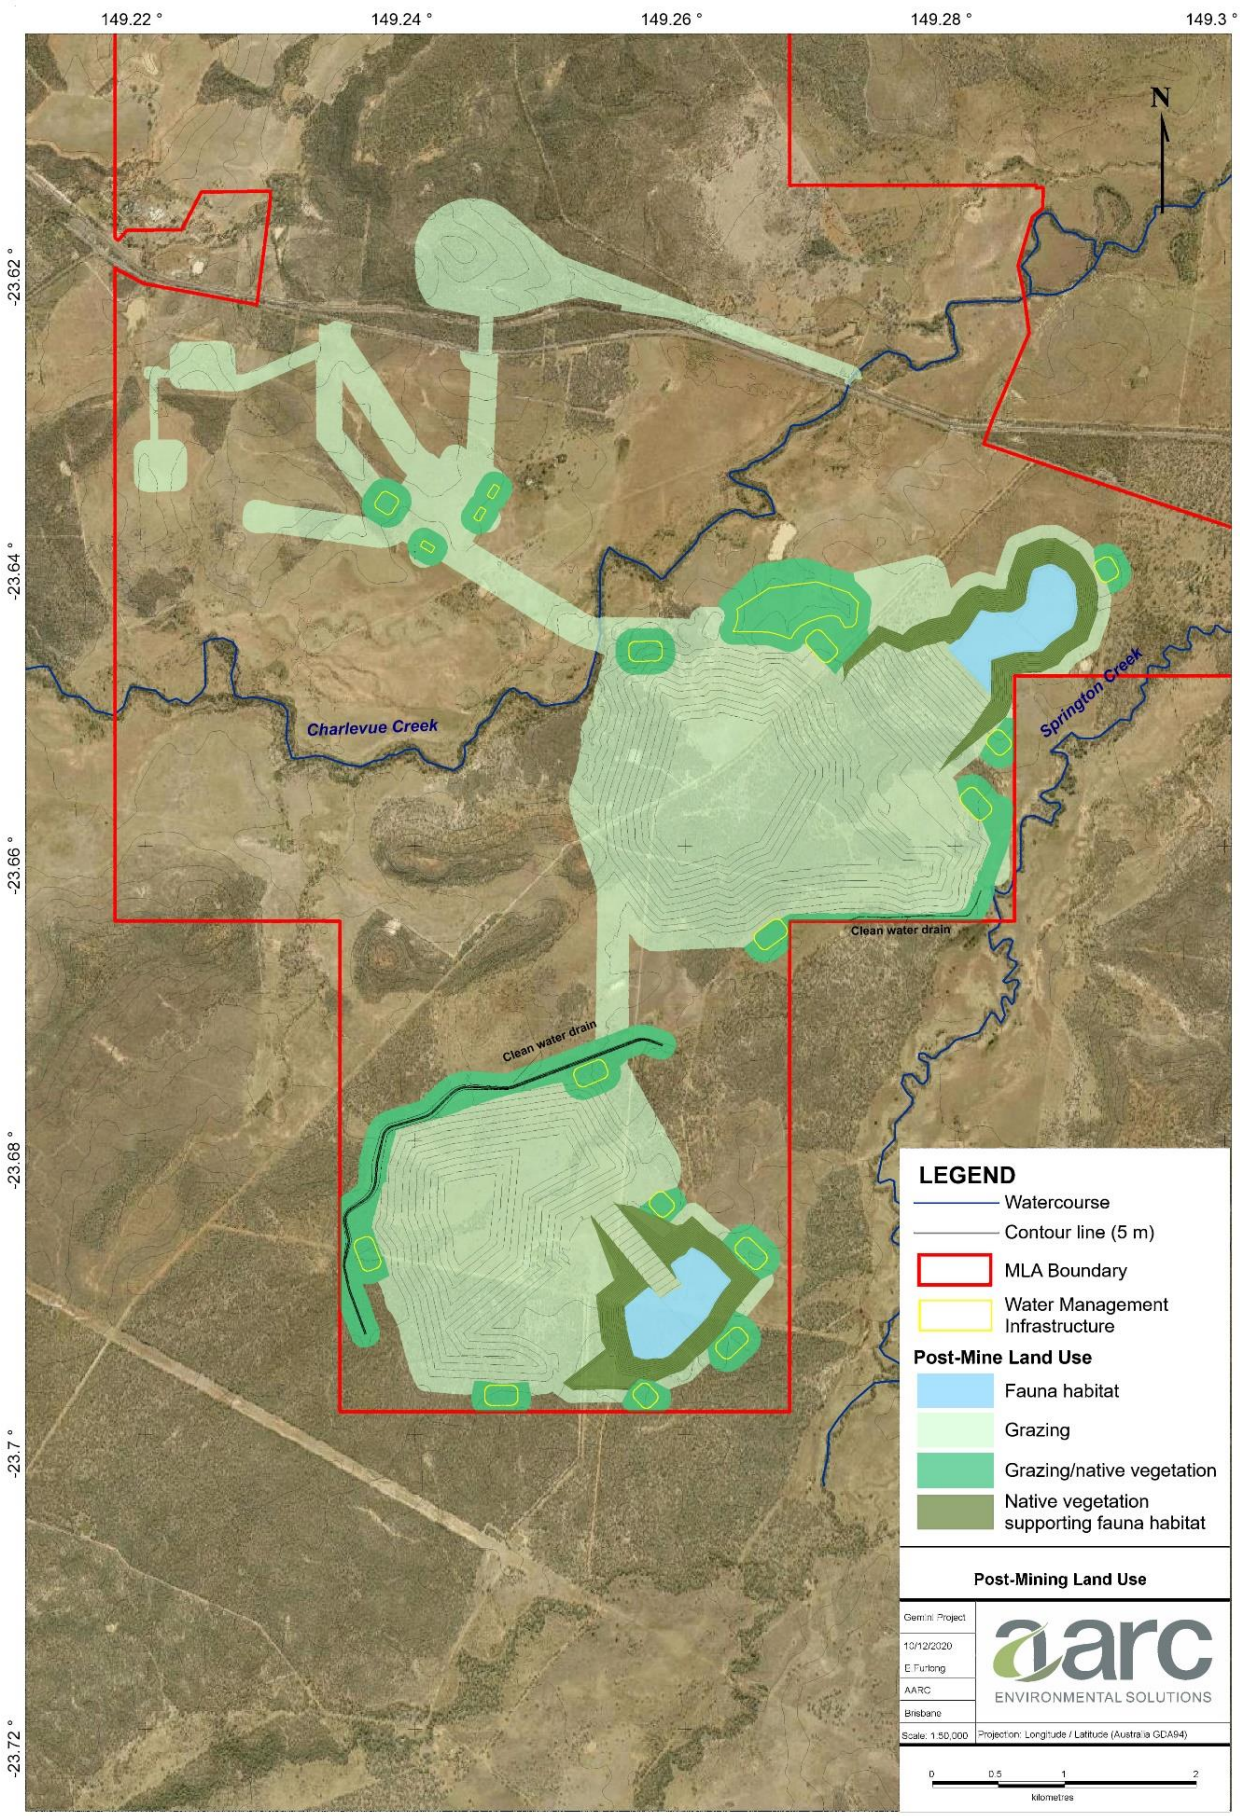

Figure 36 **Post Mining Land Uses**

The following subsections describe how progressive rehabilitation will be undertaken to achieve PMLUs for each rehabilitation functional area.

4.3.2.1 Alternative Post-Mine Closure Options Analysed

Mine planning assessed a number of options to manage and reduce final landform residual risk including backfilling the pits to a modified pre-mining topography, backfill of pits to about 80 m below the pre-mining topography and no backfilling of pits. All options required the rehandle of spoil material, the reduction of remnant highwall angles by dozer push, the reshaping of waste rock emplacements, and normal rehabilitation techniques related to topsoiling, surface preparation and revegetation. Options were evaluated on the relative basis of cost, overall project value and relative reduction in environmental risk.

The modified pre-mining topography option was based on backfilling voids to a level slightly higher than the original topography to allow for settlement over time. Once a sufficient period has been allowed for settlement, the area would be shaped and drained to manage erosion and then topsoiled and revegetated. Advantages with this option include negation of the need to stabilise highwall slopes or make safe the final void itself. The primary disadvantages with this option are:

- the significant cost of rehandling extremely large volumes of spoil at the end of mine production;
- the significant limitation on being able to undertake progressive rehabilitation given the need to rehandle a majority of waste rock material at the end of mine life; and
- the ongoing settlement of the final landform surface potentially resulting in long term stability issues.

The modified pre-mining topography option resulted in the net present value (NPV) of the project being so low that the Project could not proceed. In consideration of the margins of error within the financial model assumptions, the risk of a negative return was far too high for development. This option was therefore not considered further.

The preferred option (proposed in this application) is to backfill to 80 m below topography, based on the findings of the *Groundwater Impact Assessment* (JBT 2019) (Appendix C). This study indicated that, with controls to limit surface water draining to the pits, saline inflows would be significantly reduced if the pit was backfilled to 80 mbgl. For this option, in-pit backfill would be reshaped to 6° in line with other slopes with a corresponding grazing land use. Highwall slope management requirements would be reduced, and additional areas would be available for grazing. Only minor restrictions on progressive rehabilitation arise. While still resulting in a partially backfilled void at completion of mining, a key advantage is that water quality within the pit lakes will increase in salinity at a lower rate than otherwise.

The residual voids will comprise three principal ‘rehabilitation areas’ having differing landforms and characteristics and, as a result, differing PMLUs. These areas are described as:

- Regraded, topsoiled and revegetated low wall slopes draining to the pit water lakes and able to support a grazing PMLU.
- Two water bodies with a surface level which has been modelled to gradually increase to an equilibrium level of between 70-80 mAHD; acting as a groundwater sink and having a gradually increasing salinity. A key rehabilitation objective for this rehabilitation area is to reduce the rate of predicted water salinity present in the void primarily to allow the ecology of the residual void waterbody sufficient time to adapt to salinity changes. Backfilling the voids to 42 mAHD for Pit AB and 65 mAHD for Pit C reduces saline groundwater inflows and surface water drainage,

resulting in a significant reduction in the rate of salinity development within the pit water body. This is due to the water level adjacent the final void equal to the groundwater level within the spoil as illustrated in Figure 37.

Final void modelling suggests that during the first 200 years after closure, lake salinities will be less than 10,000 mg/L. After 500 years, salinity is conservatively modelled to increase to 30,000 mg/L. It should be noted that modelling inherently overestimates the rate of salinity increase in residual void water bodies by assuming that the source of mobile salts in overburden is infinite. Recent research is challenging this assumption, but there is little currently available data on the long-term behaviour of water bodies resident in Bowen Basin coal mine overburdens, particularly the rate of approaching a long-term equilibrium salinity level. The backfilling option adopted is intended to seal the poorer quality remnant coal seam aquifers and limit salt inputs to the pit lake from groundwater.

- Residual void high walls will be regraded to moderate slopes of approximately 22°, made safe and rehabilitated to a native ecosystem able to support native fauna as a PMLU.

Figure 37 provides progressive cross-sections depicting the proposed backfilling of spoil within AB Pit.

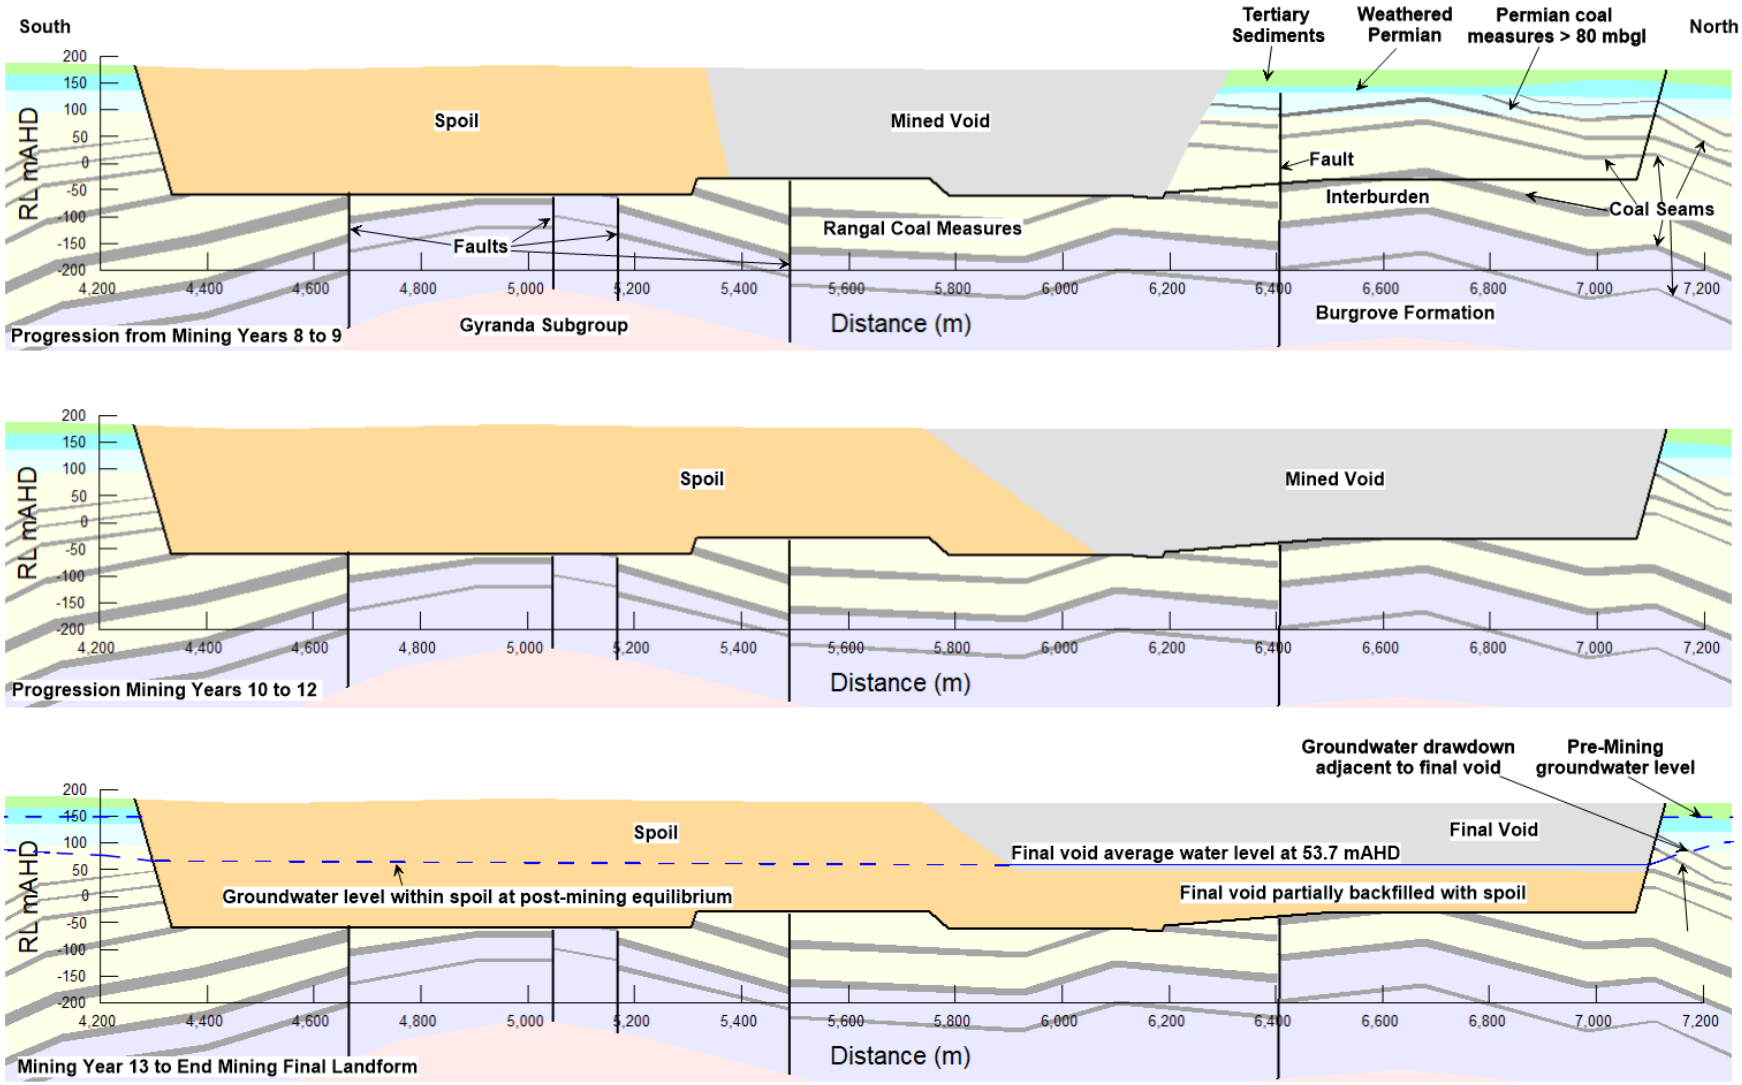

Figure 37 **Conceptual Layout of Pit AB Groundwater Levels**

4.4 REHABILITATION METHODS AND CONTROLS

Rehabilitation activities will be carried out in accordance with the following subsections. Rehabilitation activities will be subject to adaptive management where the rehabilitation methods and controls are continually improved and updated based on the results of site-specific rehabilitation trials, further land assessment (where applicable) and revisions of legislative requirements.

4.4.1 Reshaping/Landform Development

As a general guide, waste rock emplacements are constructed as benches with external faces formed from upper benches set back sufficiently from the prior bench to facilitate regrading to the design final rehabilitation slope.

Overburden placement will be undertaken using rear dump trucks in accordance with mine planning schedules and as per dump designs informed by geotechnical assessments. Standard mine survey controls will be utilised to ensure that disturbance footprints are not exceeded and that design slopes will be attained. Regrading to final landform will be undertaken using bulldozers to push to grade utilising standard survey controls.

Landform design will utilise concave slopes and terraced profiles to reduce the requirement for engineered drains. Where proposed to be utilised, and in conformance with a proposed *Master Waste Rock Emplacement Surface Drainage Plan* (discussed further in Section 4.4.6), graded banks and rock-protected spine drains will be installed to allow drainage from long rehabilitated slopes to be conveyed to natural ground level. All surface runoff from newly rehabilitated slopes will be directed into sediment dams until revegetation uptake is stable and adequate to control soil erosion. Further discussion on sediment design details and parameters is detailed in Section 3.4.3.3.

Final trimming of reshaped areas will be undertaken as required to remove excess rock and ensure correct graded bank slopes.

Topsoil spreading will then be undertaken to achieve the designated topsoil depth followed by surface preparation including at a minimum contour ripping to retain moisture and control erosion.

4.4.2 Topsoil Management

A *Topsoil Management Plan* will be developed for the Project. The overarching principle of the *Topsoil Management Plan* will be to reduce the risk of topsoil degradation and improve the chances of rehabilitation success. The objectives of the Project's *Topsoil Management Plan* are to:

- maintain a soil balance that will achieve the rehabilitation requirements throughout the life of the mine;
- maintain topsoil viability through the utilisation of best practices in soil stripping, stockpiling and application activities; and
- provide a standard practice for the Project's storage and handling of topsoil resources.

The *Topsoil Management Plan* will include the following components:

- identification and delineation of topsoil and subsoil resources including amelioration requirements;
- standard practices for topsoil and subsoil stripping;

- a topsoil and subsoil stockpiling strategy which outlines the methodologies and standard practices for the stockpiling of topsoil resources;
- procedures and methodologies used for the application of topsoil and subsoil resources;
- a topsoil and subsoil inventory which is maintained for the life of the Project;
- details of erosion and sediment controls for practices relating to topsoiling activities such as the use of sediment dams to minimise the release of water and suspended sediments into the receiving environment; and
- roles and responsibilities for the supervision of soil management.

The *Topsoil Management Plan* will reduce the risk of topsoil degradation and improve the chances of rehabilitation success through a series of management measures customised for each topsoil activity, these are described in further detail below.

4.4.2.1 Identification of Topsoil Resources

The identification and delineation of topsoil and subsoil resources will be undertaken based on the soil assessments already undertaken (AARC 2019) (Appendix I) including indicative stripping depths and topsoil qualities as summarised in Table 15.

The *Topsoil Management Plan* will detail the methods used for the further assessments of topsoil resources, where required, to confirm the topsoil stripping depth and dispersion characteristics of soils. Deficiencies in soil requirements will be identified and procedures for the amelioration of topsoils will be provided. Topsoil resources will be mapped, and GIS shapefiles will be retained for reporting purposes.

4.4.2.2 Topsoil Stripping

The *Topsoil Management Plan* will include standard methodologies for topsoil and subsoil stripping which will consider the equipment used, soil and climatic conditions under which topsoil stripping should occur, the removal of vegetation and the treatment of machinery for weeds.

4.4.2.3 Topsoil Stockpiling

A topsoil and subsoil stockpiling strategy will be developed with consideration to the management recommendations provided in the *Soil and Land Suitability Assessment* (Appendix I). To assist in maintaining a viable seedbank and promote vegetation growth, where possible, topsoil will be directly placed in prepared rehabilitation areas rather than stockpiled. Topsoil will also be planted over as soon as possible after being placed in prepared rehabilitation areas. This will assist in preventing erosion of the topsoil and making the best use of the soil's available nutrients.

Delineation of topsoils and subsoils during stripping and stockpiling is proposed to prevent dilution of the seedbank. It is recommended that subsoils are placed below topsoil during rehabilitation to increase germination, provide a suitable medium for root development and to aid in water storage within the soil profile. Mixing of topsoils and subsoils is also possible at a recommended ratio of 2:1, but may lead to additional nutrient and seed inputs to successfully establish vegetation

The topsoil and subsoil stockpiling strategy will:

- optimise the placement of topsoil stockpiles as much as practicable to:
    - exclude grazing and vehicle access;

  - minimise topsoil and subsoil handling;
  - consider climatic conditions, surface water flow and erosion controls such as the diversion of overland flow/runoff around disturbed areas;

- set stockpile design parameters including height (typically up to 3 m), shape and batter angles (no greater than 1:3) and limiting side slopes to a maximum slope of 1V:6H to reduce erosion and sediment run-off;
- describe the applicable construction equipment and practices;
- describe standard practices for the long-term storage of soil stockpiles including recommendations for soil testing and the application of fertilisers, soil ameliorants and seeding application relevant to long term stockpiling of topsoil resources;
- describe the sterile seeding for the long-term storage of stockpiles. Briefly, if the stockpiles require grass cover, they will be ripped and seeded with a quick establishment pasture, to limit erosion and maintain a viable seed bank. This will be done if the period of stockpiling is greater than one growing season or six months. In accordance with the findings of research undertaken in the Hunter Valley (Keipert et al 2005), and in order to avoid the significant deterioration that commonly occurs in the first year, topsoil will ideally be stockpiled for as short a period as possible; and
- establishment of a stockpile monitoring frequency for the control of weeds on stockpiles.

4.4.2.4 Topsoil Application

Where possible, placement of topsoil at a thickness of approximately 0.3 m is recommended across the rehabilitated area to create a growth medium of sufficient depth to hold water and support revegetation. If available, subsoils that have been identified as having a high clay content with low erosivity risk can be returned first at a depth of up to 0.5 m, prior to the addition of sandier topsoil. This may assist in providing a more suitable growth medium that holds water for long periods of time.

For the Geoffrey SMU, it is recommended that soil horizons in the natural landscape are restored during rehabilitation. The clay rich subsoils should be placed first on the rehabilitated landform, followed by the sandy A horizon over the top to recreate the A and B horizons. Placement of the subsoil layer is expected to retain soil moisture necessary for successful revegetation.

Stripping depths have accounted for the dispersive nature of the SMUs sodic subsoils. Topsoil estimates exclude any sodic subsoil material from the topsoil resource, therefore the topsoil resource is not considered sodic and dispersive. The rehabilitated landform is thus at low risk of the dispersive impacts associated with sodic soils and mitigation measures that target sodic and dispersive soils are not considered necessary.

Topsoiled areas will be ripped into the underlying spoil surface to reduce compaction from heavy machinery and to encourage surface water infiltration and minimise soil loss due to erosion. On the slopes of spoil dumps, ripping will be undertaken along the contour.

Grass and woody vegetation remaining after land clearing can be incorporated into the rehabilitation design at strategic locations to help limit runoff and erosion (by slowing down overland flow), retain active biological activity, and provide habitat for returning fauna. Additionally, mulched organic material incorporated into the soil (particularly the topsoil) will increase organic carbon levels over time, further stabilising the soil and landscape.

4.4.2.5 Topsoil Inventory

A topsoil and subsoil inventory will be maintained during the life of the Project, which accounts for the volumes and locations of topsoil as it is progressively stripped, stockpiled, and reapplied. The inventory will also address the delineation of stockpiled topsoil, protection from unplanned use or disruption and prioritisation of re-use. The soil inventory will allow early identification of potential issues such as soil balance deficits or poorer quality soils; enabling remedial actions to be planned in advance of mining operations.

4.4.3 Revegetation Program

Vegetation is generally established in rehabilitated areas through topsoil application, by direct seeding or by planting using nursery-raised tube-stock of target species. Revegetation efforts will be directed towards creating a stable and self-sustaining system, in accordance with the defined land use; that is for each defined land use the system can support the survival and reproduction of all organisms living within it, without outside intervention. Data collected from baseline assessments and relevant analogue sites will be used in a comparative analysis to determine if revegetation has achieved a self-sustaining and stable ecosystem. Species selected for rehabilitation efforts to support a self-sustaining ecosystem will provide microhabitat and cover for fauna, a natural mulch system and nutrient input from the breakdown of plant waste, stabilise soils through provision of vegetative cover and soil binding root systems to prevent erosion and promote soil aeration.

Areas identified as returning to a grazing PMLU including waste rock emplacements, mine infrastructure areas and water management areas will likely utilise grass seed mixes for the Project area that include Rhodes grass (*Chloris gayana*), Creeping bluegrass (*Bothriochloa insculpta*), Desmanthus (*Desmanthus virgatus*), Forest bluegrass (*Bothriochloa decipiens*), Queensland bluegrass (*Dichanthium sericeum*), Barbed wire grass (*Cymbopogon refractus*), Black speargrass (*Heteropogon contortus)* and Curly windmill grass (*Enteropogon acicularis*) as well as other species native to the area. Application rates are anticipated to range between 6-10 kg/ha.

For areas to be restored to native vegetation including pit low walls, species will be based on the rehabilitation objectives and will generally target species relevant to nearby remnant vegetation associations, soil types, and site conditions. Revegetation of native woodland areas for example, will include the planting of endemic species which are characteristic of pre-mining conditions, as identified through flora assessments undertaken for the Project.

Seeding will typically be scheduled to occur prior to the wet season to maximise the benefits of subsequent rainfall.

Topsoil stockpiles will be revegetated to assist in stabilisation and erosion control. Similarly, drainage lines, berms and other erosion control and stabilisation works will require revegetation with an appropriate seed mix. Application rates will vary depending on the circumstance as well as the rehabilitation species sensitivity, the growth media and the PMLU.

4.4.4 Rehabilitation Maintenance and Repair

Significant rainfall events, floods, fire, drought, pest species outbreaks or other factors may also result in a requirement to undertake additional maintenance on rehabilitated areas. Maintenance of rehabilitated areas or reparation may also be required where visual observations of rehabilitation and or rehabilitation monitoring results (refer Section 4.8) indicate that the expected trajectory towards achieving successful rehabilitation is not being met. Depending on the underlying cause of failed rehabilitation, rectification activities may include:

- earthworks repair of erosion areas;
- re-seeding / replanting failed or unsatisfactory areas;
- supplementary planting of tube-stock;
- pest and weed control;
- irrigation of plants;
- additional fertiliser or other ameliorant application to control pH and improve soil structure; and
- repair or alteration of drainage structures.

In the event that maintenance is required, a maintenance plan will be developed that properly assesses the risks of re-entering a rehabilitated area with earthmoving equipment, the sourcing of soils and topsoil, impacts on planned drainage of the site, erosion controls and revegetation methods.

4.4.5 Rehabilitation Trials

Revegetation techniques will continually be developed and refined over the life of the Project through a continual process of research, trialling, monitoring and improvement. It is common practice within mine sites to undertake site–specific rehabilitation trials to inform rehabilitation efforts and practices. Rehabilitation trials may involve refining soil preparation procedures, seed mix type, rate and application, surface cover treatment, irrigation requirements and repair methods. As such, rehabilitation trials will be used as part of adaptive management of rehabilitation and will commence as identified during mining operations.

The performance of rehabilitation trials will be assessed against the methodology outlined in Section 4.8 and dependent on the underlying principle of the trial further performance indicators may be identified on a case-by-case basis.

Subject to onsite resource capacity and availability of external research opportunities, Magnetic South may engage with external research programs such as those undertaken by ACARP and research institutions.

4.4.6 Waste Rock Landform Development and Rehabilitation

The commencement of mining necessarily sees overburden being initially placed out-of-pit to provide sufficient working space for operations to proceed. A single out-of-pit waste rock emplacement is associated with each of Pit AB and Pit C. In-pit placement of overburden will occur in Year 2 for Pit AB and about Year 15 for Pit C.

The out-of-pit waste rock emplacement for Pit AB is located to the west and south of the pit with construction coinciding with the commencement of mining. By Year 4, the full footprint of out-of-pit dumping will be reached with waste rock being placed both in-pit and within the extents of the out-of-pit waste rock emplacement. In Year 6, a small temporary out-of-pit waste rock emplacement will be constructed to the north of the pit for the purpose of providing additional pit backfilling later in the mine life.

Beyond Year 6, the majority of waste rock is placed in-pit, progressively refiling the pit from south to north as the pit progresses in the same direction. By about Year 12/13 the maximum extents of Pit AB are reached and the development of infrastructure to support Pit C commences.

Mining of Pit C commences in Year 12, again with waste rock being placed in an out-of-pit waste rock emplacement located to the west of the pit. By Year 15, waste rock from Pit C is being placed both in-pit and out-of-pit and the full disturbance footprint of the out-of-pit waste rock emplacement has been reached. Pit AB is continuing to be progressively rehabilitated, including the rehandling of spoil from the temporary out-of-pit waste rock emplacement back in-pit and all areas having been reshaped including the highwalls of Pit AB.

By Year 19, the rehabilitation of Pit AB has been completed and mining is at or near completion at Pit C, with progressive rehabilitation of the Pit C waste rock emplacements ongoing.

Figure 23 through to Figure 32 conceptually visualise the progression of the mine, including location and extent of waste rock emplacements and rehabilitation. A preliminary schedule of progressive rehabilitation milestones per rehabilitation area is provided in Section 4.6.

Minor drainage works and a pit levee are required to the southeast of Pit AB during operations to ensure high flows from an unnamed second order tributary of Springton Creek do not access the pit. In addition, a permanent drain is required to divert clean runoff from the upper reaches of an unnamed second order tributary of Springton Creek around the out-of-pit waste rock emplacement associated with Pit C. Neither of these tributaries are defined as watercourses under the Water Act.

The *Geochemical Assessment of Mining Waste Materials* (RGS 2019) (Appendix G) and *Geochemical Assessment of Coal Reject Material* (RGS 2020) (Appendix H) for the Project identified that waste rock materials have a low risk of acid generation and a high factor of safety with respect to potential for acid mine drainage (AMD).

Validation test work will be undertaken on potential spoil materials as the Project develops to enable appropriate spoil management measures to be planned and implemented as required. Where highly sodic and/or dispersive spoil is identified, this material would not be placed in final landform surfaces and would not be used in construction activities. Regardless of the spoil type, especially where engineering or geotechnical stability is required, testing would be undertaken during construction to determine the propensity of such materials to erode. Surface runoff and seepage from spoil piles, including any rehabilitated areas, would be monitored for 'standard' water quality parameters including, but not limited to, pH, EC, major anions (sulphate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), total dissolved solids (TDS) and a broad suite of soluble metals/metalloids.

Landform reshaping will occur progressively, as land is deemed available for rehabilitation, resources are available, and the mining activities do not prohibit the rehabilitation activities. As indicated in Table 18, waste rock emplacements have been designed to have externally draining slopes of a 1V:10H ratio and a maximum height of 190 mAHD (where maximum slopes adhere to 6°) constructed from rear dump truck-tipped dumps. While detailed geotechnical assessments are yet to be undertaken, the slopes proposed are at the lower end of typical design practice for waste rock emplacements in the Bowen Basin. The locations of waste rock emplacements showing proposed PMLUs are illustrated at Figure 36.

The top surfaces of both waste rock emplacements are limited in area and, given the relatively low geochemical risk currently identified, it is considered preferable to internally drain the upper surfaces of waste rock emplacements rather than increase flows down rehabilitated slopes. The practice of surface water drainage on waste rock emplacements via internal drainage is favourable on soils that have self-sealing properties, which have been recorded on site and has a low risk of failure. Internal drainage involves natural depressions or graded banks constructed with a relatively minimal slope cross section with vegetative cover which will blend into the landscape over time. Natural depressions promote internal drainage on the waste rock top surfaces without creating permanent ponding during normal and

heavy rainfall events. Further, vegetative cover will aid in the absorption of surface water and will support a cattle grazing PMLU.

Geochemical assessments indicated that there will be no detrimental impacts on water quality and therefore, if used for stock watering, water ponding on waste rock emplacements does not pose a risk to cattle (RGS 2019 and RGS 2020). If deemed necessary from the results of rehabilitation monitoring (i.e., erosion rates, habitat structure), reshaping on the top surfaces of waste rock emplacements will be conducted and land prepared for vegetative surface cover with plans developed upon consultation with a suitably qualified person.

Additionally, rehabilitated slopes will be constructed to a relatively low slope (6°) to reduce the risk of erosional instability. Given these mitigation measures, drainage from regraded rehabilitation slopes is intended to be managed with limited use of graded banks; principally by targeting sufficient surface roughness through contour cultivation and appropriate revegetation rates. However, this approach will ultimately depend on the results of further topsoil testing and the performance of early rehabilitation works. If erosion is observed in early rehabilitation efforts, graded banks and spine drains will be incorporated into the rehabilitation design, as a temporary erosion control measure.

The surface of waste rock emplacements will be progressively revegetated with a pasture crop cover mix, consistent with the proposed revegetation program.

A master *Waste Rock Emplacement Surface Drainage Plan* is proposed to be developed to detail the design and methodologies for the development of natural surface drainage depressions on waste rock emplacements and to prevent erosion on the waste rock slopes. If required, graded banks will be designed in accordance with industry recommendations (Witheridge et al. 1996), they should achieve a minimum width of 5 m and height of 500mm high (Appendix I). Larger contour drains are generally more stable and longer lasting. Rock-lined spine drains will utilise rock of between 300 – 450 mm in diameter where required. Graded banks and rock-protected spine drains are designed to blend into the landscape over time, with a relative minimal cross section to minimise the risk of failure. If necessary, these structures will be removed, and remediation activities will be undertaken. Given the overburden and topsoil materials available, the rehabilitation design parameters to be observed, and the mitigation measures and actions nominated, no significant risks associated with the rehabilitation of waste rock emplacements have been identified.

Table 18 Waste Rock Emplacement Parameters

Emplacement	PMLU	Max. Elevation (mAHD)	Typical/ Max Slope	Approx. Max. Slope Length (m)
Pit AB waste rock emplacement (in-pit and out-of-pit)	Grazing	175	6°	540
Pit AB temporary (out-of-pit)	Grazing	n/a	n/a	n/a
Pit C waste rock emplacement (in-pit and out-of-pit)	Grazing	190	6°	530

4.4.7 Rejects Placement

Coal processing is described in Section 3.6.3. Coarse rejects will be conveyed to the rejects bin. Fine rejects and slimes will be dewatered and conveyed to the rejects bin to be combined with the coarse reject material. The combined rejects will be loaded onto trucks for placement in out-of-pit spoil dumps, or in-pit behind the mining void.

Over the life of the mine, just over 9 Mt of rejects is estimated to be generated for disposal. Most coal reject materials have a relatively low risk of acid generation. While the risk of environmental harm arising

from the geochemical characteristics of materials to be handled is low, it is proposed that coal reject materials are selectively handled and encapsulated within waste rock emplacements and well away from the outside surface of rehabilitated landforms.

As such, no separate rejects facility is proposed for the Project. Representative samples of coal reject materials will be further assessed at the operational stage to ensure that the findings of the geochemical assessment (RGS 2020) (Appendix H) remain applicable.

4.4.7.1 Final Voids

Mine planning for the Project results in the northeast end of Pit AB and the east end of Pit C remaining as residual voids. Both voids will be partially backfilled with waste rock to elevate the void floor above the level of significant groundwater inflows, and to limit the potential for pit water to recharge any aquifers.

The void low wall will be rehabilitated to a gradual slope, safe for access and grazing by cattle. Small pit lakes will form on the pit floor reaching a steady state level where water losses through evaporation are equal to water inputs from rainfall, runoff and groundwater inflows. While water levels in the voids will vary over time dependent on the prevailing climatic conditions, the results of modelling indicate that an equilibrium level of approximately 70 mAHD in C Pit and 53 m AHD in AB Pit will be reached after 200 years. The steady state water level is well below the base of Tertiary aquifers negating any risk of contamination.

Perimeter drainage will be provided to limit the volume of surface water runoff, including modelled 1:1,000 storm event flows, from entering the void. The *Surface Water Assessment* (WRM 2020b) (Appendix B) confirms that pit lake water levels will not exceed 50 mbgl and that there is therefore no risk of overflow to surface waters.

Physical void characteristics are summarised in Table 19.

Table 19 Final Void Physical Characteristics

Mining Area	Approx. Pit Lake Area (ha)	Low Wall Slope	High Wall Slope
Pit AB	43	<6°	<22°
Pit C	37	<6°	<22°

Areas of the low wall capable of supporting pasture crop will be utilised as cattle grazing PMLU. The low walls may be subject to further assessment of low wall soil characteristics, stability, rehabilitation trials and stakeholder consultation to determine the final designation of land. Pit highwalls will be throw blasted and/or shaped to achieve a stable slope of 22°. Inward draining highwalls will support native vegetation post mining land use, consistent with pit lakes.

Two pit lakes with a total footprint area of approximately 81 ha will be formed as part of the final Project landform. Pit lakes have demonstrated capacity for the development of ecosystems able to behave similarly to natural wetlands (Lund and Blanchette, 2014). The underlying biophysical processes facilitating primary production are critical in allowing pit lakes to evolve into valuable ecosystems (Luek and Rasmussen, 2017; Marszelewski *et al.*, 2017; Lund and Blanchette 2014). Variables that influence primary production include bankside vegetation, nutrient concentrations in the water column (nitrogen, phosphorus and carbon), hydrology and bathymetry (Lund and Blanchette 2014).

Miguell-Chinchilla *et al.* (2014) studied the succession of macroinvertebrates in 19 pit lakes of approximately 22 years of age, that were formed as part of the reclamation process of an open cut coal

mine in Spain. Miguell-Chinchilla *et al* (2014) recorded that macroinvertebrates inhabited pit lakes along a primary succession gradient whereby the environmental conditions, including nutrient and habitat resources, determined the community structure.

The salinity of water can be classified by the level of TDS, and the following classification was used for the purpose of this EA application (DSEWPAC 2012b and Environmental Protection Agency 2020):

- freshwater up to 3,000 mg/L;
- brackish 3,000 mg/L – 5,000 mg/L;
- saline 5,000 mg/L – 35,000 mg/L; and
- hypersaline > 35,000 mg/L.

Typically, pit lakes are modelled to become increasingly saline over time (i.e., waters having a TDS greater than 5,000 mg/L). This modelling is inherently conservative as it assumes an eternal, constant, source of salinity to the void lake from spoil seepage. Water quality modelling for the Project by WRM (2019) indicates salinity of both pit voids will gradually increase over time. Salinity is predicted to remain below 5,000 mg/L in the first 100 years following mining and will remain below 10,000 mg/L for the first 200 years. The pit lake will, therefore, be classified as brackish for approximately the first 100 years and is not predicted to reach hypersaline conditions until after approximately 500 years following mining (WRM 2020b). Biodiversity generally decreases as salinity increases, however, salinity of up to 10,000 µs/cm (~6,410 mg/L) can support noteworthy ecological systems and provide a valuable refuge for species (pers comms. M.Lund December 2019).

Research indicates that pit lakes with a TDS up to ~4,500 mg/L can provide ecological value for regional species in Central Queensland (Proctor and Grigg 2006). Further, pit lakes may act as a water refuge during periods of low rainfall for mobile species such as the Grey Teal Duck (Hart 1991) has previously been recorded within the Project surrounds (AARC 2020b). Species of ducks and swans have been observed in saline pit lakes of open cut coal mines in central Queensland (pers comms. C.Cote March 2020).

Macroinvertebrates are well-adapted to brackish and brackish-saline conditions; however, species diversity typically decreases with increasing salinity. A study of pit lakes aged from 1-22 years and ranging from 330 µs/cm – 4,416 µs/cm, associated with a nearby open cut coal mine in Moura, indicated that the diversity of aquatic invertebrates was similar to nearby natural waterbodies (Proctor and Grigg 2006). The pit lakes studied by Proctor and Grigg (2006) were reported to support orders of macroinvertebrates that were also recorded on the Project site, including Diptera, Hemiptera, Odonata and Coleoptera (AARC 2020a).

In an open-cut coal mine located within the Fitzroy Basin, native fish including the Spangled Perch (a species recorded on site) have been documented to have pioneered pit lakes with TDS of up to 7,600 µs/cm region (AARC 2020a).

Proctor and Grigg (2006) concluded that in Central Queensland, final void waterbodies have the potential to provide habitat for many invertebrate taxa typical of still inland water bodies. The ability for macroinvertebrates in freshwater systems to adapt to changes in salinity is dependent on the period of acclimation where the ability to adapt to new conditions improves when changes are incremental over time (Hart 1991).

The high walls associated with pit lakes can also provide suitable refuge and brooding habitat for several mobile fauna species. In periods of low rainfall, birds, including the Grey Teal, have been recorded using

saline waters as refuges over both short- and long-term periods by drinking freshwater elsewhere (Lavery 1972). Several species of birds prefer to breed in saline conditions (Goodsell 1990). For example, the Grey Teal, Pacific Black Duck, White Faced Heron, Little Black Cormorant and Little Pied Cormorant were found by Goodsell (1990) to breed in saline conditions with TDS of up to between 14,600 mg/L (Pacific Black Duck) and 37,600 mg/L (Grey Teal). All of these species have been recorded either within the Project site or surrounds (AARC 2020b). Further, the Black Swan, a species known to inhabit the wider Project surrounds, was reported by Goodsell (1990) to breed in saline water with a TDS of up to 43,500 mg/L.

The residual high wall offers potential to provide steeper slope habitat that can be used by native nesting birds. For example, a resident Peregrine Falcon pair has been recorded successfully breeding in nests created in the high walls of an open cut mining pit in the Northern Territory (Potts and Donato 2008). Additional individual Peregrine Falcons were observed utilising the various open pit high walls for roosting. Birds documented to nest on inland, flat land or slopes may utilise the high-wall pit slopes as nesting habitat (O'Donnell and Debus 2012). Anecdotally, birds of prey have been reported to utilise the high wall as refuges in an open cut coal mine located in central Queensland (pers comms. J. Fittler March 2020); the Wedgetail Eagle, a species that has been recorded on the Project site is one example such species of bird of prey.

Insectivorous bats have been documented feeding on insects in the airspace above pit lakes in both Western Australia and central New South Wales (Griffiths *et a*l. 2014a; Griffiths *et al*. 2014b). A number of insectivorous bats have been identified on the Project Site by ANABAT surveys including the Chocolate Wattled Bat, Eastern Bent-winged Bat, Eastern Cave Bat, Goulds Wattled Bat, Inland Forest Bat, Little Pied Bat, Northern Free-tailed Bat, Troughton's Sheathtail Bat, White-striped Free-tailed Bat and the Yellow-bellied Sheath-tailed Bat (AARC 2020b).

The rock fissures and crevices present in the high-wall pit slopes provide potential refuge habitat for various cave-dwelling microbats identified within the Project Site. For example, the Little Broad-nosed Bat which roosts in hollows but which has been found in fence posts and under the metal caps of telegraph poles (Churchill 2009), Gould's Wattled Bat which has been found roosting in stumps, hollow trees and urban settings such as ceilings (ALA 2020) and the Troughton's Sheathtail Bat which has been recorded in cracks and crevices in rocky escarpments (DES 2011)), as well as species previously recorded within the Project region (e.g. the Eastern Horseshoe Bat which is known to roost in caves but also in holes and cracks in rocks (Australian Museum 2020).

Native vegetation proposed to rehabilitate the high-wall slopes will provide additional refuge for ground-dwelling fauna, including small mammals and reptiles. For example, the Delicate Mouse (*Pseudomys delicatulus*) feeds on native grass seeds and uses grass tussocks as refuges (Diete *et al*. 2015). Similarly, grass tussocks provide nature refuges for a number of mammals and reptile species found on the Project site during the fauna survey, including the Delicate Mouse, Short Beaked Echidna, Rakalie Bynoes Gecko, Elegant Snake-Eyed Skink, Prickly Knob-tailed Gecko, Eastern Stone Gecko and Box-patterned Gecko (AARC 2020b). The use of high-wall vegetation by goats, cattle, small mammals and reptiles has been observed in open-cut mines of Queensland (pers comms. C.Cote March 2020).

The ecological value of pit lakes and adjacent high-wall features can be facilitated through effective rehabilitation of the pit walls. For example, a review of the ecological processes associated with nutrient webs of natural lakes, wetlands and pit lakes, van Etten (2011) concluded that rehabilitating vegetation along the low walls can assist with improving water quality, primary production and provide suitable habitat for aquatic and terrestrial fauna. Aquatic plants along the littoral fringe have been reported to inhabit areas with consistent water levels in pit lakes with salinity less than 10,000 µs/cm, in Queensland (pers comms. J. Fittler March 2020). Further, habitat complexity including the development of

microclimates (van Etten 2011) and additional habitat could be created through the addition of cleared vegetation (i.e., tree trunks) to both the low walls and the waterbody (Luek and Rassmussen 2017).

Given that salinity is predicted to remain below 5,000 mg/L during the first 100 years of post-mining operations, the pit lake and surrounding high-wall features is predicted to provide suitable habitat for a range of native fauna, including a number of species recorded within the Project site and surrounds.

4.4.8 Mine Infrastructure Areas

Mine infrastructure areas will not be rehabilitated until mining operations have ceased. These areas will have all infrastructure removed and be regraded to their approximate original contour to ensure they are stable and sound. Footings will be either completely removed or removed to at least a depth of 1 m below surface level. Where possible infrastructure will be on-sold or sold for scrap. Clean construction and demolition waste will either be removed from site or placed within one of the final waste rock emplacements and covered. Any land identified to be subject to contamination will be subject to notification and a site investigation and either excavated and contaminated material removed to a licensed facility or, or risk assessed and listed on the Environmental Management Register.

Once reshaped, mine infrastructure areas will be subjected to rehabilitation practices including topsoiling and revegetation as described in Section 4.4.2 and Section 4.4.3. The land disturbance and other controls detailed at Section 4.7 will be implemented as appropriate. In addition, controls to address specific demolition and closure risks will be implemented.

If consultation with neighbours or other potential post-mining land users identifies any infrastructure of value to the PMLU, a written agreement will be established that transfers liability in the structure and its use to the new owner.

Haul roads will be constructed utilising spoil material sourced from initial mining operations. At closure, haul roads will have road base materials removed and be reshaped to create a stable landform that blends in with the surroundings. Minor site access roads and tracks will be rehabilitated where they are no longer required.

4.4.9 Water Management Infrastructure

Unless water storage facilities are identified by the post-mining landholder as of value to their future use of the land, and an agreement is entered into, all water storages will be drained and de-silted, and re-profiled to ensure the area is free-draining and blends in with the surrounding landscape. Disturbed areas will be seeded with a seed mix suitable for grazing / native ecosystems. Raw water dams, once no longer required, will be emptied by pumping to the final void. Dam liners will be removed and appropriately disposed of.

The temporary levee for Pit AB would be incorporated into the final landform profile on closure.

The installed clean water drains will remain post-mining. The revegetation of permanent drainage structures will incorporate geomorphic and riparian vegetation features that are consistent with the pre-mining environment. A key objective of the revegetation of permanent drainage structures will be to ensure that self-sustaining vegetation communities are achieved. Additionally, revegetation along permanent drainage structures will aim to restore habitat connectivity within the remaining portions of Springton Creek.

4.5 REHABILITATION MILESTONES

4.5.1 Schedule of Land Available for Rehabilitation

Land will become progressively available for rehabilitation throughout the life of the Project. Land is considered available for rehabilitation when:

- the land is no longer required for operating infrastructure or machinery for mining, including, for example, a dam or water storage facility;
- the land is no longer being mined and there is no plan to return to mining within 10 years after the land would otherwise have become available for rehabilitation (assuming a probable or proven ore reserve remains); and
- the land does not contain permanent infrastructure remaining on the land for a PMLU.

A preliminary schedule of when land will become available for rehabilitation is provided below in Table 20.

Table 20 Preliminary Schedule of Land Available for Rehabilitation

Rehabilitation Area	Land Available (ha)				
	Year 4	Year 8	Year 12	Year 17	Year 21
RA1: In-pit and out-of-pit waste emplacements, including dry rejects disposal areas	231.0	59.5	97.0	148.2	186.7
RA2: Temporary waste emplacements				17.5	0
RA3: Residual void lakes				40.6	35.9
RA4: Residual void high walls				64.0	69.1
RA5: Residual void low walls				127.1	60.4
RA6: Water management infrastructure					85.0
RA7: Mine infrastructure areas					731.8

4.5.1.1 Milestone 1: Infrastructure Decommissioning and Removal

Infrastructure decommissioning and removal will involve the following processes:

- disconnection and removal (or sale and removal if appropriate) of all infrastructure including pipelines, fences not a part of the PMLU, buildings, machinery, equipment, road base, water management structures;
- all wastes and temporary stockpiles will be removed.

Rehabilitation milestone 1 is applicable to all rehabilitation areas.

4.5.1.2 Milestone 2: Remediation of Contaminated Land

A contaminated land investigation of the Project site will be undertaken by a suitably qualified person. The contaminated land investigation will determine the presence of contaminated land. Remediation

activities will be undertaken and where required, consultation on appropriate remediation activities of contaminated land will be sought.

A validation report will detail the remediation of contaminated land and a site suitability statement prepared by a suitably qualified person which states that the land is suitable for the PMLU.

Rehabilitation areas for which milestone 2 is applicable include: RA6 and RA7.

4.5.1.3 Milestone 3: Landform Development and Reshaping / Profiling

On completion of construction and reprofiling of the final landform, inspection and reporting will be undertaken to provide assurance that landform development and reshaping has been undertaken in accordance with the accepted final landform design criteria.

Residual voids backfilled to 80 mbgl, necessary to support a native ecosystem land use for the final pit lake.

The geotechnical stability of landforms, including pit walls and spoil dumps, will be assessed by a suitably qualified person.

Rehabilitation areas for which milestone 3 is applicable include: RA1, RA2, RA4, RA5, RA6, RA7.

4.5.1.4 Milestone 4: Surface Preparation

Completion of earthworks associated with placement of the topsoil material on final landforms. A minimum of 0.3 m of topsoil is required on areas of land to be returned to a grazing PMLU. Deep ripping of the surfaces has been undertaken. Surface drainage features have been installed. If required, soil ameliorants have been applied. Topsoil spreading or select placement

An assessment of soil health will be completed by a suitably qualified person to verify the growth medium is suitable for achieving the intended PMLU.

Rehabilitation areas for which milestone 4 is applicable include: RA1, RA2 RA4, RA5, RA6 and RA7.

4.5.1.5 Milestone 5: Revegetation

Completed seeding of areas that have achieved milestone 4. Records of revegetation activities will be maintained, documentation of the below details will indicate completion of the milestone:

- GIS files of the areas where seeding and planting have occurred, where areas with different SMUs, seed mixes or dates of planting are mapped separately;
- date the seed mix was applied, or planting of tube stock was carried out;
- if seeding, the seed mix and rate of seeding applied;
- if planting, the number of tube stock planted;

Rehabilitation areas for which milestone 5 is applicable include: RA1, RA2, RA4, RA5, RA6 and RA7.

4.5.1.6 Milestone 6: Establishment of Target Vegetation

A minimum of 5 years of rehabilitation monitoring data will confirm that rehabilitated areas have, or are on a trajectory to, achieve a self-sustaining ecosystem. Rehabilitated areas will be assessed against target criteria and compared to analogue sites of similar characteristics and land use.

Rehabilitation areas for which milestone 6 is applicable include: RA1, RA2, RA4, RA5, RA6 and RA7.

4.5.1.7 Milestone 7: Residual Void Lake

Water level in the final void is less than 74 mAHD for C Pit and 58 mAHD for AB Pit. Water in void lakes will have a TDS of less than 10,000 mg/L when measured at the surface.

Rehabilitation areas for which milestone 7 is applicable include: RA3.

4.5.1.8 Milestone 8: Achievement of Stable PMLU

Monitoring determines that that the land is safe, structurally stable, does not cause environmental harm and is able to sustain the PMLU.

Rehabilitation areas for which milestone 8 is applicable include: RA1, RA2, RA3, RA4, RA5, RA6 and RA7.

4.5.2 Rehabilitation Indicators and Completion Criteria

The *Guideline (Resource Activities): Rehabilitation requirements for mining resource activities [ESR/2016/1875]* (DES 2014a) requires the nomination of rehabilitation performance indicators for mining resource activities. Rehabilitation performance indicators are intended to provide defensible measurements of progress towards rehabilitation targets – referred to as completion criteria.

Principles for the development of rehabilitation performance indicators are preferably specific, measurable, achievable, realistic and timely. They should be outcome-based (linked to the end land use); flexible to adapt to changing circumstances; able to evolve as the mine life progresses; subject to periodic review; and include a measurement approach that details how the criterion will have been met (DFAT 2016b; ANZMEC and MCA 2000). Baseline data described in this application has been used to inform the development of site-specific performance indicators to protect the environmental values of the Project area.

Completion criteria are the threshold values, which when met, are deemed to demonstrate that a given indicator requirement has been achieved. Completion criteria may be established through technical or engineering studies or by assessing analogue or comparative sites that are considered to represent the desired rehabilitation outcome. In many cases, completion criteria need to be developed on the basis of ongoing monitoring of analogue sites to determine seasonal behaviours or variation over time.

Milestone completion criteria relevant to each designated rehabilitation area are listed in Table 21.

Table 21 Rehabilitation Milestone Completion Criteria

Code	Milestone	Indicators	Criteria	Applicable Rehabilitation Areas
RM1	Milestone 1: Infrastructure Decommissioning and Removal	• presence of mine infrastructure equipment and materials.	• all unrequired services disconnected and removed; • all concrete, bitumen and gravel removed; • all pipelines drained and removed; • all fencing that is not part of the PMLU removed; • all buildings demolished and/or removed; • all machinery and equipment removed; • all surface water drainage infrastructure that is not retained in the final landform removed; and • all rubbish removed.	RA1, RA2, RA3, RA4, RA5, RA6, RA7
RM2	Milestone 2: Remediation of Contaminated Land	• presence of contaminated materials; and • contaminated land assessment.	• all contamination is remediated or removed; and • site investigation report prepared by a suitable qualified person which states that the site is safe for its intended use.	RA6, RA7
RM3	Milestone 3: Landform Development and Reshaping/Profiling	• landform maximum slope of spoil and voids; • void backfill depth; and • geotechnical study completed by a suitably qualified person assessing the factor of safety for all final landforms.	• all landform earthworks (excluding topsoil cover) completed; • slopes of spoil dumps conform to maximum angle of 6°; • backfilling of voids to a minimum of 80 mbgl; • highwalls of voids shaped to achieve a maximum angle of 22°; and • landform (pits and spoil dumps) assessed to be geotechnically stable by a suitably qualified person, modelled to achieve a factor of safety of ≥ 1.5.	RA1, RA2, RA4, RA5, RA6, RA7
RM4	Milestone 4: Surface Preparation	• evidence of landform surface treatment; and • soil health assessment.	• all surface drainage features installed; • topsoil placed over all reshaped surfaces to a depth of 0.3 m and deep ripped; and • soil health assessment confirms soil is suitable for target vegetation establishment. If required ameliorants have been applied.	RA1, RA2, RA4, RA5, RA6, RA7
RM5	Milestone 5: Revegetation	• rehabilitation monitoring by a suitably qualified person.	• complete seeding of all topsoiled surfaces using recommended seed mix; and • evidence of successful seed germination in rehabilitation monitoring report.	RA1, RA2, RA4, RA5, RA6, RA7
RM6	Milestone 6: Establishment of Target Vegetation	• rehabilitation monitoring by a suitably qualified person.	• average vegetation ground cover is within 2 standard deviations of equivalent analogue sites; • species richness is within 2 standard deviations of equivalent analogue sites; • weed abundance is consistent with equivalent analogue sites;	RA1, RA2, RA4, RA5, RA6, RA7

Code	Milestone	Indicators	Criteria	Applicable Rehabilitation Areas
			• for grazing areas, pasture mass, the standard unit of measuring pasture productivity (Cayley and Bird 1996) is within 2 standard deviations of analogue sites for pasture on the same SMU; and • validation by a suitably qualified person that the target PMLU is achieved.	
RM7	Residual Void Lake	• water level monitoring; • water quality monitoring; and • fauna monitoring.	• water level in the final void has achieved an RI of less than 74 mAHD for C Pit and 58 mAHD for AB Pit. Water in void lakes will have a TDS of less than 10,000 mg/L when measured at the surface.	RA3
RM8	Milestone 8: Achievement of Stable PMLU	• rehabilitation monitoring; • geotechnical study; completed by a suitably qualified person assessing the factor of safety for all final landforms; • erosion analysis completed by a suitably qualified person; • fauna surveys including camera trapping, echolocation detection, scat analysis, aquatic and terrestrial trapping and target species surveys; • surface water quality monitoring; and • groundwater quality monitoring.	• report prepared by a suitably qualified person confirming the target PMLU has been achieved and the ecosystem is self-sustaining (with required land management inputs not significantly greater than the surrounding equivalent land use); • landform (pits and spoil dumps) assessed to be geotechnically stable by a suitably qualified person, modelled to achieve a factor of safety of ≥ 1.5; • predictive analysis of erosion confirming that soil loss rates are acceptable and require land management inputs not significantly greater than the surrounding equivalent land use; • fauna survey report provides evidence of native species inhabiting or utilising pit lake / highwall ecosystems including macroinvertebrates, aquatic vertebrates, avian species, bats, and other mammals; • surface water on the site and in the receiving environment is not significantly poorer in any parameter than equivalent reference sites and the baseline quality data for the Project; • groundwater on the site and in the receiving environment is not significantly poorer in any parameter than reference sites and the baseline quality data for the Project; and • predictive modelling undertaken by a suitably qualified person, confirming that the void lake will remain a groundwater sink and that there is no risk of contamination post mining.	RA1, RA2, RA3, RA4, RA5, RA6, RA7

4.6 PRELIMINARY REHABILITATION MILESTONE SCHEDULE

A preliminary rehabilitation milestone schedule has been developed on the basis of the mine schedule described in Section 3.6.2.

Cumulative areas of rehabilitation have been calculated using geospatial data of the mining stage plans which identify the conceptual sequence of mining and rehabilitation activities particularly with respect to the functional operational steps of waste rock emplacement construction, the point at which disturbed areas become available for rehabilitation, and then completion of the activities of reshaping/topsoiling and revegetation (refer to Figure 23 - Figure 32). Variations to the mining rate will likely result in discrepancies with the predicted timing of rehabilitation activities.

A summary of the milestone schedule for each rehabilitation area is provided below (Table 22 - Table 28), and illustrated in Figure 38 to Figure 46.

Table 22 Milestone Schedule Rehabilitation Area 1

4.7 LAND DISTURBANCE MANAGEMENT AND CONTROLS

4.7.1 Land Disturbance Permit System

A *Land Disturbance Permit System* will be implemented for all land disturbance works within the Project approvals boundary including:

- the disturbance of vegetation (grasses, shrubs, or trees) by machinery or other means (clearing or slashing); and
- the disturbance of soils (topsoils, subsoil, or surface rock layer) by machinery or by soil stripping, the placement of any material or infrastructure on unstripped ground, geotechnical drills, and the development of access roads/tracks.

Prior to any land disturbance, a *Land Disturbance Permit* is to be completed. The *Land Disturbance Permit System* will focus on the minimisation of impacts of land disturbance on the environmental values of the Project and surrounds.

The objective of the *Land Disturbance Permit System* is to ensure all disturbance works are undertaken in accordance with the Project's EA conditions and in an environmentally responsible manner, minimising the impact on the environmental values of the Project site and surrounding region.

The land disturbance procedure will detail the Standard Operating Procedure for the application of land disturbance including procedures for notification periods for relevant personnel, the application process and requirements, roles and responsibilities of personnel, environmental management required for land disturbance, clearing, topsoil removing a stockpiling activities and archaeological finds.

The *Land Disturbance Permit System* will require the following components be completed prior to submission and approval of land disturbance works:

- application details (personal applicant details, a description of the works, size of the disturbance and GPS coordinates);
- map of the disturbance area;
- relevant environmental management controls including a risk assessment, emergency response, erosion and sediment controls, requirements for ecological clearance, heritage clearance;
- legislative approvals, notifications and agreements where required;
- ecological, heritage, community, or land use survey requirements/approvals/notification requirements;
- possible environmental issues identified;
- rehabilitation requirements, where applicable;
- list of contractors and contact details required for any activities associated with land disturbance activities;
- visual inspections of facilities and services; and
- appropriate internal communications established.

4.7.2 Erosion and Sediment Control

A ESCP for the Project has been developed to address the construction, operational and rehabilitation/closure phases of the Project, to the comply with Schedule F31 and F32 of the Project's EA. The ESCP is provided in Appendix P and been designed using a three-tier approach beginning with management, control and treatment; which aims to minimise soil erosion and generation of sediment during disturbance activities and minimise the potential impact of the Project on the water quality of the receiving waters. The ESCP details the following:

- activities with the potential to result in soil erosion or sediment generation, including:
    - land clearing, construction activities and maintenance of haul and access routes;
    - movement of equipment; and
    - surface water run-off from waste rock material, coal, and topsoil stockpiles.
- the description, location and design of erosion and sediment control structures including the sediment dams associated with Pit AB and Pit C (Figures 8 - 12 of Appendix P);
- mitigation measures to reduce soil erosion and sediment migration into receiving waters, these measures include but are not limited to:
    - silt fences, coir logs, hay bales or other flow reduction and sediment entrapment devices;
    - traffic control measures and haul route bunding;
    - pit protection levees;
    - diversion channels;
    - cleaning of vehicles and equipment within designated cleaning areas;
    - sediment traps and dams;
    - cleaning protocols of sediment drains and entrapment devices;
    - waste rock stockpiles designed to slope of 1V:10H (adhering to a slope of 6°) to prevent landform instability and dispersal; and
    - rapid revegetation of disturbed areas and hydromulching of areas subject to short term exposure;
- sediment quality monitoring will be undertaken in accordance with a *Receiving Environment Monitoring Program* (REMP) to ensure the effectiveness of employed control measures, including the enforcement of sediment quality trigger values (further details of the REMP are provided in Section 7.4.4.1, and the REMP Design Document is included as Appendix Q);
- routine inspection and audits of the site, including periodic inspections of site drainage will be undertaken and used to inform the requirement of correction actions;
- any incidents of soil instability and erosion will be reported to the designated environmental representative on-site to facilitate management measures;

- decommissioning processes and requirements; and
- annual review requirements and responsibilities.

Erosion and sediment control structures will be designed and installed in accordance with *Best Practice Erosion and Sediment Control* (IECA Australasia 2008) and *Soil Erosion and Sediment Control: Engineering Guidelines for Queensland Construction Sites* (Witheridge & Walker 1996), as appropriate.

Four sediment dams associated with Pit AB will be installed in mining year 1 and five sediment dams associated with Pit C will be installed in mining year 13. Sediment dam design is discussed in further detail in Section 3.4.3. Temporary erosion and sediment control structures including sediment dams will be retained until re-vegetation within the sediment dam catchment has been established; and surface water run-off meets the water quality trigger values of the receiving water ways as detailed in Schedule F of the Project's EA. The time period of sediment dam retention is likely to be dictated by the germination of seeds which occurs on average within a year from planting. The sediment dam and associated drainage infrastructure would then be decommissioned and contour profiles consistent with the surrounding landscape to allow surface runoff to shed directly into the receiving environment.

The ESCP has been developed as a supporting document for the *Land Disturbance Permit System* (refer Section 4.7.1) and mine water management system (refer Section 3.4.3). Erosion and sediment controls will be routinely inspected and maintained for capacity and structural integrity including inspections following significant rainfall events.

4.7.3 Contaminated Land

The risk of land contamination will be similar to existing mining operations and is likely to be confined to accidental spills such as small diesel spills, and/or spills of chemicals likely to be onsite. Contaminated land management involves preventative management of incidental land contamination by 'Notifiable Activities' listed in Schedule 3 of the EP Act which include:

- item 7: Chemical storage (other than petroleum products or oil under item 29);
- item 15: Explosives production or storage;
- item 29: Petroleum product or oil storage; and
- item 37: Waste storage, treatment or disposal. Risk of contaminated land is associated with inappropriate storage and handling of chemicals, explosives, and waste.

The risk of contamination to land within the Project areas will be minimised through the following measures:

- sediment dams or stormwater dams will be installed and adhere to the design parameters of the '*Manual for assessing consequence categories and hydraulic performance of structures*' (DES 2016) to ensure all catchment areas downstream of the mine infrastructure area will contain any spills or contaminated stormwater run-off;
- explosives storage will be managed in accordance with AS 2187:2006 *'Explosives—Storage, transport and use*' (Standards Australia 2006);
- waste products including oil and other chemicals will be stored and disposed of according to the relevant material data safety sheets to minimise contamination risk;

- all unexpected contamination will be remediated and validated under supervision of a suitably qualified person in accordance with an *Emergency Response Plan* predefined for all hazardous materials stored on-site (the administering authority will be notified within 24 hours of detection being known);

- a contaminated land register and map will be maintained on-site detailing any contamination events, subsequent location and remediation protocols issued;

- chemical and hydrocarbon storage areas will be designed and bunded in accordance with '*AS 1940:2017, The storage and handling of flammable and combustible liquids*' (Standards Australia 2017);

- provision of training to staff on the prevention of spills and the use of spill kits; and

- a register of spill kits will be maintained, and all kits will be inspected for completeness at least quarterly.

With the implementation of the above standard operating procedures, the Project is not predicted to have an impact on the environmental values of land and water resources.

4.7.4 Weed and Pest Management Plan

A *Weed and Pest Management Plan* will be developed in accordance with the Biosecurity Act and the Central Highlands Regional Council *Pest Management Plan 2015-2020.* The objective of the Project's *Weed and Pest Management Plan* is to maintain the environmental values associated with the Project site and surrounding region and to support the local council weed and pest management objectives. The *Weed and Pest Management Plan* will be developed and implement prior to the construction of the Project.

The *Weed and Pest Management Plan* will focus on minimising the occurrence and spread of weeds through the implementation of:

- preventative measures to reduce the risk of weeds and pests on site and the spread of weeds and pests outside the Project boundaries and include;
    - wash down facilities for vehicles identified as a risk of spreading weeds;
    - the inclusion of weed and pest identification and reporting procedures for the Project in induction and training materials distributed to all employees;
    - seeding of fast-growing grass cover to topsoil stockpiles requiring long term storage and rehabilitated areas;
    - inclusion of weed and pest monitoring;
    - weed disposal procedures;
- control measures to minimise the impacts of weeds and pests on environmental values and to prevent the spread of weeds and pests outside the Project boundaries which may include:
    - the manual removal of weeds in instances of isolated weed presence;
    - herbicide application treatments; and

- liaison with local council and surrounding landholders, where required on the control of pests.

The *Weed and Pest Management Plan* will include the following components:

- a description of weed and pest animal species listed under the Biosecurity Act and known to occur on the Project site;
- identification of and commitment to appropriate management strategies to control the occurrence of pest fauna and weed species on the Project site;
- a system for early detection and eradication of new weed and pest fauna species;
- management strategies to prevent the introduction of new pest species onto the Project site;
- delineation of the roles and responsibilities of Project personnel in relation to pest and weed management on the Project site.

The *Weed and Pest Management Plan* will address weeds and pests across the Project as well as in rehabilitation areas. The first few years following planting are the most important for controlling the spread of invasive species. As pioneer species, weeds tend to out-compete native species on disturbed soils before desirable species have had time to set roots and adequately cover a rehabilitated area. During the first three growing seasons, botanical surveys and hand removal of weeds or targeted herbicide applications will be pursued as appropriate. Weed cover should be comparable to analogue sites. Regular monitoring will be undertaken specifically targeted at identified pest and weed species, and management plans implemented as appropriate to the findings of monitoring results.

4.7.5 Grazing and Agriculture Management

A *Grazing and Agriculture Management Plan* will be developed by a suitably qualified person in consultation with the landowner / leaseholder.

Grazing by cattle on rehabilitated areas will only commence once the completion criteria for the area has been met. Fencing around grazing areas / native ecosystems will be undertaken in a manner to enable standard grazing management practices. A suitable stocking rate will be determined subject to the performance of grazing trials and revegetation following the closure of the mine.

In Queensland, the underlying principle to the standard management practices of grazing and agricultural management is to utilise land in a sustainable manner while protecting the environmental value of land. Standard Management practices include the following (DERM 2011):

- managing erosion management through stock fencing (including exclusion zones of riparian corridors and watering points), vegetative cover and stocking rates;
- paddock planning layout management to manage grazing pressure and conserving the biodiversity values of land in accordance with the EPBC Act and *Vegetation Management Act 1999* (VM Act);
- weed and pest management;
- soil management; and
- fire management.

4.8 REHABILITATION MONITORING AND MEASUREMENT

Rehabilitation monitoring for the Project has the goal of assessing compliance with the rehabilitation objectives and agreed completion criteria.

Rehabilitation monitoring will be used to track the progress of revegetated areas and determine requirements for intervention, such as weed control or supplementary planting. Additionally, rehabilitation monitoring will also:

- evaluate coverage and application of topsoil prior to seeding;
- monitor drains and assess water quality to determine whether substantial silting of inverts and/or any localised failure of drain embankments has occurred;
- evaluate topsoiled areas following rainfall events (particularly on slopes) to assess whether significant rill development or loss of topsoil has occurred;
- evaluate the behaviour of placed topsoil over time (erosion or dispersion, compaction, salting or hard setting);
- assess the germination success in revegetated areas (including recording of diversity and abundance);
- monitor revegetation success over time (e.g., survival rate, plant growth, species diversity, weed content, fauna usage);
- evaluate potential threats to rehabilitated areas (e.g., weed invasion, pest species, dispersive soils or potentially acid forming (PAF) low-capacity materials, erosion); and
- record key rehabilitation information (e.g., photographic records, surveys, file notations).

To monitor the success of progressive rehabilitation, permanently marked transects will be established. These transects will generally be monitored for a minimum of five years or longer until criteria area achieved. The results will then be used to continually inform and assess the effectiveness of rehabilitation strategies and methodologies, as well as enabling movement towards progressive certification. Where new monitoring techniques and technologies are identified, these will be adopted as appropriate.

4.8.1 Monitoring Methodology

A transect based approach (consistent with the BioCondition methodology) will be utilised for rehabilitation monitoring. This approach aims to provide a measure of the capacity of a terrestrial ecosystem to maintain biodiversity values at a local or property scale and allows a comparative assessment of pre- and post-mining ecosystems.

BioCondition monitoring assesses a suite of parameters at different landscape positions on each site, namely on flats, slopes and in troughs. Repeated edaphic (soil properties) and biological measurements are taken over time for various parameters that indicate changes in ecosystem function as rehabilitation proceeds. In general, the method involves monitoring two groups of sites:

- **analogue / reference sites:** selected to best reflect the pre-mining land use (i.e., cleared pasture for cattle grazing) to obtain relevant and realistic rehabilitation criteria for the matching

PMLU. Analogue sites will be chosen as close as possible to the rehabilitated area so that the same climatic and environmental conditions existed at both sites to the extent possible; and

- **rehabilitated sites:** monitored for rehabilitation performance, successful or otherwise.

Multiple analogue/reference sites will be established on and around the Project that best represent pre-mining ecosystems. For this Project, reference sites representative of the proposed PMLU of low intensity grazing on native and improved pastures will be established prior to the commencement of the Project.

Structured, periodic monitoring of reference sites will provide an understanding of the pre-mining landscape, assisting in the future planning and refinement of rehabilitation strategies, as well as providing data for determination of completion criteria when assessing rehabilitation success.

Rehabilitation transect sites will also be established within rehabilitated landforms post mining. At each site, the following parameters will be monitored annually:

- aspect and slope;
- tree density (trees/ha);
- shrub density (shrubs/ha);
- herb/grass density (grasses/ha);
- groundcover (%);
- species composition;
- chemical and physical indicators of soil;
- erosion indicators (depth of rills or erosion lines, surface crusting, slopes); and
- photographic records of the site.

In addition to rehabilitation transect monitoring, other related site environmental monitoring will continue throughout and following the life of the mine (e.g., surface water monitoring). These data sets will also work to further inform rehabilitation success.

In accordance with current standards, rehabilitation monitoring will ultimately aim to demonstrate that domain specific completion criteria have been continuously met for a period of three years or greater.

4.8.2 Review of Rehabilitation Monitoring Data

Rehabilitation monitoring data will be used to review rehabilitation success. This will occur through:

- tracking revegetation and/or regeneration progress against performance indicators and completion criteria;
- assessing the performance of landform designs and rehabilitation concept methods;
- evaluating the effectiveness of environmental management measures/controls; and
- identifying the requirement for intervention strategies or ameliorative/contingency measures.

The results of any industry rehabilitation trials and investigations will also continue to be used to inform and refine future rehabilitation concepts, practices and measures.

4.9 CLOSURE AND RELINQUISHMENT

4.9.1 Closure Planning

A *Closure Plan* will be developed for the Project during the first five years of the Project life. The C*losure Plan* will extend the preliminary rehabilitation requirements described in Table 21 and develop detailed planning for the post-mining closure phase of the Project.

The *Closure Plan* will update and refine landform design criteria, particularly residual void slope highwall and low wall slope design and completion criteria on the basis of experience gained during mining operations. Any agreements in relation to retained infrastructure will also be addressed.

The *Closure Plan* will also refine rehabilitation maintenance requirements and provide an update on findings from rehabilitation monitoring undertaken.

4.9.2 Final Rehabilitation Report and EA Surrender

At the point in time that rehabilitation monitoring indicates that completion criteria are being achieved for all or part of the rehabilitation undertaken for the Project, either a final or progressive rehabilitation report will be compiled and submitted to the administering authority for consideration in accordance with Section 264 or Section 318ZF of the EP Act.

The final or progressive rehabilitation report will contain an environmental risk assessment which will identify any residual risks and costs. However, achievement of the completion criteria is anticipated to result in minimal residual risk due to the low risk of acid mine drainage, slope design of the waste rock emplacements is consistent with standard design practices in the Bowen Basin, the exclusion of dispersive/sodic soils from the final landform surfaces and overall landform design consistency with the surrounding environment. Residual risk is predicted to be limited to maintenance of fencing and signage around the residual void and fencing requirements and land management associated with standard cattle grazing management.

Where relinquishment requires the transfer of ownership or management of infrastructure and/or land to other parties, evidence that these parties have been involved in the process and understand the liability and responsibilities associated with the transfer will be provided. Written legal agreement with the subsequent party owners will be sought to identify acceptance of the mining legacy and any outstanding costs of remediation, monitoring and reporting. Legal agreements will be undertaken in accordance with the relevant legislative requirements at the time of relinquishment.

5.0 LAND

This section provides a description of the existing land values within and surrounding the Project. It aims to identify the Project's potential impacts on the existing values and propose mitigation measures and management strategies to prevent or minimise adverse environmental effects.

This section is informed by the *Soil and Land Suitability Assessment* (AARC 2019) presented as Appendix I.

5.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objective relevant to potential impacts to land as described in the EA guideline for *Application requirements for activities with impacts to land [ESR/2015/1839]* (DES 2017b) is:

The activity is operated in a way that protects the environmental values of land including soils, subsoils, landforms and associated flora and fauna.

The Project would achieve all of the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

(a) activities that disturb land, soils, subsoils, landforms and associated flora and fauna will be managed in a way that prevents or minimises adverse effects on the environmental values of land;

(b) areas disturbed will be rehabilitated or restored to achieve sites that are:

(i) safe to humans and wildlife;

(ii) non-polluting;

(iii) stable; and

(iv) able to sustain an appropriate land use after rehabilitation or restoration;

(c) the activity will be managed to prevent or minimise adverse effects on the environmental values of land due to unplanned releases or discharges, including spills and leaks of contaminants; and

(d) the application of water or waste to the land is sustainable and is managed to prevent or minimise adverse effects on the composition or structure of soils and subsoils.

5.2 DESCRIPTION OF ENVIRONMENTAL VALUES

5.2.1 Landform and Visual Amenity

Landform

The topography of the Project area varies from flat to undulating hills, with elevation ranging between 120-150 mAHD. The landscape is strongly influenced by the presence of Charlevue Creek and its associated floodplains, which have relatively lower elevations than the surrounding landscape of undulating hills. An elevated ridgeline is located 2-5 km east of the Project at an elevation of 170 mAHD.

The major water body associated with the Project is Charlevue Creek, which dissects the MLA, flowing in a northeast direction. This creek begins within the boundaries of Blackdown Tablelands National Park,

flowing northeast before joining with Springton Creek and the Fitzroy River, eventually reaching the Pacific Ocean approximately 46 km north of Gladstone. Two significantly smaller creeks, Stanley and Springton, cross the Project boundaries in the northwest and southeast respectively. These two creeks eventually converge with the Mackenzie River. Associated tributaries, agricultural dams and unnamed drainage features also appear across the site.

Visual Amenity

Visual amenity refers to the quality and appreciation of a geographical location in the context of valued features, characteristics and attributes. The existing visual environment of the Project and surrounding area is typical of the Bowen Basin; with a predominant rural landscape character comprised primarily of grazing land and areas of bush reserve. To the west, views of the Arthurs Bluff State Forest can be seen from the eastern MLA boundary.

The landscape amenity is dissected by major transport infrastructure including the Capricorn Highway and the Blackwater Railway. A number of small towns and rest stops are located along the Capricorn Highway serving the local residents and mining communities. Along the transport route heading west of the Project, coal mines and associated infrastructure can occasionally be observed from public transport corridors.

The mining infrastructure relevant to potential visual exposure, includes:

- The out-of-pit waste rock emplacement of Pit AB (beginning at the commencement of mining activities) will be located approximately 2 km south of the Capricorn Highway. The topography surrounding the waste rock emplacement is relatively flat with minimal obstruction by natural features. The Pit AB waste rock emplacement will have a maximum height of 175 mAHD and be progressively rehabilitated throughout the life of mine to resemble the surrounding landscape of gently undulating hills. Whilst the Pit AB void is a depression below natural ground surface and not expected to be visible from public or private sensitive locations.

- The out-of-pit waste rock emplacement of Pit C (beginning Year 12) will be located approximately 500 m north of the Cooinda Road diversion. The Pit C waste rock emplacement will have a maximum height of 190 mAHD and also rehabilitated throughout the life of mine.

- All haul roads are internal to the MLA and are located 1 km, or more, away from the closest residential dwelling.

- The TLO will be located approximately 300 m north of the Capricorn Highway connecting to the existing Blackwater Railway. The Blackwater Railway services coal export from the Bowen Basin and is a dominant visual feature along the length of the Capricorn Highway with rail infrastructure and trains frequently visible. The proposed TLO will contain a rail spur, rail loop and train loading bin.

- An overland conveyor will transport export material from the CHPP to the TLO, crossing over the Capricorn Highway (conceptual design provisions are shown in Figure 12 to Figure 14). The proposed overhead conveyor will cross the transport route at a minimum height elevation of 7m and 10m in length, similar to that of the existing conveyor across the Capricorn Highway at Boonal, approximately 28 km west.

A *Visual Amenity Assessment* was undertaken by AARC (Appendix O). A total of five photographic vantage points were selected as representative points to reflect the visual landscape at major sensitive receptor locations and also relatively high traffic areas within the local region (refer to Table 29 for detailed vantage point descriptions). A number of visual simulations were produced at each vantage

point to identify the risk of any visual modification to the surrounding landscape, potential impacts on visual amenity are summarised below in Section 5.3.2.

Table 29 Visual Amenity Vantage Points

Vantage Point	Location Description	Coordinates (Lat/Long)	Approximate Distance from MLA
VA1	Southern side of Capricorn Highway facing south west towards Pit AB between the pit and the residence of the Rubina property. This property is owned by the proponent and as the residence will be vacated prior to the commencement of operations, it is not considered to be a sensitive receptor.	-23.641, 149.292	Within MLA
VA2	Southern side of Sanders Road facing west towards Pit C at the entrance to the residence on the Namoi Hills property along the eastern boundary. This property is owned by the proponent and as the residence will be vacated prior to the commencement of operations, it is not considered to be a sensitive receptor.	-23.696, 149.281	1.3 km
VA3	Northern side of Sanders Road facing north towards Pit AB at the entrance to the residence on the Namoi Hills property along the eastern boundary. This property is owned by the proponent and as the residence will be vacated prior to the commencement of operations, it is not considered to be a sensitive receptor.	-23.694, 149.280	1.2 km
VA4	Southern side of Capricorn Highway facing south towards Pit AB. This location is closest to the northern boundary of the Namoi Hills property.	-23.629, 149.272	Within MLA
VA5	Western side of Cooinda Road facing north towards Pit C at the entrance to the residence on the Glenwood property.	-23.720, 149.246	2.4 km

5.2.2 Native Title and Cultural Heritage

Native title determination areas described by the National Native Title Tribunal is extinguished within the boundary of the ML. As such, a native title process is not required to be undertaken as part of the MLA process.

The Proponent will comply with the *Aboriginal Cultural Heritage Act 2003* and the supporting *Duty of Care Guidelines* (DATSIP 2004) when undertaking activities within the area of EPC 881 and the proposed ML.

A *Cultural Heritage Management Plan* has been developed for the Project and signed in accordance with the *Aboriginal Cultural Heritage Act 2003*.

5.2.3 Geology

Regional Geology

The Gemini Project coal deposit is hosted within the Permian Rangal Coal Measures and the Yarrabee Structural Zone. Seven seams or seam groups have been identified at site, which belong to either the Rangal Coal Measures or the underlying Burngrove Formation (BOYD 2019). In descending stratigraphic order, the seams include the Aries, Castor, Pollux, Orion, Pisces, Virgo and Leo seams. The seams contain several individual plies that have identified for mining at the site.

The site surface geology is shown in Figure 47. It predominantly comprises sediments of the Tertiary Duaringa Formation and Quaternary alluvium associated with ephemeral creeks including Charlevue Creek and Springton Creek.

Figure 48 shows the project location in relation to the underlying Bowen Basin solid geology (i.e., the surficial unconsolidated Quaternary and Tertiary units have been removed, revealing the relationship between the underlying Triassic and Permian sediments, as well as the prevalence of regional-scale faults). The two mining areas (Pit AB and Pit C) are in areas where folding has brought the coal seams close to surface at depths that can be economically mined.

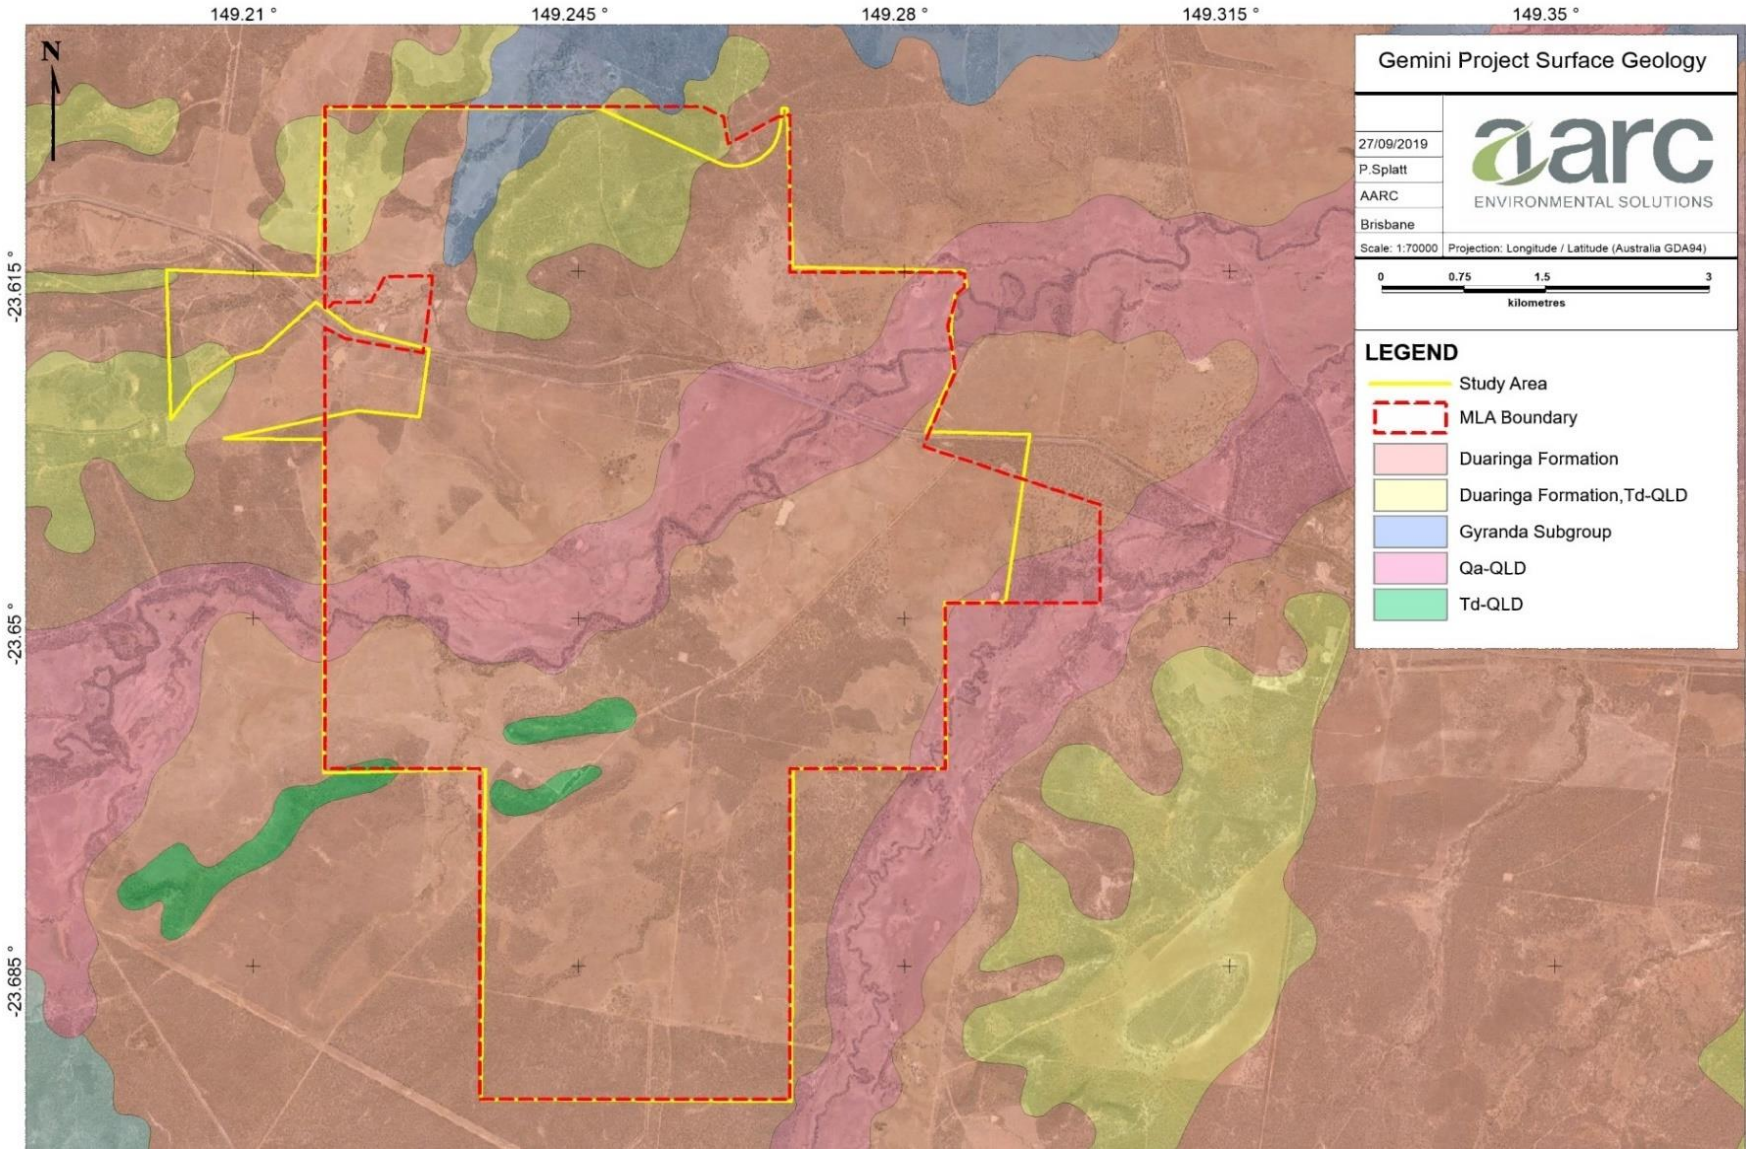

Figure 47 Surface Geology

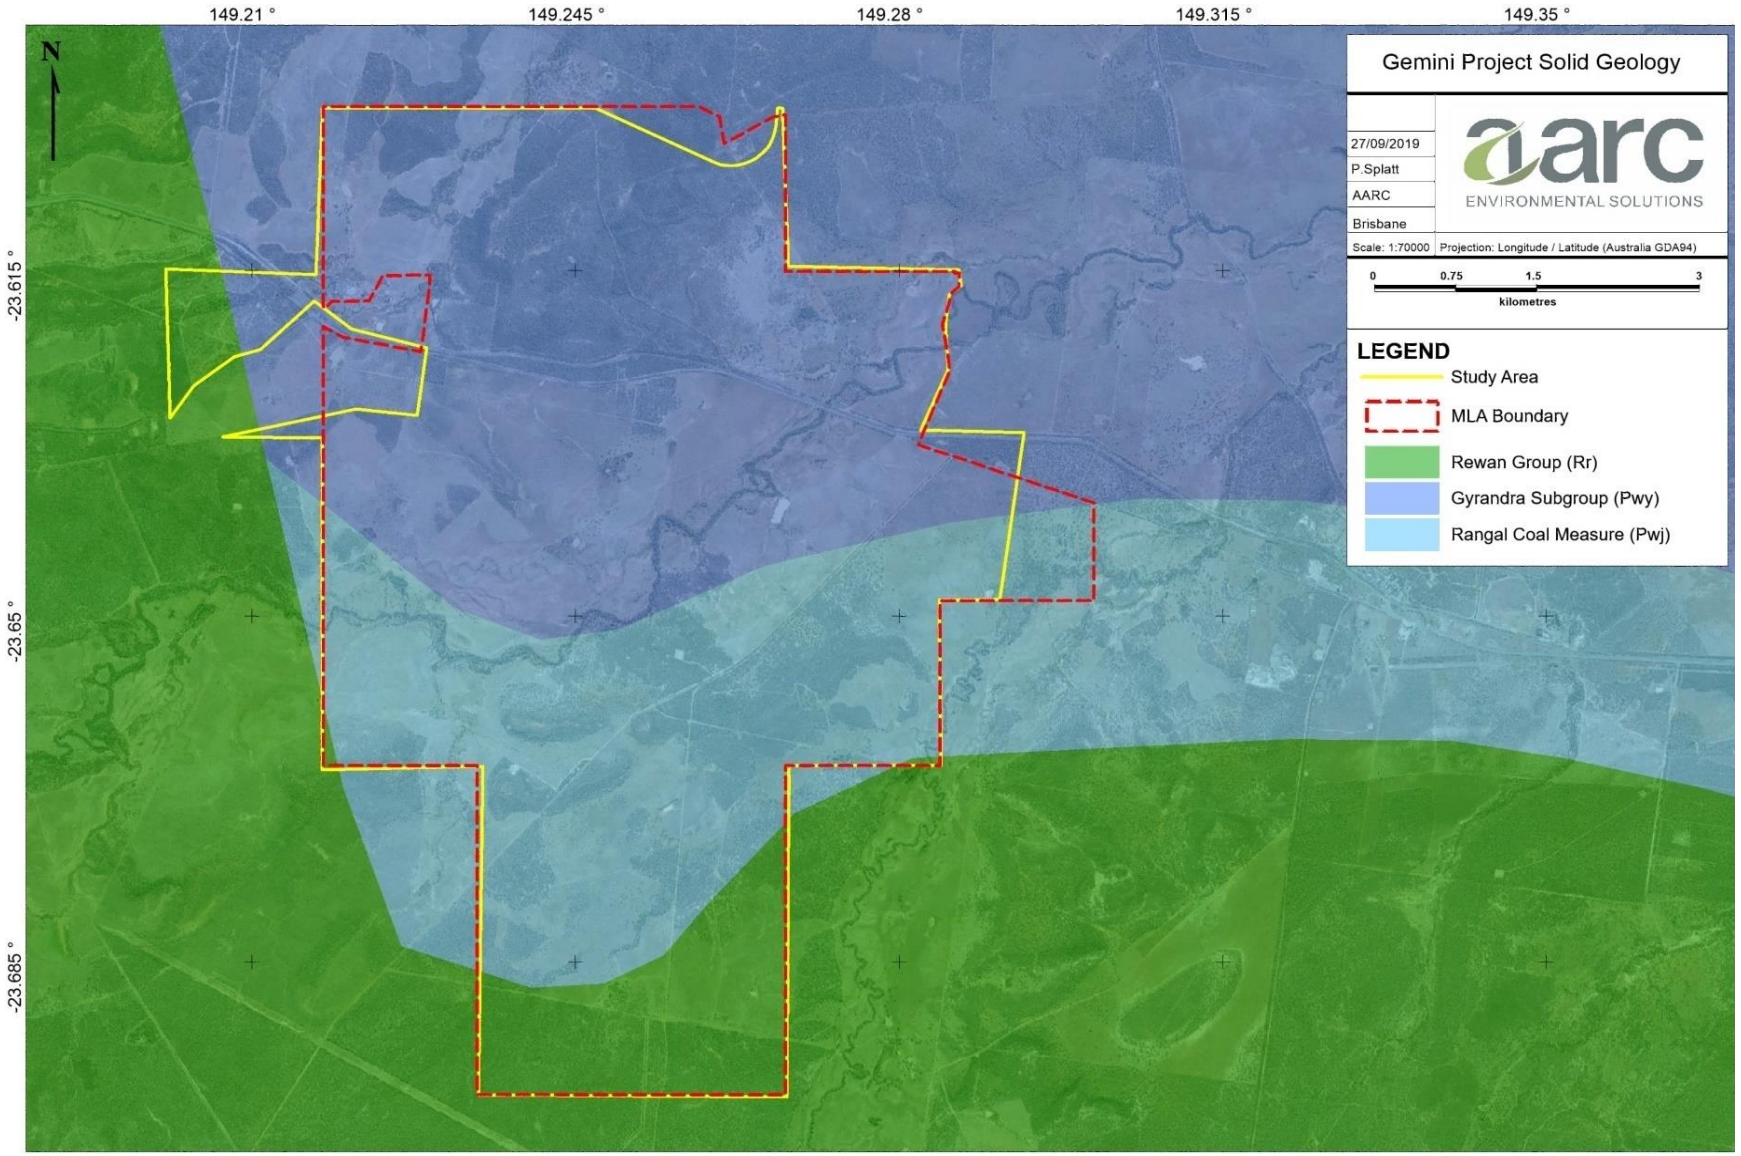

Figure 48 Solid Geology

5.2.4 Land Systems

Two land systems are mapped within the Project area and are described as follows.

Dingo Land System

The Dingo land system is characterised by fluvial plains surrounding significant waterways. It is mostly composed of stable flood plains traversed by a branching pattern of drainage floors. The majority of deposits are weathered alluvium, with slopes of coarser or finer textured alluvium (depending on flow patterns). Channels can be up to 30 m wide and 3 m deep, with fringing riparian vegetation. Main drainage floors can then extend 800 m outwards, with deep texture contrast sandy loams over mottled clays, and open spaces of *Eucalyptus tereticornis* (blue gum) and *Eucalyptus crebra* (narrow-leaved ironbark) with sparse shrubs. Large plains surround drainage features (up to 3 km wide) which can contain either deep texture contrast soils with *Eucalyptus populnea* (poplar box) woodlands, or deep layered soils on alluvium with woodlands of blue gum and narrow-leaved ironbark. Slopes within this land unit are usually the result of strongly Gilgai shrink-swell clays, forming depressions of finer soil textures with *Acacia harpophylla* (brigalow) scrub.

Geology in this unit is comprised of weathered Quaternary alluvium.

Melbadale Land System

The Melbadale land system is characterised by the shallow dissection of weathered tertiary land surfaces, forming undulating plains dominated by complex depositional mid and lower slopes, with minor lateritic upper slopes in some places. This land system features moderately dense branching drainage patterns, with local relief usually less than 15 m. Depending on the steepness of terrain, upper slopes are often dominated by deep loamy red earths (gentle slopes) with narrow-leaved ironbark, or shallow fine sandy loams (steep terrain) with *Acacia shirleyi* (lancewood) forests. Mid to lower slopes are often associated with deep texture contrast soils of loamy sands overlying mottled sandy clays, with grassy woodlands of open-spaced narrow-leaved ironbark and shrubs. Lower slopes are often associated with deep light to medium clays, with tall forests of narrow-leaved ironbark. Tributaries have variable soil textures depending on slope, though stratified loams and texture contrast soils are common.

Geology in this land system is comprised of Quaternary to late Tertiary colluvial/alluvium, laterised tertiary sandstone, conglomerate, and shale.

5.2.5 Soils

A *Soil and Land Suitability Assessment* was undertaken within the MLA by AARC (2019) and attached as Appendix I.

Methodologies employed throughout this study are detailed in Appendix I and followed procedures in the *Australian Soil and Land Survey Field Handbook* (NCST 2009) and the *Guidelines for Surveying Soil and Land Resources* (McKenzie et al 2008). The soil survey was based on a free-survey technique with soil profile and observation sites located to best represent all soil types present in the Project. At the time of the survey, the Project MLA was subject to frequent changes, therefore, the study area was based of the EPC 881 boundary, land owner access, and a 5 km buffer around the boundary of the Walton State Forest.

Within the Project, a total of 12 SMUs were described. Table 30 provides an overview of each SMU and its extent within the MLA. The spatial distribution of the SMUs has been mapped at a scale of 1:70,000 and is depicted in Figure 49.

No acid sulphate soils have been identified within the Project area.

Table 30 SMUs Within The Study Area

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Anderson	37.80	0.61	Hard setting soil unit associated with isolated hills. Soil textures grade from loams at the surface, to light medium clays with depth, sometimes exhibiting red mottling. Vegetation associated with this unit includes *Eucalyptus crebra*, *Corymbia clarksoniana*, and *Acacia rhodoxylon* with *Erythroxylon australe* in the shrub layer. The Anderson SMU has a very strongly acidic pH throughout the profile, ranging from 4.6 in the topsoil, to 4.8 in the lower subsoil. EC and chloride results indicate that at all depths, salinity is very low, with EC ranging from 0.064 deciSiemens per metre (dS/m) in the topsoil, to 0.02 dS/m in the subsoil layer. Chloride concentrations reflected this result, decreasing with depth from 30 mg/kg to 10 mg/kg, both well below toxic limits.
Barry	156.50	2.54	Hard setting soil associated with rivers, drainage lines and levees. Surface soils in this unit are comprised of clay loams to medium clays, grading into light or medium clays at variable depths. Dominant vegetation includes *Eucalyptus tessellaris*, *Eucalyptus populnea* and *Eucalyptus tereticornis*, with *Bauhinia hookeri, Carissa spinarum* and *Cassia brewsteri* in the shrub layer. The Barry SMU has a slightly acidic pH (6.5) which increases gradually with depth, becoming neutral at 0.2 m (6.8), and increasing to pH 7.2 with depth. EC is very low throughout the profile, ranging from 0.063 dS/m in the topsoil, to 0.012 dS/m in the lower subsoil. Chloride concentrations reflect this result, ranging from 20 mg/kg to <10 mg/kg with depth.
Charlevue	232.90	3.77	Hard setting soil associated with plains and rises. Textures within this unit grade from sandy clay loams or light clays in the surface soil, to medium heavy clays in the subsoil horizons. Dominant vegetation includes *Eucalyptus populnea* and *Eucalyptus crebra,* with *Flindersia dissosperma* (sometimes dominant) and *Carissa spinarum* in the shrub layer. The Charlevue SMU has a variable pH, ranging from 5.4 (strongly acid) in the topsoil to 7.9 (moderately alkaline) in the lower subsoil. EC is medium in the surface soil (0.28-0.43 dS/m) and increases to high in the subsoil (0.46 dS/m). Chloride is considered to be high from 0.2 m depth downwards (>600 mg/kg), which can cause toxicity by interfering with plants' osmotic capacity.
Cooinda	34.90	0.57	Hard setting soil associated with plains. Texture development within this unit is gradual, changing from a sandy clay loam in the topsoil, to a sandy light clay at mid-depth, and a medium heavy clay in the deeper subsoil. Dominant vegetation includes *Eucalyptus populnea* and *Flindersia dissosperma* (sometimes dominant), with *Carissa spinarum* in the shrub layer. The pH of the Cooinda SMU ranges from moderately acid (5.6) in the topsoil, to neutral (6.8) in the lower subsoil. EC is very low throughout the profile, with topsoil values of 0.015 dS/m, increasing to 0.043 dS/m in the subsoil. Chloride levels reflect EC, increasing from <10 mg/kg to 40 mg/kg with depth.

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Ellesmere	14.60	0.24	Hard setting soil associated with isolated hills of weathered tertiary surfaces (laterite). Textures within this unit grade from fine sandy loams in the surface soil to medium clays in the subsoil horizons. Dominant vegetation is *Acacia shirleyi*, with *Erythroxylon australe* in the shrub layer. The Ellesmere SMU is a highly acidic soil unit, ranging from 4.6 (very strongly acid) in the topsoil to 5.5 (strongly acid) in the lower subsoil layer. EC is very low throughout the profile, changing from 0.02 dS/m in the topsoil, to 0.026 dS/m in the lower subsoil. Chloride concentrations are very low, consistently presenting at <10 mg/kg.
Geoffrey	4,079.00	66.10	This unit consists of texture contrast soils with soft surface conditions, associated with undulating plains and rises. Textures range from loamy sands to sandy light clays, overlying sandy medium clays with conspicuous orange or red mottling. Where these soils were exposed due to insufficient groundcover, extensive washouts and large erosion gullies were observed. In these areas, overland flow had removed coarse sandy material, leaving the easily eroded clays exposed to surface runoff. The Geoffrey SMU was often cleared, though when present dominant vegetation included *Eucalyptus crebra*, *Melaleuca leucadendra*, *Casuarina cunninghamiana* and *Corymbia clarksoniana*, with *Alphitonia excelsa*, *Petalostigma pubescens*, and *Acacia rhodoxylon* in the shrub layer. Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Geoffrey SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0-0.6 m) are moderately acidic, with pH gradually increasing with depth from 5.8 to 6.0. The clay B2 horizon has a pH value over two units higher (8.1) and is classified as 'moderately alkaline'. This is likely due to the increased CEC of the clay in the B2 horizon compared with the sand in the upper horizons.
James	145.20	2.35	Hard setting red soils associated with hills and rises. Textures within this unit vary depending on slope, with lesser developed soils found on crests (sandy clay loams to clay loams) and more developed/deeper soils found on mid slopes (clay loams to light medium clays). Dominant vegetation includes *Acacia rhodoxylon, Eucalyptus crebra,* and *Corymbia clarksoniana.* The pH in the James SMU is slightly acidic throughout the profile, with very little variation. It increases gradually with depth from 6.2 in the topsoil, to 6.4 in the lower subsoil. EC is very low at all depths, ranging from 0.013 dS/m in the topsoil to 0.015 dS/m in the subsoil. Chloride levels reflect this result, presenting at <10 mg/kg throughout the profile.

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Kosh	927.60	15.03	Hard setting soil associated with alluvial plains, plains and low rises. Textures within this unit are gradational, changing from sandy clay loams and light clays in the topsoil, to medium heavy clays in the lower subsoil. Commonly, this unit was cleared for grazing, with regrowth consisting of scrub species including *Vachellia nilotica*, *Carissa spinarum, Capparis lasiantha, Cassia brewsteri*, and *Eucalyptus spp.* shrubs. When present, vegetation included *Eucalyptus tereticornis, Acacia hemiglauca, Acacia salicina, Bauhinia hookeri, Eucalyptus crebra* and *Eucalyptus populnea*. Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Kosh SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0 to 0.6 m) are moderately acid, with pH gradually increasing with depth from 5.8 to 6.0. The low CEC calculated for this unit resulted in extremely low concentrations of exchangeable cations. In the surface soil, calcium and magnesium were relatively equally represented, though concentrations of these cations were extremely limited.
Namoi	177.60	2.89	Hard setting soil associated with hills and rises. Textures within this unit are gradational, changing from a sandy clay loam in the topsoil to a light medium clay in the subsoil. Dominant vegetation includes *Eucalyptus crebra,* with *Heteropogon contortus* and juvenile *Acacia spp.* The pH in the Namoi SMU is slightly acidic throughout the profile, with very little variation. It increases gradually with depth from 6.2 in the topsoil, to 6.4 in the lower subsoil. EC is very low at all depths, ranging from 0.013 dS/m in the topsoil to 0.015 dS/m in the subsoil. Chloride levels reflect this result, presenting at <10 mg/kg throughout the profile. CEC remains fairly consistent with depth, ranging from 4.3 milliequivalent per 100 grams (meq/100g) (very low) in the topsoil to 5.8 meq/100g (very low) in the subsoil.
Nigel	286.40	4.64	Hard setting soil associated with isolated high relief areas of tertiary land surface. Textures within this unit are rudimentary, grading from sands to sandy light clays. Vegetation is variable between sites, but includes *Acacia shirleyi, Acacia rhodoxylon, Eucalyptus crebra, Melaleuca leucadendra, Corymbia clarksoniana,* and *Eucalyptus tessellaris.* The pH within the Nigel SMU is highly variable, changing from 6.3 (slightly acid) in the topsoil to 8.5 (strongly alkaline) in the lower subsoil. EC follows a similar pattern, changing from very low between 0.0-0.3 m depth, to medium in the subsoil. CEC increases with depth from low (6.8 meq/100g) to moderate (17.4 meq/100g), likely due to the increased clay content in the subsoil layers.

SMU	Surface Area (ha)	Percent of Study Area (%)	General Description
Normanby	48.50	0.79	Deep red earth with soft surface condition, associated with plains, and the flat areas of upper slopes. Textures within this unit are relatively consistent throughout the profile, ranging from loamy sands to sandy light medium clays. Vegetation is mostly cleared, but when present includes *Eucalyptus crebra* and *Alectryon oleifolius*. The Normanby soil unit has a neutral to slightly acidic pH throughout the soil profile, decreasing with depth from 6.7 to 6.1. EC is very low throughout the profile, ranging from 0.036 dS/m in the topsoil to 0.003 dS/m in the subsoil. Chloride levels reflect this result, presenting at less than 10 mg/kg at all depths. CEC measurements are considered very low, ranging from 2.4 meq/100g to 1.6 meq/100g with depth. The Normanby soil unit has limited nutrient holding capacity of this soil can be attributed to its low clay content and low organic matter levels.
Wallace	32.00	0.52	Shallow, self-mulching, cracking clay associated with upper slope flats. Textures within this unit grade from medium heavy clays to heavy clays, with the B3/C horizon met at approximately 0.24 m depth. The Wallace SMU is extensively cleared, with the boundary of the unit corresponding to an increase in standing vegetation. The dominant grass species is likely *Aristida latifolia*, with confirmation required during the wet season when an accurate identification can be made. The pH within the Wallace SMU is variable changing from 6.8 (neutral) in the topsoil to 7.4 (slightly alkaline) in the lower subsoil. EC changes from low in the topsoil to very low in the lower subsoils (0.09 - 0.038). CEC increases with depth from high (39 meq/100g) to very high (44 meq/100g), likely due to the increased clay content in the subsoil layers. High clay content, low sodicity, and desirable nutrient concentrations make this unit one of the best growth mediums in the survey area.

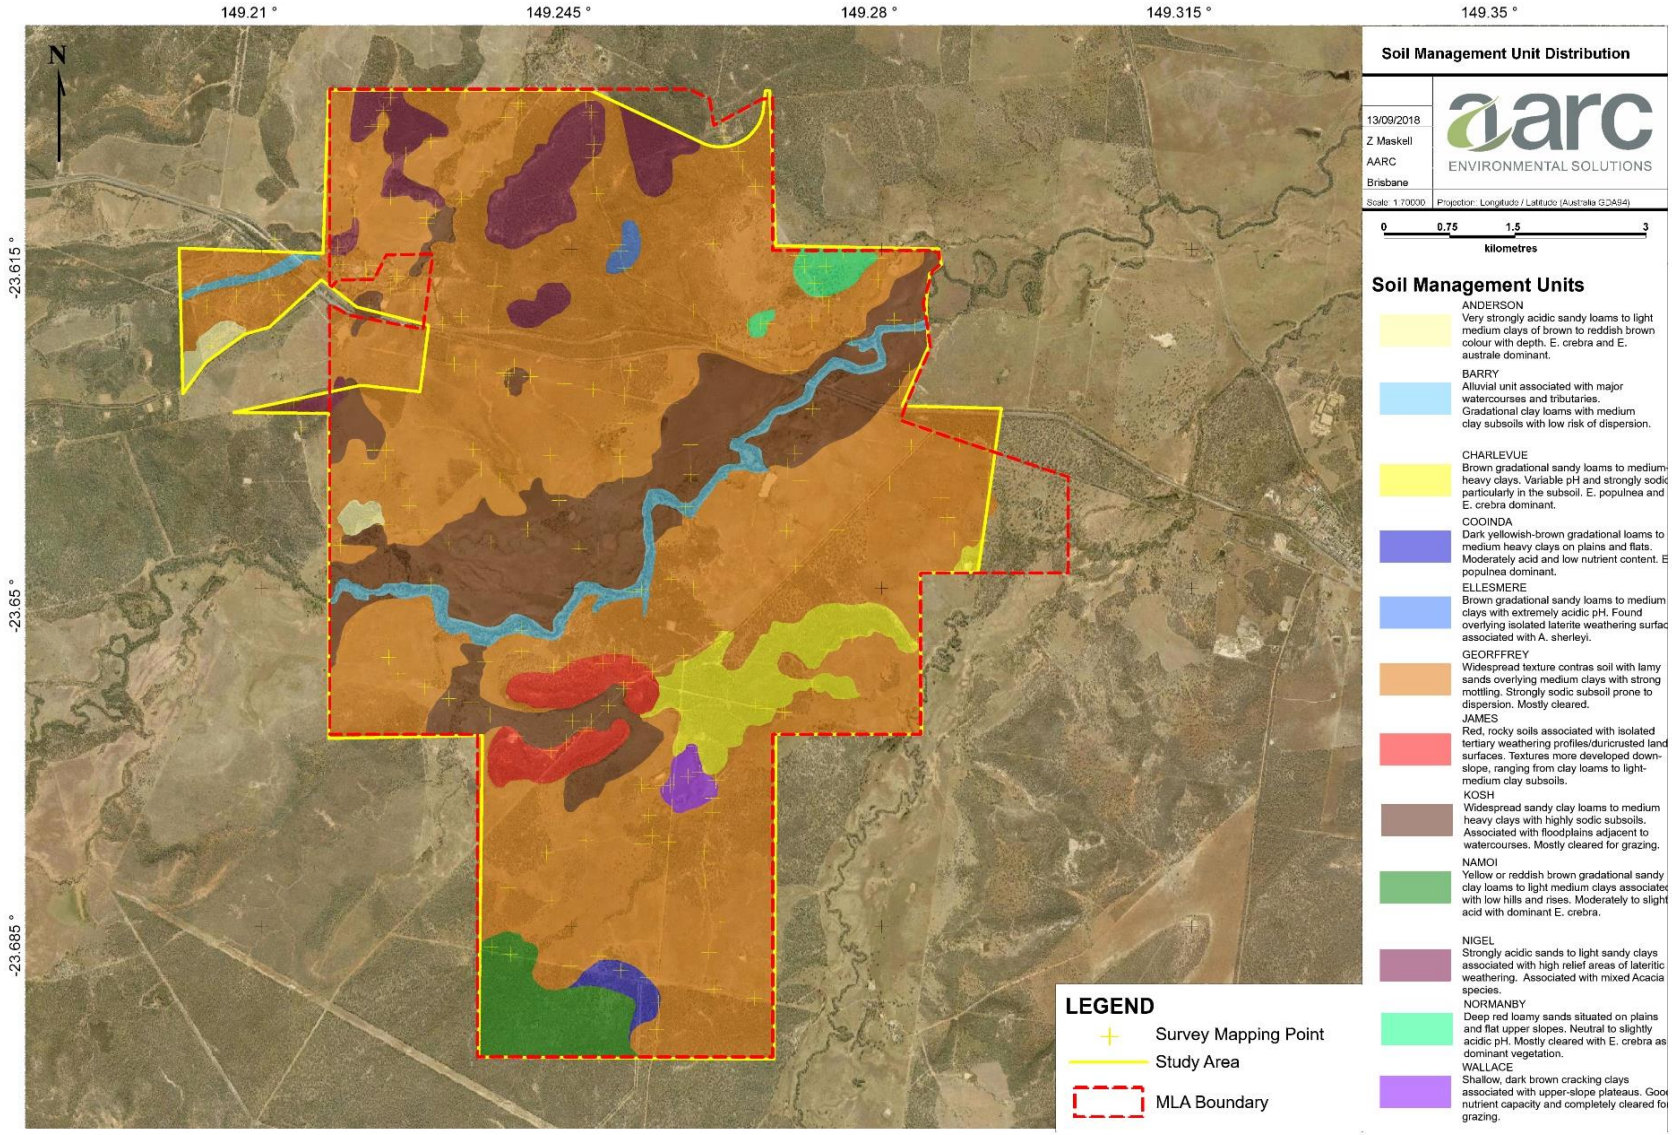

Figure 49 **Distribution of SMUs**

5.2.6 Land Suitability

The *Soil and Land Suitability Assessment* (AARC 2019) (Appendix I) considers environmental factors including climate, soils, geology, geomorphology, erosion, topography and the effects of pre-mine land use. The classification indicates the potential of the land to be used for a range of agricultural activities.

The assessment for land suitability (cattle grazing and dryland cropping) was carried out in accordance with the methodologies described in:

- *Guidelines for Agricultural Land Evaluation in Queensland* (DSITI & DNRM 2015); and
- Chapter 10 (Suitability framework for the inland Fitzroy and southern Burdekin area) of the *Regional Land Suitability Frameworks for Queensland* (DNRM & DSITI 2013).

An interpretation of the data collected on the physical, chemical and nutritional characteristics of the soil was made to rank the land according to the five-class land suitability system provided in the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland* (DME 1995). The five land suitability classes used for assessing the land are defined in Table 31.

Table 31 Agricultural and Conservation Land Classes

Agricultural Land Class	Type	Description
Class 1	Agricultural	Suitable land with negligible limitations. This is highly productive land requiring only simple management practices to maintain economic production.
Class 2	Agricultural	Suitable land with minor limitations which either reduce production or require more than the simple management practices of class 1 land to maintain economic production.
Class 3	Agricultural	Suitable land with moderate limitations which either further lower production or require more than those management practices of class 2 land to maintain economic production.
Class 4	Agricultural	Marginal land, which is presently considered unsuitable due to severe limitations. The long-term significance of these limitations on the proposed land use is unknown or not quantified. The use of this land is dependent upon undertaking additional studies to determine whether the effect of the limitation(s) can be reduced to achieve sustained economic production.
Class 5	Agricultural	Unsuitable land with extreme limitations that preclude its use.

Notes: green shading suitable
orange shading unsuitable

The land use of the Project area is more suitable for cattle grazing than dryland cropping based on the average land suitability class across the identified SMUs of the Project.

A summary of the land suitability classes for both dryland cropping and cattle grazing for each SMU identified within the study area is provided in Table 32.

Table 32 Land Suitability Classes for SMUs

SMU	Land Suitability Class (Grazing)	Land Suitability Class (Cropping)
Anderson	4	4
Barry	2	3
Charlevue	4	5
Cooinda	3	5
Ellesmere	3	5
Geoffrey	3	5
James	4	4
Kosh	2	5
Namoi	3	4
Nigel	4	5
Normanby	4	4
Wallace	3	5

Notes: green shading suitable
orange shading unsuitable

Cattle Grazing Suitability

Within the study area, the suitability of land for cattle grazing is most limited by nutrient deficiency, ESP, and vegetation. Low nutrient levels and high sodicity in the soils may limit livestock production through a reduction in pasture growth and nutritive value of pasture species. Vegetation regrowth species can also impact the suitability of the land if they contain woody or poisonous species. In addition to this, high density regrowth and a woody shrub layer may reduce the carrying capacity of the land, making it unsuitable for grazing.

While no Class 1 land was identified within the study area, examination of the land suitability limitations for cattle grazing (Figure 50) indicate 1,080.5 ha of the study area is suitable for cattle grazing with minor limitations (Class 2), while 4,338 ha is suitable for cattle grazing with moderate limitations (Class 3). The remaining area (750.84 ha) was comprised of Class 4 land, with no Class 5 land identified.

Figure 50 shows the distribution of land suitability classes for cattle grazing across the Project.

Dryland Cropping

Land suitability for dryland cropping on the study area is most limited by soil water availability, soil wetness, erosion, and surface condition. Plants require suitable quantities of water to reach optimum production, and therefore maximum rooting depth, with the ability of the soil to take in water (wetness) playing a large part in crop survival. Topsoil and subsoil erosion also limit the ability of the soil to support crops. Soil preparation for sowing in the form of tillage may increase the risk of soil dispersion through slaking caused by the manipulation of soil aggregates by machinery. Surface condition also limits the soil classes, with hard setting soils found across most SMUs. Surface condition directly impacts seedling emergence and establishment by reducing seed-soil contact.

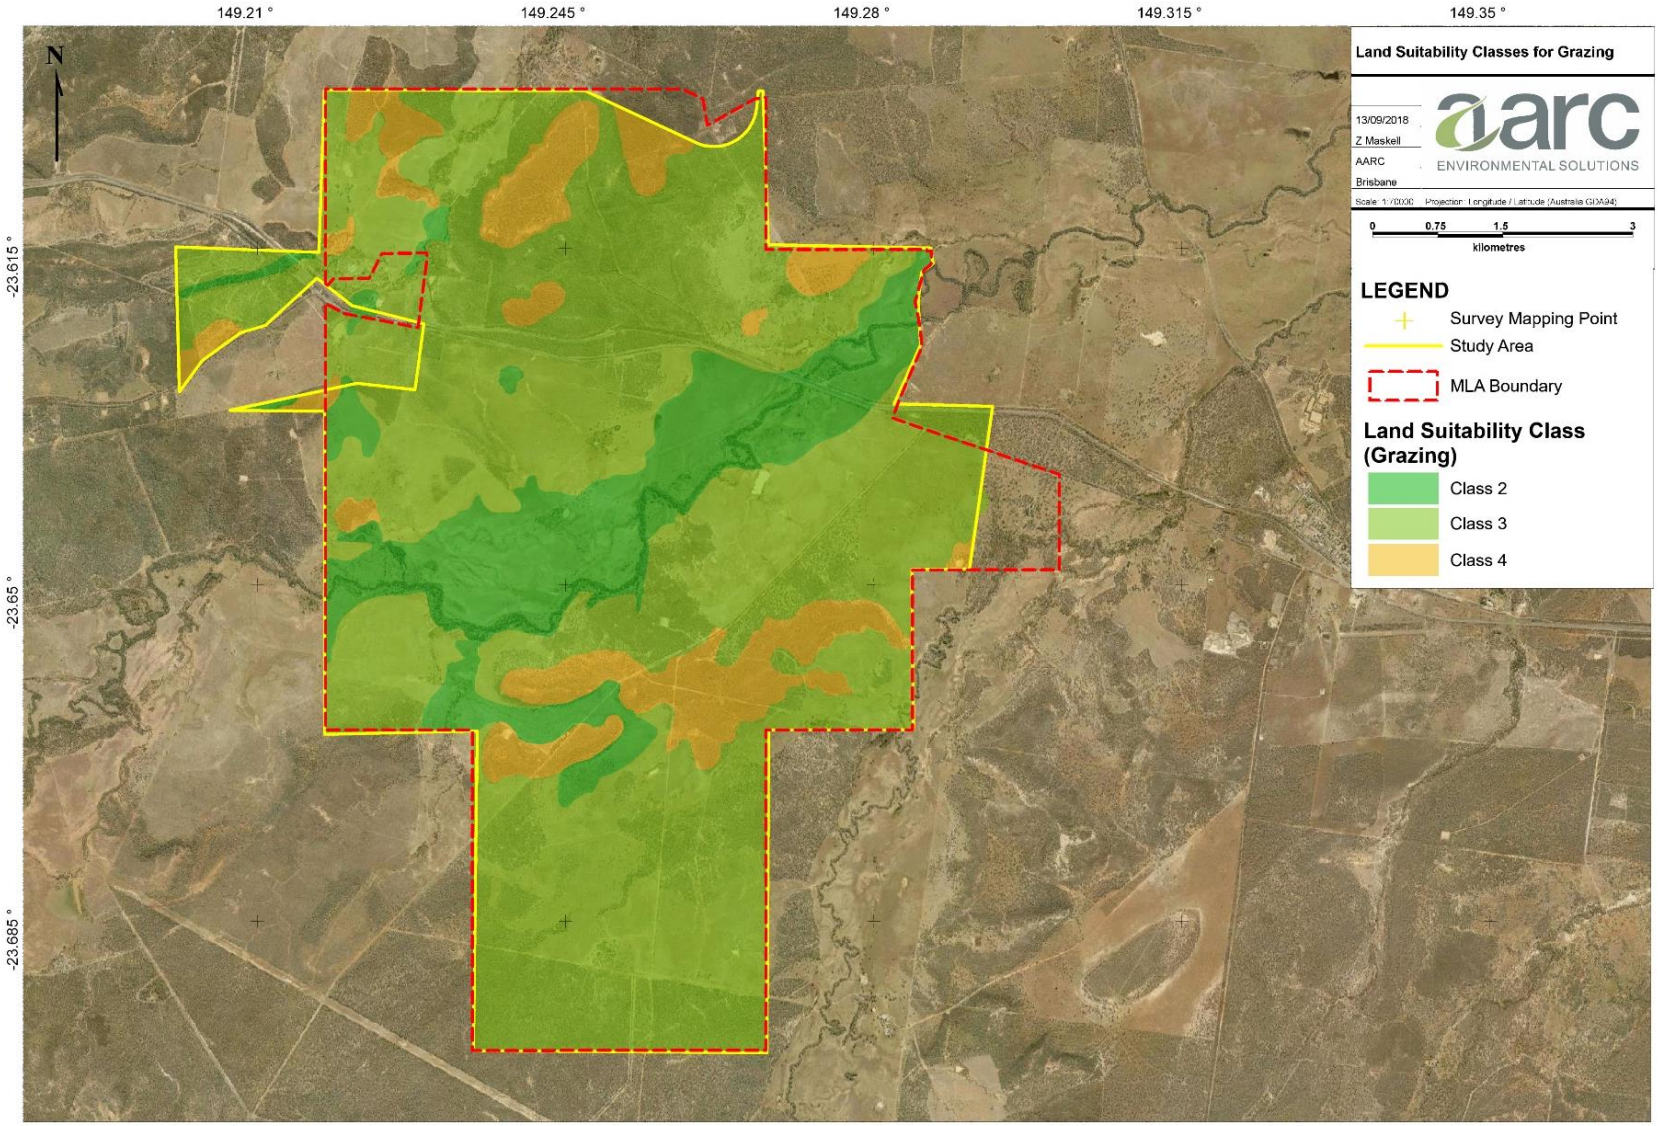

Figure 50 Land Suitability Classes - Cattle Grazing

In central Queensland, Class 1, 2 and 3 lands for dryland cropping are required to have the capacity to store sufficient levels of moisture to sustain a crop cycle from planting to harvesting with minimal rainfall. Class 4 lands are considered marginal for dryland cropping, requiring significant levels of rainfall for crop success. Class 5 lands are unsuitable for dryland cropping due to severe limitations.

Examination of the land suitability limitations for dryland cropping (Figure 51) indicates that 156.5 ha of the study area is suitable for cropping with moderate limitations (Class 3), and 409.1 ha of land is marginally suitable for cropping (Class 4). The remaining 5,607 ha of land is unsuitable (Class 5) due to land and soil limitations. Figure 51 shows the distribution of land suitability classes for broadacre cropping across the Project.

5.2.7 Land Use

The Project is located within the 'Central Queensland Regional Plan' area. Queensland land use mapping classifies the Project area as 'grazing modified pastures'. Other minor land use classifications over the site include 'residential', 'reservoir/dam', 'marsh/wetland', and primarily in association with the Capricorn Highway; 'transport and communication', 'utilities', 'services', and 'other minimal use'.

Dominant land uses within the local region are:

- grazing modified pastures;
- mining;
- other minimal use;
- managed resource protection; and
- production forestry.

The land within the Project boundary is currently used for low intensity cattle grazing and resource exploration activities. Cattle grazing being the major land use within the Project reflects the land suitability assessment which describes the site as mostly Class 2 and 3, suitable for grazing with minor to moderate limitations. The majority of the area has been cleared for cattle grazing; however, some patches of remnant vegetation remain, including riparian vegetation associated to Charlevue Creek.

The land in and around the Project is also used for purposes other than cattle grazing; including road transport, stock routes, protected areas, and coal mining. These land uses are discussed in Section 2.1.

5.2.8 Areas of Regional Interest

The Project activities are not in areas located within mapped areas of regional interest; however, a strategic cropping land trigger area exists northeast of the Project. The Project does not intersect any areas mapped as priority living areas, priority agricultural areas, strategic cropping land or strategic environmental areas.

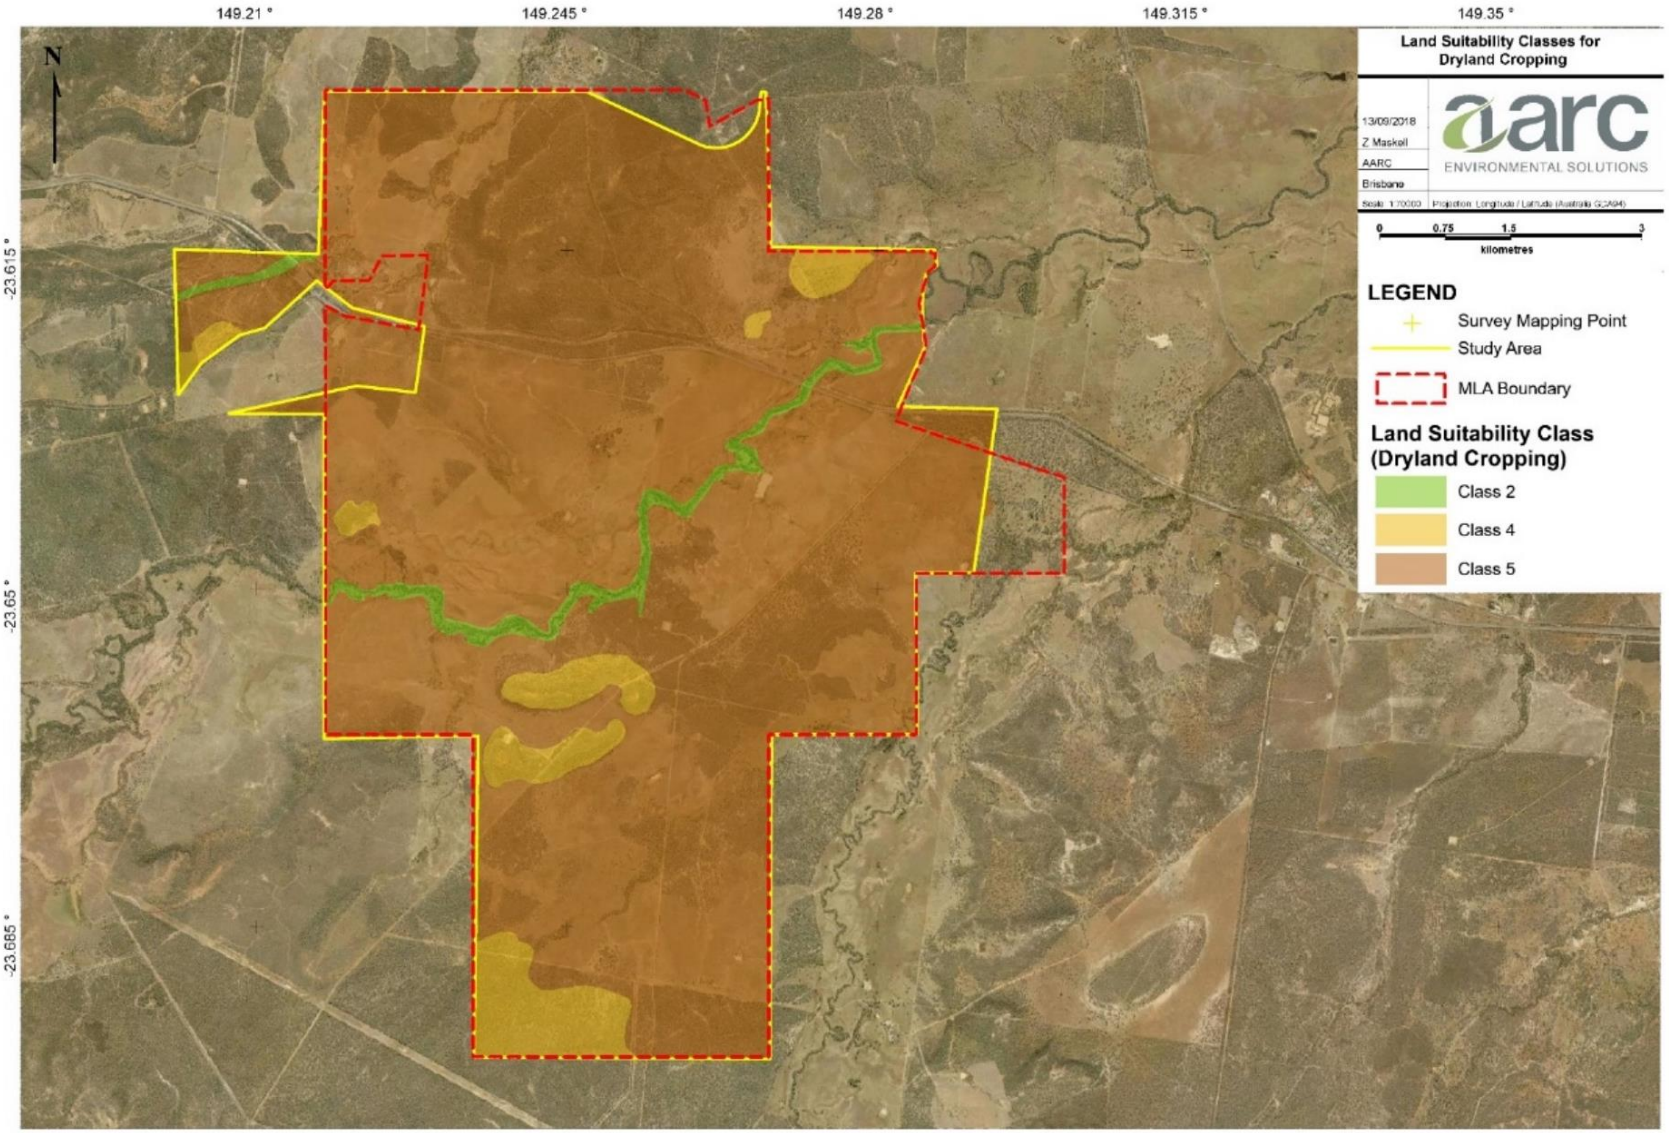

Figure 51 **Land Suitability Classes - Dryland Cropping**

5.3 POTENTIAL IMPACTS

5.3.1 Landform

Project activities involved in the construction of elevated landforms, open-cut pits and voids may impact land values by modifying the pre-mine topography. Some changes to the local topography will be temporary, such as the development of bunds and drains.

Waste rock emplacements associated with Pit AB and Pit C will be developed during operation. Where possible, spoil will be hauled and placed in-pit, behind the mining void. However, rehabilitated out-of-pit waste rock emplacement areas will remain as permanent features in the post-mining landform facilitating a slope of 1:10 vertical to horizontal ratio (V:H) and a maximum height of 190 m. Rehabilitated final void lakes are also proposed in the final landform, below the pre-mining topography.

Impacts from mining activities on the landform values of the Project may result in alteration to hydrological regimes within drainage features and an increase in Project landform exposure to erosion and instability.

Disturbance of vegetation and the topsoil layer can lead to the mobilisation of soil through the process of erosion, particularly water erosion through heavy rainfall or overland flow. The risk of erosion at the Project will be increased by the following activities:

- clearing of vegetation;
- topsoil stripping and stockpiling;
- construction of infrastructure; and
- exposure of slopes.

Erosion of rehabilitated landforms reduces the likelihood of revegetation success, and in extreme cases can compromise the structural integrity of the landform, making it unstable and unsafe. In addition, if not managed correctly, erosion can result in the release of suspended sediments and potential contaminants into the receiving environment. Soils and spoil within the Project have some dispersive characteristics within their subsoils, and will be potentially subject to erosion, particularly on artificial slopes.

5.3.2 Visual Amenity

Based on the findings of the *Visual Amenity Assessment* (AARC 2020c), the visual impacts arising from the Project are predominantly considered low. In terms of the significance of visual impacts for surrounding sensitive receptors, the following key points were identified:

- Magnetic South have purchased properties all vantage points which include a residence. The dwelling vacancy and lack of visual exposure at these vantage points means the visual sensitivity is significantly reduced and the subsequent visual impacts are minimised in the immediate surrounds of the Project
- Low impacts for visual amenity were predominantly identified across all assessed vantage points, except for vantage point VA1 observing a moderate impact and visual exposure to the final landform of the waste rock emplacement to Pit AB. The property of vantage point VA1 is owned by the proponent and will be vacated prior to the commencement of mining activities.

- The overhead conveyor is not expected to be visible from any nearby local residences, or sensitive receptors (2.9 km east on the Ellesmere property owned by the proponent and 2.9 km west at the Redrock Park property). Local topography, and the retention of existing vegetation outside of the disturbance footprint, would provide natural screening to obscure any visual modification that the conveyor might impose in either direction.

- Residual short-term and intermittent moderate visual impacts will be unavoidable for road users exposed to the overhead conveyor across the Capricorn Highway when using the main transport route; however, all mining infrastructure areas, including the overhead conveyor will be subject to decommissioning and rehabilitation. Therefore, the identified moderate impacts of the conveyor will be limited to the operational phases of the Project.

In summary, the exposure of mining infrastructure is limited to the spoil crest of Pit AB and the overhead conveyor across the Capricorn Highway connecting the TLO facility. Visual elements of the Project are not anticipated to have a significant impact for those residing in nearby properties and therefore impacts are predominantly limited to intermittent exposure when using nearby roads. In-depth descriptions of each visual simulation at the five vantage points are provided in Appendix O.

5.3.3 Soils

Mining activities, including the stripping, stockpiling, handling, and compaction of soil, have the potential to impact its physical, chemical and biological properties. Potential impacts from mining activities on the existing soils within the Project area may include:

- potential soil and land contamination through:
    - spills from mine-affected water storages or pipelines;
    - spillage of chemicals or fuel; and
    - effluent irrigation from the STP;
- loss of soil physical structure due to excavation and handling;
- loss of the soil seedbank; and
- impacts on soil fertility due to mixing with subsoils or resulting from changes in chemistry when subsoils are exposed to oxygen.

5.3.3.1 Sodic Soils

As shown in Table 30, the Project Area is dominated by the Geoffrey and Kosh SMU. These SMUs are, therefore, reflective of the predominant soil characteristics of the Project area. The subsoils of the Geoffrey and Kosh SMUs are considered strongly sodic (ESP > 14%). This indicates that subsoil may become dispersive if exposed to surface water run-off for prolonged periods of time post topsoil striping.

This dispersion can initiate the processes of sheet of gully erosion which can contribute to a loss of ground cover, surface crusting and subsequent reduction in seedling emergence as well as sedimentation of downstream water bodies. Additionally, dispersion can cause the collapse of soil structure. Collapse of soil structure reduces the porosity of soil, which subsequently increases the risk of waterlogging and reduces soil aeration and thus microbial activity.

While these SMUs have sodic subsoils, topsoil layers are not considered sodic. Stripping depths have accounted for this and have been determined to exclude any sodic subsoil material from the topsoil

resource. This topsoil resource used for rehabilitation is therefore not considered sodic and dispersive. Specialised segregation and demarcation of topsoil is therefore not considered necessary for any topsoil stockpiling within the Project area. Rehabilitated landforms are thus at low risk of the beforementioned impacts associated with sodic soils. Mitigation measures that target sodic and dispersive soils is not considered necessary. Although, it is recommended that stockpiles should be monitored monthly for evidence of erosion/structural instability.

5.3.4 Land Suitability and Land Use

Project activities will disturb and alter the current land use of low intensity cattle grazing in the short term. Cattle grazing within the Project area is categorised predominantly as land suitability class 3; suitable for cattle grazing with moderate limitations. A total area of 4, 338 ha of class 3 land exists within the Project's disturbance footprint occupying 70.20% of this extent. The remaining disturbance footprint of the Project is categorised as class 2 (17.49%) and class 4 (12.31%).

The Project aims to achieve a PMLU for all areas of rehabilitation, with no proposed NUMAs. Primarily, the land will be returned to cattle grazing land use across flat and gentle slopes. Secondly, the proposed post-mining beneficial land use will allow for the establishment and support of native ecosystems on areas of steeper slopes (i.e., treated high walls). Establishment of native ecosystems is defined as the establishment of vegetation that allows colonisation by surrounding non-weed species such that vegetation will progress towards native bushland with no designated agricultural or grazing use.

The rehabilitated final voids will remain in the post mining landform in a safe, geotechnically stable and non-polluting condition. As described in Section 4.4.7.1, the void will contain a fresh to brackish pit lake that is expected to provide suitable habitat for fauna species, particularly migratory and marine bird species. The final voids will provide a reduced land suitability of class 5.

5.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

The Project will be managed to minimise the extent and severity of land disturbance.

5.4.1 Landform

Management practices to minimise impacts to landform values are provided below:

- land clearing will be limited to the minimum area required for safe operation of the Project. An internal *Land Disturbance Permit System* is proposed to prevent unnecessary or unauthorised impacts to land values during construction and operation;
- erosion and sediment control structures will be developed and implemented during operation in accordance with *Best Practice Erosion and Sediment Control* (IECA Australasia 2008);
- waste rock emplacements will be constructed to a slope of 1V:10H (adhering to a maximum slope of 6°) and a maximum height of 190 mAHD;
- construction of contour banks on slopes is proposed at a spacing of 80 m for slopes of 1V:10H to manage runoff and prevent erosion and associated landform instability;
- highwalls within Pit AB and Pit C will be pushed back after mining to form a slope angle of approximately 22° to ensure stability of the final landform. Treated upper slopes will be rehabilitated to achieve a PMLU suitable for native ecosystems; and

- erosion monitoring and maintenance is proposed throughout the mine life and during mine closure, until it can be demonstrated that final landforms are stable.

5.4.2 Visual Amenity

A series of management actions and measures can be employed to reduce unfavourable conditions at the selected vantage points, or sensitive receptors to minimise potential impacts on visual amenity. These measures, include:

- the use of neutral tones for infrastructure cladding to reduce any stark colour contrast between the visual modification and surrounding visual landscape and environment;
- placement of infrastructure where practical at greater distances from sensitive places (residences and transport corridors);
- placement, configuration and direction of lighting to reduce light emissions during the operational phase of the Project, in accordance with AS 4282:1997 '*Control of the obtrusive effects of outdoor lighting*' (Standards Australia 1997);
- establishment of important visual buffer zones (i.e., vegetation screening) between points of high visual impact and vulnerable sensitive receptors;
- as soon as land becomes available, out-of-pit overburden dumps be rehabilitated to reduce contrast between altered landforms and the unaffected surrounding landscape;
- overburden dumps designed to have a final landform that does not contrast significantly with the existing topography; and
- decommissioning of infrastructure in accordance with a *Closure Plan* to ensure the post-mine visual amenity resembles the previous landscape character as much as possible.

These mitigation and management strategies would support the retention of visual amenity during both construction, operation, and decommissioning of the proposed Project.

5.4.3 Land Contamination

5.4.3.1 Emergency Response and Spill Management Plan

An *Emergency Response and Spill Management Plan* will be developed to inform staff and contractors of the procedure for responding to a spill or potentially hazardous release. The objective of the *Emergency Response and Spill Management Plan* is minimising the risk of harm to persons and the environment.

The *Emergency Response and Spill Management Plan* will include the following components:

- identification of potential hazards and spill types;
- a register of hazardous chemicals and dangerous goods including the storage location and quantity;
- requirements for a risk assessment to be undertaken prior to the commencement of mining and ancillary activities;
- resource requirements for responding to spills;

- storage and handling requirements for all chemicals and hydrocarbons stored onsite including appropriate bunding, standard operating procedures and access to spill kits;
- a detailed response procedure including and emergency response plan for spills requiring evacuation; and
- reporting, investigation and review requirements following a spill or potentially hazardous release in accordance with the *Coal Mining Safety and Health Act 1999* (CMSH Act) and Coal Mining Safety and Health Regulation 2017 (CMSH Regulation) which will also be included in induction and training manuals.

Management measures to reduce the risk of spills and the consequent impact on the environmental values of land and water resources will be targeted at avoiding spills, minimising the risk of spills and the impacts on persons and the environment and the management of spill events. These will be used as key principles in the development of the *Emergency Response and Spill Management Plan.*

Avoid

Hazardous chemicals and dangerous goods will be stored in accordance with relevant Australian Standards, in bunded containment and inspections of the areas are regularly undertaken. Hazardous chemicals and dangerous goods will be handled strictly in accordance with the Material Safety Data Sheets

In the response to handling spills, safety is paramount. Spill containment or clean up should only be undertaken by trained personnel and when considered safe to do so.

Minimise

The risk of spills on human health and the environment will be minimised through the following mitigation measures:

- a detailed spills response procedure which will outline the following:
    - identification of the spill type, size and location i.e., sediment dam, topsoil stockpile, coal stockpiles etc;
    - control processes to isolate the sources and elimination of possible sources of ignition;
    - containment measures for the spill area to prevent the spill spreading into the surrounding environment and the exclusion of personnel or machinery from the spill area;
    - clean up procedures to be implemented including methodologies and application for the use of each spill kit item and disposal requirements for waste;
    - notification requirements for surrounding sensitive receivers;
- resource requirements for responding to spills in a timely manner including:
    - trained personnel in spill response procedures and training materials to ensure all staff onsite are aware of the hazards and risks associated with the hazardous chemicals and dangerous goods stored onsite;

  - spill kits with stocked with appropriate response requirements for hazardous chemicals and dangerous goods stored on site;
  - spill kits appropriately located onsite for quick response handing;
  - signage in work areas indicating the location of the nearest spill kit;

- the development of Standard Operating Procedures for the spill management for all hazardous chemicals and dangerous goods in accordance with the CMSH Regulation and Australian Dangerous Goods Code*;*
- management of site water system to operate below maximum operating level and the implementation of a spillway to direct mine water dam overflows to the mine pit; and
- requirements for risk assessments for activities involving the storage or handling of hazardous chemicals or dangerous goods to identify and reduce the risks associated with each activity/hazardous chemical or dangerous good.

Manage

The hazards associated with spills onsite will be managed through the following:

- A standardised framework for reporting requirements following a spill or potentially hazardous release including the requirement for the investigation and notification of any contamination to land resulting from a spill or release event to the DES in accordance with the Project's EA.
- An annual review of the *Emergency Response and Spill Management Plan* will be undertaken and may be revised due to the following;
  - updates to relevant legislation or policy or industry best practices;
  - procedures based on post-incident evaluation; and
  - new hazardous materials brought onto site.

5.4.3.2 Fuel and Hazardous Storage Management Plan

A *Fuel and Hazardous Liquids Storage Management Plan* will be developed. The *Fuel and Hazardous Liquids Storage Management Plan* will minimise the risk of harm to the environment and human health and address the regulatory requirements for the storage and handling of hazardous chemicals and dangerous goods as detailed in the:

- CMSH Act and CMSH Regulation;
- Australian Dangerous Goods Code;
- RS 17 Recognises Standards for Hazardous Chemicals (2019); and
- Relevant Australian Standards.

The *Fuel and Hazardous Liquids Storage Management Plan* will consist of the following components:

- a register of hazardous chemicals and dangerous goods;
- a system for the recording of material safety data sheet;
- labelling requirements for all hazardous chemicals and dangerous goods;
- standard operating procedures for the storage, handling, use and disposal of each hazardous chemical and dangerous good;
- placard requirements for the storage of hazardous chemical and dangerous goods;
- a framework for performing risk assessments for the storage, handling, use and disposal of each hazardous chemical and dangerous goods;
- a monitoring program to assess the performance of storage and handling practices and to ensure the integrity of materials prior to use;
- training requirements for relevant personnel; and
- reporting, investigation, and review procedures following incidents regarding hazardous chemicals and dangerous goods.

The management of *Fuel and Hazardous Liquids Storage Management Plan* focuses on mitigation measures that improve employee awareness of the hazards associated with hazardous materials and that minimise the risk of adverse impacts to human health and the environment. A brief summary some of the *Fuel and Hazardous Liquids Storage Management Plan* components are provided below.

Storage

Fuels will be stored within the MIA, with additional self-bunded tanks located as required in the mining area, depending the current location of the main fleet and advancing mine face.

Fuels (including diesel) will be delivered to the Project by contractors. The transport, storage and handling of fuels (including diesel) will be undertaken in accordance with relevant legislation and guidelines.

Storage and handling practices will ensure that the chemical and goods are:

- protected against damage and deterioration;
- secure to prevent loss, misuse and theft; and
- liquids are bunded to contain spillage.

Register

An up-to-date register of hazardous chemicals and dangerous goods will be maintained in accordance with the CMSH Regulation and will record:

- any hazardous chemical or dangerous good used, handled, stored or produced at the mine;
- current safety data sheet for all hazardous chemicals and dangerous goods;
- the storage location; and

- storage incompatibilities.

The register must be readily accessible by each worker required to use, handle, store or produce a hazardous chemical or dangerous good at the mine.

Labelling

The labelling requirements for all incoming hazardous materials are to be inspected upon receiving the hazardous material onsite and is the responsibility of the site senior executive. Labelling must meet the requirements set out in Part 7, Division 2 of the CMSH Regulation including:

- a warning of the presence of chemical or good;
- identification of chemical or good;
- to the extent necessary for managing risk, provides basic information about using, handling, storing, producing, or transporting the chemical or goods;
- if it is not practicable to mark or label a hazardous chemical or dangerous good, the site senior executive must ensure a notice that gives the warning, identification and basic information of the hazardous material is place in a conspicuous place as near as practicable to the chemical or good; and
- labelling must meet the requirements stated in the Globally Harmonised System, a recognised standard, the Australian Dangerous Goods Code or AS 1345.

Standard Operating Procedures

In accordance with the CMHS Regulation, Standard Operating Procedures are required for using, handling or storing of a hazardous chemical or dangerous good. In developing a standard operating procedure, the site senior executive must ensure regard is had to the material safety data sheet for the chemical or good.

Risk Assessments

Risks to be managed with regard to the conditions outlined in Part 7, Division 2, section 56F of the CMHS Regulation and consideration given to the hazardous properties of the chemical or goods

Monitoring Program

Regular monitoring to confirm the location and quantity of chemical or goods onsite, deterioration of the chemical or goods or any packaging, ensure the chemical are fit for intended use, detect leaks spills and unintended emissions, detect misuse, theft, disposed is monitoring shows deterioration or unfit.

Training

All equipment and vehicle operators will be trained in the safe operation of the equipment (including operating procedures for the refilling and maintenance of fuel storage tanks and mine vehicles) and the relevant emergency response and spill management procedures in the event of an incident.

5.4.4 Soils

Impacts to soil will be mitigated to reduce the risk of soil degradation and improve the chances of rehabilitation success. Mitigation strategies for soil include:

- Topsoil across the disturbance area will be stripped to a depth that excludes any constraining layer/properties (i.e., above a sodic/highly saline soil horizon) to ensure the topsoil resource is of good quality.

- Progressive rehabilitation of landforms and direct placement of topsoil will be carried out to help preserve the seed bank and reduce erosion.

- If topsoil resources are to be stockpiled for a period in excess of six months, testing of soil properties (including physiochemical analysis) will occur prior to use in rehabilitation. This monitoring information is only required prior to topsoil application to assess changes in topsoil quality (changes to soil chemistry and biological activity as a result of being stockpiled). Key parameters would include pH, ESP%, CEC (major cations), organic matter content and other essential nutrients such as nitrate, phosphorous and sulphate.

- If topsoil degradation has occurred, the subsequent action will be to apply fertilizers, soil ameliorants, and the application of a seed mix (refer to Section 4.4.3) to increase the likelihood of rehabilitation success. The most significant risk to topsoil is deterioration as a result of stockpiling for extended periods of time, however, topsoil is not anticipated to deteriorate to the point of becoming unsuitable for use in rehabilitation works (AARC 2019).

5.4.5 Erosion Protection Measures

Erosion protection measures developed to reduce the risk and impacts of erosion include:

- topsoiled areas will be deep ripped to reduce compaction from heavy machinery, encourage infiltration of water and prevent erosion. Areas will be ripped along the contour to reduce the velocity of runoff water down the slope. Ripping depths will vary depending on the type of spoil material, depth of topsoil and equipment used for rehabilitation operations;

- ensuring that when required, stockpiles are generally less than 2 m high and contoured to encourage water to drain;

- where required, seeding of topsoil as soon as possible after placement onto rehabilitated areas, to ensure root masses assist in preventing erosion;

- topsoil stockpiles will be placed away from drainage areas, roads, machinery, transport corridors, and stock grazing areas;

- topsoil stockpiles will be seeded or covered with a water-shedding lining to prevent unnecessary erosion of soil; and

- seeding of topsoil as soon as possible after placement onto rehabilitated areas, to ensure root masses assist in preventing erosion.

5.4.6 Topsoil Handling Procedures

A *Topsoil Management Plan* will be developed for the Project. The overarching principle of the *Topsoil Management Plan* will be to reduce the risk of topsoil degradation and improve the chances of rehabilitation success. The objectives of the Project's *Topsoil Management Plan* are to:

- maintain a soil balance that will achieve the rehabilitation requirements throughout the life of the mine;

- maintain topsoil viability through the utilisation of best practices in soil stripping, stockpiling and application activities; and
- provide a standard practice for the Project's storage and handling of topsoil resources.

Section 4.4.2 provides further details on topsoil handling for the Project.

5.4.7 Land Suitability and Land Use

Potential impacts on soil can be mitigated through:

- determining PMLUs that align with pre-mining land use and the surrounding properties;
- a final landform design that aims to maximise PMLU areas;
- progressive rehabilitation to return the land to a productive land use as soon as practicable; and
- ongoing monitoring, maintenance and rehabilitation trials to ensure a safe, stable and non-polluting landform.

The majority of areas in the final landform will be restored to a PMLU of cattle grazing. The exceptions being water management features such as ponds and drains, which will be returned to a PMLU of native ecosystems or equivalent. This includes the final pit lake and high walls, that will be restored to achieve a fauna habitat land use. These areas are expected to be unsuitable for grazing and will achieve a reduced land suitability score of 5.

5.4.8 Cultural Heritage Management Plan

A *Cultural Heritage Management Plan* has been developed in accordance with the *Aboriginal Cultural Heritage Act 2003* and the supporting *Duty of Care Guidelines* (DATSIP 2004). The Cultural Heritage Management Plan has been developed in consultation with Traditional Owner groups and any other relevant representatives. The *Cultural Heritage Management Plan* has been developed upon formal assessment of cultural heritage by a suitable qualified person and the outcomes of the assessment will be utilised to inform the Cultural Heritage Management Plan.

The objective of the *Cultural Heritage Management Plan* is to minimise the potential impacts of the Project's activities on the cultural heritage of the site through a knowledge of the site's cultural heritage and an effective monitoring and reporting framework for the management of cultural heritage and responsibilities within the Project in compliance with all Aboriginal cultural heritage management requirements under legislation, guidelines, and existing consents.

The *Cultural Heritage Management Plan* includes the following components to at minimum:

- establish the roles and responsibilities of personal relating to the coordination, implementation, management, and future conduct of matters arising in relation the *Cultural Heritage Management Plan*;
- provide a summary of the potential impacts to the cultural heritage of the Project site;
- provide procedures for the management of known and unexpected finds, where;
    - options to avoid, minimise or mitigate these impacts in a culturally appropriate fashion are developed;

  - outline details for an aboriginal find procedure (described further below);
  - detail the process to follow for the findings of human skeletal remains (described further below);
- provide procedures for consultation with relevant parties;
- include cultural heritage assessment requirements in the *Land Disturbance Permit* for Project activities involving any ground disturbance, where;
  - information regarding cultural heritage will be identified, collated and documented;
- provide a standard procedure for the reporting of the discovery of any Aboriginal cultural heritage in the Project area, where reporting is undertaken as soon as reasonably practical to the designated personnel and also as required by law; and
- distribute Indigenous cultural heritage awareness information and legal obligations in employee/contractor induction programs.

5.4.8.1 Aboriginal Object Find

At any time throughout the life of the Project, if suspected Aboriginal material has been uncovered due to the Project's activities, work in the surrounding area is to stop immediately and the following procedure followed:

- a temporary fence or barrier with a buffer zone of at least 10 m around the known edge of the site is to be erected around the site and no unauthorised entry or earth disturbance is to be carried out until the area has been assessed;
- an appropriately qualified archaeological consultant is to be engaged to identify the material and prepare an assessment report including recommended mitigation measures; and
- if the object is confirmed to be of cultural heritage significance, the relevant traditional owner groups and government personnel will be notified.

The process for handling of objects of cultural heritage significance is defined and provided in the *Cultural Heritage Management Plan* following consultation with the relevant Traditional Owner groups and government bodies.

5.4.8.2 Human Skeletal Remains Find

If suspected human skeletal remains (that are or may be those of an Aboriginal person) are uncovered due to the Project's activities it is important that all personnel adhere to provisions of the *Aboriginal Cultural Heritage Act 2003*, *Coroner's Act 2003* and the *Criminal Code Act 1899* section 236(2). The following actions should be followed:

- work in the vicinity of the find is to stop immediately, until works are authorised to resume;
- the site should be cordoned off with a buffer zone of at least 10 m around the known edge of the site and the remains left untouched. No unauthorised entry or earth disturbance is to be carried out until the area has been assessed;
- the discovery should be reported to the nearest Police Station as soon as possible; and

- a process for the reporting and handling of remains that are confirmed to be of Aboriginal origin, where the remains have not been removed by the coroner, have been developed during consultation in the development of the *Cultural Heritage and Management Plan* with the relevant Traditional Owner groups and the Department of Aboriginal and Torres Strait Islander Partnerships.

6.0 FLORA AND FAUNA

This section provides a description of the existing flora and fauna values within the Project. It aims to identify the Project's potential impacts on the existing values and propose mitigation measures and management strategies to prevent or minimise adverse environmental effects.

This section also discusses potential impacts to wetland values and groundwater dependent ecosystems (GDEs), however all other water values are discussed in Section 7.0 and Section 8.0.

This section is informed by:

- *Terrestrial Ecology Assessment* (AARC 2020b) (Appendix J);
- *Aquatic Ecology Assessment* (AARC 2020a) (Appendix K);
- *Groundwater Dependent Ecosystem Assessment* (3D Environmental 2020) (Appendix F);
- *Surface Water Assessment* (WRM 2020b) (Appendix B); and
- *Groundwater Impact Assessment* (JBT 2019) (Appendix C).

6.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objective relevant to potential impacts to flora and fauna as described in the EA guideline for *Application requirements for activities with impacts to land [ESR/2015/1839]* (DES 2017b) is:

The activity is operated in a way that protects the environmental values of land including soils, subsoils, landforms and associated flora and fauna.

The Project would achieve all of the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

(a) activities that disturb land, soils, subsoils, landforms and associated flora and fauna will be managed in a way that prevents or minimises adverse effects on the environmental values of land;

(b) areas disturbed will be rehabilitated or restored to achieve sites that are:

(i) safe to humans and wildlife;

(ii) non-polluting;

(iii) stable; and

(iv) able to sustain an appropriate land use after rehabilitation or restoration;

(c) the activity will be managed to prevent or minimise adverse effects on the environmental values of land due to unplanned releases or discharges, including spills and leaks of contaminants; and

The environmental objective relevant to potential impacts to wetlands as described in the EA guideline for *Application requirements for activities with impacts to water* (DES 2017c) is:

The activity will be operated in a way that protects the environmental values of wetlands.

The Project would achieve the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

a) *there will be no potential or actual adverse effect on a wetland as part of carrying out the activity; and*

b) *the activity will be managed in a way that prevents or minimises adverse effects on wetlands.*

The environmental objective relevant to potential impacts to surface ecological systems (i.e., GDEs) as described in the EA guideline for *Application requirements for activities with impacts to water* (DES 2017c) is:

The activity will be operated in a way that protects the environmental values of groundwater and any associated surface ecological systems.

The Project would achieve the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

(a) there will be no direct or indirect release of contaminants to groundwater from the operation of the activity; and

(b) *there will be no actual or potential adverse effect on groundwater from the operation of the activity.*

Or, the activity will be managed to prevent or minimise adverse effects on groundwater or any associated surface ecological systems.

6.2 DESCRIPTION OF ENVIRONMENTAL VALUES

6.2.1 Regional and Local Setting

The Project is located within the Brigalow Belt bioregion. This bioregion occupies over a fifth of Queensland; from Townsville in the north to near the border of New South Wales in the south. The Brigalow Belt bioregion is characterised by brigalow (*Acacia harpophylla*) woodland but presents other vegetation such as semi evergreen vine thickets, dry eucalypt woodlands and native bluegrass (*Dichanthium sp.*) grasslands. Due to the size of Brigalow Belt bioregion, it covers a broad climatic gradient as well as a diversity of soils and topography, the Brigalow Belt hosts a high diversity flora and fauna (DES 2018a).

As a result of agricultural and development activities, most of the relatively undisturbed areas are confined to the rugged parts of the landscape with less development value (DES 2018a), parks and reserve areas. At a local level, the Project is positioned in a relatively flat landscape, dissected by Charlevue Creek, which has a lower elevation than the surrounding land. The Project is also crossed by Stanley Creek and Springton Creek, as well as small tributaries associated with the main waterways.

Several protected areas and state forest surround the study area. State Forests in Queensland have been traditionally used as a source of supplies such as timber; however, the presence of large areas of remnant vegetation now act as ecological corridors that connect isolated habitats. The Project is situated south of Taunton National Park (Scientific), (Taunton Nation Park), a scientific reserve under the *Land Act 1994 (Queensland)*, established to protect a population of Bridled nail-tail wallabies. Taunton National Park connects to the Walton State Forest via Wallaby Late Nature Refuge, which contains suitable remnant and regrowth remnant areas used by the bridle nail-tail wallaby for feeding and shelter.

Walton State Forest connects to the sandstone ridges and plateau located at the west and south of the Project on which is located Arthur's Bluff State Forest, Blackdown Tableland National Park and Dawson Range State Forest. Dawson Range Forest is connected via remnant vegetation, to Duaringa State Forest, which, like Walton State Forest, is not located in the sandstone plateau. State mapped ecological corridors connect all the protected areas mentioned above.

Importantly, none of the described protected areas and state forests are directly connected to the study area, which is comprised of predominately pastureland and fragmented remnant vegetation. This fragmentation is the result of farming activities, including historical vegetation clearing to facilitate grazing and selective logging (e.g., Rosewood (*Acacia rhodoxylon*).

6.2.2 Terrestrial Flora

An assessment of terrestrial flora ecological values was conducted within EPC 881 (herein referred to within Section 6.0 as the study area) (Appendix J). Six field surveys were undertaken between 2017 and 2019 covering a range of seasonal and climatic conditions to ensure temporal and seasonal survey requirements for the Brigalow Belt bioregion were met. The dates of these surveys were:

1) 4th - 12th May 2017;
2) 18th - 30th September 2017;
3) 16th - 23rd February 2018;
4) 22nd - 29th March 2018;
5) 1st - 2nd August 2019; and
6) 19th August 2019.

The surveys were conducted in accordance with the following guidelines:

- *Site examination for threatened and endangered plant species* (Goff, Dawson & Rochow 1982);
- *Management of endangered plants* (Cropper 1993); and
- *Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland (V5.0)* (Neldner *et al.* 2019).

Threatened Ecological Communities

Desktop assessments identified four threatened ecological communities (TECs) that could potentially occur within 10 km of the study area:

- Brigalow (*Acacia harpophylla* dominant and co-dominant);
- Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions;
- Weeping Myall Woodlands; and
- Poplar Box Grassy Woodland on Alluvial Plains.

Vegetation surveys over the Project determined that communities recorded within the study area do not meet the condition thresholds to constitute a TEC (Appendix J).

Regional Ecosystems

Flora surveys confirmed the presence of six vegetation communities classed as remnant vegetation within the study area. Table 33 outlines the regional ecosystems (REs) characteristic of each vegetation community, where applicable, as well as a short description of the vegetation present. Figure 52 displays the distribution of vegetation communities on the study area.

Table 33 Summary of Vegetation Communities

Vegetation Community	Regional Ecosystem	VM Act Status	Biodiversity Status	Community Description
VC1	11.5.2	LC	NC	Narrow-leaved ironbark (*Eucalyptus crebra*) and Clarkson's bloodwood (*Corymbia clarksoniana*) woodland with a sparse shrub layer on sand plains.
VC2	11.7.2	LC	OC	Lancewood (*Acacia shirleyi*) and/or rosewood (*Acacia rhodoxylon*) woodland on lateritic duricrust.
VC3	11.3.25	LC	OC	Blue gum (*Eucalyptus tereticornis*) or River gum (*Eucalyptus camaldulensis*) with *Bauhinia spp.* and *Casuarina cunninghamiana* fringing woodland on drainage features.
VC4	11.3.2	OC	OC	Poplar box (*Eucalyptus populnea*) woodland on alluvial plains.
VC5	11.5.2 / 11.3.25	LC	NC / OC	Mixed polygon where the dominant vegetation community was VC1 (*Eucalyptus crebra* and *Corymbia clarksoniana* woodland) but along ephemeral creeks and with an important presence of blue gums (*Eucalyptus tereticornis*).
VC6	11.3.25 / 11.3.2 / 11.5.2	LC / OC / LC	OC / OC / NC	Mixed polygon as a result of combination of VC3 with elements of VC4 and some elements of VC1 due to edge effect.

Notes: VM Act *Vegetation Management Act 1992*
LC least concern
OC of concern
NC no concern at present

Flora Species of Conservation Significance

Field surveys included targeted searches for flora species of conservation significance. Surveys covered all potential habitat within the study area based on database searches and field observations. Targeted searches across the study area detected the presence of one flora species of conservation significance; *Cerbera dumicola,* listed as near threatened under the *Nature Conservation Act 1992* (NC Act).

Cerbera dumicola is a shrub or small tree growing to 4 m high (DES 2018d). The species occurs across a range of habitats in central and southern Queensland and is associated with a range of vegetation communities. The species is regionally abundant, having been recorded outside of the study area on multiple occasions (AVH 2019). *Cerbera dumicola* was identified during the vegetation surveys in two very localised rocky areas associated with vegetation community (VC) 2 and VC1 (on an ecotone with VC2) (Figure 53). This species was not identified within similar habitat types elsewhere in the study area during targeted searches.

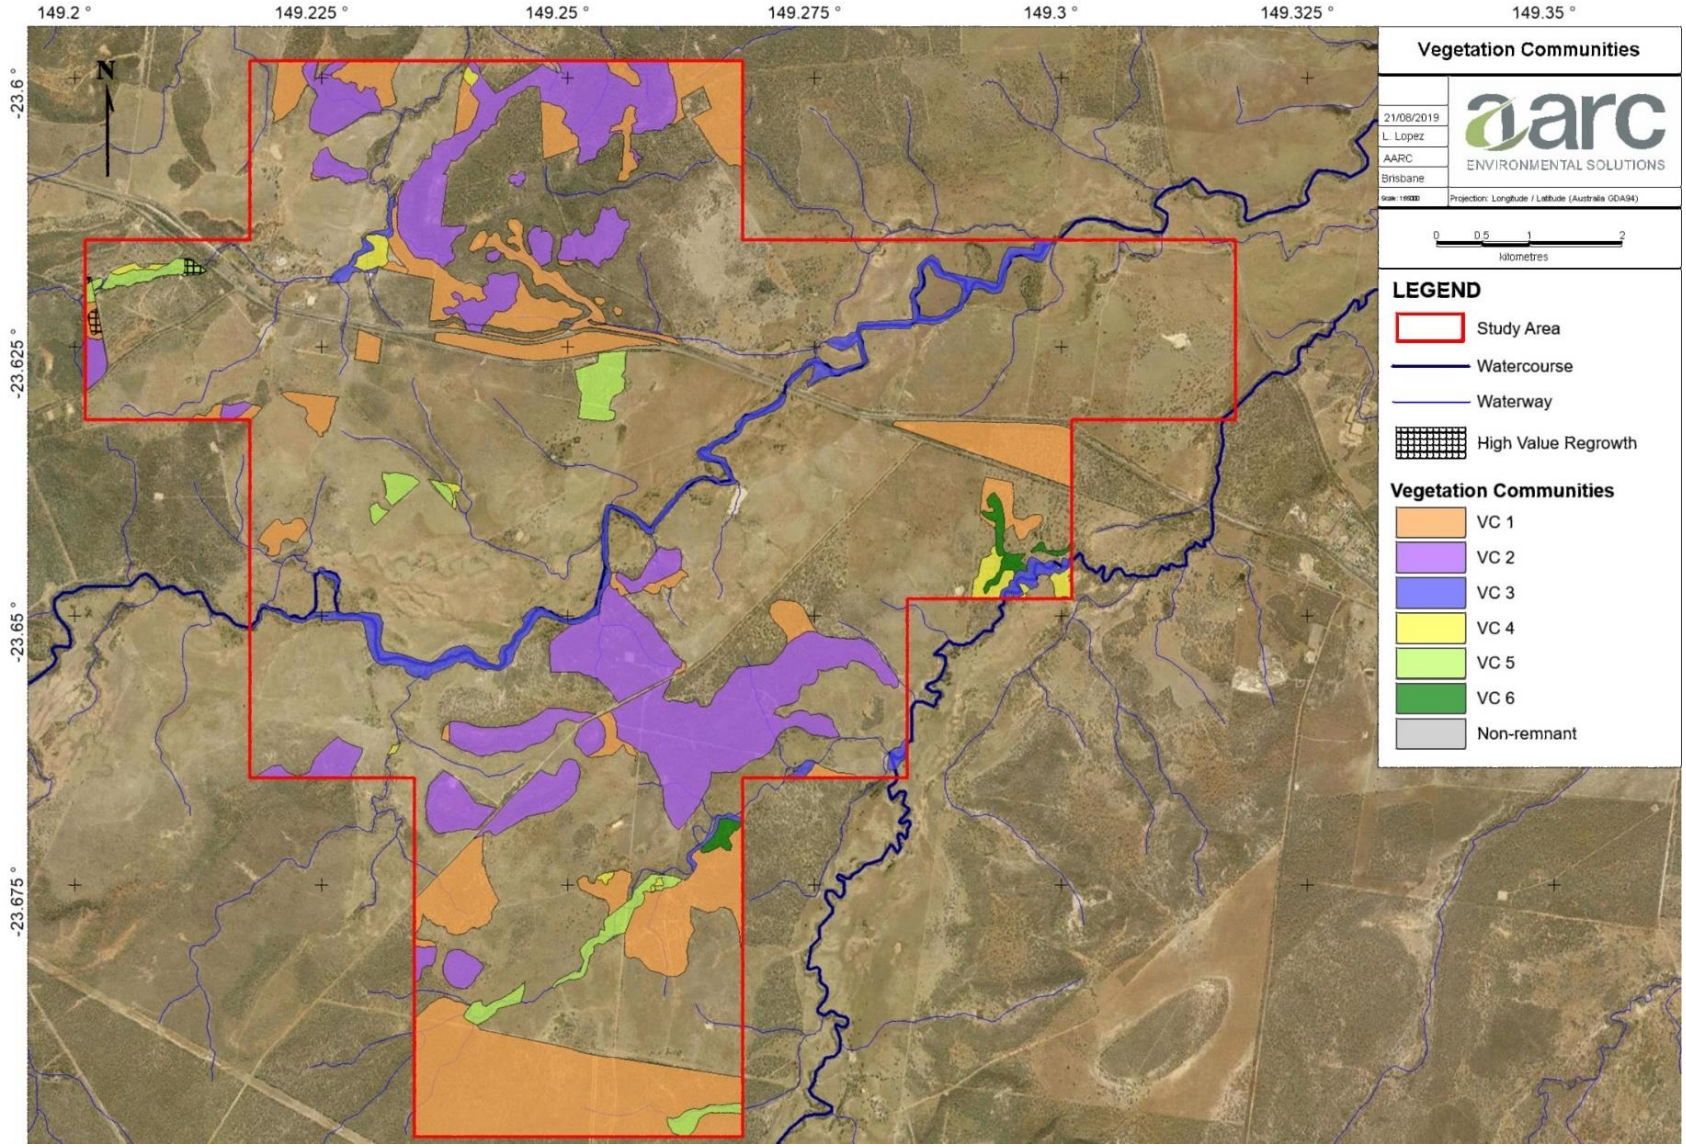

Figure 52 Vegetation Communities

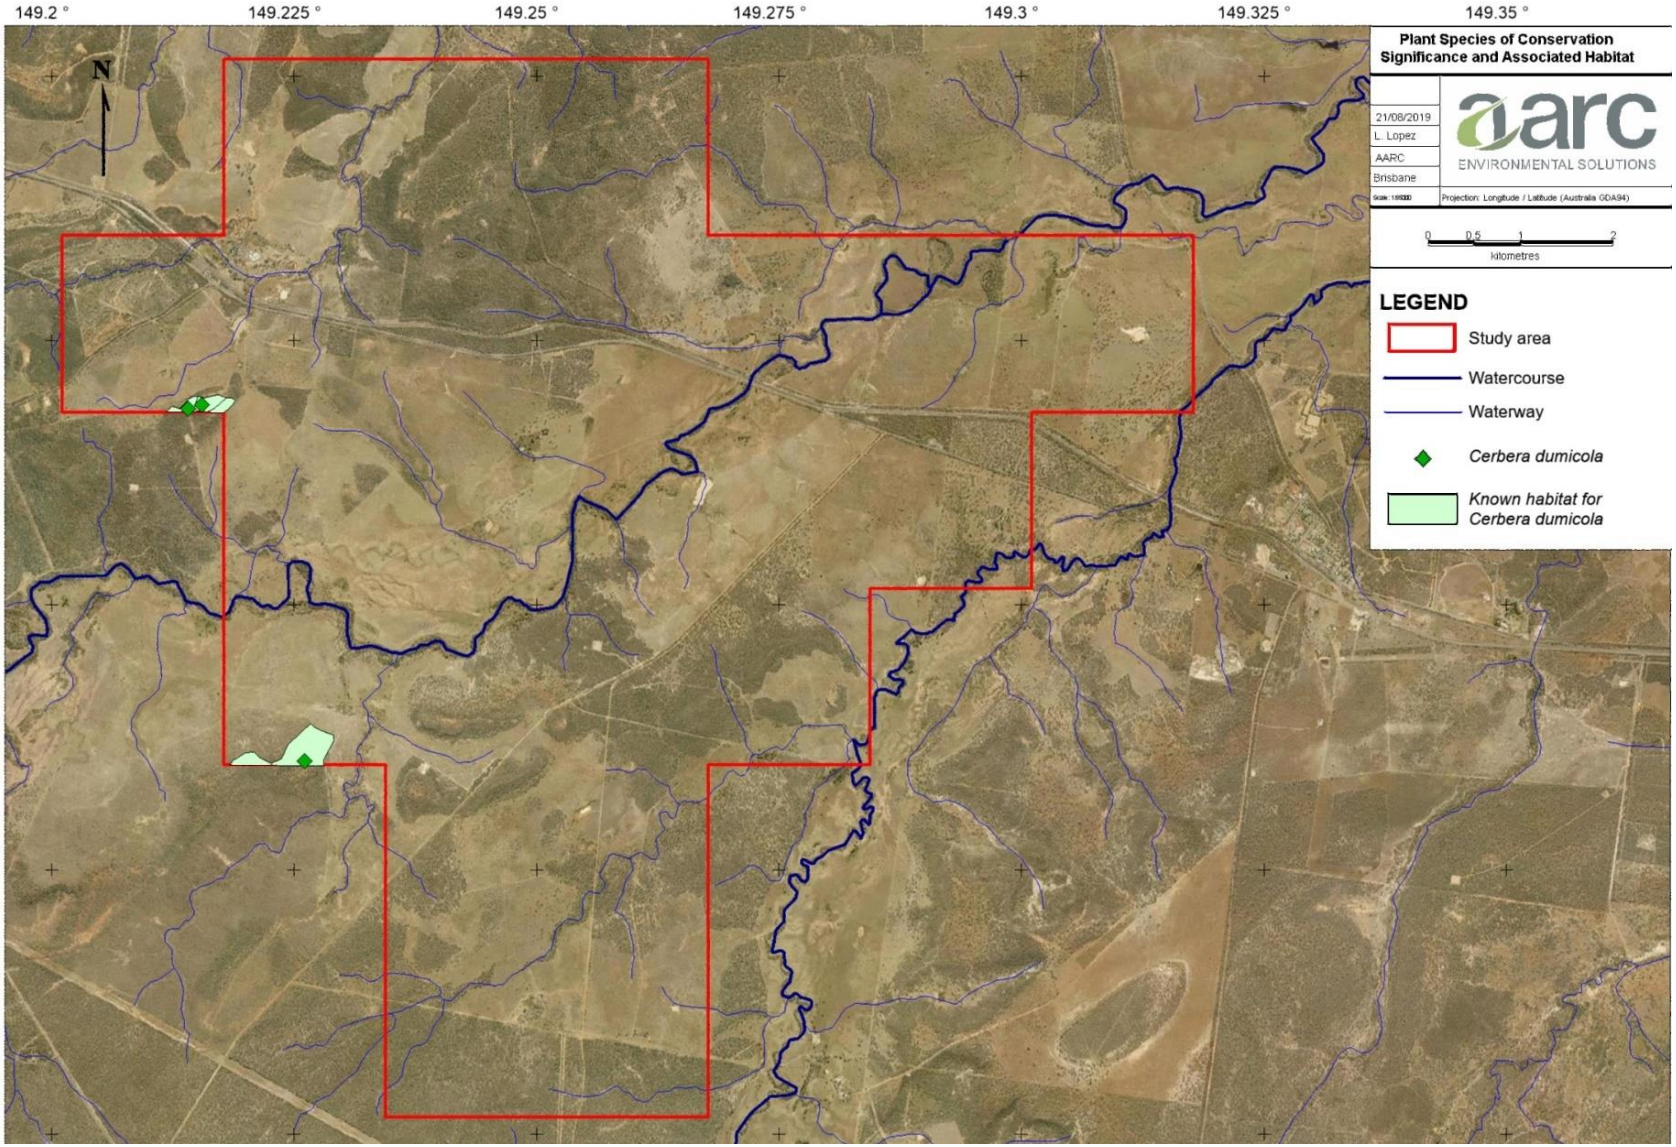

Figure 53 ***Cerbera dumicola*** **Locations and Known Habitat**

Weed Species

A total of 33 introduced flora species were recorded on the study area. Five of which are classed as WoNS and/or as RIS under the Biosecurity Act (DAF 2018a). Introduced plant species are classified as WoNS if they present a serious threat to industry, water supply, human health/safety, plant communities and/or cultural values.

Weeds of management concern (i.e., WoNS or Biosecurity Act RIS) identified within the study area are listed in Table 34. A full list of all introduced species can be found in Appendix J.

Table 34 Weed Species of Management Concern

Scientific Name	Common Name	WoNS	Biosecurity Act RIS (Category 3)
Harrisia martinii	Harrisia cactus	-	x
Cryptostegia grandiflora	Rubber vine	Yes	x
Opuntia tomentosa	Velvety tree pear	Yes	x
Parthenium hysterophorus	Parthenium	Yes	x
Bryophyllum sp.	Mother of millions	-	x
*Vachellia farnesiana**	Mimosa bush	-	-

Notes: * Considered a noxious weed of management concern.
Category 3: A person must not distribute the invasive plant either by sale or gift, release it into the environment.

Wetlands

Field surveys concluded that all the potential lacustrine and palustrine wetlands identified within the study area from desktop searches (Appendix J) were either not present or were identified as artificial (farm) dams. The only natural wetlands within the study area are riverine wetlands associated with riparian and vegetation along Charlevue Creek, Springton Creek and some larger tributaries. These have been mapped as VC3, VC5 and VC6 (Figure 52).

Outside the study area, there is a large palustrine wetland (approximately 82 ha) located approximately 4 km east of the MLA boundary. This wetland, identified as of high ecological significance (HES) under the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* (EPP (WWB)), is not connected to the study area through any waterbodies or watercourses. Current government mapping and field inspections of the mapped wetlands identified the vegetation as non-remnant. Field assessment identified the presence of flora species known to inhabit wetland environments. No water was observed during the site inspection (Appendix K).

Groundwater Dependent Ecosystems

The above-mentioned wetlands have the potential to be partially dependent on groundwater (BoM 2019b). Within the study area high potential terrestrial GDEs and moderate potential aquatic GDEs were identified by database searches in association with Charlevue Creek and Springton Creek. Moderate potential terrestrial GDEs were also mapped in association with some of the smaller waterways.

The HES wetland located 4 km to the east of the study area was also identified as potentially groundwater dependant during the database searches.

The *Groundwater Dependent Ecosystem Assessment* (Appendix K) identified two areas within the study area containing terrestrial GDEs, both dependent on alluvial perched groundwater systems that recharge from surface flow. One of these GDEs is located within Charlevue Creek while the other one is situated within a tributary of the Springton Creek. This study also determined that the HES does not constitute a GDE and therefore, is not discussed further.

Based on the location of the aquifer, salinity data and stable isotope comparisons between water sampled from the trees and groundwater, it is concluded that both perched aquifers are hydraulically disconnected from the regional groundwater table. Furthermore, the results indicate that the trees sampled are not utilising groundwater from the regional Tertiary, alluvial or Permial coal seam aquifers to any significant degree.

Assessment of impact to potential GDEs within the Project has been addressed in Section 6.3.1 and Appendix F.

6.2.3 Terrestrial Fauna

An assessment of terrestrial fauna ecological values was conducted within the study area by AARC (2020b) (Appendix J). Four field surveys were undertaken between 2017 and 2018 covering a range of seasonal and climatic conditions to ensure temporal and seasonal survey requirements for the Brigalow Belt bioregion were met. The dates of these surveys were:

1) 4-12 May 2017;
2) 18-30 September 2017;
3) 16-23 February 2018; and
4) 22-29 March 2018.

The surveys were conducted in accordance with the guidelines:

- *Survey guidelines for Australia's threatened bats* (DEWHA 2010a);
- *Survey guidelines for Australia's threatened birds* (DEWHA 2010b);
- *Survey guidelines for Australia's threatened mammals* (DEWHA 2011a);
- *Survey guidelines for Australia's threatened reptiles* (DEWHA 2011b); and
- *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland (V 3.0)* (Eyre *et al.* 2018).

Fauna Species of Conservation Significance

Field surveys across the study area detected the presence of four fauna species of conservation significance, the southern Squatter pigeon (*Geophaps scripta scripta*), the Greater glider (*Petauroides volans*), the Short-beaked echidna (*Tachyglossus aculeatus*) and the Rufous fantail (*Rhipidura rufifrons)*.

The southern squatter pigeon and the greater glider are listed as vulnerable under the EPBC Act and the NC Act. The short-beaked echidna, listed as special least concern under the NC Act, was recorded across several sites over the survey seasons. The Rufous fantail is listed as a migratory species under the EPBC Act, but it is not listed under the NC Act.

The observed locations of these species within the study across the field surveys are displayed in Figure 54.

Pest Species

Four introduced and/or pest fauna species listed as RIS under the Biosecurity Act were identified within the study area (Table 35). A further two species; the cane toad (*Rhinella marina*) and the house mouse (*Mus musculus*), are not invasive species declared under the Biosecurity Act, but are recognised as invasive pests in Queensland.

Table 35 Introduced Fauna Species

Scientific Name	Common Name	Biosecurity Act RIS			
		Category 3	Category 4	Category 5	Category 6
Canis familiaris/ Canis lupus dingo	Wild dog/dingo	x	x	x	x
Oryctolagus cuniculus	Rabbit	x	x	x	x
Felis catus	Feral cat	x	x	-	x
Sus scrofa	Feral pig	x	x	-	x

Notes: Category 3: the invasive animal must not be distributed either by sale or gift or released into the environment.
Category 4: the invasive animal must not be moved.
Category 5: the invasive animal must not be kept.
Category 6: the invasive animal must not be fed.

6.2.4 Aquatic Ecology

To describe the aquatic ecology values of the Project, an assessment of aquatic ecological values was conducted within the study area by AARC (2020a) (Appendix K).

Four field surveys were undertaken between 2018 and 2020 covering a range of seasonal and climatic conditions to ensure temporal and seasonal variation. The dates of these surveys were:

1) 23rd -24th February 2018;
2) 3rd - 9th April 2019;
3) 1st - 2nd August 2019; and
4) 17th - 23rd March 2020.

Field surveys employed standard methodologies derived from:

- *Australian River Assessment System (AusRivAS) Physical Assessment Protocol* (Parsons *et al.* 2002);
- *Queensland AusRivAS Sampling and Processing Manual* (DNRM 2001);
- *Monitoring and Sampling Manual: Environmental Protection (Water) Policy 2009* (DES 2018c).
- *Survey guidelines for Australia's threatened birds* (DEWHA 2010b);
- *Survey guidelines for Australia's threatened reptiles* (DEWHA 2011b); and

- *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland (V 3.0)* (Eyre et al. 2018).

Aquatic ecology values pertaining to flora, fauna, wetlands and GDEs are discussed within this section. Refer to Section 7.0 for discussion of values pertaining to water quality and hydrology.

Aquatic Ecosystems

The waterways of the study area are ephemeral, experiencing periodic flows. The aquatic setting of the Project is described in Section 5.2.1.

Charlevue Creek and Springton Creek are the major determined watercourses under the Water Act, all other waterways crossing the Project are determined drainage features. Extensive clearing for agricultural purposes has been undertaken across much of the study area including the removal of riparian vegetation. The removal of riparian vegetation and direct stock access to the waterways has resulted in bank instability, erosion and occurrence of weeds.

Priority was given to aquatic fauna sampling along the major watercourses; specifically, Charlevue Creek and Springton Creek. Charlevue Creek and Springton Creek were identified to be of higher ecological value than the other surrounding waterways. In this regard, additional fauna survey methods were completed at the chosen sites along Charlevue Creek and Springton Creek in order to identify any riparian fauna species that are reliant on the existing aquatic values within the study area.

Site scoping identified the potential for aquatic trapping to be undertaken along Stanley Creek, however the ephemeral nature of this waterway combined with its low stream order Stanley Creek resulted in not enough water to have aquatic fauna trapping undertaken or to allow for macroinvertebrate sampling to occur.

Water Quality

Surface water quality was found to be generally poor. Results for physico-chemical parameters were outside of the water quality objective (WQO) guideline values for the protection of aquatic ecosystems at many sites. Exceedances included, pH, suspended solids, dissolved oxygen, turbidity, ammonia, nitrogen, phosphorus and sulphate. Petroleum hydrocarbons were also found to exceed WQO guideline values at several sites, considered likely due to the highway and agricultural practices. However, no exceedances of the WQOs for dissolved metals were detected at any site, across all sampling periods during 2020. Water quality is discussed in detail in Section 7.0 (Surface Water).

Stream Sediment Quality

Stream sediment quality was found to contain a high proportion of sand particles with some sites containing a mixture of silt, clay and gravel. No particles were large enough to be classified as cobbles (>6 cm).

Metal concentrations in stream sediment were generally low, except for one exceedance of the Sediment Quality Guideline (SQG) for nickel levels along a tributary of Springton Creek. The 2018 sample was the highest (28.1 mg/kg), with a continued reduction in nickel levels present over the following two surveys to levels barely exceeding the low trigger value (21.9 mg/kg in 2019 and 21.3 mg/kg in 2020). Stream sediment quality is discussed in detail in Section 7.0.

Biological Indicators

Macroinvertebrate diversity, abundance and Plecoptera, Ephemeroptera and Trichoptera (PET) taxa richness were generally low with a high percent tolerant taxa. SIGNAL scores were correspondingly low and consistent with the expected results for ephemeral streams in an agricultural setting. The AusRivAS

predictive modelling found the aquatic environments to be significantly impaired through to highly degraded. Ephemeral creeks are commonly known to have impaired habitats as a result of limited water availability and separation of micro-habitats. Based on the extent and severity of this impairment, the assessment indicates poor water quality and low availability of macroinvertebrate habitat was present.

Aquatic Habitat Condition

The habitat bioassessment identified most sampling sites as having moderate biological health with evidence of bank erosion, and sparse vegetative cover; whilst the remainder were either poor or good, with none as excellent. This assessment indicates a primarily low to moderate quality of habitat available and correlates with the general low diversity and abundance of aquatic fauna present.

The condition assessment revealed most sites had a moderate to major impact from localised influences such as clearing practices disturbing or removing the riparian zone, erosion from cattle access and increased run-off (due to clearing practices), and ephemeral waterways being vulnerable to frequent instream and geomorphological changes. All sites had an indiscernible or minor influence from local or regional upstream major industries (i.e., mining, agriculture, water extraction etc) or urbanisation, with the exception of few sites with farmer dams slightly upstream.

Species of Conservation Significance

Database searches identified four fauna species of conservation significance with potential to occur within 50 km of the study area. No aquatic flora of conservation significant were identified by the desktop searches.

The *Aquatic Ecology Assessment* (AARC 2020a) (Appendix K) confirmed the absence of threatened aquatic fauna or flora within the study area. This is consistent with the highly ephemeral nature of watercourses and the disturbed condition occurring as a result of past clearing and agricultural land use.

The *Rheodytes leukops* (Fitzroy River turtle) was previously identified as potentially impacted by the 'Dingo West Project', subject to the particular manner in which the Project is undertaken (EPBC Referral Decision (2010/5775)). This was based on the likely habitat for the turtle occurring approximately 54 km downstream of the Project. The *Aquatic Ecology Assessment* (AARC 2020a) (Appendix K) confirmed that the species did not inhabit watercourses within or immediately downstream of the Project and concluded that suitable habitat for the species was not present. From this survey, the *QEOP: Significant Residual Impact Guideline* (EHP 2014) was used to determine whether or not the impacts of the Project will, or is likely, to have a significant residual impact on the Fitzroy River turtle. The assessment found the Project is considered unlikely to result in a significant residual impact.

Fish Passage

The *Queensland Waterways for Waterway Barrier Works* (DAF 2013) identifies watercourses within the Project as providing value for fish passage mapped as moderate to major risk to proposed infrastructure. Despite watercourses within the study area only containing water for very short periods of the year (post rainfall), during a flow event Charlevue Creek and Springton Creek would be utilised by fish species.

Fish passage was assessment using the *QEOP: Significant Residual Impact Guideline* (EHP 2014) to determine whether or not the impacts of the Project will, or are likely to, have a significant residual impact. The assessment identified that the Project is unlikely to result in a significant residual impact on waterways providing for fish passage. Additionally, there are no known migratory aquatic species likely to rely on the watercourses for regular movement or as access to known breeding locations.

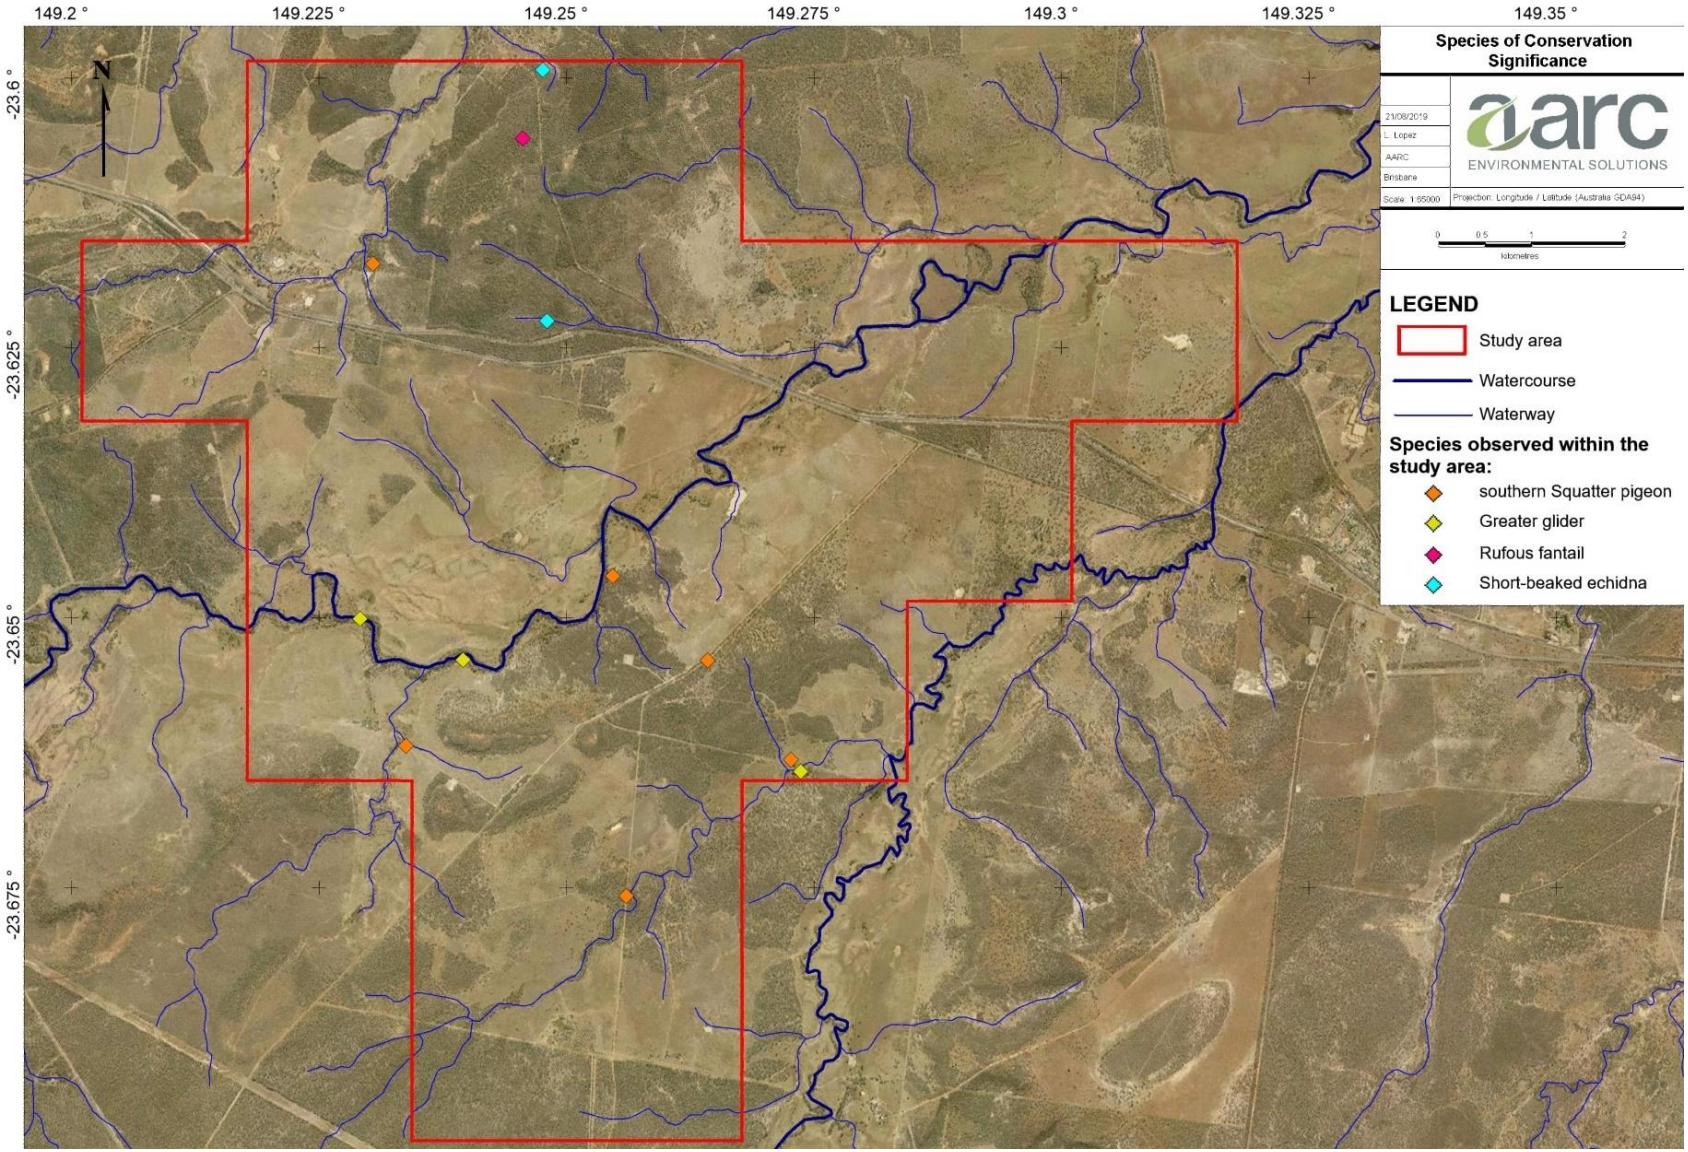

Figure 54 Locations of Fauna Species of Conservation Significance

6.3 POTENTIAL IMPACTS

6.3.1 Terrestrial Flora

Vegetation Communities

The Project will include vegetation clearance and land disturbance during the construction and operation of the mine. The extent of land disturbance would be approximately 1953 ha, of which, approximately 711 ha of remnant vegetation clearing is required over the life of the Project.

Other potential impacts to vegetation communities include:

- removal of habitat for terrestrial flora and fauna;
- further habitat fragmentation and loss of connectivity. It is noted that existing vegetation clearing due to agricultural land use has already limited habitat connectivity due to the highly fragmented remnant vegetation remaining on site; and
- potential for reduced condition of neighbouring vegetation communities due to the introduction of weeds or the release of contaminants associated with mine operations.

Flora Species of Conservation Significance and Habitat

Cerbera dumicola has been identified during the vegetation surveys in two very localised rocky areas associated with VC2 and VC1 (Figure 53). This species was not identified elsewhere in the study area.

The proposed mining activity proposes no impacts to populations of *Cerbera dumicola*.

Weed Species

Project development has the potential to create or enhance conditions for invasive weed species, which may spread and out-compete native and pasture species. Weed species may be introduced via the spread of seed on persons, vehicles and equipment, and may quickly colonise disturbed areas if left untreated.

The introduction of weed species can reduce native species abundance and diversity through competition. This can lead to the reduced condition of vegetation and native fauna habitat.

Wetlands

The Project has potential to impact on wetlands via:

- direct clearing;
- changes in hydrology;
- erosion and sedimentation; and
- contaminant release.

Groundwater Dependent Ecosystems

Where wetlands exhibit a degree of dependence on groundwater for survival, drawdown from the mine can result in a reduced ecosystem condition, changes to vegetation composition or die back.

Water quality data, groundwater level and groundwater drawdown estimation (JBT 2019) (Appendix C) were to assess GDEs and the associated impact of drawdown (AARC 2020b) (Appendix J).

Data from the *Groundwater Dependent Ecosystem Assessment* (Appendix F) together with the data obtained over several studies by JBT Consulting (Appendix C) were used in the assessment of the GDEs and the associated impact of drawdown.

Potential Impacts on GDEs within the study area

The GDEs identified within the study area are riverine type wetlands, including riparian vegetation on watercourses and floodplains.

The impacts identified to the GDEs within the study have been assessed within the GDE study (Appendix F) and summarised below:

- Direct clearing: the GDE located within the tributary of Springton Creek falls within the footprint of the mine and therefore subject to unavoidable vegetation clearing. Direct impacts on riparian vegetation (vegetation clearing) have been addressed above in this section. Impact mitigation as well as offsets requirements have been addressed in Sections 8.1.1.1 and 9.1.1 respectively of Appendix J.

- Groundwater drawdown: groundwater modelling estimated that the Project has the potential to cause a maximum drawdown of 5 m (steady-state post-mining drawdown) at some locations below the Charlevue and Springton Creeks (Appendix C), on the Tertiary and alluvial sediments (regional groundwater table). This drawdown will not have an impact on the riparian habitat identified as GDE within Charlevue Creek based on the limited hydraulic connectivity between the regional groundwater table and the perched aquifer that supports the GDE (Appendix F). Further, considering that the Project's is situated downstream of the Charlevue Creek's GDE and there will be no loss of catchment area, it is unlikely the Project will reduce the surface flows that replenish the associated perched aquifer (Appendix F).

6.3.2 Terrestrial Fauna

Fauna Species of Conservation Significance and Habitat

Field surveys across the study area detected the presence of four fauna species of conservation significance. Three of these species are listed under the NC Act, the southern Squatter pigeon (*Geophaps scripta scripta*), the Greater glider (*Petauroides volans*) and the Short-beaked echidna (*Tachyglossus aculeatus*) whilst the Rufous fantail (*Rhipidura rufifrons*) is listed as Migratory species under the EPBC Act).

Potential impacts of the Project to threatened fauna species include:

- direct clearing of habitat within the Project defined impact areas;

- further habitat fragmentation and loss of connectivity, particularly along Charlevue Creek which provides partial connectivity to larger downstream riparian communities. It is noted that existing vegetation clearing due to agricultural land use has already limited connectivity within this community;

- potential for fauna mortality through interactions with vehicles on roads and/or heavy machinery used for land clearing;

- potential for habitat degradation through increased risk of release of contaminants or sediments into receiving environments within and downstream of the Project; and

- potential for increased invasive flora and fauna.

Southern squatter pigeon (Geophaps scripta scripta)

Suitable habitat for the southern Squatter pigeon exists in open grassy woodland throughout the study area. Within this suitable habitat, fifteen birds were observed during the ecological surveys; the majority during spring 2017. The species is regionally abundant, having been observed outside of the study area on multiple occasions, with the species observed multiple times on local roads and elsewhere in the local area. No breeding activity was observed within the study area.

It is unlikely that the proposed Project will have a significant impact on the southern squatter pigeon; either the local population or the population in its entirety due to:

- the species being highly mobile;

- the abundance of equivalent and more suitable habitat outside of the study area in adjacent areas;

- the observed high local abundance of the southern squatter pigeon within and surrounding the study area; and

- the likely suitable habitat to be provided by rehabilitated land, post mining.

Greater glider (Petauroides volans)

The preferred habitat of the greater glider consists of tall, montane, moist eucalypt forests with relatively old trees and abundant hollows. It favours forests with a diversity of eucalypt species, due to seasonal variation in its preferred tree species. Critical microhabitat is an abundance of large hollows in large, old trees for daily denning shelters and breeding purposes. The species is absent from cleared areas and has little ability to disperse between fragments across cleared areas, with habitat connectivity critical to species survival (TSSC 2016).

Suitable habitat for the great glider within the study area is confined to the Eucalypt riparian woodlands such as along the Charlevue Creek; that features tall open woodland containing hollows and a sparse shrub layer.

It is unlikely that the proposed Project will have a significant impact on the greater glider; either the local population or the population in its entirety due to:

- no significant impact proposed to habitat within the study area, specifically Charlevue Creek. Proposed disturbance within this habitat is limited to the development of a small culvert crossing;

- the observed abundance of greater gliders within the study area and within the broader central Queensland region; and

- the abundance of equivalent and more suitable habitat outside of the study area in adjacent areas.

Short-beaked echidna (Tachyglossus aculeatus)

The Short-beaked echidna is found in a variety of habitat types including open forests, grasslands and heavily vegetated woodlands. Suitable habitat for the species exists across the study area.

It is unlikely that the proposed Project will have a significant impact on the short-beaked echidna, either the local population or the population in its entirety due to:

- the known abundance and wide-ranging distribution of the species;
- the presence of ample equivalent or better suited habitat surrounding the Project;
- the relatively small extent of impact proposed by the Project; and
- the likely suitable habitat to be provided by rehabilitated land, post mining.

Rufous fantail (Rhipidura rufifrons)

The Rufous fantail is generally found in rainforest, dense wet forests, swamp woodlands and mangroves, preferring deep shade, and is often seen close to the ground. During migration, it may be found in more open habitats, such as those within the study area.

It is unlikely that the proposed Project will have a significant impact on the rufous fantail, either the local population or the population in its entirety due to:

- the rufous fantail is a common and secure species (Blakers, Davies & Rielly 1984);
- the study area does not contain the preferred habitat type for the species;
- the species is highly mobile and likely only passing through the Project on its migratory path;
- no known breeding sites or nesting habitat was identified on the study area; and
- ample equivalent or higher quality habitat exists surrounding the study area.

It should be noted that the Rufous fantail is listed migratory under the EPBC Act and is not listed under the NC Act. For the purpose of this assessment, only listed species under the NC Act are further assessed, and therefore the Rufous fantail has not been discussed further.

Pest Species

Pest species compete with, and prey on native fauna. Construction and operation of the Project increases the risk of pest species on the study area through:

- generation of food and other waste that may attract pests; and
- creation of artificial ponding areas providing habitat for pest species such as cane toads.

6.3.3 Aquatic Ecology

The aquatic ecology values within the study area are limited to riverine ecosystems including Charlevue Creek, Springton Creek, and some tributaries. The creeks are highly ephemeral, experiencing periodic flows only following heavy or repeat rainfall events. Past clearing for agricultural purposes has been undertaken across much of the study area including the removal of riparian vegetation. The removal of

riparian vegetation and direct stock access to the waterways has resulted in bank instability, erosion and occurrence of weeds.

The Project has potential to impact on aquatic ecology values through:

- the release of MAW to the receiving waterways and associated impacts to ecosystem health;
- potential for spills and leaks from the mining operation to cause contamination in the receiving waterways;
- direct impacts to riverine ecosystems via land disturbance for vehicle crossings or diversion of drainage features;
- risk of increased erosion from cleared lands or mine infrastructure such as spoil dumps, resulting in increased sediment loads entering the aquatic ecosystems; and
- impediments to fish or other aquatic fauna movements due to the construction of crossings or other infrastructure.

6.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

6.4.1 Terrestrial Flora

Vegetation Communities

To minimise and mitigate impacts to vegetation communities on the Project the following management strategies will be implemented:

- clearing of land and vegetation will be limited to areas defined in the Project approval and required for safe operation; and managed through:
    - an internal *Land Disturbance Permit System* will be implemented to minimise the chances of unauthorised clearing; and
    - areas to be cleared will be clearly defined and demarked to equipment operators;
- inductions and training materials provided to employees will identify the EVs of the site as well as the company procedures for managing impacts within its authority;
- rehabilitation will be undertaken progressively and will aim to return the land to the pre-mining land use where possible; and
- where impact to Matters of State Environmental Significance (MSES) cannot be avoided and are authorised by the Project approval, environmental offsets will be provided.

Flora Species of Conservation Significance

Suitable habitat for the *Cerbera dumicola* exists to the west of the Project, within the MLA. The proposed mine construction and development will not impact on the populations. To ensure no inadvertent impacts to *Cerbera dumicola* the following management strategies will be implemented:

- an internal *Land Disturbance Permit System* will be implemented to minimise the chances of unauthorised clearing and impacts to the populations within the MLA;

- inductions and training materials provided to employees will identify the EVs of the site as well as the company procedures for managing impacts within its authority; and

- existing populations will be monitored for abundance, distribution and health over the mine life.

It should be noted that the Rufous fantail is listed migratory under the EPBC Act and is not listed under the NC Act. For the purpose of this assessment, only listed species under the NC Act are further assessed, and therefore the Rufous fantail has not been discussed further.

Weed Species

To control the abundance and spread of weed species the following management strategies will be implemented:

- a *Weed and Pest Management Plan* will be prepared and implemented prior to construction (refer to section 4.7.4 for full description);

- as required, weeds within the MLA will be controlled using herbicides and other recommended methods;

- inductions and training materials provided to employees will assist the identification of common weeds and will include procedures for reporting; and

- access to vehicle wash down facilities will be provided for vehicles at risk of spreading weeds.

Wetlands/GDEs

Wetlands/GDEs include riverine vegetation on the MLA, particularly riparian vegetation associated with Charlevue and Springton creeks. In addition, a HES wetland is located to the southeast of the Project. To manage potential impacts on wetlands, the following will be undertaken:

- sediment and erosion control structures will be installed and maintained near all at risk areas to prevent sediment release to wetlands;

- a REMP has been developed for the project (Appendix Q), and will be implemented including monitoring of water, sediments, riparian/riverine vegetation health and biological indicators in aquatic environments;

- the release of MAW will be in accordance with the quality controls provided in the *Model Mining Conditions* (DES 2017e) and the Project's EA conditions;

- the development of a SWMS and associated ESCP; and

- groundwater bores adjacent to Charlevue Creek (DW7076W) and Springton Creek (DW7292W1), have been fitted with dataloggers. This data will allow the assessment of the range of water levels within the alluvium and the response of groundwater levels within the alluvium to rainfall recharge, stream flow events and mining activities.

6.4.2 Terrestrial Fauna

Fauna Species of Conservation Significance

Fauna species of conservation significance identified on the Project include; the southern Squatter pigeon (*Geophaps scripta scripta*), the Greater glider (*Petauroides volans*), the short-beaked echidna

(*Tachyglossus aculeatus*) and the Rufous fantail (*Rhipidura rufifrons*) (migratory). The proposed mine construction and development will not have a significant impact on these Species. To ensure no inadvertent impacts occur the following management strategies will be implemented:

- an internal *Land Disturbance Permit System* will be implemented to minimise the chances of unauthorised clearing and impacts to the threatened fauna within the MLA;
- inductions and training materials provided to employees will identify the EVs of the site as well as the company procedures for managing impacts within its authority;
- vehicles speeds will be limited within the MLA, to minimise the risk of collision;
- vegetation clearing will be done in a staged manner, allowing time for fauna to leave the area; and
- pre-clearing inspections will be undertaken by qualified staff to minimise the risk of fauna mortality.

Pest Species

To prevent the introduction of pest species and to control their spread, the following management strategies will be implemented for the Project:

- a *Weed and Pest Management Plan* will be prepared and implemented prior to construction (refer to section 4.7.4 for full description);
- rubbish and food scraps will be managed so as not to encourage pest species;
- inductions and training materials provided to employees will assist the identification of common pests and will include procedures for reporting; and
- control of feral cats and other animals will be undertaken within the MLA.

6.4.3 Aquatic Ecology

Aquatic ecology values are primarily attributed to Charlevue Creek and Springton Creek within the MLA. The following mitigation measures will be implemented to protect existing values:

- sediment and erosion control structures will be installed and maintained near all at risk areas to prevent sediment release to wetlands;
- fish passage will be managed during all phases, such that:
    - crossing design should provide for the fish passage during low and high flow events:
    - crossing design will be developed upon finalisation of the Mine Design Plans. Crossing designs for fish passage will be designed in accordance with the management measures in the *Accepted Development Requirements for Operational Work that is Constructing or Raising Waterway Barrier Works* (DAF 2018b) (i.e., using box culverts to permit crossing during low flow events, enabling fish passage to be maintained within / through the Project area) and the performance outcomes detailed in State Code 18: Constructing or raising waterway barrier works in fish habitats (DILGP 2020)

  - upon finalisation of crossing design plans by a suitably qualified person development approval will be sought in accordance with the *Planning Act 2016*.

- the release of MAW, will be in accordance with the quality controls provided by the *Model Mining Conditions* (DES 2017e);

- fuel and hazardous liquids will be stored in a bunded facility, in accordance with relevant Australian Standards;

- an *Emergency Response and Spill Management Plan* will be implemented during construction and operation to minimise the risk of contaminant release to aquatic ecosystems;

- open-cut pits will be appropriately bunded or located in a manner that prevents surface water from entering the voids during a 1:1000-year flood event and dams will be appropriately bunded or located in a manner that prevents surface water from entering or damaging the dams during a 1:1000-year flood event. *This is consistent with the EPBC Referral Decision: not a controlled action if undertaken in a particular manner;* and

- a REMP will be implemented and will include monitoring of water, sediments, riparian/riverine vegetation health and biological indicators in aquatic environments.

6.5 ENVIRONMENTAL OFFSETS

The offsets framework requires environmental offsets to be delivered where an activity is likely to result in a significant residual impact on a prescribed environmental matter. The *Queensland Environmental Offset Policy Significant Residual Impact Guideline* (EHP 2014) was used to determine whether Project impacts are considered to be significant. This guideline outlines the criteria for identifying when an impact on a prescribed environmental matter (i.e., MSES) may be significant. The significant impact criteria provide a trigger for consideration of offsets (EHP 2014).

As part of the ecological assessments (AARC 2020a; AARC 2020b), significant impact assessments were conducted for all prescribed environmental matters identified in the study area. A summary of results from the assessment is provided in Table 36, and the full assessments can be found in Appendix J and Appendix K.

Of the prescribed matters that will be significantly impacted by the proposed disturbance further details of the impact assessment and offset requirements are summarised in Table 37.

Magnetic South is committed to delivering environmental offset requirements for matters with a significant residual impact as a result of the Project. Offsets will be delivered as either a financial settlement or proponent-driven offset (i.e., a land-based offset or *Direct Benefit Management Plan*), or a combination of both.

Table 36 Summary of Project MSES and Likelihood of Significant Residual Impact

Protected Matter		NC Act Status	VM Act Status	Likelihood of Occurrence Within Study Area	Likelihood of Significant Impact
Of concern RE 11.3.2		n/a	OC	Present	Yes
REs located within the defined distance from the defining banks of a VM Act watercourse		n/a	n/a	Present	Yes
Connectivity area		n/a	n/a	Present	Yes
Wildlife Habitat and Essential Habitat	Southern squatter pigeon	V	n/a	Present	No
	Greater glider	V	n/a	Present	No
	Short-beaked echidna	SLC	n/a	Present	No
Waterways providing for Fish Passage		n/a	n/a	Present	No
HES Wetlands		n/a	n/a	Not present	No

Notes:
n/a not applicable
OC of concern
NT near threatened
V vulnerable
SLC special least concern

Table 37 Summary of MSES Impact Assessment and Gemini Project Offset Requirements

MSES	Total Impact Area (ha)	Impact Assessment	Offset Requirement	Habitat Description
Of concern RE11.3.2	2.57	Clearing is non-linear and exceeds the clearing threshold.	Offset Required	This vegetation community was characterised by *Eucalyptus populnea* (poplar box) woodland on alluvial plains. It was represented in several small to moderate patches within the study area and is subject to pressures from grazing, exotic species invasion.
REs located within the defined distance from the defining banks of a VM Act watercourse	58.32	Clearing of watercourse vegetation is required. The clearing widths and areas exceed significant impact guidelines. REs supporting watercourse vegetation includes RE 11.3.25, RE 11.5.2, RE 11.3.2 and RE 11.7.2.	Offset Required	A number of VM Act watercourses traverse the MLA. Impacts will occur to watercourse vegetation that is associated with RE 11.3.25, RE 11.5.2, RE 11.3.2 and RE 11.7.2.
Connectivity area*	710.72	The *Landscape Fragmentation and Connectivity Tool** was applied to the proposed extent of disturbance area. The results found that significant impact would occur to connectivity at both local scale and to core remnant areas.	Offset Required	The *Landscape Fragmentation and Connectivity Tool* determined that there is significant impact to the connectivity of the remnant vegetation within the Project.

Notes: * *Landscape Fragmentation and Connectivity Tool* is based on current government mapping.

7.0 SURFACE WATER

This section provides a description of the existing surface water values within and surrounding the Project. It aims to identify the Project's potential impacts on the existing values and propose mitigation measures and management strategies to prevent or minimise adverse environmental effects.

This section is informed by the *Surface Water Assessment* (WRM 2020b) presented in Appendix B. A *Flood Impact Assessment* (WRM 2020a) was also conducted to inform the *Surface Water Assessment* (WRM 2020b).

Surface water values pertaining to flora, fauna and wetlands are addressed in Section 6.0.

7.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objective relevant to potential impacts to surface water as described in the EA guideline for *Application requirements for activities with impacts to water [ESR/2015/1837]* (DES 2017c) is:

The activity will be operated in a way that protects the environmental values of waters.

The Project would achieve all of the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

a) *the storage and handling of contaminants will include effective means of secondary containment to prevent or minimise releases to the environment from spillage or leaks;*

b) *contingency measures will prevent or minimise adverse effects on the environment due to unplanned releases or discharges of contaminants to water;*

c) *the activity will be managed so that stormwater contaminated by the activity that may cause an adverse effect on an environmental value will not leave the site without prior treatment;*

d) *the disturbance of any acid sulphate soil, or potential acid sulphate soil, will be managed to prevent or minimise adverse effects on environmental values;*

e) *acid producing rock will be managed to ensure that the production and release of acidic waste is prevented or minimised, including impacts during operation and after the environmental authority has been surrendered;*

f) *any discharge to water or a watercourse or wetland will be managed so that there will be no adverse effects due to the altering of existing flow regimes for water or a watercourse or wetland; and*

g) *the activity will be managed so that adverse effects on environmental values are prevented or minimised.*

Of the performance outcomes described above, (d) assessment of acid sulphate soils is addressed in Section 5.0, (e) assessment of acid producing rock is addressed in Section 13.0 and (f) assessment of impacts to wetlands are addressed in Section 6.0.

7.2 DESCRIPTION OF ENVIRONMENTAL VALUES

The following documents were consulted to assist in identification of the surface water EVs for the Project:

- *Environmental Protection (Water and Wetland Biodiversity) Policy 2019*;
- *Environmental Protection (Water) Policy 2009 Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin* (EHP 2011a); and
- *Water Resource (Fitzroy Basin) Plan 2011*.

The EPP (WWB) is the primary instrument for surface water management under the EP Act; it governs discharge to land, surface water and groundwater, aims to protect EVs and sets water quality guidelines and objectives.

Schedule 1 of the EPP (WWB) outlines the *Environmental Protection (Water) Policy 2009 Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin* (EHP 2011a) as the relevant document for defining EVs and WQOs for the Project region, as described in Section 7.2.3.

The *Water Resource (Fitzroy Basin) Plan 2011* sets out the allocation and sustainable management of water resources in the Fitzroy Basin. The plan also identifies outcomes for sustainable management of water, the water plan area, general and specific surface water and groundwater outcomes, as well as general and specific ecological outcomes.

7.2.1 Drainage Network

The Project area lies within the Fitzroy River Basin, which encompasses an area of 142,545 km^2 and contains the Comet, Connors, Dawson, Don, Nogoa and Mackenzie Rivers, which make up its six sub-catchment areas (BoM 2018; DES 2018b). The study area lies within the Mackenzie River catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River Basin (Figure 55).

The Project area also lies within the local site catchments of Springton Creek and Charlevue Creek (Figure 56). Charlevue Creek flows through the Project area in a northeast direction. This watercourse begins within the boundaries of Blackdown Tablelands National Park, flowing northeast before joining with Springton Creek and the Fitzroy River, and eventually flows into the Pacific Ocean approximately 46 km north of Gladstone. Springton Creek flows though the Project area in a north-northeast direction. These two creeks eventually converge with the Mackenzie River. First and second order streams associated with Charlevue Creek and Springton Creek also occur in the study area.

Stanley Creek traverses the northwest corner of the Project area and flows in a northeast direction to join with Duckworth Creek (offsite), which then joins with Springton Creek further downstream of the Charlevue - Springton Creek confluence (Figure 57).

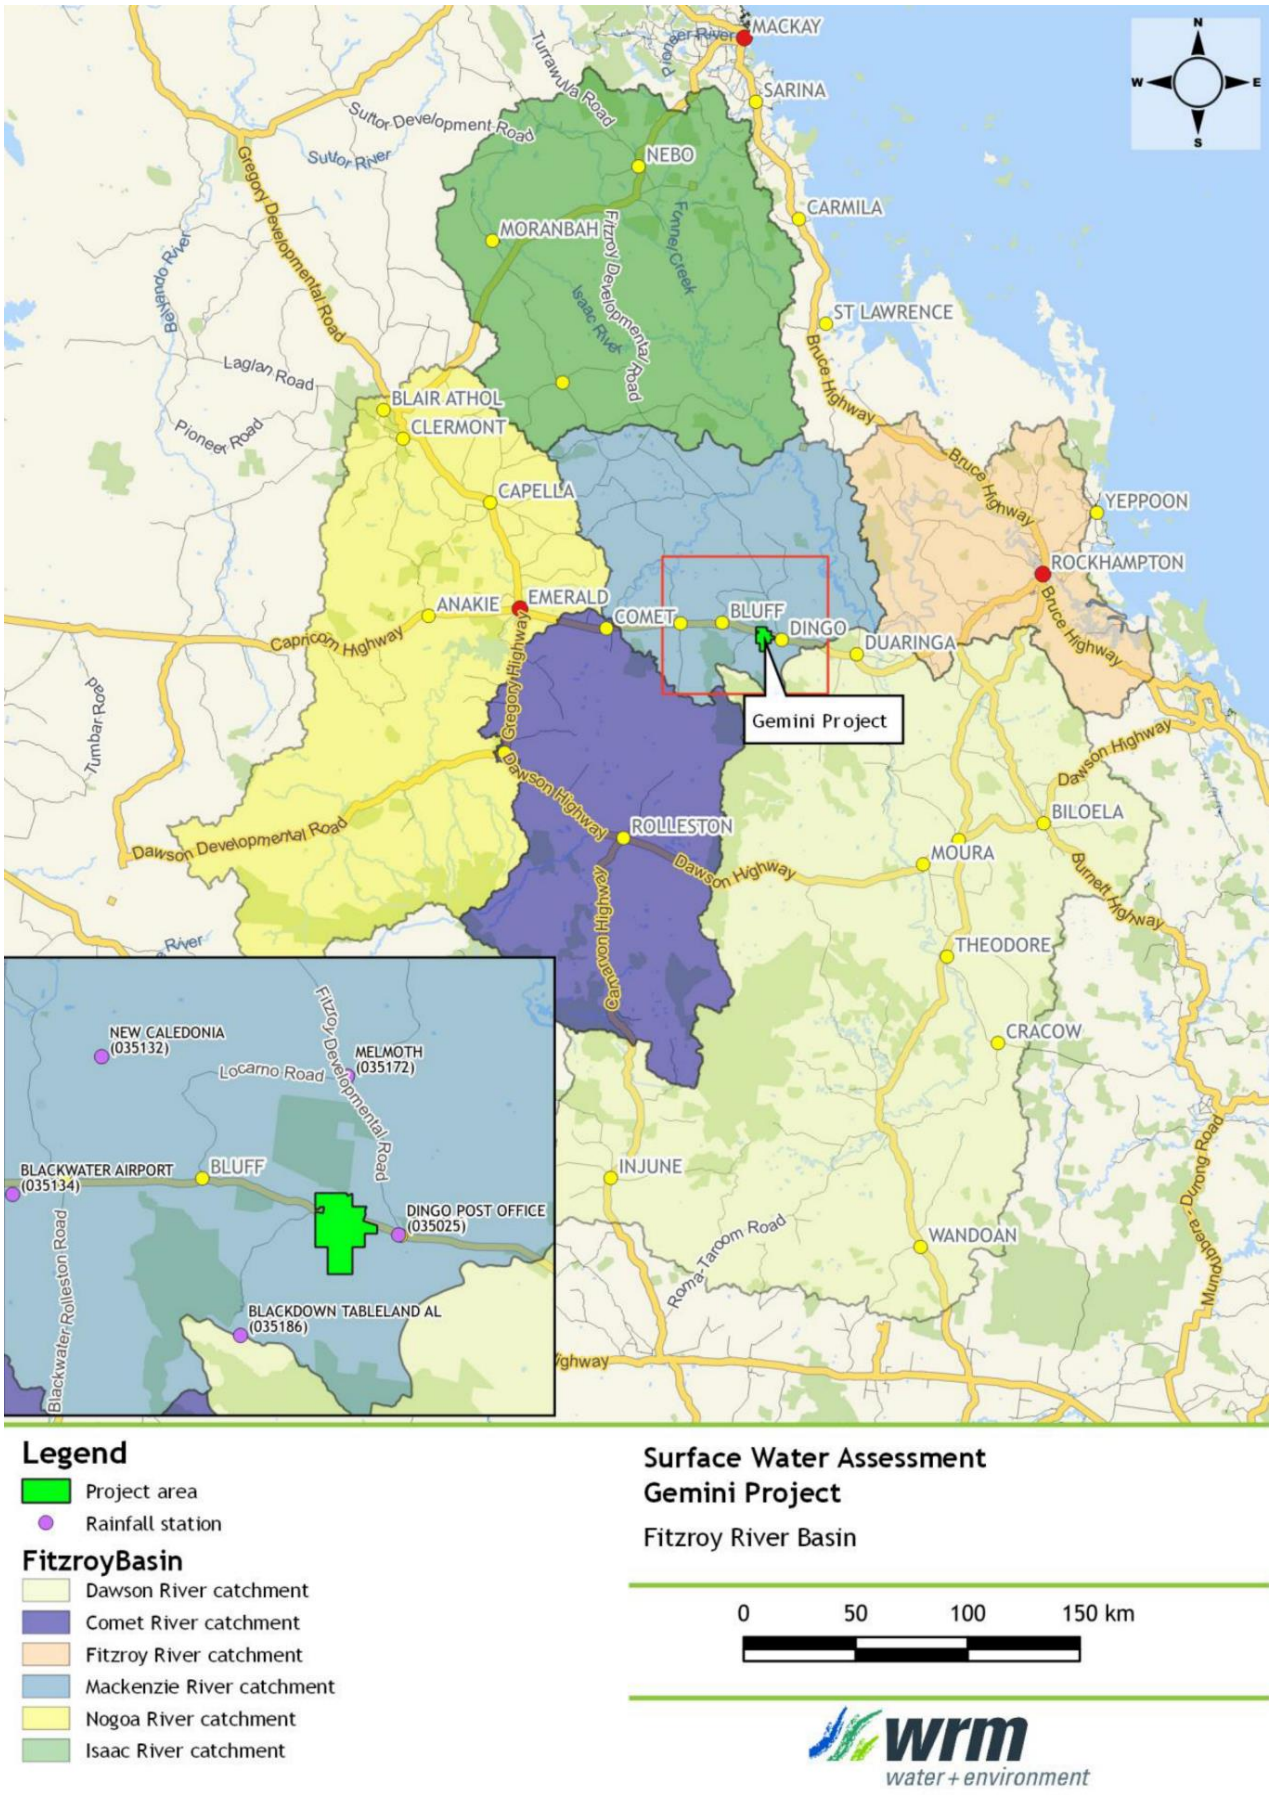

Figure 55 Fitzroy River Basin

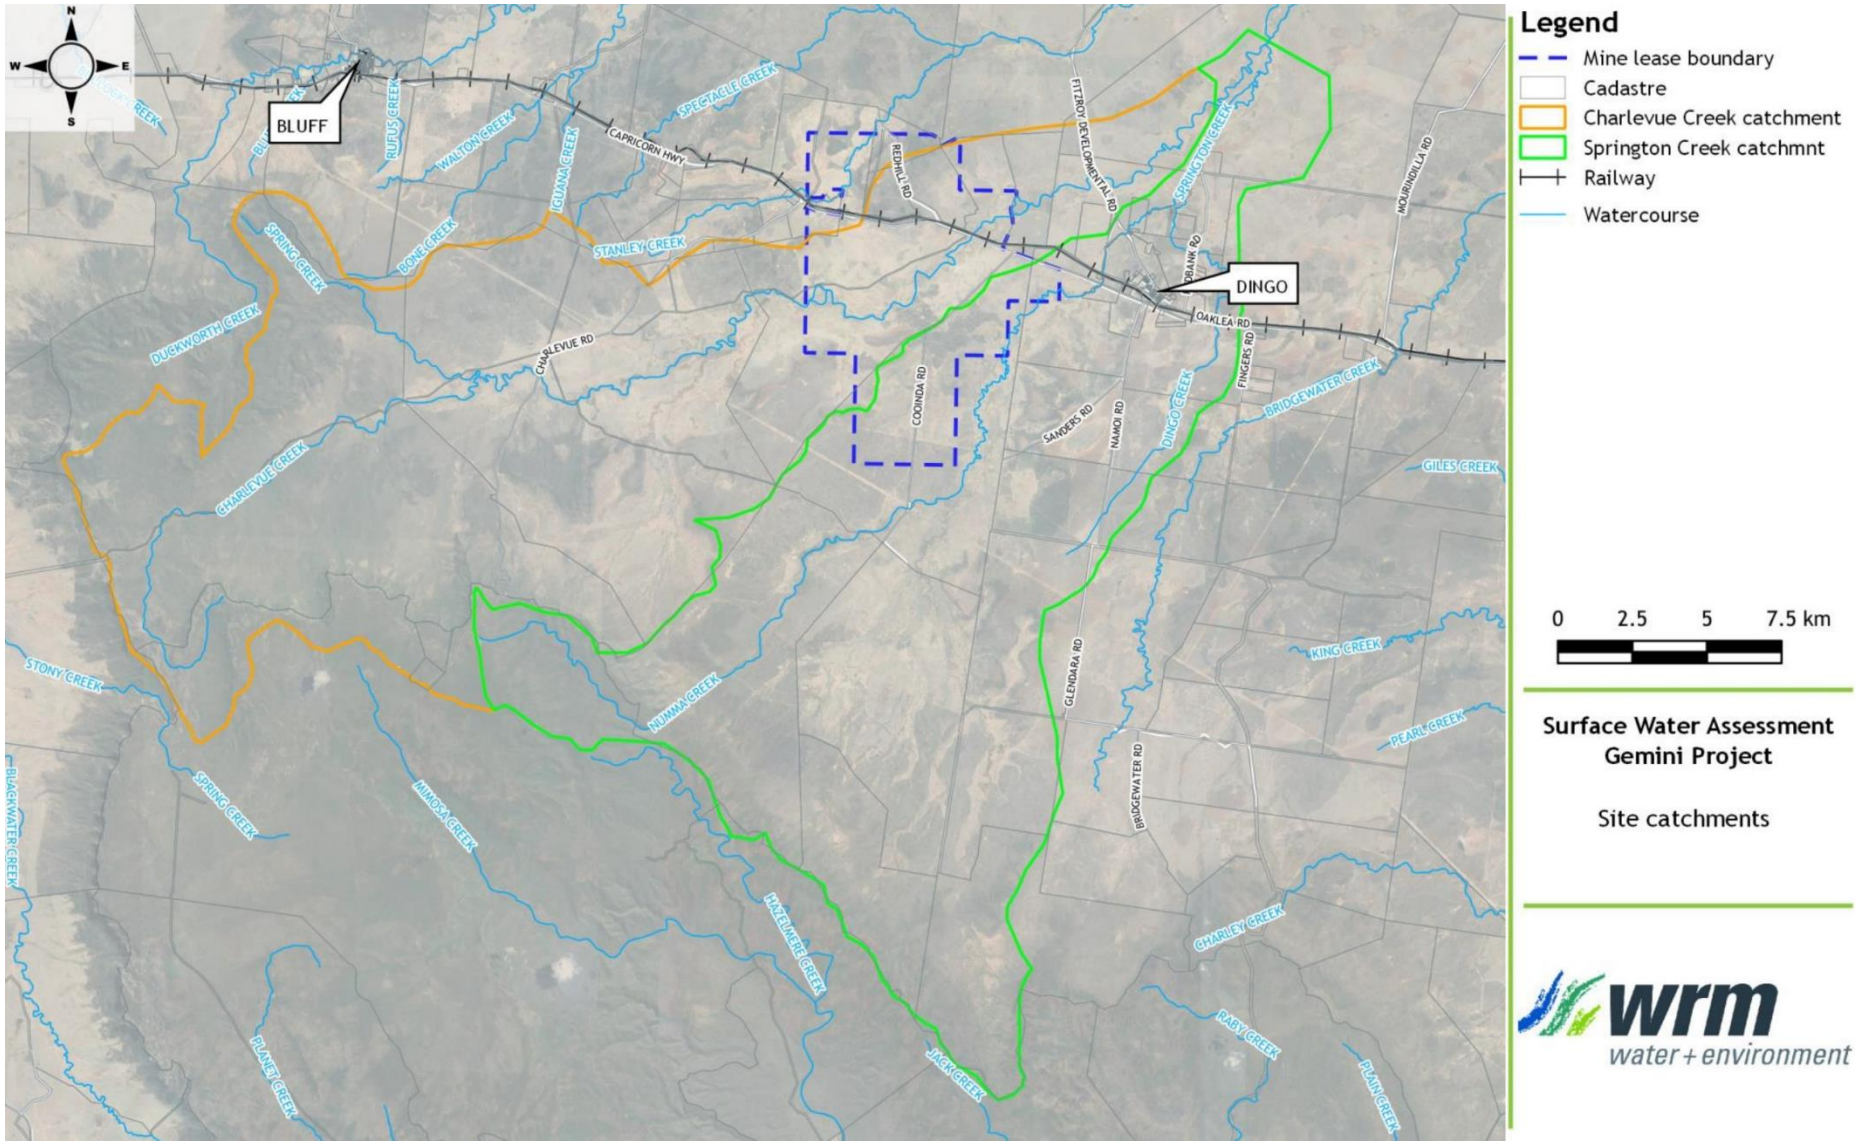

Figure 56 Local Catchments

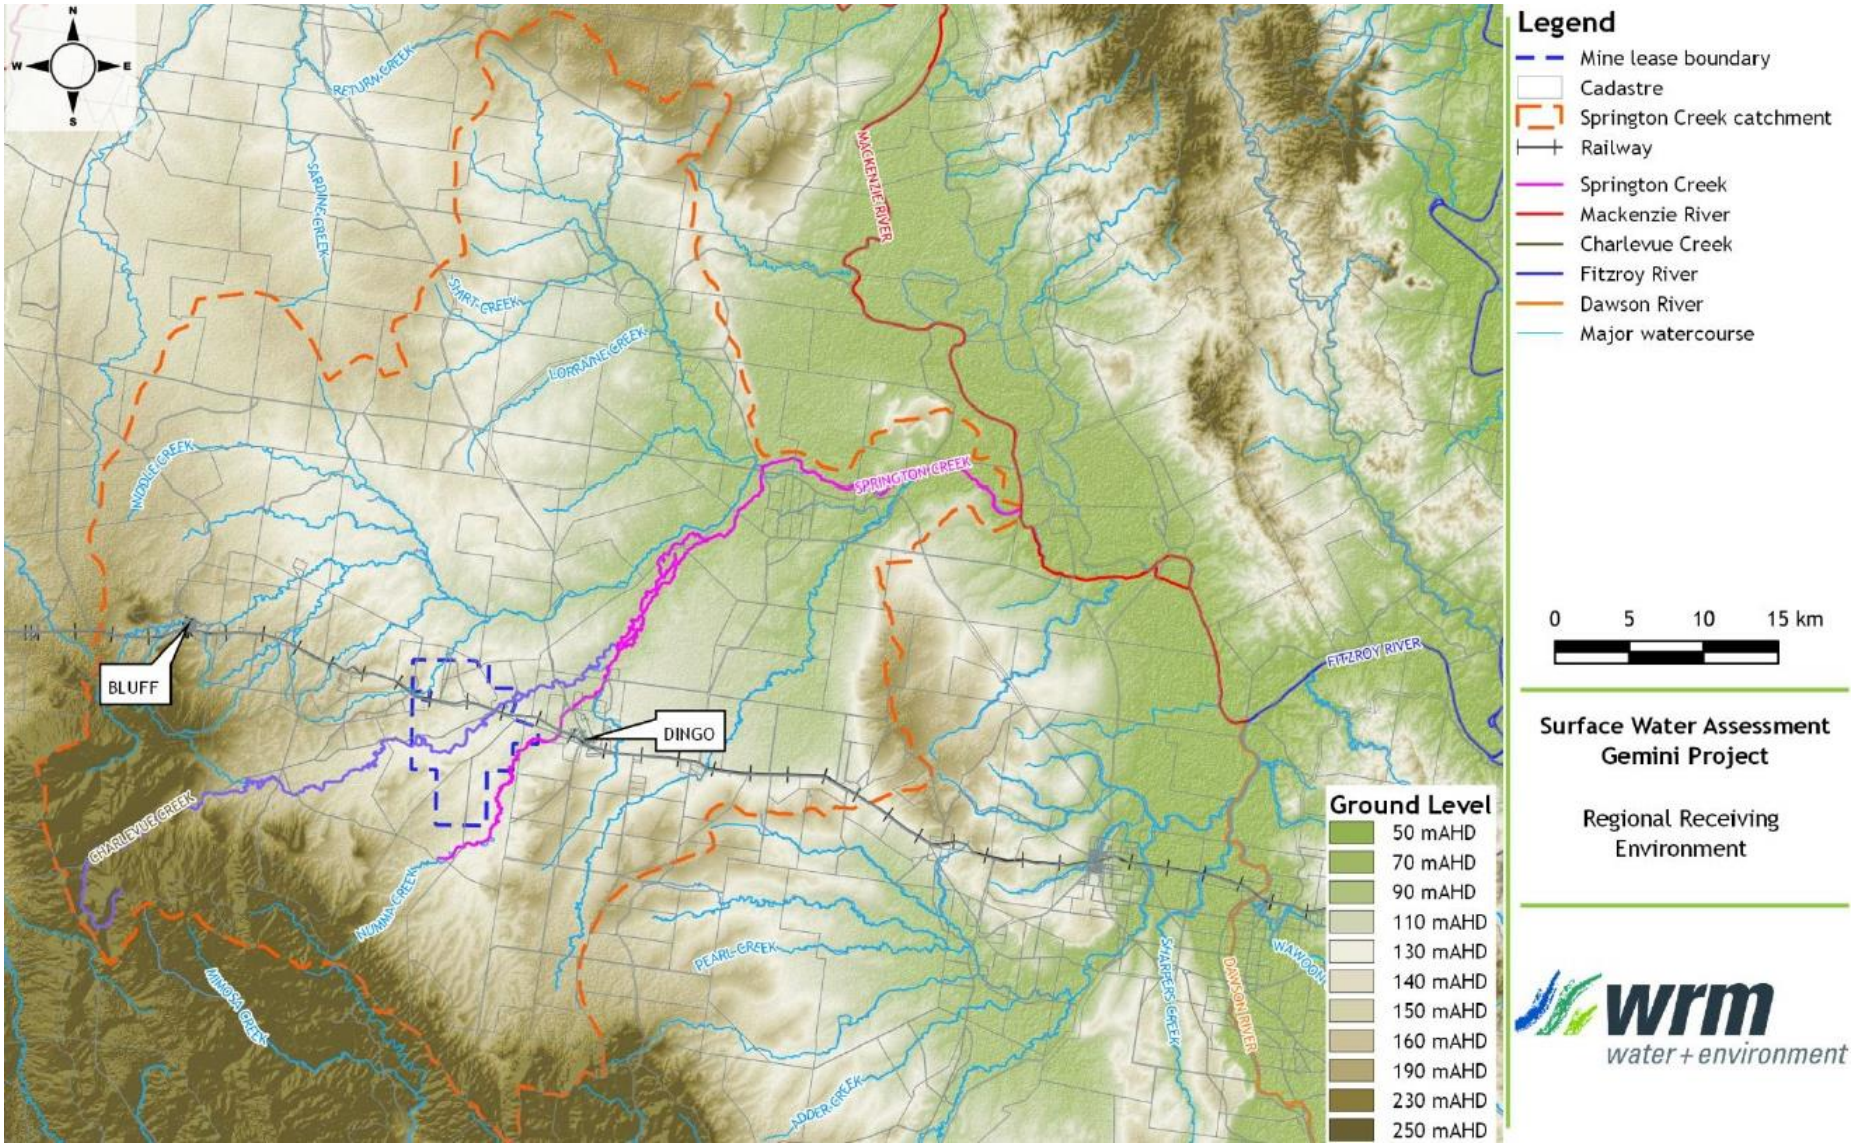

Figure 57 Regional Receiving Environment

Local Stream Morphology

All local waterways are ephemeral, with streamflow mostly occurring shortly after rainfall between September and April. Stream flows are highly variable, with most channels remaining dry during winter to early spring when rainfall and runoff is low, although some pools hold water for extended periods. Typical depth of channels reaches up to 0.8 m and a channel widths range between 1.2 and 3.5 m.

Within the Project, Springton Creek and Charlevue Creek cross alluvial floodplains. The reaches of Springton Creek and Charlevue Creek in the proposed mining area have well-defined channels, typically characterised of predominant sandy beds with a mixture of silt and clay at varying proportions, and well-established riparian vegetation.

The riparian vegetation constituted a mixture of low to moderate disturbance and were located within remnant and non-remnant environs. Disturbance of clearing for agricultural purposes and direct stock access to waterways have contributed to bank instability, erosion and occurrence of weeds. Further details are addressed in Section 6.0.

Topography of the surrounding land varies from flat to undulating, with elevation within the Project ranging from 120-150 mAHD. The landscape is influenced by Charlevue Creek, which has a lower elevation than the surrounding landscape.

7.2.2 Wetlands

The assessment of wetlands within and outside of the Project area is provided in Section 6.0, along with the description of potential impacts and mitigation measures proposed. To avoid duplication, no further discussion of wetlands is included in this section.

7.2.3 Surface Water Quality

Regional Water Quality Objectives

The document *Environmental Protection (Water) Policy 2009 for the Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin* (EHP 2011a) provides WQOs to support and protect the different EVs identified for waters within the Mackenzie River southern tributaries of the Mackenzie River sub-basin. Ten EVs are nominated broadly to the mapped areas of this zone, of which the following are relevant to the Project and its receiving waters:

- aquatic ecosystems (slightly to moderately disturbed (SMD)); and
- water suitable for stock watering.

The guideline WQOs for the protection of aquatic ecosystems and for stock watering are provided in Table 38. Collected water samples in February 2018 and April 2019 have been compared to these WQO values to characterise the existing water quality of the site-specific waterways and drainage features.

Local Surface Water Quality Assessment

As part of an ongoing surface water monitoring program implemented at the site in 2018, water quality sampling across Charlevue Creek, Springton Creek and Stanley Creek included field readings of pH, EC and temperature and has occurred following two flow events to date. Surface water samples were also collected at each waterway that contained standing or flowing water. Location of the survey sites are displayed in Figure 59.

Flow data is unavailable for the period preceding the sampling events, however, results of the site water balance model have been used to estimate the relative magnitude of the flow events occurring in the days prior to the samples being taken.

As runoff was observed to have essentially ceased at the time of sampling, the modelled runoff for the 'undisturbed' catchment type over the 7 days prior to the sampling events on 23 February 2018 and 8 April 2019 was compared to the range of modelled weekly totals estimated over the period of climate record from 1889. The results are plotted in Figure 58 below, which shows that during both periods the modelled runoff would have been exceeded in the wettest 3% to 4% of weeks in the climate record (noting that runoff greater than 1 mm/week would only occur about 6% of the time).

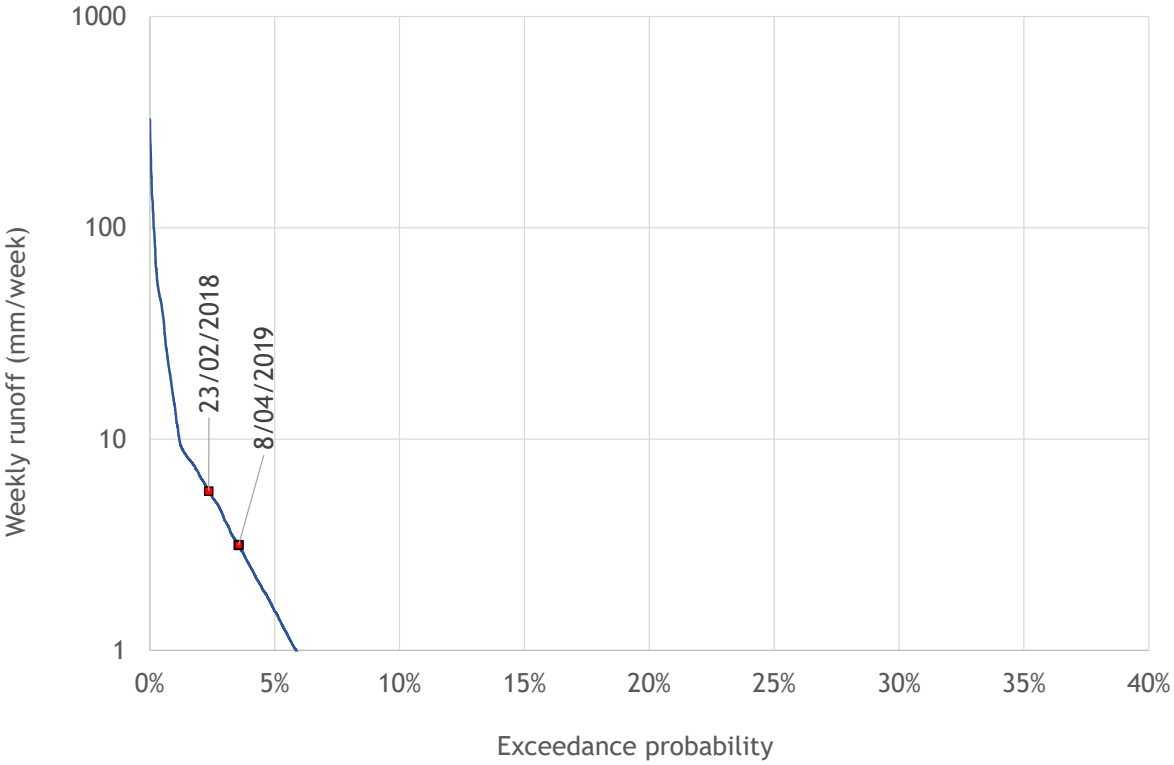

Figure 58 **Water Quality Monitoring Dates on Flow Frequency Curve**

Samples were analysed at a National Association of Testing Authorities (NATA) accredited laboratory for various physico-chemical parameters, metals, nutrients, hydrocarbons and pesticides and assessed against WQOs. Exceedances of WQOs are highlighted orange in Table 39 and Table 40.

Exceedances of WQOs for turbidity across all sites and years were observed, which can be attributable to soil erosion, runoff, pollution and algal blooms; however, some waterways can have naturally high levels of suspended solids and turbidity (Fondriest Environmental Inc. 2014).

Low levels of dissolved oxygen were observed across most sampling sites in 2018 and 2019. The low levels of dissolved oxygen were recorded in stagnant pools along ephemeral waterways, which naturally experiences dissolved oxygen values below 50% saturation (EHP 2011a). Therefore, these exceedances are not a reliable indicator of the long-term health of the system.

Petroleum hydrocarbons across sampling sites at the three waterways exceeded WQO values during the 2018 survey. Site DWR5, which is located upstream of Charlevue Creek, recorded the highest exceedance of petroleum hydrocarbons, which is mostly likely attributable to the agricultural and pastoral land uses close to or at this site. Although there were no recorded exceedances during the 2019 survey, it will continue to be closely monitored due to the existing and consistent local source of petroleum hydrocarbons.

Orange cells denote an exceedance of the WQO

Given the higher carbon chain fractions being reported, possible sources include; crude oil, heavy fuel oils, lubricating oils, asphalts and pitch and even waxes and other related products. Sites DWR1 (Stanley Creek) and DWI6 (Springton Creek) occur along the Capricorn Highway, which is a possible point source for the petroleum hydrocarbons observed at these locations.

Macroinvertebrate diversity, abundance and PET richness were generally low, which is reflective of the system's low waterway health at time of sampling.

All laboratory analysis results for dissolved metals, total metals, and petroleum hydrocarbons are presented in Appendix K.

7.2.4 Stream Sediment Quality

Stream Sediment Quality Objectives

Baseline levels of metals in stream sediments provide an additional indication of waterway health. Stream sediment quality sampling was carried out at all sites in 2018 and 2019. Samples were tested for various contaminants and results were compared to the SQG values listed in *Australian and New Zealand Guidelines for Fresh and Marine Water Quality* (ANZG 2018) (Table 41).

Table 41 SQG Objective Values

Contaminant	Sediment Quality Guideline Value (mg/kg)	
	Low Value	High Value
Arsenic	20	70
Cadmium	1.5	10
Chromium	80	370
Copper	65	270
Lead	50	220
Nickel	21	52
Mercury	0.15	1
Zinc	200	410

7.2.4.1 Stream Sediment Characteristics

Stream sediment quality was well below the relevant SQG low and high trigger values for all parameters except nickel, which exceeded the SQG low trigger value at DWR6 during both years. This site is located along an unnamed waterway which feeds into Springton Creek at DAI5.

Particle size analysis and particle size classification demonstrated that Stanley Creek (DWR1) the stream sediment is predominantly sand with small amounts of clay and silt. However, further downstream along Stanley Creek (DWI1), sediment is characterised as sand (92-96%) with negligible presence of gravel, silt or clay.

Charlevue Creek stream sediment is characterised by high percentages of sand (56-94%) at the majority of sites with variable levels of clay (1-24%) and silt (1-17%). Though minor, the presence of gravel was recorded across the sites along Charlevue Creek. Sites DWR4, DAI2, and DAI5 presented lower levels of sand (9-45%), and higher percentages of clay (25-41%) and silt (17-66%). Of these sites only DWR4 had higher levels of fine particles during both the 2018 and 2019 sampling periods. This site was located along a natural depression which flows into Charlevue Creek.

Along Springton Creek stream sediment levels vary between sites but remain consistent across sample years. Springton Creek itself is characterised by predominantly sand, with consistent levels of clay and silt.

Particle size analysis is presented graphically in Figure 60 and all stream sediment laboratory analyses are provided in Appendix K.

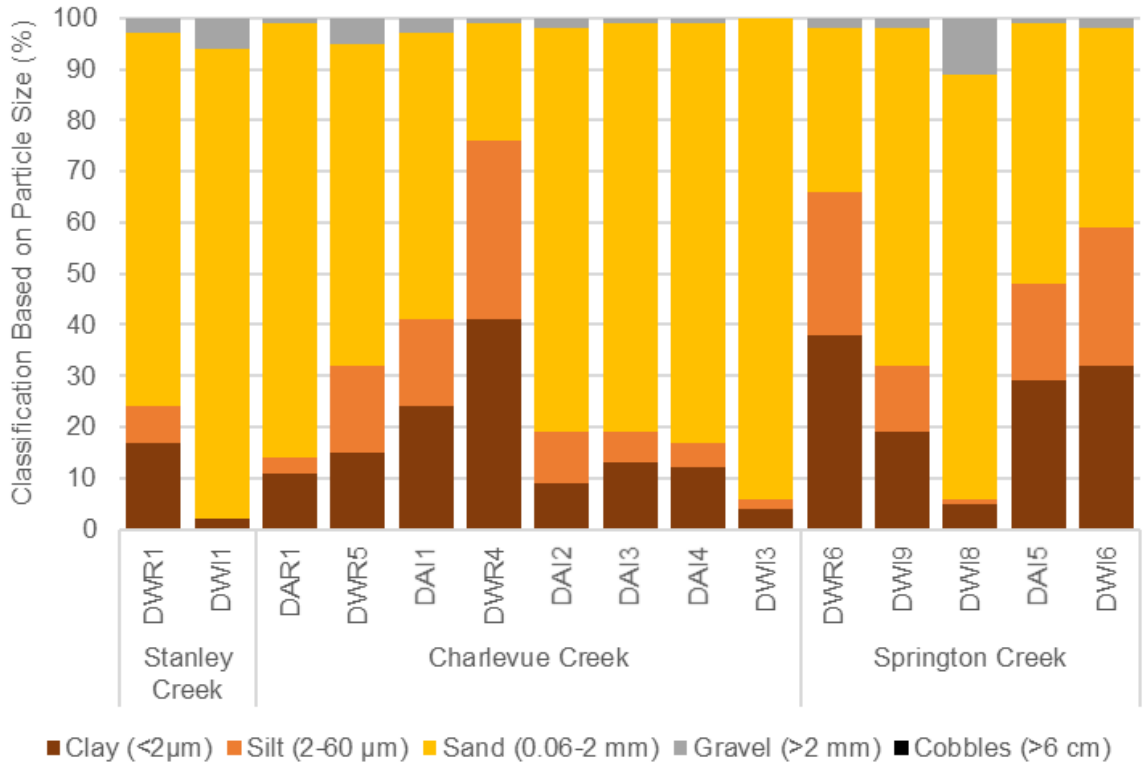

Figure 60 Stream Sediment Particle Size Analysis

7.2.5 Existing Flood Conditions

The *Flood Impact Assessment* (WRM 2020a) attached to Appendix B; defines existing flood conditions across the Project area for a range of design events, in terms of peak water level, peak velocity and water depth.

The XP-RAFTS flood model was used to estimate design discharges for the 50%, 10%, 2%, 1% and 0.1% AEP as well as the probable maximum flood (PMF) design discharge using an ensemble of design temporal patterns. In absence of gauged streamflow data, the resulting peak discharges were validated against the rational method and regional flood frequency estimation estimates (refer to Appendix B).

The XP-RAFTS modelling was then adopted as inflows to the TUFLOW hydraulic model to estimate flood extents and depths along the channel and floodplain of Charlevue Creek and Springton Creek for the nominated design events.

Under existing conditions, all flow generally remains contained within the Charlevue Creek and Springton Creek floodplain channels during a 50% AEP flood event with water depth of <1.5 m. The extent of flooding is more widespread during a 10% AEP event along the drainage features, with small areas of localised inundation with depth of up to 2.5 m along Charlevue Creek floodplains. This flood extent is generally consistent for the 2%, 1% and 0.1% AEP and PMF events, however, flood depth can increase up to 4 m in some areas along the floodplains and reaches up to more than 5 m in the main

channels. This predicted flooding regime is mainly attributable to the flat and undulating topography of the area.

Flood extent along the unnamed tributary of Springton Creek throughout all modelled AEP events are not widespread and are contained within close proximity to the main channel with shallow depths of up to 1.5 m. Peak flood depth reaches up to 2.5 m during the PMF event.

The general flooding patterns along the two drainage features indicate that flood velocity increases (up to 3.0 m/s) respective to decreasing AEP. Flood modelling also indicate lower flood velocity (less than 1.0 m/s) with further distance from the main creek channels.

Flood velocity during PMF event can reach a maximum of 4.0 m/s across most of the predicted flooding areas.

Figure 61 and Figure 62 illustrate the flooding extents, depths and velocity for 1% AEP event.

Graphical representation of all modelled existing flood conditions, showing extent, depth and velocity are provided in Appendix B.

7.3 POTENTIAL IMPACTS

The potential impacts of the Project on the surface water EVs include:

- impacts on regional water availability due to the potential need to obtain water from external sources to meet operational water requirements of mining operations;
- short-term and/or long-term loss of catchment area draining to local drainage paths due to capture of runoff within the SWMS and the open-cut pits;
- adverse impacts on the quality of surface runoff draining from the disturbed areas to the various receiving waters surrounding the Project;
- adverse impacts associated with the release of contaminants in MAW;
- impacts on flood levels at the Capricorn Highway and the Blackwater Railway upstream of the proposed rail loop and TLO facility; and
- potential impacts of the Project on flood levels and flood velocities of Charlevue Creek and Springton Creek.

7.3.1 Project Water Availability

Raw water for the Project will be sourced from the Bedford Weir, which is part of the Nogoa-Mackenzie River pipeline network, via a spur pipeline from the Blackwater Pipeline (see Section 3.5.2). The site water balance model indicates that due to the relatively low water requirements of the CHPP, the mine site water requirements of the Project can largely be sourced from water collected within the SWMS under average rainfall conditions. During low rainfall periods, the reliance of water supply from the external pipeline is expected to increase.

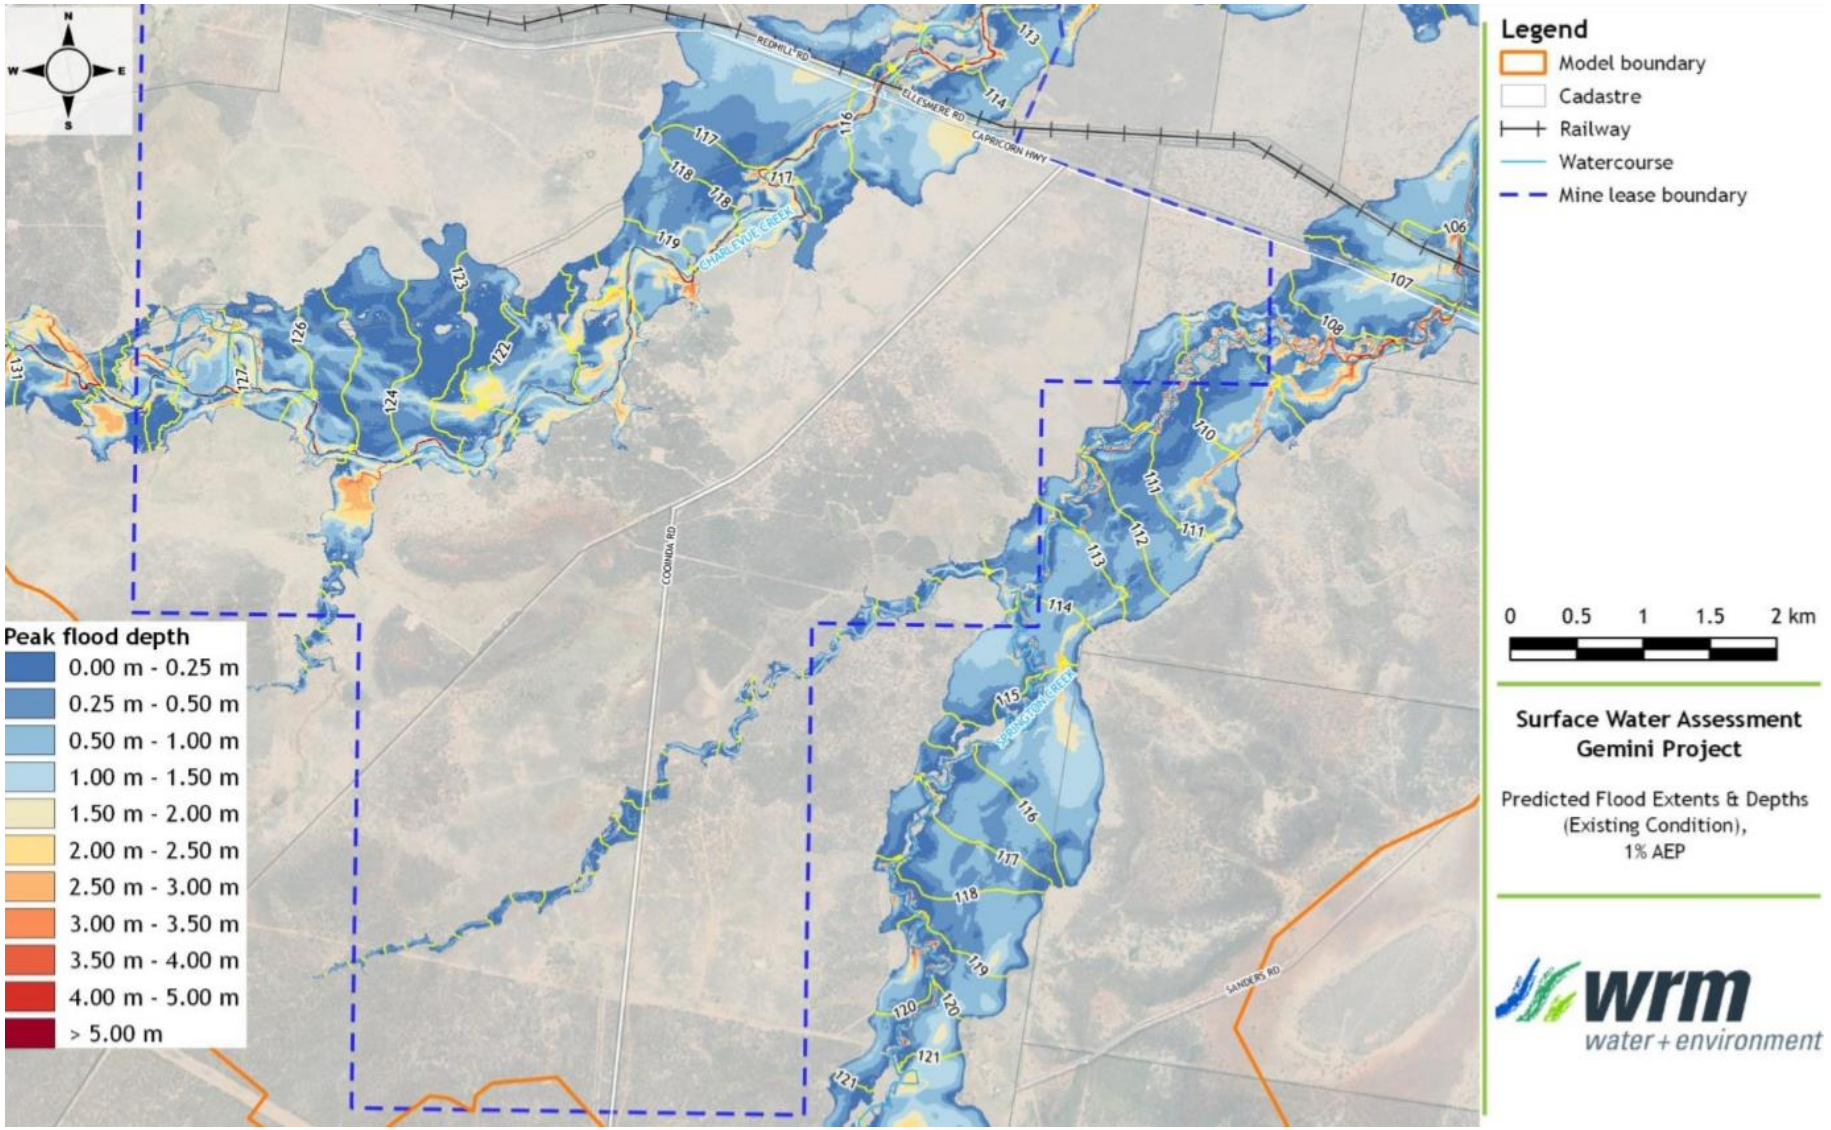

Figure 61 Predicted Flood Extent and Depth For Existing Conditions (1% AEP)

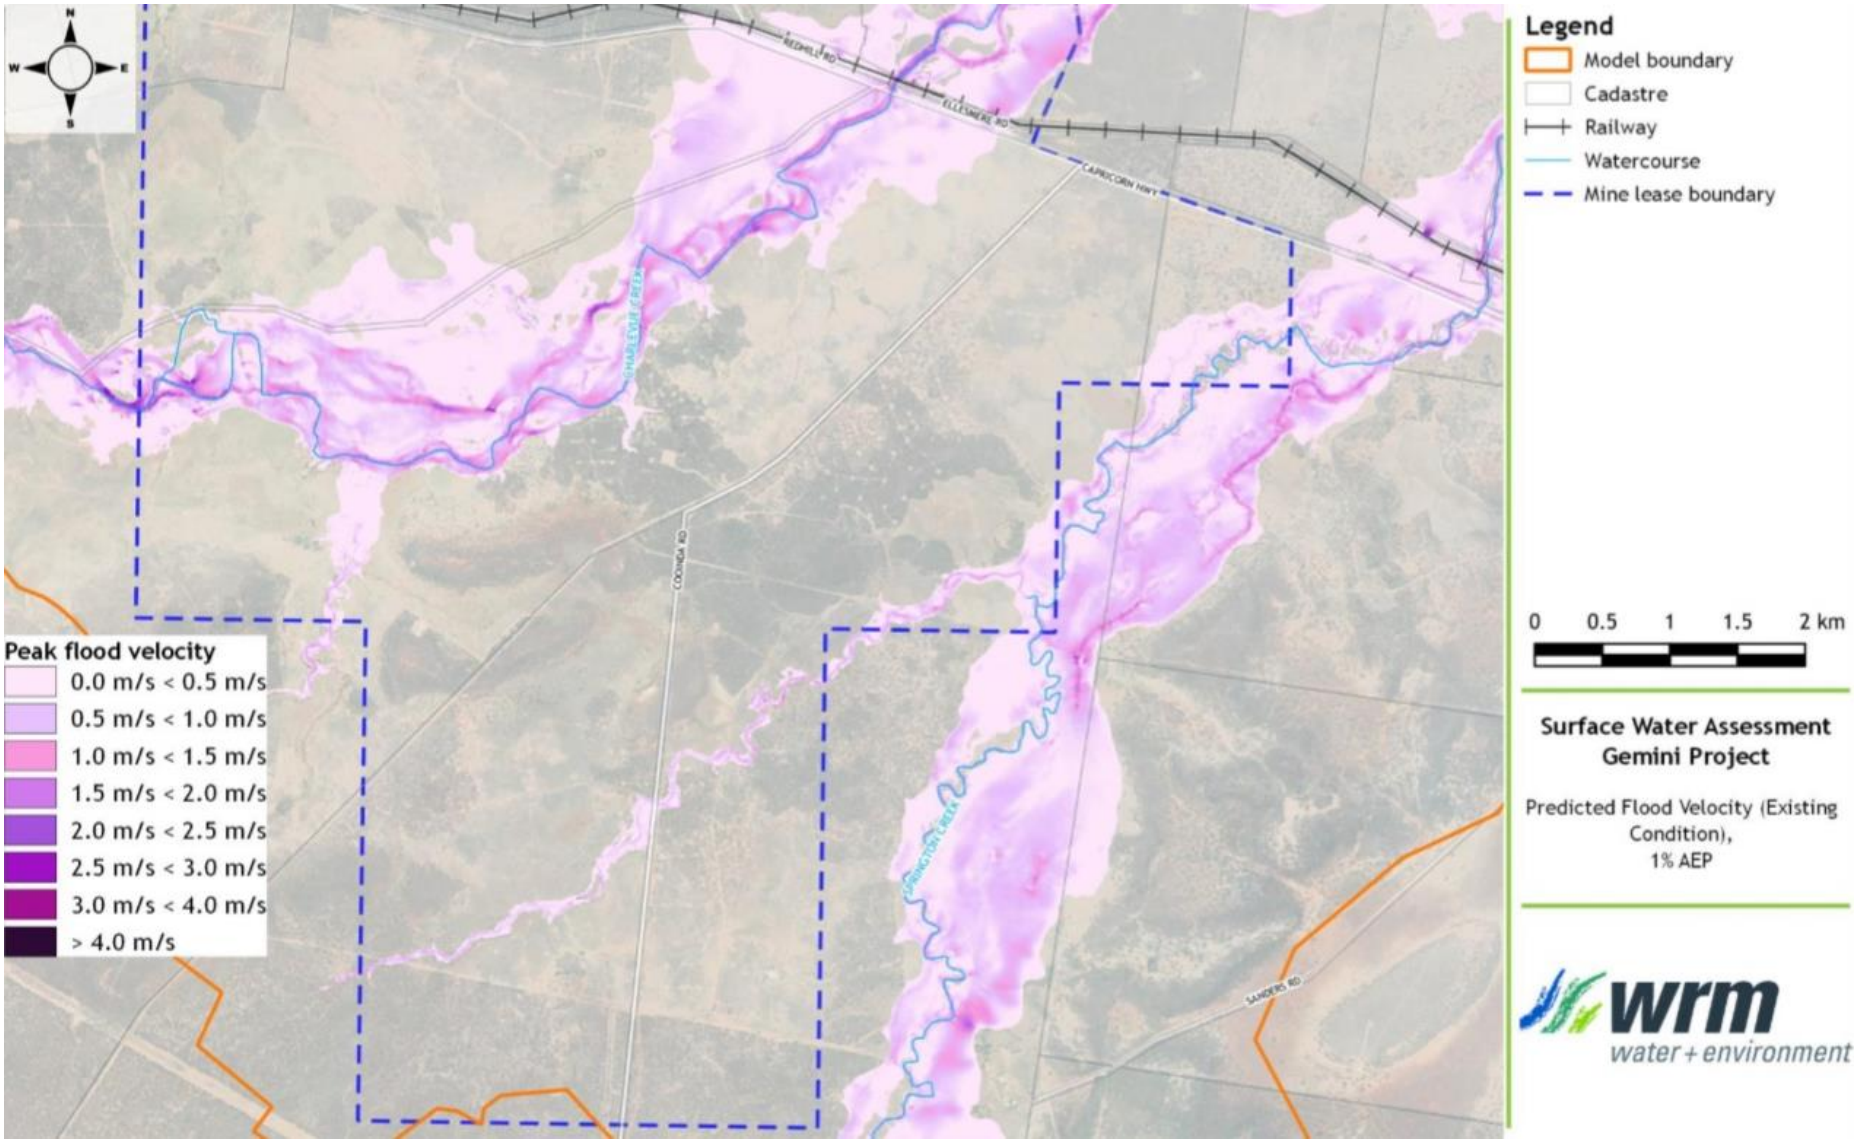

Figure 62 Predicted Flood Velocity for Existing Conditions (1% AEP)

Figure 63 demonstrates the raw water requirements from the pipeline based on the median model performance. Water requirements from the external pipeline are highest in the early Project stages. Under very dry conditions, the demand could reach 500 Ml/a, however, median demand for Year 1 is less than 100 Ml/a. During later years, accumulated stored pit and sediment dam water is sufficient to supply demands in all but the driest years.

The raw water supply contract will be sufficient to ensure continued operation even in the driest of years.

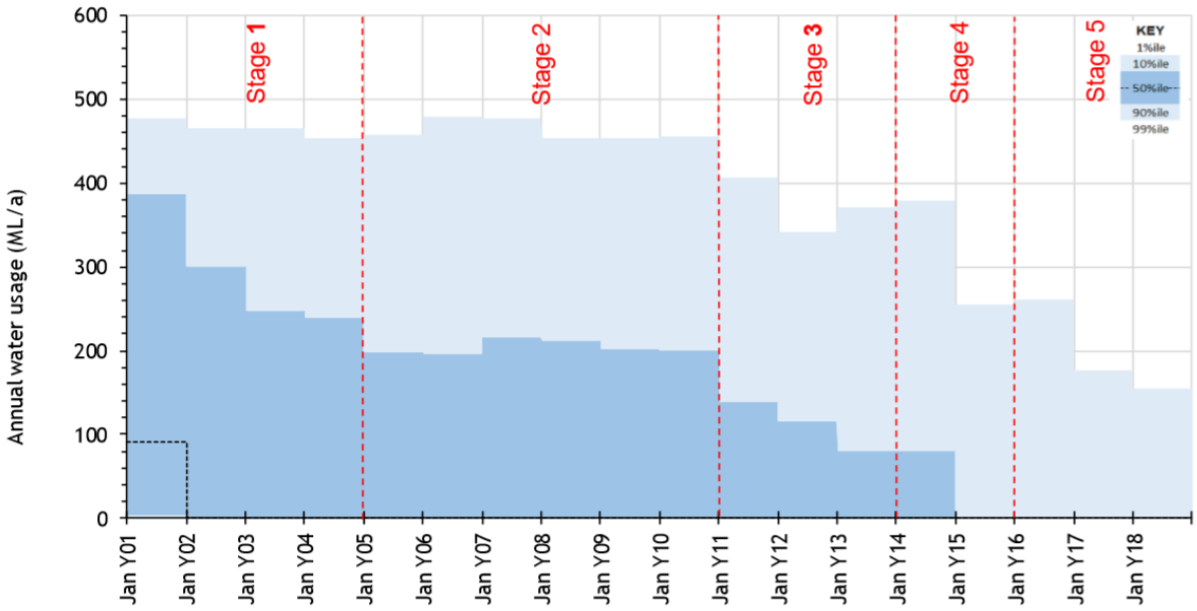

Figure 63 Raw Water Pipeline Usage

7.3.2 Loss of Catchment Area

During operations, the Project will intercept runoff from disturbed areas of the mine site. The SWMS will capture runoff from areas that previously would have flowed to receiving waters of Springton Creek and Charlevue Creek, and therefore, the catchment areas will change with the development of the Project (Table 42). The maximum captured catchment areas at Year 18 represent:

- 1.0% of Charlevue Creek catchment upstream of the confluence with Springton Creek;
- 3.6% of Springton Creek catchment upstream of the Charlevue Creek confluence; and
- 2.3% of the total combined Springton Creek catchment area, downstream of the confluence with Charlevue Creek.

Table 42 Catchment Intercepted by SWMS at Year 18

	Charlevue Creek Catchment	Springton Creek Catchment	Total Combined Catchment
	Upstream of Confluence		*Downstream of Confluence*
Total Area Intercepted by SWMS	336.9 ha	1,174.9 ha	1,511.8 ha
Total Catchment Area	32,243 ha	32,497 ha	64,740 ha
Proportion of Catchment Area Intercepted by SWMS	1%	3.6%	2.3%

After mine closure, the SWMS will be decommissioned with some residual impact on streamflow due to surface water runoff to the final voids from some areas (Table 43). The maximum captured catchment area at mine closure consists of approximately:

- 0.03% of Charlevue Creek catchment upstream of the confluence with Springton Creek;
- 1.1% of Springton Creek catchment upstream of the confluence Charlevue Creek; and
- 0.6% of the total combined Springton Creek catchment area, downstream of the confluence with Charlevue Creek.

Table 43 Catchment Intercepted by Final Void at Mine Closure

	Charlevue Creek Catchment	Springton Creek Catchment	Total Combined Catchment
	Upstream of Confluence		*Downstream of Confluence*
Total Area Intercepted by Final Void	10.0 ha	345.0 ha	355.0 ha
Total Catchment Area	32,243 ha	32,497 ha	64,740 ha
Proportion of Catchment Area Intercepted by Final Void	0.03%	1.1%	0.6%

The impact on environmental values as a result of this catchment loss is expected to be negligible, based on an estimate of the impact of catchment loss on the frequency of low flows, as illustrated in Figure 10.1 of Appendix B.

7.3.3 Impacts on Surface Water Quality

Land disturbance associated with mining has the potential to adversely affect the quality of surface runoff by increasing sediment loads and transporting contaminants from spoil and coal seams. However, with implementation of the SWMS, environmental risks resulting from disturbed area runoff are expected to be low.

MAW includes runoff from processing and coal stockpile areas, groundwater, and wastewater from the CHPP. This water will be contained in designated mine water dams onsite and will only be released in accordance with EA conditions.

Other runoff from disturbed areas, such spoil dumps, will be intercepted by sediment dams designed in accordance with the SWMS. Discharge from sediment dams directly into the receiving environment (after settlement of suspended sediments) would only occur during rainfall events. The discharge is expected to have insignificant impacts on water quality, as overburden runoff quality is expected to be relatively benign.

7.3.4 Mine Affected Water Releases

The results of the water balance modelling show no uncontrolled spills from the MAW system to receiving waters; as any unplanned overflows from mine water dams would overtop back into the pit. Additionally, the model results also show that the maximum modelled water level for both voids is well below the surface overflow level.

The release of MAW from the Project will occur in accordance with the *Model Mining Conditions* (DES 2017e) only; as set out in the EA. Relatively small volumes of water are expected to be released to Charlevue Creek, primarily due to the relatively low and infrequent flows in this waterway. Such release events would likely only occur post significant rainfall and flow within local catchments. Such conditions present opportunity for release without environmental harm, while reducing the risk of accumulating legacy water in the void. The proposed EA conditions for water release are provided in Section 15.0.

7.3.5 Post-mining Final Void Lakes

Pit AB and Pit C is proposed to be backfilled progressively during mining, with two final voids at the end of mining which will meet the rehabilitation objectives addressed in Section 4.3. Key water inputs in the voids include rainfall on pit lake water surfaces, runoff from pit faces and rehabilitated upstream catchment areas and groundwater interception. Further information regarding the final void configuration has been addressed in Section 4.4.7.1 and Table 21.

The voids are intended to be partially backfilled to a level that prevents the interchange of water between the coal seams and the lakes, resulting in lower water levels and salinities than would otherwise be the case. Backfilling with waste rock material will elevate the void floor above the level of groundwater flows to prevent pit water transiting into any aquifers.

The final pit floor of Pit AB will be at an elevation of approximately 40 mAHD, which is 72 m below the natural surface elevation. Pit C final pit floor will be at an elevation of approximately 60 mAHD or approximately 60 m below the natural surface elevation. Final void modelling suggests that during the first 200 years after closure, lake salinities will be less than 10,000 mg/L. After 500 years salinity is conservatively modelled to increase to 30,000 mg/L, however, modelling is based on an assumption that salt levels in spoil leachate do not decline over time.

Final voids were modelled to remain as a groundwater sink and do not present a risk of overtopping. The maximum modelled water level for Pit AB is 57.6 mAHD, which is approximately 54 m below the void overflow level/natural surface elevation (112 mAHD). Similarly, the maximum modelled water level for Pit C is around 73.5 mAHD, which is 54.4 m below the void surface overflow level/natural surface elevation of approximately 128 mAHD. Modelled water levels in the voids are presented in Table 44.

Table 44 Final Void Surface Water Model

Water Level	Pit AB (mAHD)	Pit C (mAHD)
Long term equilibrium water levels	52.9	70.3
Maximum long-term water levels	57.6	73.5
Minimum long-term water levels	47.4	66.0
Overflow level at natural surface	112.0	128.0

7.3.6 Impacts on Flooding

As part of the *Flood Impact Assessment* (WRM 2020a), modelling was undertaken to determine the change in flood behaviour in Charlevue Creek, Springton Creek and its unnamed tributary during developed conditions. The results are as follows:

- the Project will temporarily increase Charlevue Creek flood levels immediately upstream of the proposed haul road crossing. In a 1% AEP flood event, these impacts are contained within the MLA (Figure 64);

- the works at Pit AB will increase flood levels in Springton Creek by up to 0.22 m in a 1% AEP flood (Figure 65). These impacts would extend off-lease onto land owned by Magnetic South, and reduce with distance downstream of the boundary;

- there will be localised off-lease impacts on flood levels in the unnamed tributary of Springton Creek immediately upstream of Pit AB and Pit C;

- the proposed rail loop will not have an impact on Charlevue Creek or Springton Creek flooding;

- there will be no impact on flood levels at these waterways at Capricorn Highway, Blackwater Railway, or downstream of the Project;

- there are four locations where (based on the flood model results) floodwaters could potentially come into contact with the overburden dumps:

    - north-eastern end of Pit C – due to flow backing up to the west of the haul road crossing of the engineered drainage feature. Modelled flow velocities in this area are less than 0.4 m/s in the 0.1% AEP design flood, and would therefore not cause the migration of sediment from the final landform;

    - western side of Pit AB – due to water backing up a minor tributary of Charlevue Creek. Flow velocities in this area are expected to be less than 0.2 m/s, and therefore the likelihood of migration of sediment from these dumps is minimal;

    - eastern side of Pit AB – due to flow on the left (western) floodplain of Springton Creek. Flow velocities against the final landform are modelled to be less than 1.2 m/s in the 0.1% AEP flood, and therefore the likelihood of erosion of the dump toe is minimal; and

    - southern side of Pit AB – due to water overflowing from the unnamed tributary of Springton Creek upstream of the inlet to the engineered drainage feature. During operations, this section of the dump would be protected by a temporary levee, which would be incorporated into the final landform profile on closure. In events up to the 0.1% AEP design flood, modelled flow velocities are less than 1 m/s along most of the length of the proposed levee. Such flows would be non-erosive – and especially given the relatively short flow durations in this small catchment, the risk of migration of sediment in floodwaters would be minimal. During detailed design of the engineered drainage feature, provision will be made to ensure that flows will be non-erosive along the final landform post-closure.

Graphical representation of all modelled developed flood conditions, showing extent, depth and velocity are provided in Appendix B.

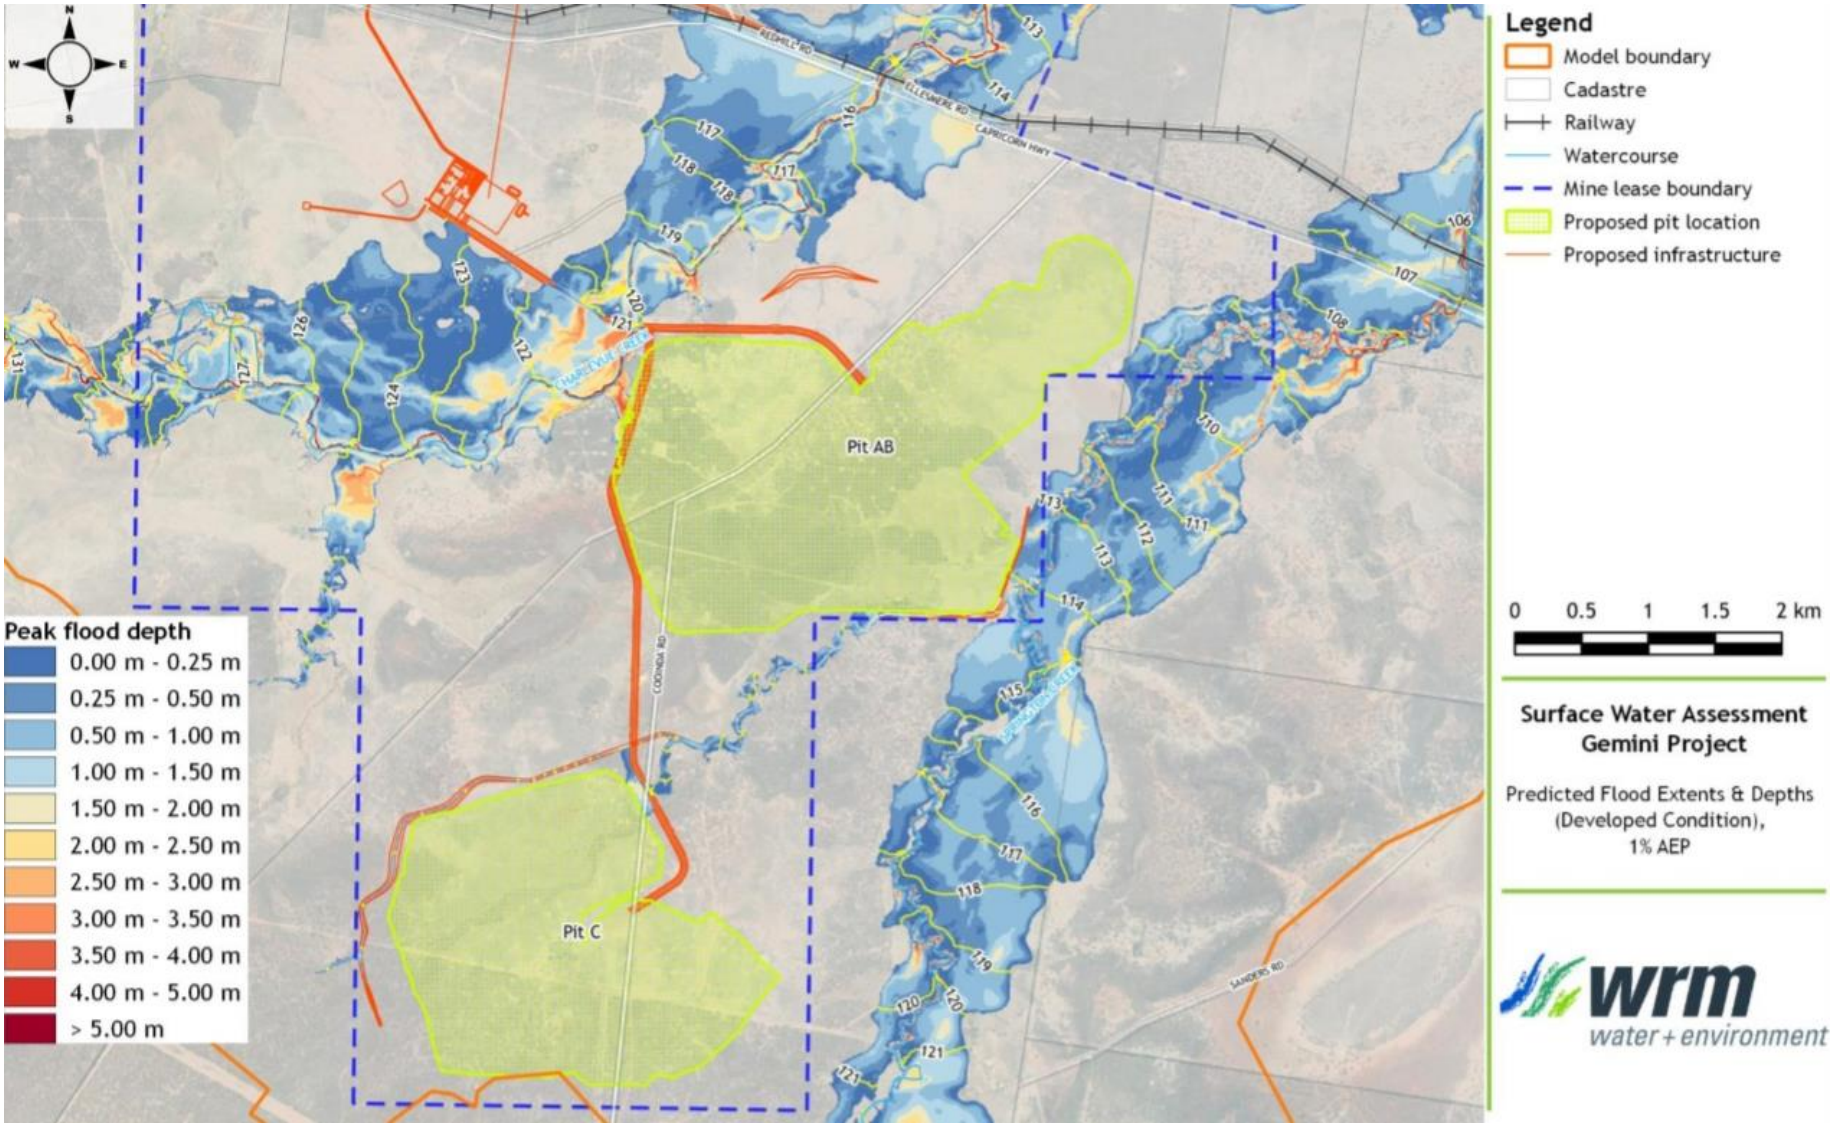

Figure 64 Predicted Flood Extent and Depth for Developed Conditions (1% AEP)

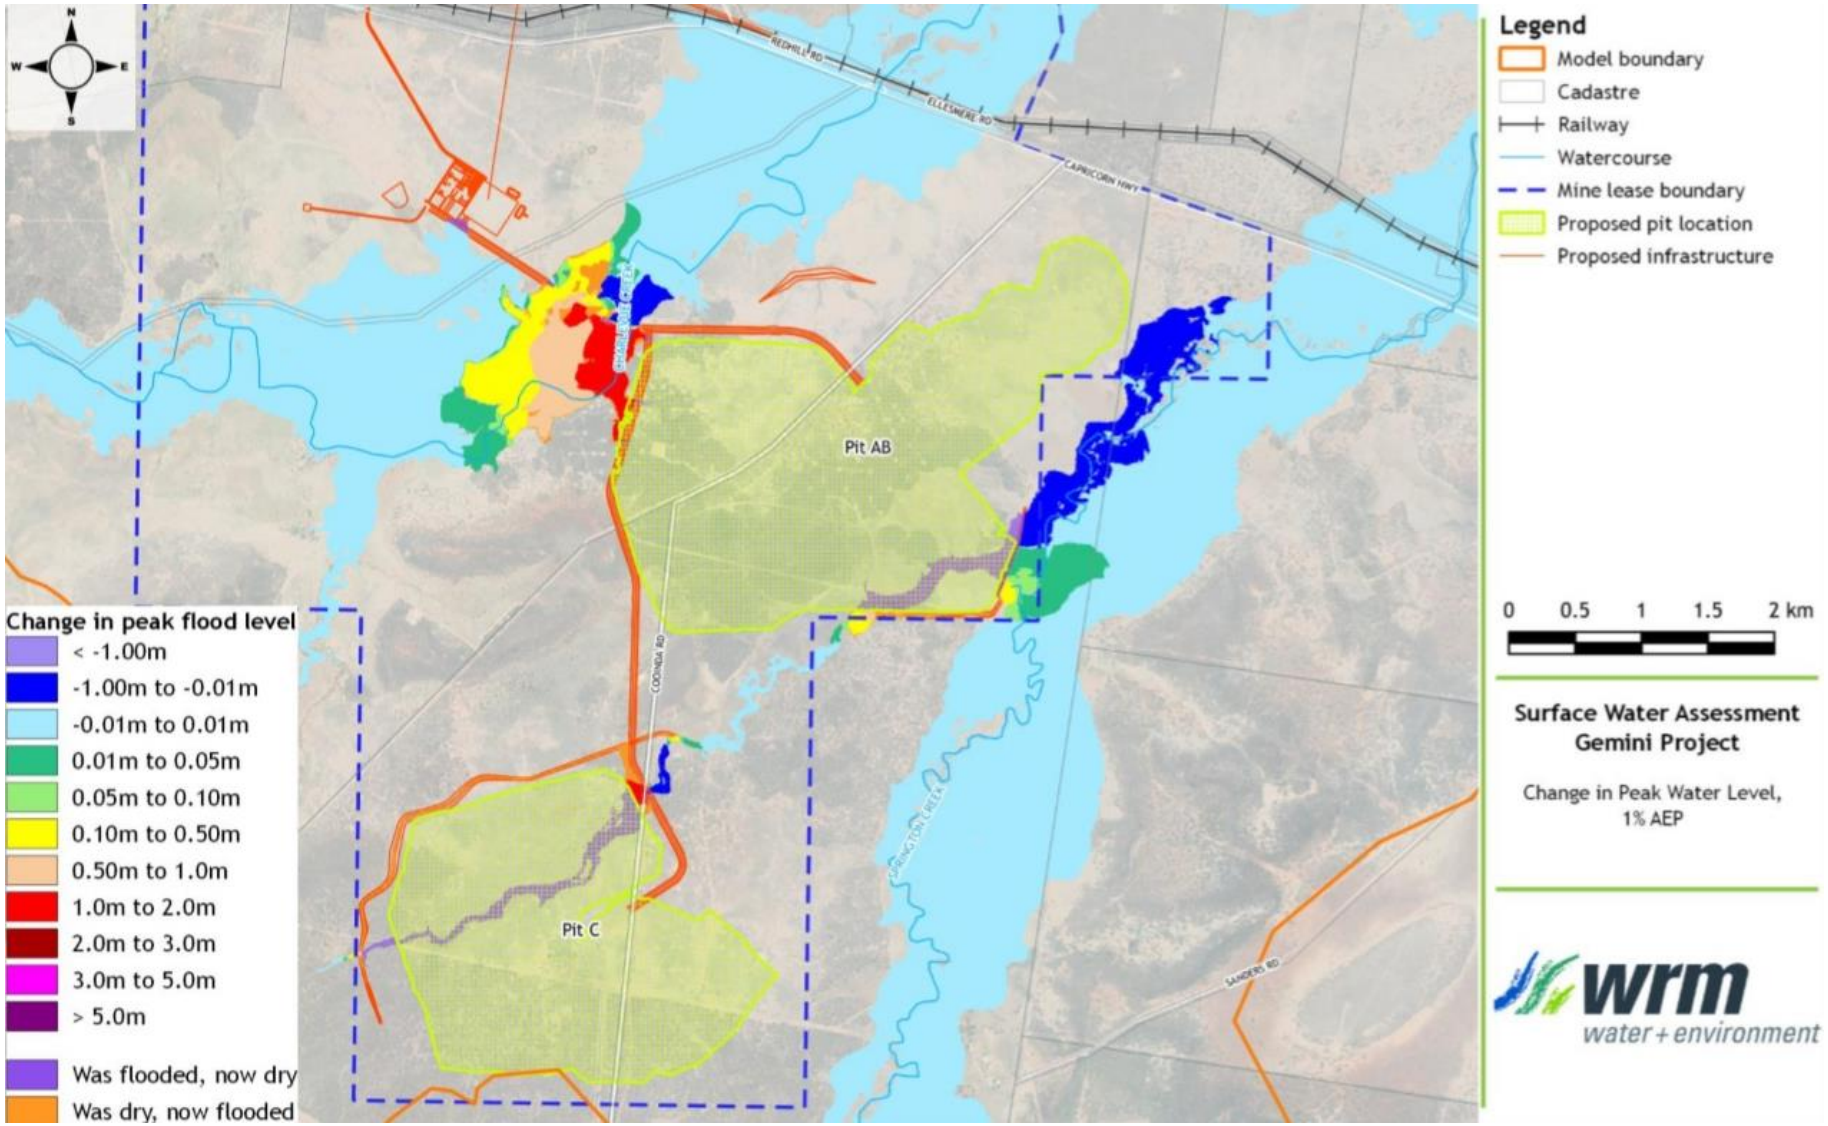

Figure 65 Change in Peak Flood Level from the Project (1% AEP)

7.3.7 Cumulative Impacts

Bluff PCI Project, located approximately 12 km west of the Project, is the nearest operation to the Gemini Project, and also contributes to the Springton Creek catchment, downstream of both Projects (Figure 57). The Walton Coal Project is proposed within the same catchment. The Bluff PCI Project and Walton Coal Project are of relatively small scale and short mine life.

Water supply for the Bluff PCI Project and Walton Coal Project are to be partially sourced from the Jellinbah Mine. Therefore, the potential cumulative impacts of these projects on flows in Springton Creek will be minimal.

Waterways that traverse the Gemini Project eventually flow into the Mackenzie River, which is a major tributary within the Fitzroy River basin. The Fitzroy River basin is the largest catchment in Queensland; draining into the Pacific Ocean and also the largest catchment draining into the Great Barrier Reef. However, it does not contribute significant freshwater flows to the coastal environment when compared to river systems further north.

Potential impacts (increased sediment load and salinity) on the water quality of the Fitzroy River basin and the connecting tributaries in the catchment will be mitigated through the use of the SWMS, including sediment basins, progressive rehabilitation, spill controls, release controls and water quality monitoring.

Provided that uncontrolled and controlled releases from the three Projects are managed in accordance with respective EA conditions, the proposed management approach for mine water from the Gemini Project is expected to have negligible cumulative impact on surface water quality and associated EVs.

Given the scale and nature of the three projects, cumulative impacts on flooding are not expected to lead to any adverse impacts on human populations, property or other environmental or social values.

7.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

7.4.1 Site Water Management Plan

The *Site Water Management Plan* will be developed in accordance with the Project's proposed EA conditions and will be informed by the *Surface Water Assessment* (Appendix B). The overarching objectives for the *Site Water Management Plan* is to minimise the impact of the Project's activities on the environmental values of the Project site and surrounding environment. The *Site Water Management Plan* will:

- minimise the use of clean water on site;
- minimise the requirement to source water from external supplies;
- minimise impacts on the receiving environment;
- minimise the impacts of flooding on mining operations; and
- minimise cumulative impacts with other mines in the region.

The Project's *Site Water Management Plan* will include the following components:

- an overview of the water management strategy and a description of the site water balance;
- design details of water management infrastructure;

- a description of baseline environmental values and water quality trigger values;
- reference to *a REMP* and *Groundwater Monitoring Program*;
- a description of the monitoring locations, methods, and reporting procedures for a *Site Water Management Monitoring Program*;
- a risk assessment to determine the risk of contaminates on the receiving environment;
- a response procedure for the reporting of unexpected exceedances of water quality trigger values;
- the reporting requirements and annual review process applicable to the Project's *Site Water Management Plan;* and

The *Site Water Management Plan* will focus on minimising impacts to surface water and groundwater quality and resources in accordance with the management hierarchy. The management hierarchy for surface water and groundwater as set out in the EPP (WWB) requires that, to the extent that it is reasonable to do so, surface water and groundwater impacts must be dealt with in the following order of preference:

- reduce the production of wastewater or contaminants by reducing the use of water:
- prevent waste and implement appropriate waste prevention measures;
- evaluate treatment and recycling options and implement appropriate treatment and recycling;
- evaluate the options for wastewater or contaminants in the following order of preference:
    - appropriate treatment and release to a waste facility or sewer;
    - appropriate treatment and release to land; and
    - appropriate treatment and release to surface waters or groundwaters.

Reduce the production of wastewater or contaminants by reducing the use of water

The production of wastewater or contaminants by reducing the use of water will managed through the following;

- defined operating rules for water related activities (refer Table 6.7, *Surface Water Impact Assessment,* Appendix B); and
- through the use of water efficient infrastructure including the use of belt press filters in the CHPP.

Prevent wastewater and implement appropriate waste prevention measures

The mine affected water system is a closed system designed to prevent the releases of mine affected water to the environment. Overflows of the Mine Water Dam have been designed to be directed via a diversion drain to the mine pit. The mine affected water system will manage runoff and seepage form the mine pits, CHPP, coal stockpiles and MIA. There is some potential for seepage of water from the Mine Water Dam to Charlevue Creek. This dam will be designed with a floor and sides of material that will limit seepage to avoid environmental harm.

The sediment water system is designed to capture sediments transported from runoff from overburden dumps. Overburden runoff quality is expected to be relatively benign and will potentially discharge to the receiving environment. The sediment water system will be managed under an *Erosion and Sediment Control Plan.*

Clean water from undisturbed areas is generally diverted around the areas of disturbance.

The *Site Water Management Plan* will manage water storages and transfers within the site in order to maximise onsite storage to meet reasonably anticipated periods of wet and dry weather.

Evaluate treatment and recycling options and implement appropriate treatment and recycling

The *Site Water Management Strategy* has been designed to promote the use/recycle lesser quality water in preference to higher quality water and to use potentially contaminated water in preference to imported raw water or uncontaminated water through the transfer of water onsite where:

- The Mine Water Dam receives pumped groundwater and surface runoff dewatered from Pit AB and Pit C. Water will be transferred from the Mine Water Dam for reuse at the CHPP, to meet the TLO water demands and for other uses as required.

- The TLO Dam comprises a series of sediment traps and small drainage dams that will be used to capture washdown and overflow from trains and sumps before it is directed to the TLO Dam. Water collected in this small dam will pumped to the Mine Water Dam.

Evaluate the options for wastewater or contaminants

To avoid significant downstream impacts, the system has been designed to achieve a high level of containment without the need for controlled releases. However, should water quality allow, the release water from site only in accordance with the conditions of the EA, such that the released water will not significantly impact on the values of the receiving waters or downstream properties;

Any unplanned overflows from the Mine Water Dam, would overflow to the mine pit. The only potential mine water release points are the MIA Dam spillways. However, these dams will be operated in such a way that the risk of release is small. Runoff from overburden dumps will be managed under an erosion and sediment control plan to reduce sediment loads to background levels before release. Water would be discharged either via sediment dam spillways or perforated riser pipes.

The potential impacts on receiving water quality and downstream flow are to be managed by the SWMS, which are discussed in Section 3.4. This includes:

- clean water drains to divert two sections of the unnamed tributary of Springton Creek around disturbed areas;

- sediment water drains to divert water from waste rock emplacement areas, and areas yet to be rehabilitated;

- sediment water dams to store water from waste rock emplacement areas and allow settlement of sediment loads before discharging treated water or recycling back to the CHPP;

- mine water drains to divert water from MIA, CHPP and coal stockpile areas into the MAW system; and

- mine water dams to store water pumped out of the pit, and capture water from the MIA, CHPP and coal stockpile areas.

7.4.2 Mine Affected Water Release

If any controlled releases are to occur, it would be in accordance with the EA conditions; consistent with the *Model water conditions for coal mines in the Fitzroy basin [ESR/2015/1561]* (DES 2013). The model conditions provided in this document are used as a basis for proposing specific water related protection commitments of EVs in the application documentation. The conditions include minimum flow and quality criteria and include commitments for monitoring during release events.

Section 6.9 of the *Surface Water Assessment* (WRM 2020b) outlines the potential for accumulation of water in the mine water dam and the mine pits. The mine water dam would overflow to Pit AB. The results show that the risk of discharge from the Pits is negligible, and that mining operations could be sustained in the long-term by transferring excess water to Pit AB once mining there was complete. The likelihood of discharging mine affected water from the pit MAW system is minimal. As mentioned previously, at the MIA and CHPP, the MAW system has been sized to ensure the likelihood of discharge is small.

Water would only be discharged from the system when there are significant flows in the receiving waters in accordance with the EA conditions.

7.4.3 Flood Mitigation

The proposed mine operations and associated infrastructure are largely located outside of Charlevue Creek and Springton Creek flood inundation areas, as illustrated in Figure 64.

Flood management controls for the Project include construction of a temporary flood protection levee for Pit AB. The flood levee design will ensure that the mine void is outside the 0.1% AEP flood event as well as the PMF event during operations and at final landform. Design of the flood level is provided in Section 3.4.3.1.

Clean water drains are also designed to divert clean water from the unnamed tributary of Springton Creek around disturbed areas; largely Pit AB and Pit C. It is therefore proposed that the design of the drains will take into account key design principles and requirements for the functionality of permanent diversions, including for operations, maintenance, monitoring and revegetation.

7.4.4 Receiving Water Monitoring

The *Aquatic Ecology Assessment* (AARC 2020a) (Appendix K) identified exceedances of regional WQOs, including high turbidity and suspended solids in the existing receiving waters. In this instance, the regional WQOs have not been considered a reliable indicator of the local system's long-term health. Site-specific reference/baseline values will be developed after a period of monitoring to assess future local water quality data. As a result, water quality in surrounding the Project will be monitored in accordance with a REMP that has been detailed below.

7.4.4.1 Receiving Environment Monitoring Program

A REMP Design Document has been developed for the Project in accordance with the *Model Mining Conditions* (DES 2017e) to demonstrate compliance with the EA release conditions. The REMP Design Document has detailed:

- release characteristics (quality and quantity);
- environmental values of the receiving environment that may be affected by a release and need to be enhanced and protected under the EPP (WWB);

- spatial extent of suitable test sites (including the location of monitoring sites and a controlled background reference);
- temporal context (including timing and frequency of sampling);
- monitoring indicators (including physical, chemical and biological);
- water quality objectives to measure chosen indicators;
- methodologies; and
- all implemented quality control and assurance procedures.

The REMP Design Document speculates that monitoring measures will be undertaken in line with Queensland's *Monitoring and Sampling Manual 2009* (DES 2018c) during periods of stream flow, ideally towards the end of the wet season, when safe access is available, and will include the following measures:

- monitoring of water quality parameters, including but not limited to; pH, EC, major anions (sulphate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS, and a broad suite of soluble metals/metalloids;
- sediment and macroinvertebrate sampling;
- visual records of vegetation;
- stream morphology; and
- stream flow (level and velocity).

Data collection during the REMP will be undertaken annually at the two downstream sites and two upstream sites of the Project (Table 45) to compare background data and ensure any impacts to the local receiving environment are accurately reflected in the results of the REMP report.

Table 45 Receiving Water Monitoring Locations

Description	Location in Relation to the Project	Latitude	Longitude
Springton Creek US	Upstream	-23.6976	149.2738
Springton Creek DS	Downstream	-23.6434	149.3145
Charlevue Creek US	Upstream	-23.6305	149.2715
Charlevue Creek DS	Downstream	-23.6469	149.2104

Notes: Coordinates relevant to GDA94.

Monitoring will also occur at these locations during any controlled release of mine affected water. The receiving water thresholds that govern release opportunities are, pH (6.5 - 8.5), EC 310 µS/cm and sulphate 10 mg/L with streamflow parameters yet to be determined until a streamflow gauge is installed along Charlevue Creek. Under these provisions, the release of mine affected water into Charlevue Creek will only occur during periods of natural stream flow; and when receiving conditions are able meet the thresholds required to maintain relevant site-specific baseline water quality values.

Further details on the management of the receiving environment are provided in the REMP Design Document (Appendix Q).

7.4.5 Site Water Management System Monitoring

Onsite SWMS monitoring will be implemented to validate the SWMS performance against the design assumptions regarding water quality and water quantity. Monitoring will be specifically undertaken at the mine water dams and sediment dams. If required, adaptive management decisions will be undertaken where necessary to ensure protection of the surface water environment.

Mine Water Dam Monitoring

Any surface runoff and seepage water collected in mine water dams and the process water dam will be monitored for 'standard' water quality parameters including, but not limited to; pH, EC, major anions (sulphate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS and a broad suite of soluble metals/metalloids.

Sediment Dam Monitoring

Monitoring of sediment dams will be used to validate the anticipated runoff quality reporting to sediment dams and haul road runoff dams. Initial monitoring will occur on a regular (e.g., monthly) basis to demonstrate the water quality of stored waters is consistent with the relevant operating parameters to allow releases from sediment dams to occur when required. Subject to demonstrating water quality is in accordance with the WQOs, the frequency of monitoring and suite of parameters for the sediment dam monitoring will be reviewed and updated accordingly when a release occurs.

8.0 GROUNDWATER

This section provides a description of the existing groundwater values within and surrounding the Project. It aims to identify the Project's potential impacts on the existing values and propose mitigation measures and management strategies to prevent or minimise adverse environmental effects.

This section is informed by the *Groundwater Impact Assessment* (JBT 2019) presented as Appendix C.

Surface water values have been discussed in Section 7.0, and GDEs within Section 6.0, and groundwater inflows are discussed in Section 3.4.5 and Section 4.0.

8.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objective relevant to potential impacts to groundwater as described in the EA guideline for *Application requirements for activities with impacts to water [ESR/2015/1837]* (DES 2017c) is:

The activity will be operated in a way that protects the environmental values of groundwater and any associated surface ecological systems.

The Project would achieve one of the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation whereby:

1. *both of the following apply:*

    (a) *there will be no direct or indirect release of contaminants to groundwater from the operation of the activity; and*

    (b) *there will be no actual or potential adverse effect on groundwater from the operation of the activity; or*

2. *the activity will be managed to prevent or minimise adverse effects on groundwater or any associated surface ecological systems.*

8.2 DESCRIPTION OF ENVIRONMENTAL VALUES

The EPP (WWB) describes EVs to be protected or enhanced in Queensland. The Project is located within the 'Mackenzie Groundwaters' region within the broader Fitzroy Basin. The EVs identified on the *WQ1310 – Fitzroy Basin Groundwater Zones map* (EHP 2011b) for this region and their relevance to the Project are:

- **aquatic ecosystems:** values that are potentially associated with groundwater include those that support GDEs and are discussed in Section 6.0;
- **cultural & spiritual:** the groundwater that may be impacted by the Project is not known to have any cultural and spiritual value;
- **industrial use:** the groundwater that may be impacted by the Project may be suitable for industrial purposes, however, other than coal mining, there is no known industrial users of groundwater;
- **agricultural purposes:** groundwater use for agricultural purposes is limited to livestock and is discussed in Section 8.2.2; and

- **drinking water:** the groundwater that may be impacted by the Project is not known to be used as a drinking water supply due to its poor quality, as discussed in Section 8.2.2.

The values relevant to the MLA and surrounding area include:

- agricultural uses, where groundwater is extracted from surrounding agricultural bores; and
- aquatic ecosystems, where shallow groundwater may support GDEs in some capacity.

The *Groundwater Impact Assessment* (JBT 2019) (Appendix C) describes site-specific EVs in detail. The following sections provide a summary.

8.2.1 Geology and Hydrogeology

The surface geology of the Project predominantly comprises sediments of the Tertiary Duaringa Formation and Quaternary alluvium associated with ephemeral creeks. The underlying Bowen Basin solid geology is illustrated in Figure 66, showing the Project location in relation to the underlying Triassic and Permian sediments, as well as the prevalence of regional-scale faults. The target mining areas are located where folding has brought the coal seams closer to the surface at economically mineable depths.

There are 48 registered bores (listed as 'existing' or 'abandoned but useable') within 10 km of the MLA, with the majority of bores screened within Tertiary units (26 bores) or the Permian coal measures (15 bores). Aquifer data and groundwater EC data from the Department of Natural Resources, Mines and Energy (DNRME) groundwater database is displayed in Figure 67, and detailed in Table 4-5 of Appendix C.

The Project comprises a groundwater monitoring bore network of 38 bores at 17 sites (Figure 68), with locations detailed in Table 4-1 of Appendix C.

Analysis of available monitoring data from these regional and local bore networks concludes that groundwater occurs within three main groundwater units at site, including:

- Quaternary alluvium associated with Charlevue Creek and Springton Creek;
- Tertiary sediments of the Duaringa Formation; and
- Permian Rangal Coal Measures, where groundwater occurs preferentially within the coal seams.

A minor occurrence of Tertiary basalt has been identified from geological drilling to the north of Pit C. The area of basalt is approximately 600 m long, 200 m wide and 20 m thick and has been interpreted as a localised basalt paleochannel (JBT 2019). One groundwater monitoring bore has been located within the basalt (bore DW7105W1); the bore is 23 m deep and the basalt is dry at the bore location. The basalt flow is interpreted to be dry (as it is above the regional groundwater level) and of limited extent and is therefore not an important groundwater feature within the project area. Extensive geological drilling across the project area has shown no other evidence of basaltic flows or intrusions (JBT 2019).

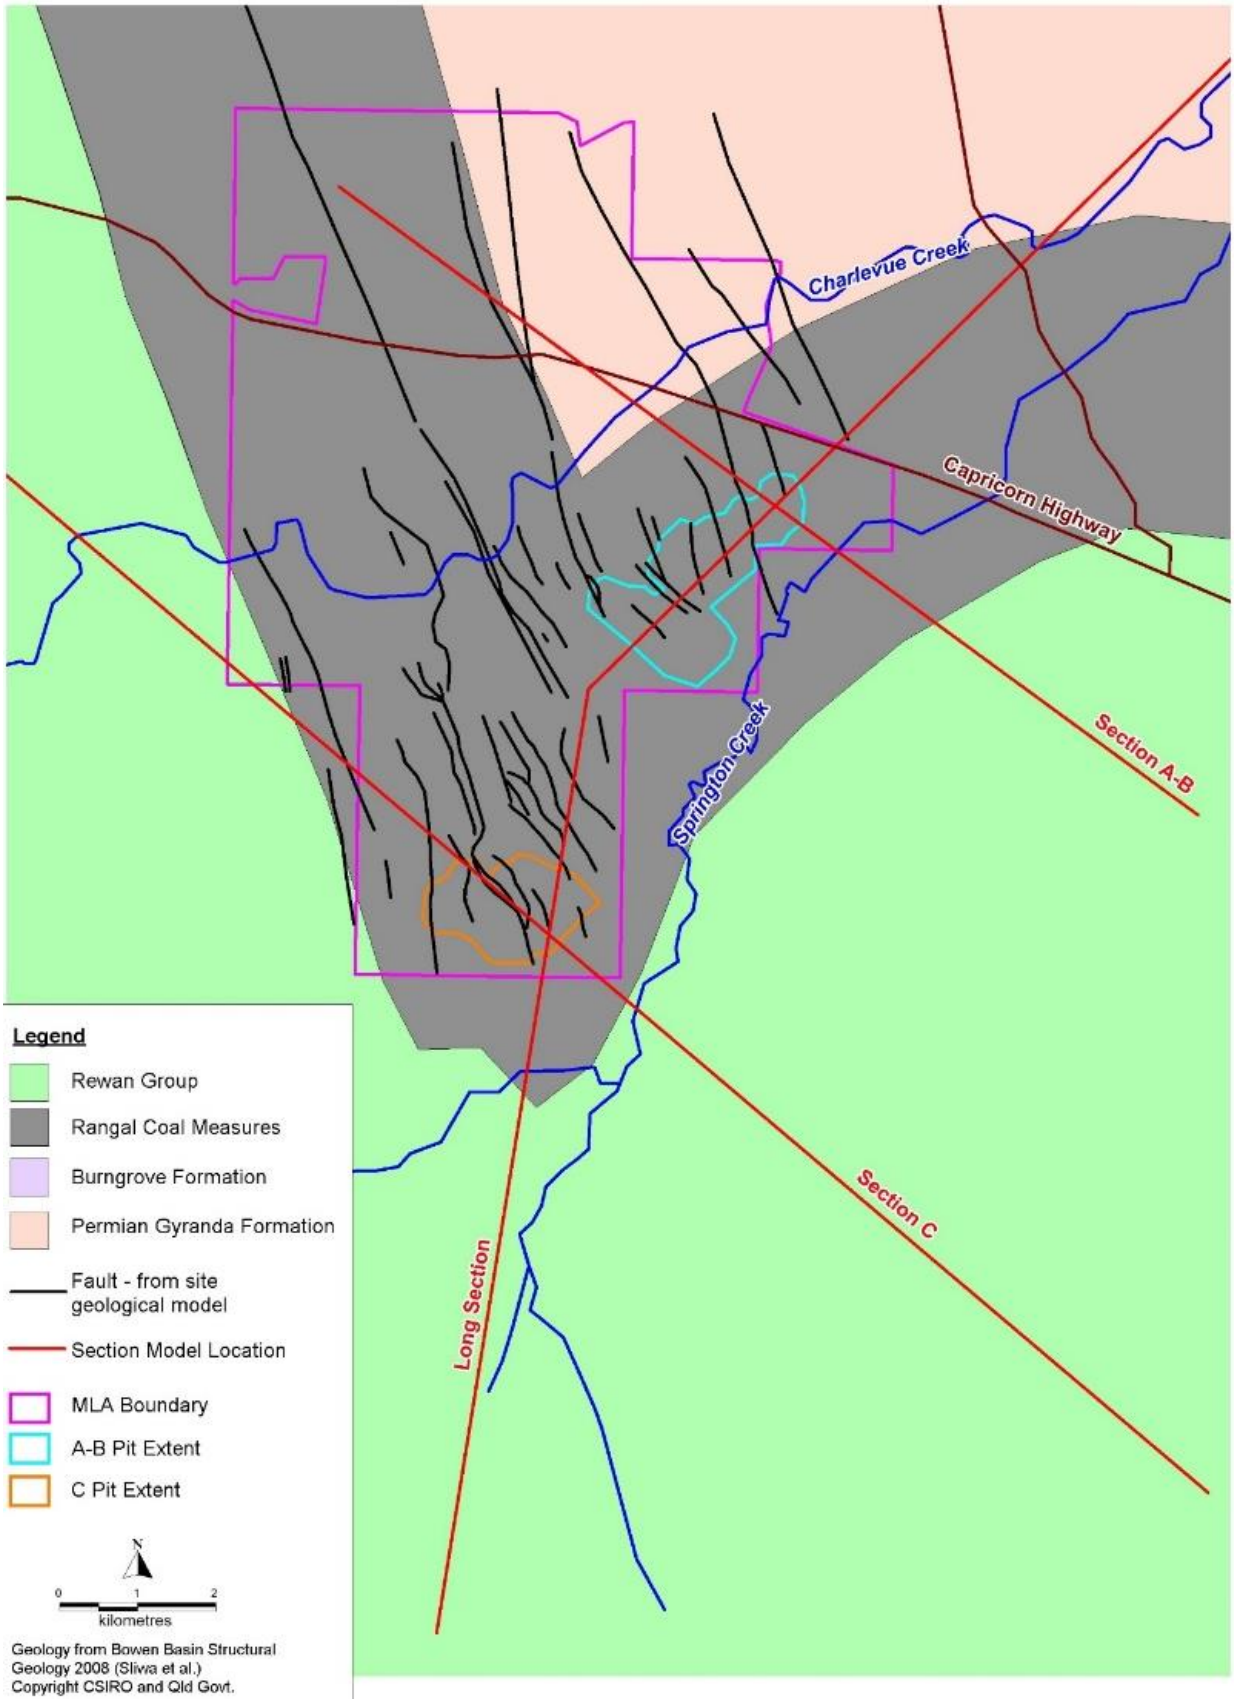

Figure 66 Project Location and Bowen Basin Solid Geology

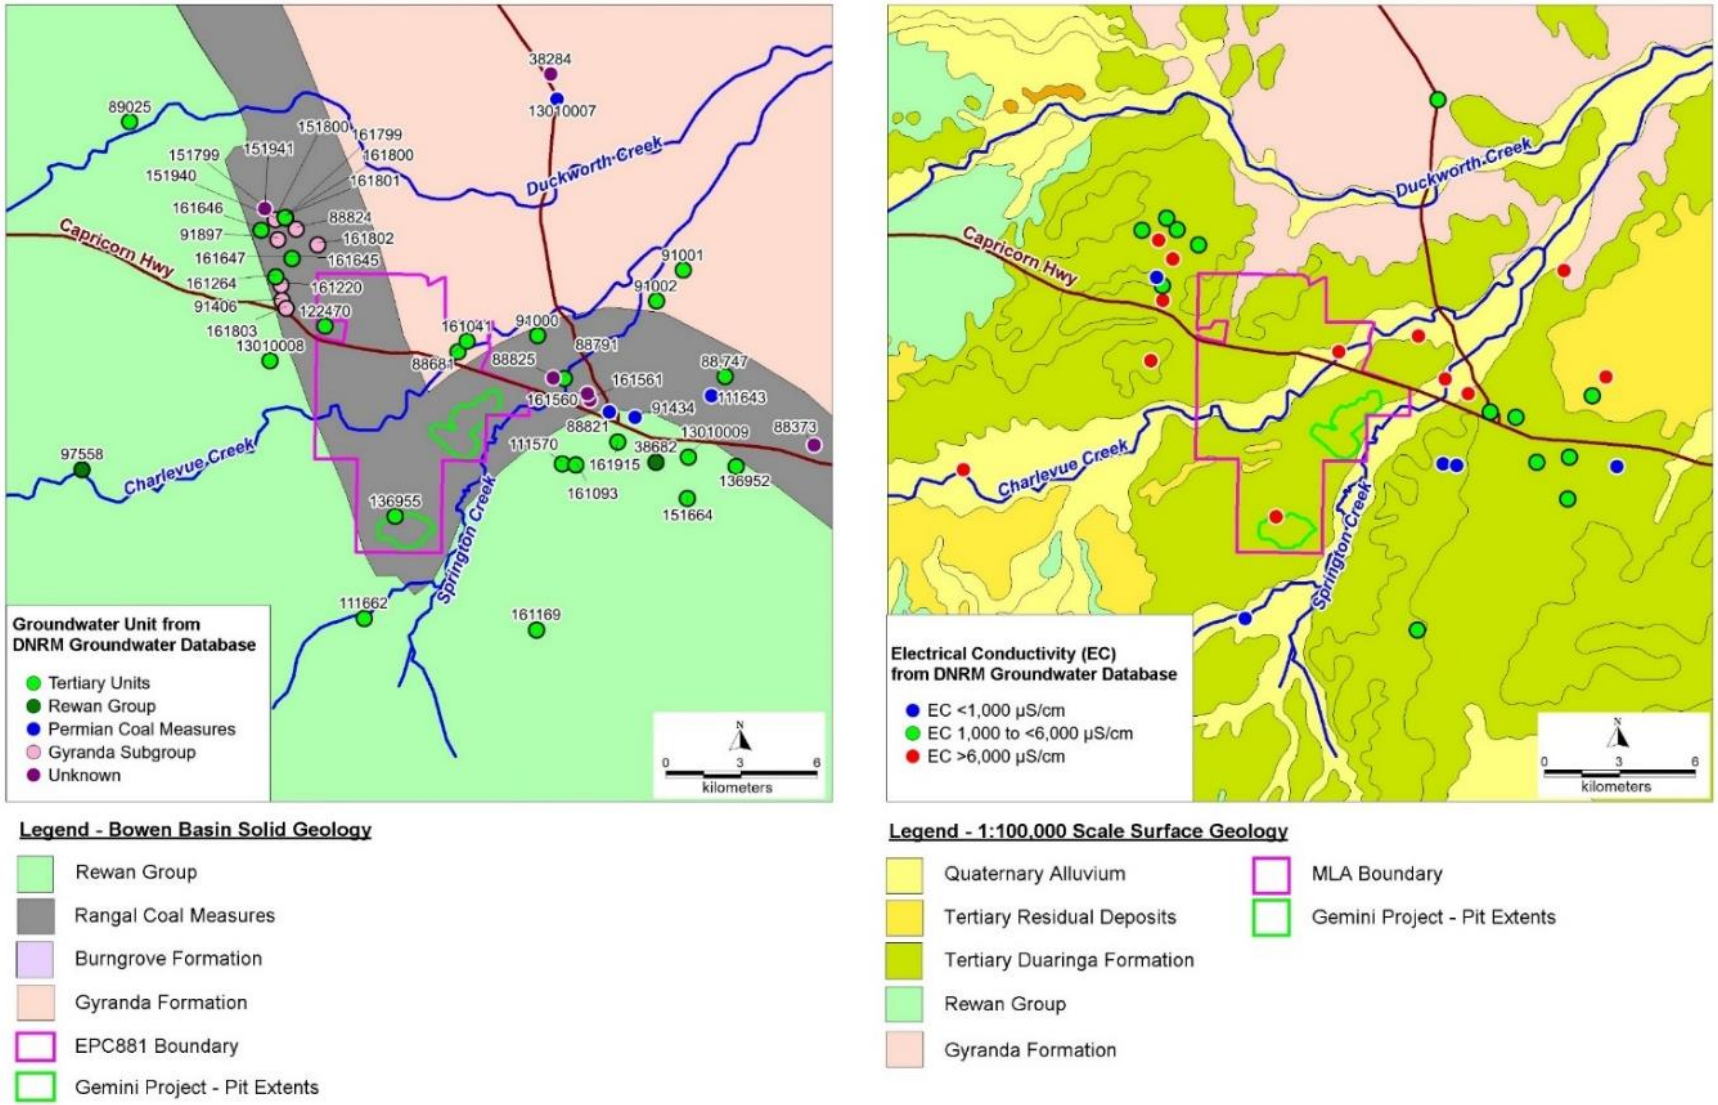

Figure 67 DNRME Groundwater Database - Aquifer and EC data

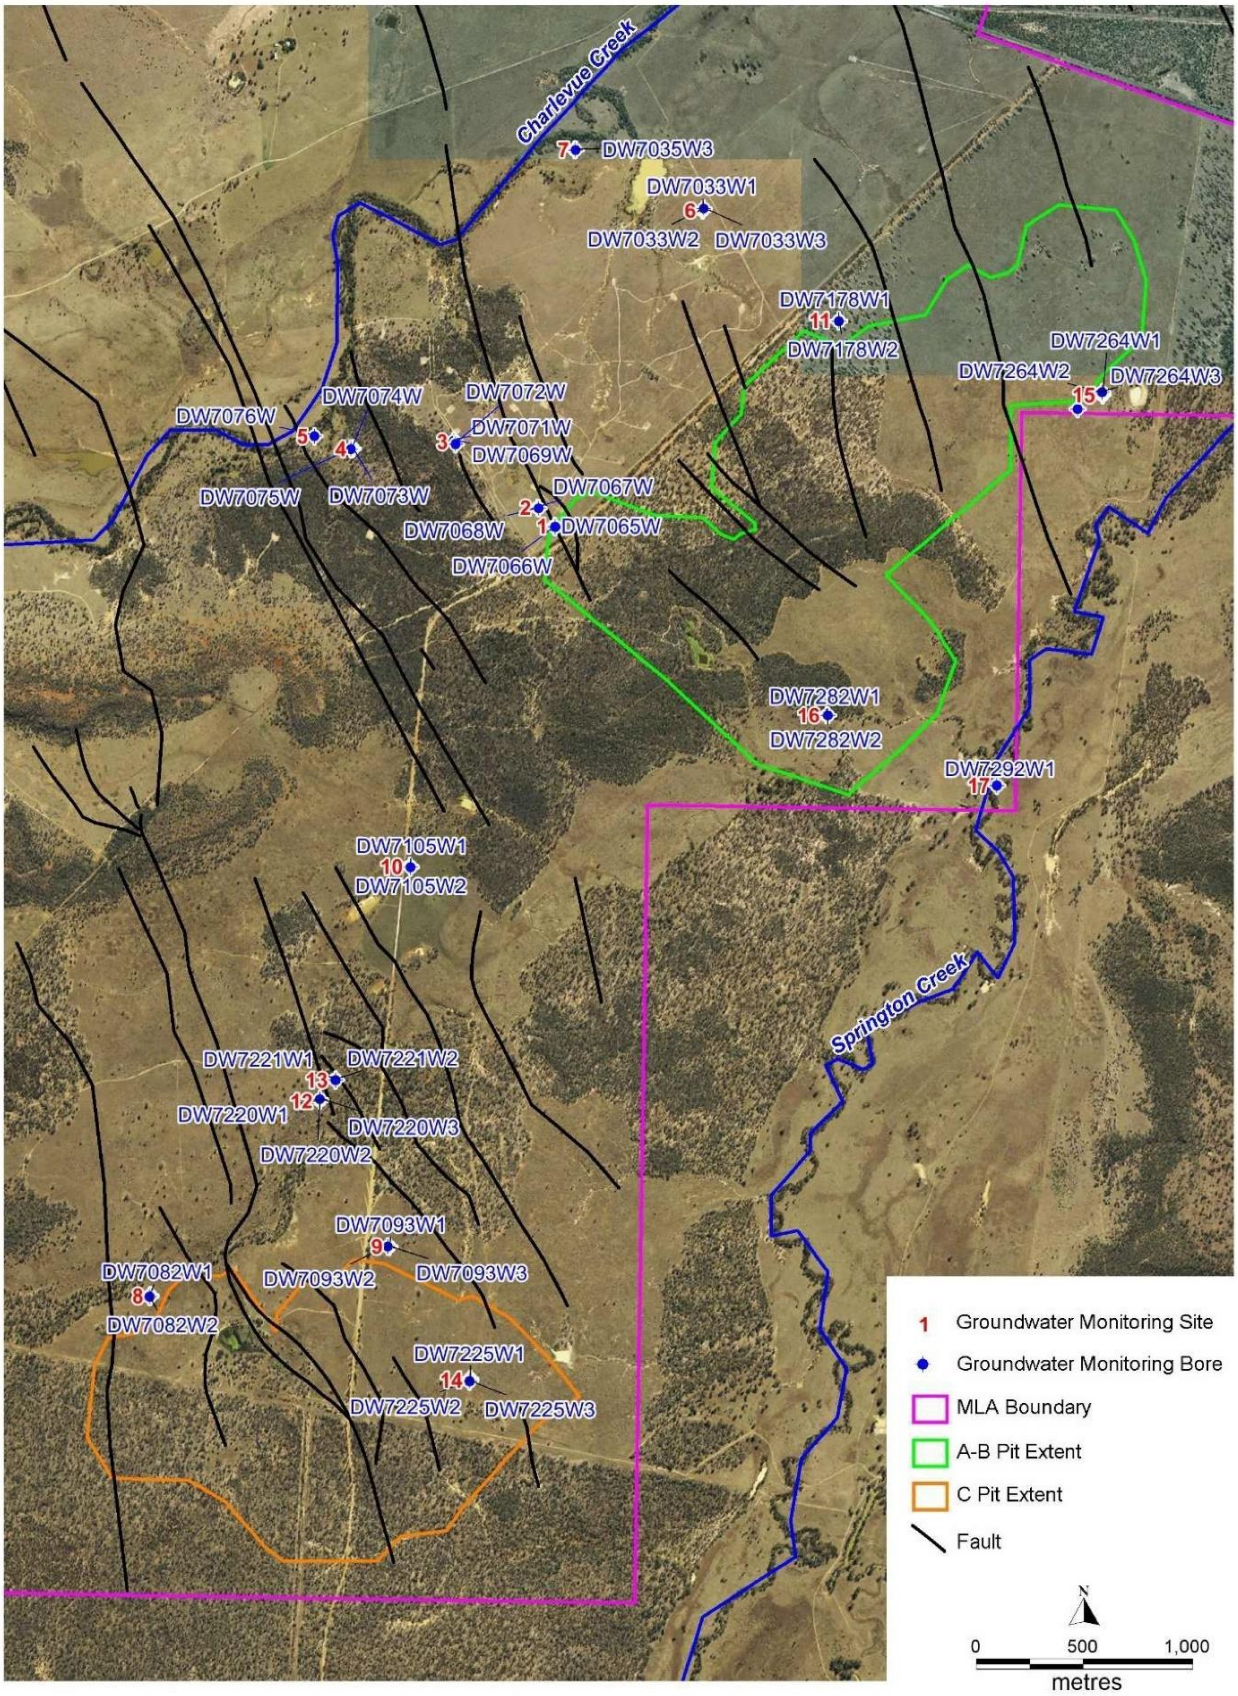

Figure 68 Groundwater Monitoring Bore Network

Detailed discussion of the installation and monitoring of the Project groundwater monitoring network can be found within Section 4.0 of Appendix C. Utilising data from the local and regional bore networks, an overview of the site-specific groundwater aquifers as described as follows. Characteristics of the aquifers are discussed in further detail in Section 8.2.2 Section 8.2.3 and Section 8.2.4.

Quaternary Alluvium

The Project has two monitoring bores within the Quaternary alluvium which is present within ephemeral waterways to the east and west of the mining areas (Springton Creek and Charlevue Creek, respectively). Recharge to alluvium is via direct rainfall recharge and occurs at a low rate. This is consistent with the observation of elevated salinity in the shallow sediments, likely due to the low rate of recharge, as well as high residence times for groundwater.

Tertiary Sediments

There are 26 registered bores in the region screened within Tertiary units and ten Project monitoring bores (one within Tertiary basalt); five of which are dry (including the Tertiary basalt bore). The presence of dry bores within the Tertiary, as well as a variation in water level between the topographically elevated base of Tertiary and topographically lower base of Tertiary, suggest that a continuous water surface does not exist in the Tertiary sediments and that the elevation of the base of Tertiary will be a control on the presence of groundwater within the sediments. From review of available data, it is assessed that it is probable that the Tertiary sediments are dry above 120 mAHD and likely dry above 110 mAHD. The Tertiary sediments exhibit similar recharge and salinity characteristics to the Quaternary alluvium.

Permian Rangal Coal Measures

There are 15 registered bores in the region screened within Permian coal seams and 26 Project monitoring bores (including three within the overburden/interburden sediments); only one of which is dry (Aries seam). Within the Permian coal measures the coal seams are the primary conduits for groundwater flow with no significant trend for upward or downward movement of groundwater between the coal seams. However, a trend occurs for groundwater movement through the coal seams from the southwest to the northeast, and also from the northwest to the southeast, towards a depression that is centred on the area where Pit AB is proposed to be developed. The coal seams are recharged in subcrop areas where the coal seams directly underlay Tertiary and/or Quaternary sediments. The extremely high salinity of groundwater within the coal measures supports an interpretation of a low rate of recharge to these units.

8.2.2 Groundwater Quality

Regional Groundwater Quality

ANZG (2018) outline a livestock drinking limit for salinity for beef cattle of 4,000 mg/L (equates to an approximate EC of 6,000 µS/cm). Bores that recorded a salinity in excess of this were assessed to be of limited or no use for stock watering.

The majority of bores within or close to the MLA recorded EC in excess of 6,000 µS/cm (refer to Table 4-5 in Appendix C). JBT (2019) noted that the EC of groundwater within the Tertiary sediments was often in excess of 10,000 µS/cm and at some sites in excess of 20,000 µS/cm (highly saline); which was consistent with groundwater quality data from the Project bore network. The majority of Tertiary bores outside the tenement area recorded an EC of <6,000 µS/cm, with four bores in Tertiary sediments to the east or south of the project area recording an EC <1000 µS/cm (mostly fresh). There is potential these bores may be used for stock-watering purposes.

Local Groundwater Quality

Groundwater quality data is available from samples taken between December 2018 and October 2020. Results are presented in Appendix D and have been summarised in Table 46.

Table 46 Summary of Groundwater Quality Results from Monitored Bores

Groundwater Unit		Field pH	EC (µS/cm)	Sulphate (mg/L)	Boron (mg/L)	Copper (mg/L)	Zinc (mg/L)
Quaternary Alluvium	Range	5.53-7.49	1,560-16,600	10-249	0.16-4.71	0.002-0.452	0.009-0.570
	Mean	6.77	10,221	140	2.83	0.129	0.142
	Median	7.21	14,300	184	3.89	0.096	0.053
Tertiary Sediments	Range	5.77-7.47	1,400-22,600	25-635	0.12-1.6	0.001-0.160	0.008-0.426
	Mean	6.5	12,413	170	0.85	0.014	0.079
	Median	6.75	9,880	146	0.78	0.007	0.058
Coal Seams	Range	5.56-8.5	959-32,800	2-841	0.1-2.1	0.001-1.470	0.007-0.420
	Mean	6.66	18,173	384	0.872	0.022	0.069
	Median	6.55	19,900	348	0.88	0.007	0.055

All groundwater units (Quaternary alluvium, Tertiary sediments and Permian coal measures) recorded very high EC above the ANZG (2018) livestock drinking limit for beef cattle of approximately 6,000 µS/cm. Salinity increases with aquifer depth, and it is unlikely that groundwater units within the Project are used for stock watering. Due to the high salinity of the groundwater, samples were also relatively high in sulphate, especially for the coal seams.

Groundwater quality was typically above the ANZG (2018) freshwater ecosystem protection trigger value (95% species protection) for boron (all samples), copper and zinc (majority of samples) as well as aluminium, arsenic, lead and nickel (a number of samples for each analyte).

The pH (field testing) of groundwater within the Project area was mostly neutral, with the Quaternary alluvium ranging from 5.53 to 7.49; the Tertiary sediments ranging from 5.77 to 7.47; and the Permian coal seams ranging from 5.56 to 8.5.

8.2.3 Hydraulic Conductivity

Falling head tests were undertaken on 25 bores from the Project bore network to obtain site-specific hydraulic conductivity data from all Project groundwater units. Hydraulic conductivity and air-lift yield data for each monitoring bore is in Table 4-2 of Appendix C (JBT 2019) and summarised for each groundwater unit in Table 47.

A total of 17 slug tests were performed on bores that are screened within the coal seams. The hydraulic conductivity decreased with depth with the difference evident when comparing coal seam bores screened at a depth of less than 80 mbgl to bores screened at a depth greater than 80 mbgl.

Table 47 Hydraulic Conductivity and Air-Lift Yield Data Per Groundwater Unit

Groundwater Unit	No. of Tests	Hydraulic Conductivity (metres per day)			Average Air-lift Yield (L/s)
		Min	Max	Geometric Mean	
Quaternary Alluvium	1	0.097	-	-	-
Tertiary	5	0.027	3.805	0.27	0.548
Permian Coal Seams	17	0.002	5.387	0.13	1.185
Coal Seams <80 mbgl	11	0.012	5.387	0.37	1.578
Coal Seams >80 mbgl	6	0.002	0.245	0.02	0.320
Permian Interburden	2	0.001	0.002	-	-

The relationship between hydraulic conductivity and depth is shown graphically in Figure 69. Of particular interest is the data for the coal seam bores, where the trend for lower hydraulic conductivity with increasing depth is illustrated via the trend line and the 95% confidence interval that has been applied to the data.

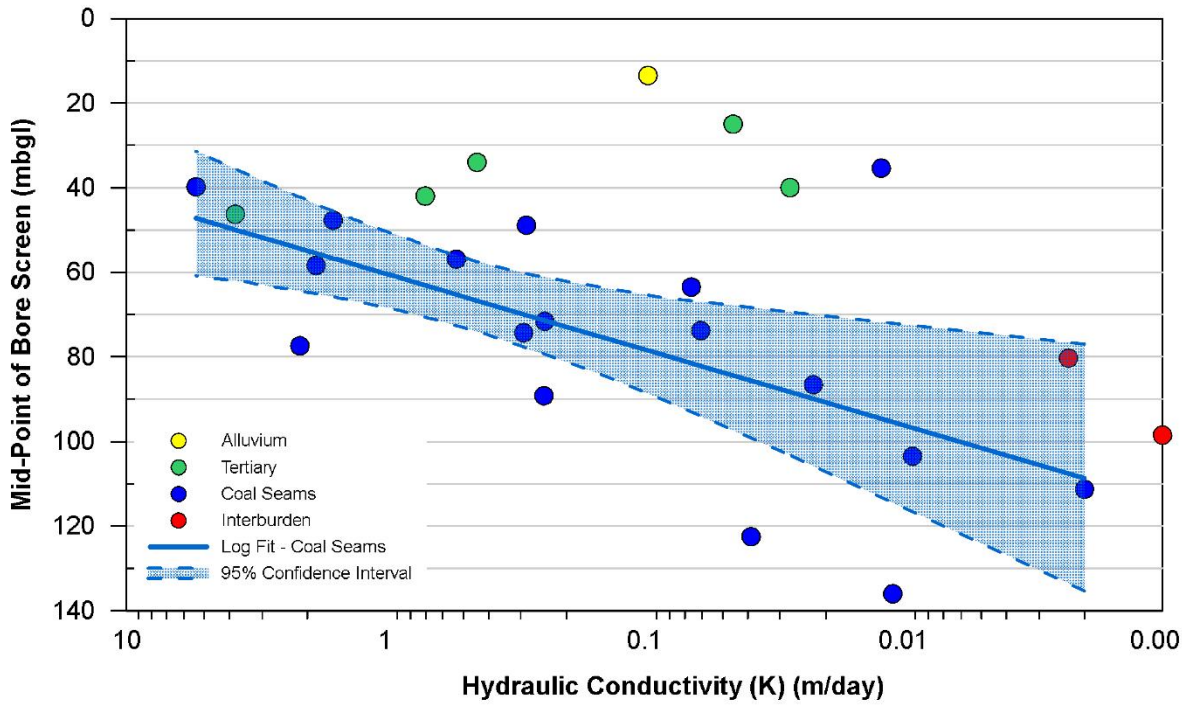

Figure 69 Relationship Between Hydraulic Conductivity and Depth

8.2.4 Groundwater Level

The most recent groundwater level data for the Project monitoring network bores is detailed in Appendix D. Figure 70 and Figure 71 illustrate water level data for Tertiary and coal seam groundwater units, respectively.

Six of the monitoring bores were dry; five within Tertiary sediments (depth: 14 m to 23 m) and one within the Aries seam (depth: 31.6 m).

Of the five dry sites; two were drilled to base of Tertiary, indicating that the Tertiary is dry at these locations, whilst the other three were not constructed to the full depth of Tertiary sediments. There was a significant reduction in depth to base of Tertiary to the west and northwest of Pit AB, where the base of Tertiary lowers from approximately 100 mAHD to 70-80 mAHD. The bores within the lower elevation area of base of Tertiary tended to record water levels in the order of 90 to 95 mAHD, whereas the bores in the higher elevation area tended to range between 105 to 113 mAHD.

The data for bores within the coal seams suggest that the coal measures are continuously saturated and that there is no significant trend for upward or downward movement of groundwater between the coal seams. Figure 71 shows the pre-mining groundwater level contours for the coal measures; indicating a trend for groundwater movement within the coal seams from the southwest to the northeast, and also from the northwest to the southeast, towards a depression that is centred on the area where Pit AB is proposed to be developed.

Bore DW7076W is located adjacent to Charlevue Creek (refer Figure 68) and screened in the Quaternary alluvium. The bore has been fitted with a data logger that records water level at 3-hourly intervals which will allow the relationship between creek flow and water level to be established over time. To date, the water level has been relatively stable, displaying a slight downward water level trend between 9-10 mbgl. A downward spike in water level following sampling is evident in the bore hydrograph (Figure 72), indicating that sampling events may have some influence on water level. An increase in water level after February 2020 suggests some correlation between rainfall events and associated streamflow, and water level. Further data will continue to be collected to establish the long-term water level trend.

Bore DW7292W1 is screened in the Quaternary alluvium adjacent to Springton Creek. The bore was initially fitted with a data logger in April 2020. However, the logger was found to be faulty and was replaced in July 2020, and records water level at 6-hourly intervals which will allow the relationship between creek flow and water level to be established over time. To date, the water level has been relatively stable, displaying a slight downward water level trend between 10-11 mbgl. A downward spike in water level following sampling is evident in the bore hydrograph (Figure 73), indicating that sampling events may have some influence on water level.

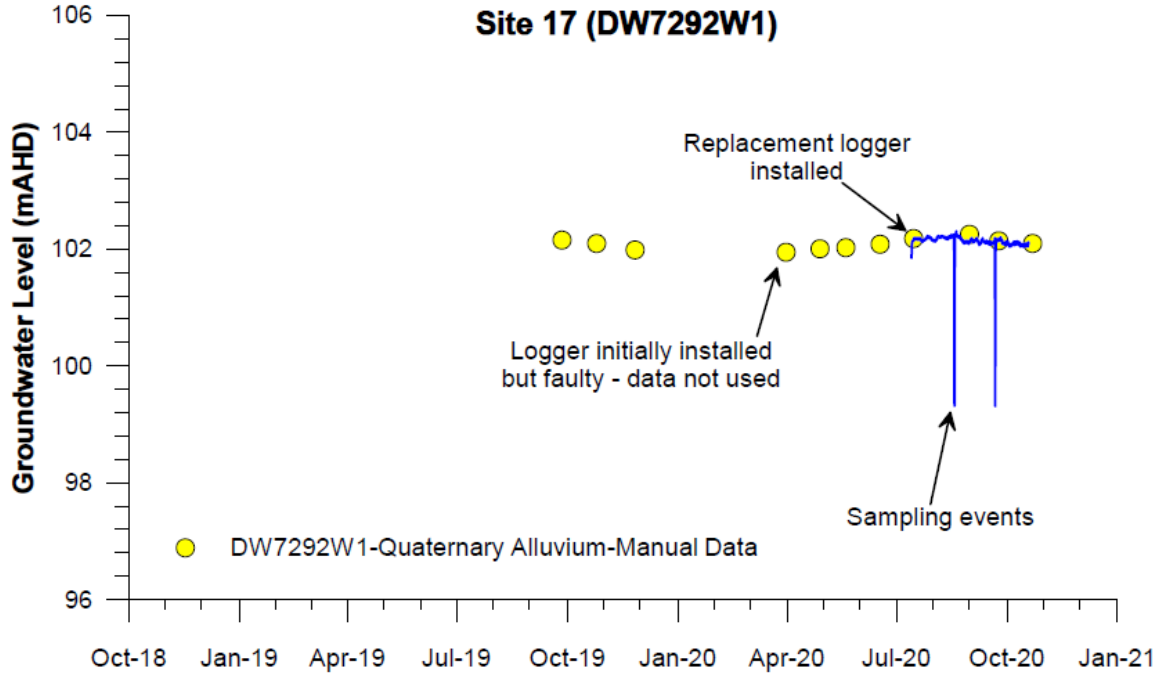

Figure 73 Water Level Data (Quaternary Alluvium - Bore DW7292W1)

8.3 POTENTIAL IMPACTS

The proposed mining activity has potential to impact groundwater values of the Project via:

- A drop in surrounding groundwater level occurring as a result of drawdown from the mining activity. The change in water level has potential to reduce the availability of water in existing groundwater bores. In addition, the drop in groundwater level may also reduce available supply for potential GDEs, where they exist within the zone of influence.

- An increased risk of groundwater contamination either via spills or leaks that might occur during the operation and have potential to seep to shallow aquifers, or in the post mining landform, subject to the final void equilibrium level and the associated risk of water in the void seeping in surrounding aquifers.

It is noted that the risk of groundwater drawdown from the project is limited to the take of Associated Water only. Groundwater is not proposed to be extracted as a source of water for any other related activity. The total predicted take of associated water is detailed in Table 48 (JBT 2019; JBT 2019, pers. comm., 8 October). For the purpose of future associated water reporting, JBT (2019) concluded that it would be more reasonable to assume the rate of inflow prior to development of the spoil aquifer, (approximately ~500 m^3/day) as the water that is developed from the spoil is derived mainly from rainfall recharge to the spoil and does not represent water from the natural formation. It is estimated that annual take of associated water will range from 150 Ml/a to 345 Ml/a.

Table 48 Estimated Take of Associated Water

Year	Pit AB		Pit C		Total
	m^3/day	Ml/a	m^3/day	Ml/a	Ml/a
1	626	228	0	0	228
2	626	228	0	0	228
3	433	158	0	0	158
4	433	158	0	0	158
5	508	185	0	0	185
6	508	185	0	0	185

10	493	180	0	0	180
11	493	180	0	0	180
12	493	180	121	44	224
13	493	180	121	44	224
14	493	180	241	88	268
15	453	165	241	88	253
16	453	165	239	87	253
17	248	91	239	87	178
18	248	91	163	59	150

The *Groundwater Impact Assessment* (JBT 2019) (Appendix C) was undertaken to assess the impacts of the Project. The following sections provide a summary of impacts relating to groundwater drawdown and the risk of contamination.

The potential for impacts of the Project on GDEs is described within Section 6.0. The potential impacts associated with final void water levels are described in more detail within Section 4.0.

Additional impacts from groundwater leaching have been identified in the *Land-Based Effluent Disposal Assessment* (Appendix N). According to the Model for Effluent Disposal through Land Irrigation (MEDLI) model scenario, elevated levels of nitrogen can be leached into the groundwater table when more nitrogen is added than removed to the soil (i.e., heavy rain periods). A construction and operational average of nitrate is predicted to leach 0.17 kg/ha/year via deep drainage during extremely impermeable conditions and during extremely permeable conditions, an average of 1.29 kg/ha/year. These conditions are still well within the accepted limit of 5 kg/ha/year. The irrigation scheme will still need to be managed via use of an appropriate irrigation rate and set back distances to minimise any impact on groundwater and any potential GDEs. The management measures of sewage effluent are discussed in Section 12.7.1.1.

8.3.1 Groundwater Model

To estimate the extent of water level impact from the proposed project, the *Groundwater Impact Assessment* (JBT 2019) (Appendix C) utilised 2-dimensional seepage modelling using the program Seep/W.

Section 5.0 of Appendix C details the essential elements of the conceptual model used to inform the Seep/W numerical model. The choice of the numerical model code was based on an assessment of the model platform and appropriate to the study requirements (assessment details in Section 6.1 of Appendix C). Sections 6.2 through to 6.5 (of Appendix C) present technical details of model inputs, whilst Section 6.7 details the uncertainty analysis.

8.3.2 Assessment Criteria

Criteria against which groundwater drawdown was assessed is based on the 'bore trigger thresholds' for the Water Act. A 'bore trigger threshold' as defined under section 362 of the Act; is a decline in the water level in the aquifer that is:

(a) the prescribed threshold for the area (if a regulation prescribes the bore trigger threshold for an area in which the aquifer is situated); or

(b) otherwise:

(i) for a consolidated aquifer – 5 m; or

(ii) for an unconsolidated aquifer – 2 m.

The potential for impact on existing groundwater users is discussed in Section 8.3.4, whilst the potential for water level impact on GDEs is discussed in Section 6.0.

8.3.3 Modelling Results

Water Quality

Modelling predicted that a permanent cone of depression will develop, directing groundwater flow towards the final voids. Therefore, the risk of the Project impacting on water quality (via outflow to the groundwater system) was assessed to be low.

It was, however, assessed that the Project could impact groundwater quality if the water within the final void were able to exit the void via unconsolidated sediments (i.e., the base of Tertiary) and flow via the groundwater system towards sensitive environmental receptors such as Springton Creek. For this reason, an assessment of the potential for water within the final voids to exit the void via the base of Tertiary sediments was undertaken. This assessment concluded that there is no outlet via the base of Tertiary for water within the final void of either Pit AB or Pit C, for either the maximum 'base case' water level or the maximum 'high inflow case' water level. It is concluded that there is a low risk of the Project impacting on groundwater quality.

Groundwater Level

The modelled drawdown extent at the end of mining is shown in Figure 74, and at post-mining equilibrium (i.e., steady-state post-mining drawdown) in Figure 75. The contours are shown as drawdown extent based on extrapolation of data points from each of the cross-section models (as depicted on Figure 74 and Figure 75).

At the end of mining, the 5 m drawdown extent is approximately 2 km from Pit AB and 1.8 km from Pit C, on the western side of the mining areas. On the eastern side, the 5 m extent is approximately 2 km from both Pit AB and Pit C. The 5 m extent of drawdown is approximately 1 km from Pit C at the southern end of the mining area, and approximately 2 km from Pit AB at the northern end. The 2 m drawdown contour extends approximately a further 1 km, than the 5 m drawdown extent.

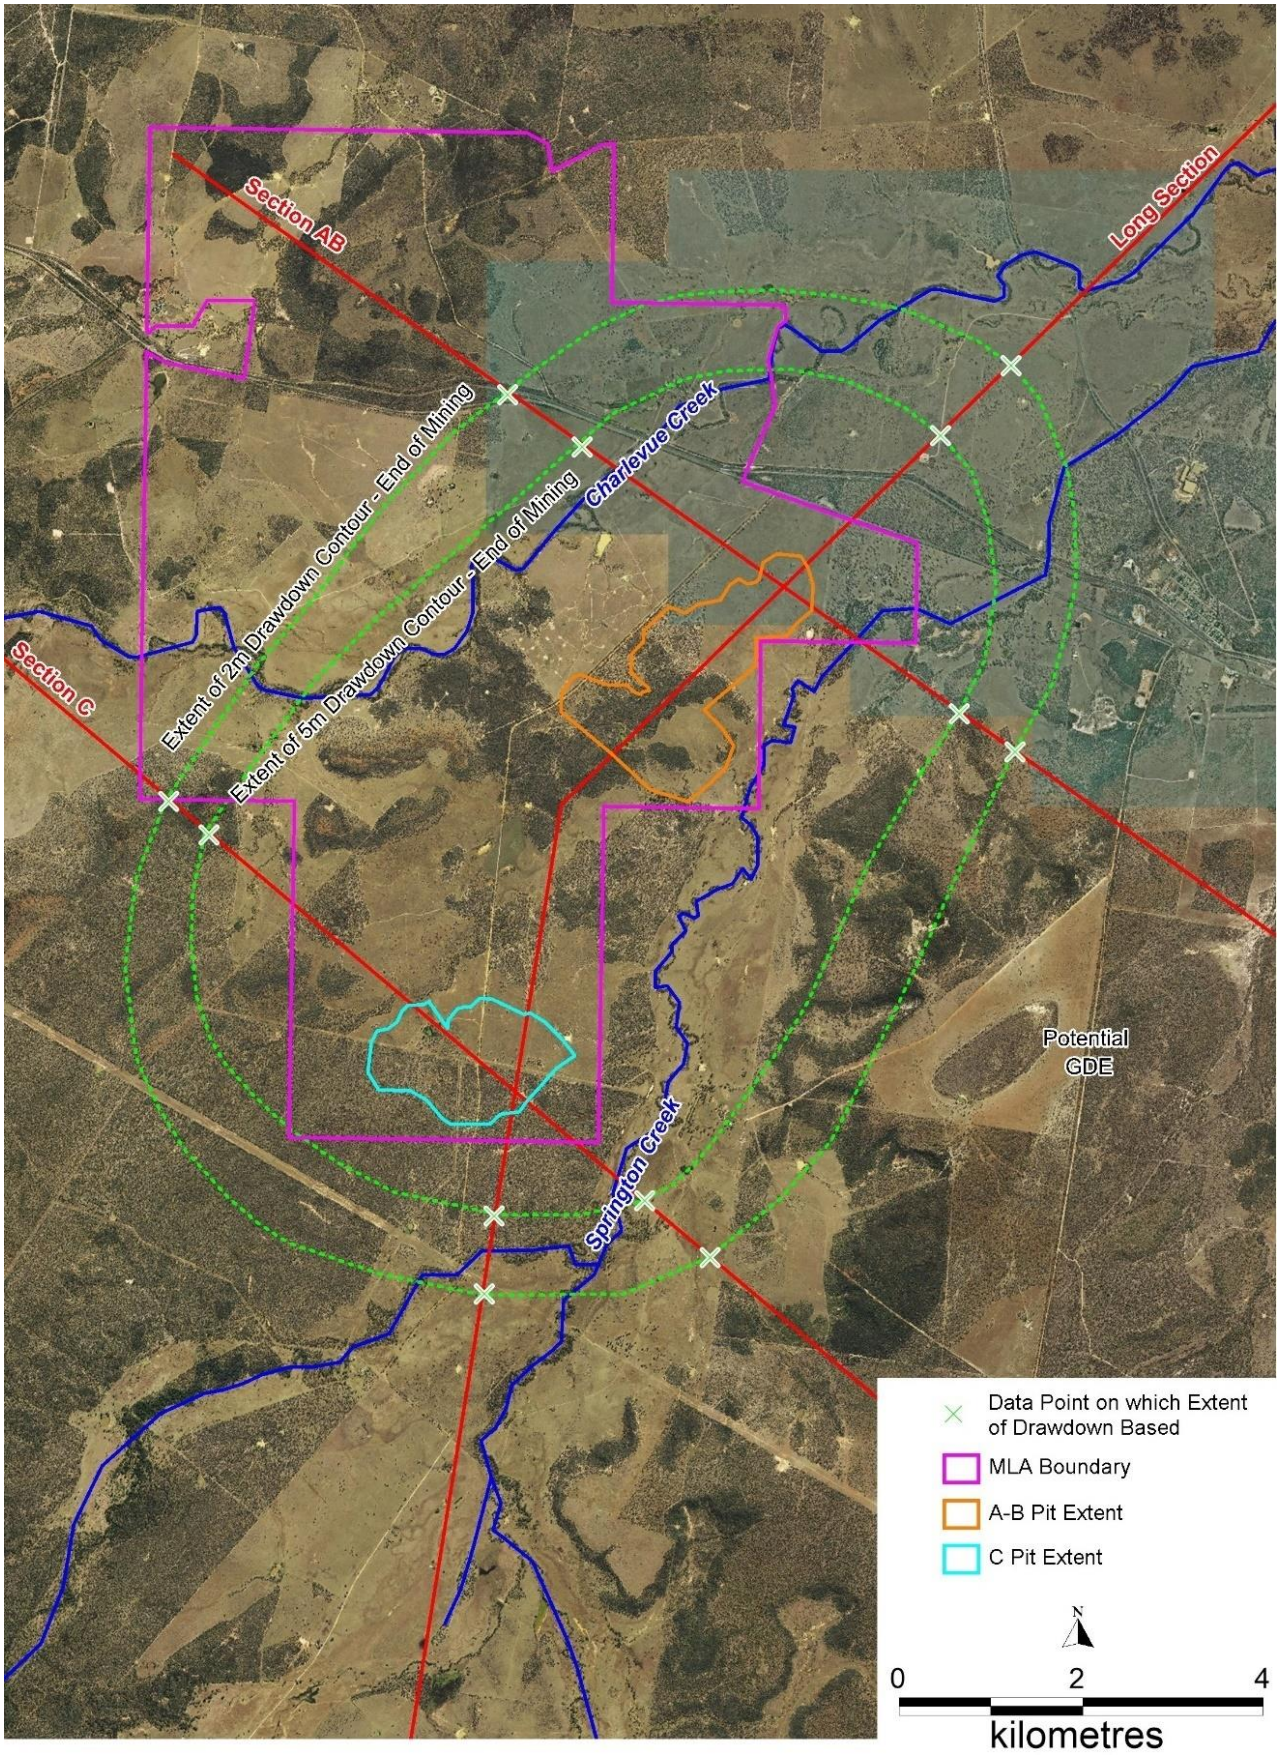

Figure 74 Water Level Drawdown Contours (2m and 5m) - End Of Mining

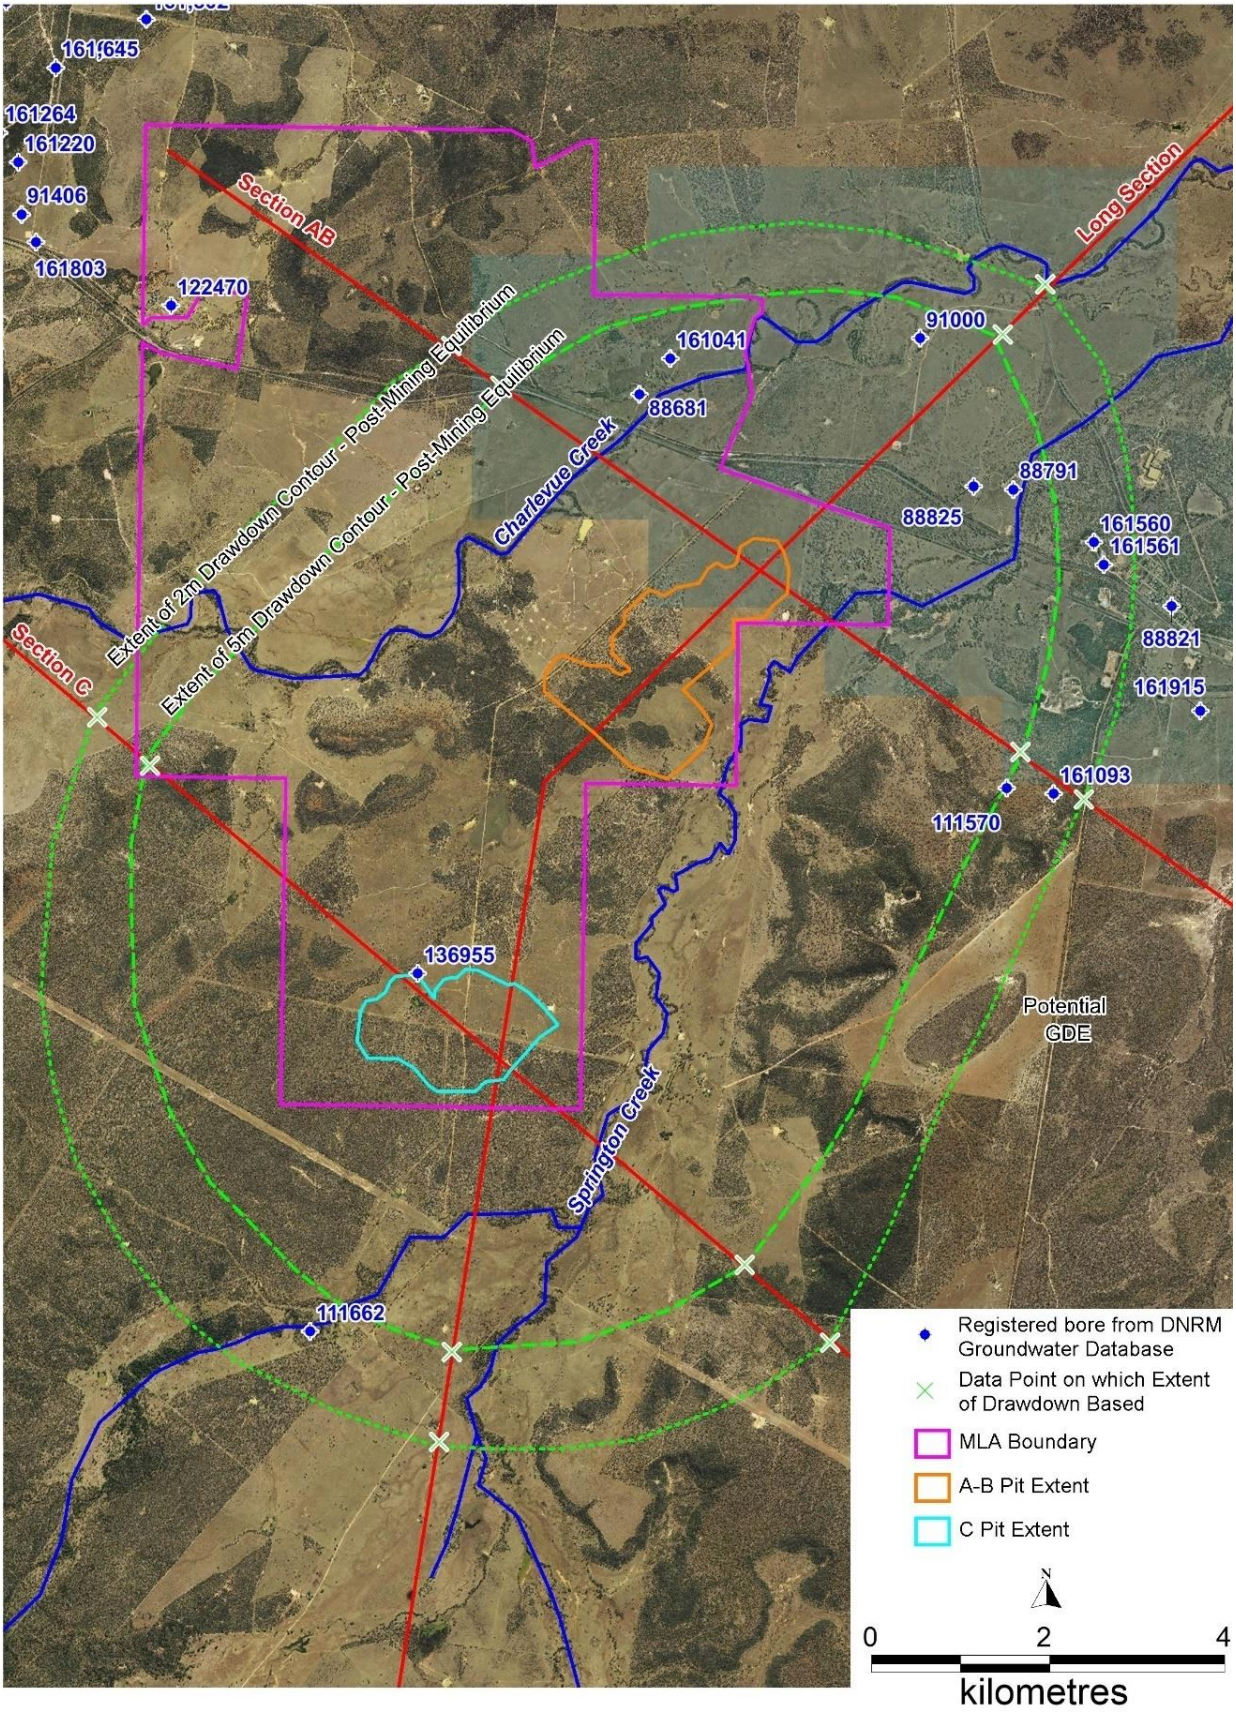

Figure 75 Water Level Drawdown Contours (2m and 5m) - Post-Mining Equilibrium

At post-mining equilibrium, the 5 m drawdown extent is approximately 2 km further from Pit C at the southern side and 2 km further from Pit AB at the northern end of the mining area, than at end of mining. The drawdown contours also extend further to the east and west another approximately 2.5 km. There are no mining operations within the zone of predicted drawdown from mining at the Gemini Project; therefore, there are no cumulative impacts to assess.

8.3.4 Impacts on Existing Groundwater Users

Groundwater Level

Figure 74 (end of mining) and Figure 75 (post-mining equilibrium) show 11 registered groundwater bores (from the DNRME groundwater database) within the 2 m drawdown zone. Summary data for the bores within this zone are shown in Table 49 and summarised as follows:

- seven bores (111662, 136955, 111570, 161093, 88973, 161041 and 88681) are located on land that is owned by Magnetic South;
- two bores (161560 and 161561) appear to be monitoring bores for the Dingo Landfill;
- three bores record groundwater that is highly saline and assessed to be of no beneficial use (in excess of the upper limit of salinity tolerance for beef cattle, sheep, horses and pigs with no loss of production, with a decline in animal health at progressively higher salinity values (ANZG 2018). These bores recorded EC values of 10,000 µS/cm (88681), 19,200 µS/cm (88791) and 14,660 µS/cm (91000);
- two bores (88825 and 161041) are sites with relatively little available data, but which are located within the zone of potential impact to the northeast and west-northwest of Pit AB respectively; and
- two bores (111570 and 161093) recorded relatively fresh groundwater (<1,000 µS/cm) at shallow depth. While these bores are located within the extent of 2 m drawdown, they were assessed to be isolated from the regional groundwater system as discussed in detail with relation to GDEs in Section 7.2.1 of Appendix C. At these sites it is noted that they are not located within the zone of potential impact at end of mining but are within the zone of potential impact at post-mining equilibrium.

Based on the assessment of bores within the zone of influence, it is unlikely that the Project will significantly impact on the availability of groundwater for agricultural land use.

Where there is remaining uncertainty over the presence, or the productive use of bores within the zone of influence, further assessment in the form of a bore plan and assessment will be undertaken prior to development. It is further noted that make-good agreements will be put in place where it is determined that drawdown affects the utility of the bore.

Water Quality

Considering the mining activity is predicted to result in a permanent cone of depression, and the lack of an outlet via the base of Tertiary for water within the final void of either Pit AB or Pit C, it was concluded that the risk of significant groundwater contamination was very low.

The risk of spills or leaks causing contamination is assessed to be manageable and unlikely to result in environmental harm.

Table 49 Bores from DNRME Groundwater Database Within 2 M Drawdown Zone

RN	Aquifer	EC (µS/cm)	SWL (mbgl)	Original Bore Name	Comment
88681	Duaringa Formation	10,000	-	-	Extremely saline - no beneficial use based on water quality.
88791	Duaringa Formation	19,200	-20	New Bore	Extremely saline - no beneficial use based on water quality.
88825	Unknown	-	-	Windmill	-
91000	Duaringa Formation	14,660	-20	Mackenzie OLO	Extremely saline - no beneficial use based on water quality.
111570	Tertiary-Undefined	240	-16	Ward	Refer to Appendix C (Section 7.2.1) for discussion.
111662	Tertiary-Undefined	750	-17	Smith	Located on land owned by Magnetic South.
136955	Tertiary-Undefined	10,300	-21	-	Located within MLA on land owned by Magnetic South.
161041	Duaringa Formation	-	-29	-	-
161093	Tertiary Mafic Volcanics	710	-19.5	-	Refer to Appendix C (Section 7.2.1) for discussion.
161560	Unknown	28,102	-	Dingo Landfill MW2	Assumed to be a monitoring bore at Dingo Landfill.
161561	Unknown	-	-	Dingo Landfill MW1	Assumed to be a monitoring bore at Dingo Landfill.

SWL surface water level

8.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

Overall, the *Groundwater Impact Assessment* (JBT 2019) (Appendix C) concluded that there is a low risk the Project would impact on groundwater quality, groundwater level or potential GDEs. The management and monitoring strategies will ensure groundwater resources are managed and risk remains low. Magnetic South is committed to implementing procedures for monitoring and complaints resolution to control magnitude of risk.

Impacts and mitigation measures for protection of potential GDEs is discussed in detail within Section 6.0.

Associated Water Take

Monitoring and annual reporting of associated water take will be in accordance with the requirements of the *Mineral Resources Act 1989*.

Landholder Bores

Magnetic South will prepare an *Underground Water Impact Report* for submission and approval in accordance with the Water Act. The report will identify aquifers that are predicted to be impacted by the exercise of underground water rights; establish obligations to monitor impacts on aquifers and springs;

impose a strategy to mitigate impacts on any spring of interest; assist with management of impacts of the exercise of water rights by resource tenure holders; and establish underground water obligations (make good obligations of the resource tenure holder for private water bores.

Where it has been determined that an impact on landholder bores exists, a *Baseline Assessment Plan* will be prepared (as required by the Water Act) identifying water bores located on a holder's tenure and setting out a timetable for undertaking baseline assessments of those bores.

If required, bore assessments and 'make good agreements' will be established (in accordance with the Water Act) with any relevant stakeholders.

Groundwater Monitoring and Evaluation Program

The Project groundwater monitoring bore network established for the baseline studies will continue to be monitored throughout operation and decommissioning. A copy of the *Groundwater Monitoring and Management Plan* for the Project is included as Appendix E, with the main elements summarised below.

The monitoring program will record groundwater levels and water quality from existing monitoring bores to provide long term groundwater level data from the Project area, and to detect and quantify potential drawdown occurring during and post mining.

The groundwater monitoring bore network was designed based on the following considerations:

- bores are located within all groundwater units present at site (Quaternary alluvium of Charlevue Creek and Springton Creek, Tertiary sediments, Permian coal seams and interburden units);
- the majority of bores were located in the area of the AB pit, as this pit is planned to be developed first;
- the bores are broadly aligned in two transects to provide drawdown data within the mined area, immediately adjacent to the mined area, and at distance towards Charlevue Creek and Springton Creek;
- bores are located within all groundwater units that exist between the AB Pit and the C Pit, to provide information on the extent of drawdown between the pits and as a way of providing drawdown data to validate the groundwater model;
- additional bores are located within and immediately adjacent to the C Pit, within all groundwater units encountered in that area (to base of mining) to provide both water level and water quality data in that area;
- the spatial and vertical layout of the bore monitoring network (which includes 38 bores at 17 sites) will allow:
    - assessment of the variability of water quality across the site and within vertically separated groundwater units at the same location (e.g., coal measures and overlying Tertiary sediments);
    - assessment of the potential for upward vs downward groundwater movement at a single location;
    - assessment of groundwater flow direction within the distinct groundwater units; and

- assessment of recharge potential of the various groundwater units, particularly the Quaternary alluvium where water level loggers have been fitted to bores DW7076W and DW7292W.

Compliance and reference bores have been selected as follows:

- The compliance bores provide a spatial coverage within all groundwater units identified at site and where possible are located close to mining areas (within the zone of predicted impact) but not within the disturbance footprint of mining (i.e., within the proposed pit area).

- Reference bores have been selected to be located within the same groundwater units but at locations that are distant from the area where mining is first proposed to commence (the AB Pit Area). As mining progresses towards the C Pit area, the existing reference bores are likely to become the compliance bores for that area.

Because a large number of Tertiary monitoring bores are dry, the proposed compliance bore network for Tertiary bores is limited to the bores that contain water. One bore (DW7225W1) is located within the mining footprint of the C Pit, though mining of the AB Pit will occur in advance of mining in this area. The bore is included to provide spatial coverage of the Tertiary sediments but will require replacement once mining in the C Pit area commences.

Bores within the alluvium are targeted for monitoring via water level dataloggers to allow assessment of the range of seasonal water level variation at these sites, with data loggers fitted to bores DW7292W1 (Springton Creek alluvium) and DW7076W (Charlevue Creek alluvium).

A summary of the Project groundwater monitoring bore network is provided in Table 50.

Table 50 Groundwater Monitoring Bores

Site	Bore ID	Unit Monitored	Easting (GDA94)	Northing (GDA94)	Collar RL (mAHD)	Monitoring Frequency
Control Bores						
2	DW7068W	Tertiary	730785	7382391	134	2-Monthly
3	DW7069W	Permian	730397	7382699	132.57	2-Monthly
	DW7071W	Permian	730394	7382703	132.4	2-Monthly

Groundwater Trigger Values

Based on the baseline monitoring data collected to date, trigger levels have been proposed for the compliance monitoring bores within the groundwater monitoring network. The trigger levels are proposed as interim trigger levels and it is proposed that the levels are further reviewed after collection of an additional 2 years of data. Trigger levels are provided in Table 51, and have been proposed based on the following rationale:

- for EC and sulphate the trigger level is based on the 95th percentile of the data for each groundwater unit;
- for pH, the proposed trigger level range is based on the range of site data;
- for metals/metalloids where the data is generally below the ANZG (2018) aquatic ecosystem protection limit for moderately disturbed system (95% protection), the proposed trigger level is based on the ANZG (2018) limits;
- for mercury, the proposed trigger is based on the limit of reporting (LOR) of the analytical method FIMS; and
- for metals/metalloids where the site background data is generally above the ANZG (2018) freshwater protection limit, the proposed trigger level is based on the 95th percentile of the data for each groundwater unit.

Data for each of the proposed compliance bores compared to the proposed trigger levels are shown graphically in Appendix D.

Table 51 Proposed Groundwater Quality Trigger Levels

Parameter	Groundwater Unit			Figure No (6)
	Quaternary Alluvium	Tertiary	Permian	
pH (pH units)	5.5 – 8.5 (1)	5.5 – 8.5 (1)	5.5 – 8.5 (1)	25

(4) LOR of FIMS analytical method
(5) All metals and metalloids to be measured as total (unfiltered) and dissolved (filtered).
(6) Figures provided in Appendix D

Proposed groundwater level triggers are based on the bore trigger thresholds in the *Water Act 2000* as shown in the excerpt below:

> ***bore trigger threshold**, for an aquifer, means a decline in the water level in the aquifer that is—*
>
> *(a) if a regulation prescribes the bore trigger threshold for an area in which the aquifer is situated — the prescribed threshold for the area; or*
>
> *(b) otherwise—*
>
> *(i) for a consolidated aquifer—5m; or*

(ii) for an unconsolidated aquifer—2m.

Proposed water level triggers are therefore:

- consolidated aquifers (Permian Sediments/ Rewan Group) – 5 m/year; and
- unconsolidated aquifers (Quaternary Alluvium, Tertiary sediments) – 2 m/year

The assessment of water quality data will be undertaken as follows:

- two consecutive exceedances of a trigger value as defined in Table 4-1 will constitute a trigger level exceedance; and
- four consecutive exceedances of a trigger value as defined in Table 4-1 will constitute a limit exceedance.

9.0 AIR QUALITY

This section provides a description of existing air quality within and surrounding the Gemini Project. It aims to predict any changes in air quality as a result of the Project and propose mitigation measures and management strategies.

The *Air Quality and Greenhouse Gas Assessment* (Katestone 2020) provided in Appendix L has been conducted to determine the likely impacts of the Project on airborne concentrations and dust deposition rates. Particulates considered in this assessment are:

- total suspended particulate matter (TSP);
- particulate matter with equivalent aerodynamic diameters of 10 µm or less (PM_{10}); and
- particulate matter with equivalent aerodynamic diameters of 2.5 µm or less ($PM_{2.5}$).

9.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objective relevant to potential impacts to air, as described in the EA guideline for *Application requirements for activities with impacts to air [ESR/2015/1840]* (DES 2017a) is:

The activity will be operated in a way that protects the environmental values of air.

The Project would achieve all of the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

(a) fugitive emissions of contaminants from storage, handling and processing of materials and transporting materials within the site are prevented or minimised;

(b) contingency measures will prevent or minimise adverse effects on the environment from unplanned emissions and shut down and start up emissions of contaminants to air; and

(c) releases of contaminants to the atmosphere for dispersion will be managed to prevent or minimise adverse effects on environmental values.

9.2 DESCRIPTION OF ENVIRONMENTAL VALUES

In accordance with the *Environmental Protection (Air) Policy 2019* (EPP (Air)) the EVs pursuant to air quality to be enhanced or protected include the qualities of the air environment that are conducive to protecting:

- the health and biodiversity of ecosystems;
- human health and wellbeing;
- the aesthetics of the environment, including the appearance of buildings, structures and other property; and
- agricultural use of the environment.

9.2.1 Land Use

The Project and surrounding area is currently used predominately for cattle grazing with most of the area cleared of remnant vegetation for agricultural purposes.

To the east of the Project lies Dingo, a small town of approximately 450 people, and includes residences, sporting facilities (sports oval, tennis courts), a primary school, and local businesses (post office, hotel, shops, etc).

The study area covers approximately 400 km^2 and extends beyond the borders of the MLA in order to assess the potential impact of the Project on the air quality of the wider community. The context of the land considered in the air quality assessment of the Project is shown below in Figure 76 through topographical contours expressed in mAHD.

9.2.2 Climate and Wind Characteristics

Meteorological modelling was used to generate wind speed and direction inputs for the impact assessment as described in Appendix A of the *Air Quality and Greenhouse Gas Assessment* (Katestone 2020) (refer Appendix L). The local meteorological conditions relating to the Project have been described in Section 2.2 of this document.

9.2.3 Existing Air Quality

9.2.3.1 Existing Sources of Emissions

Ambient dust levels across the area will be influenced by natural sources of dust such as wind erosion and fires, as well as dust emissions from existing anthropogenic sources in the area, possibly including local agriculture or horticulture, and existing mines.

The National Pollution Inventory (NPI) is a public database of annual emissions of 93 substances reported by industries across Australia. The closest facility currently reporting to the NPI program is more than 10km away from the Project and unlikely to contribute to existing levels of dust within the study domain. There are seven NPI reporting facilities within a 50 km radius of the Project including six mines and one quarry. Potential contributions from the surrounding facilities, including the Bluff Coal Mine, on sensitive receptors are expected to be adequately accounted for in the Blackwater monitoring data used to determine background particulate concentrations utilised in the cumulative assessment of the Gemini Project. Further, the closest reporting facility the Bluff Mine is currently in care and maintenance with no certainty of return to operations.

These existing seven facilities are listed in Appendix L and are considered far enough away from the Gemini Project to have a minimal impact on the local dust levels near the Project or will be adequately accounted for in the ambient background monitoring data.

9.2.3.2 Ambient Air Quality

The *Air Quality and Greenhouse Gas Assessment* (Katestone 2020) (Appendix L) has estimated the expected background concentrations of relevant air contaminants (Table 52). A total of 12-months of data (April 2019 to April 2020) from the DES monitoring station at Blackwater, approximately 35 km west of the Project, was relied upon to characterise the existing environment. It is noted that DES does not conduct monitoring for TSP and dust deposition, therefore either alternative data sources have been utilised or calculated using the existing DES monitoring data (each parameter data source has been listed in Table 52). For the purposes of the cumulative impact assessment, the ambient background concentrations of PM_{10} and $PM_{2.5}$ were taken as the 70th percentile 24-hour average from the Blackwater

monitoring site. Use of the 70th percentile value was based on the methodology published by EPA Victoria (EPA Victoria 2007) and is accepted in Queensland.

On the occasions where the 24-hour background concentrations of PM_{10} and $PM_{2.5}$ exceeded the EPP (Air) objectives at the Blackwater monitoring site; a discussion on temporal and meteorological variation has been included in Table 4 of Appendix L to explain existing exceedances.

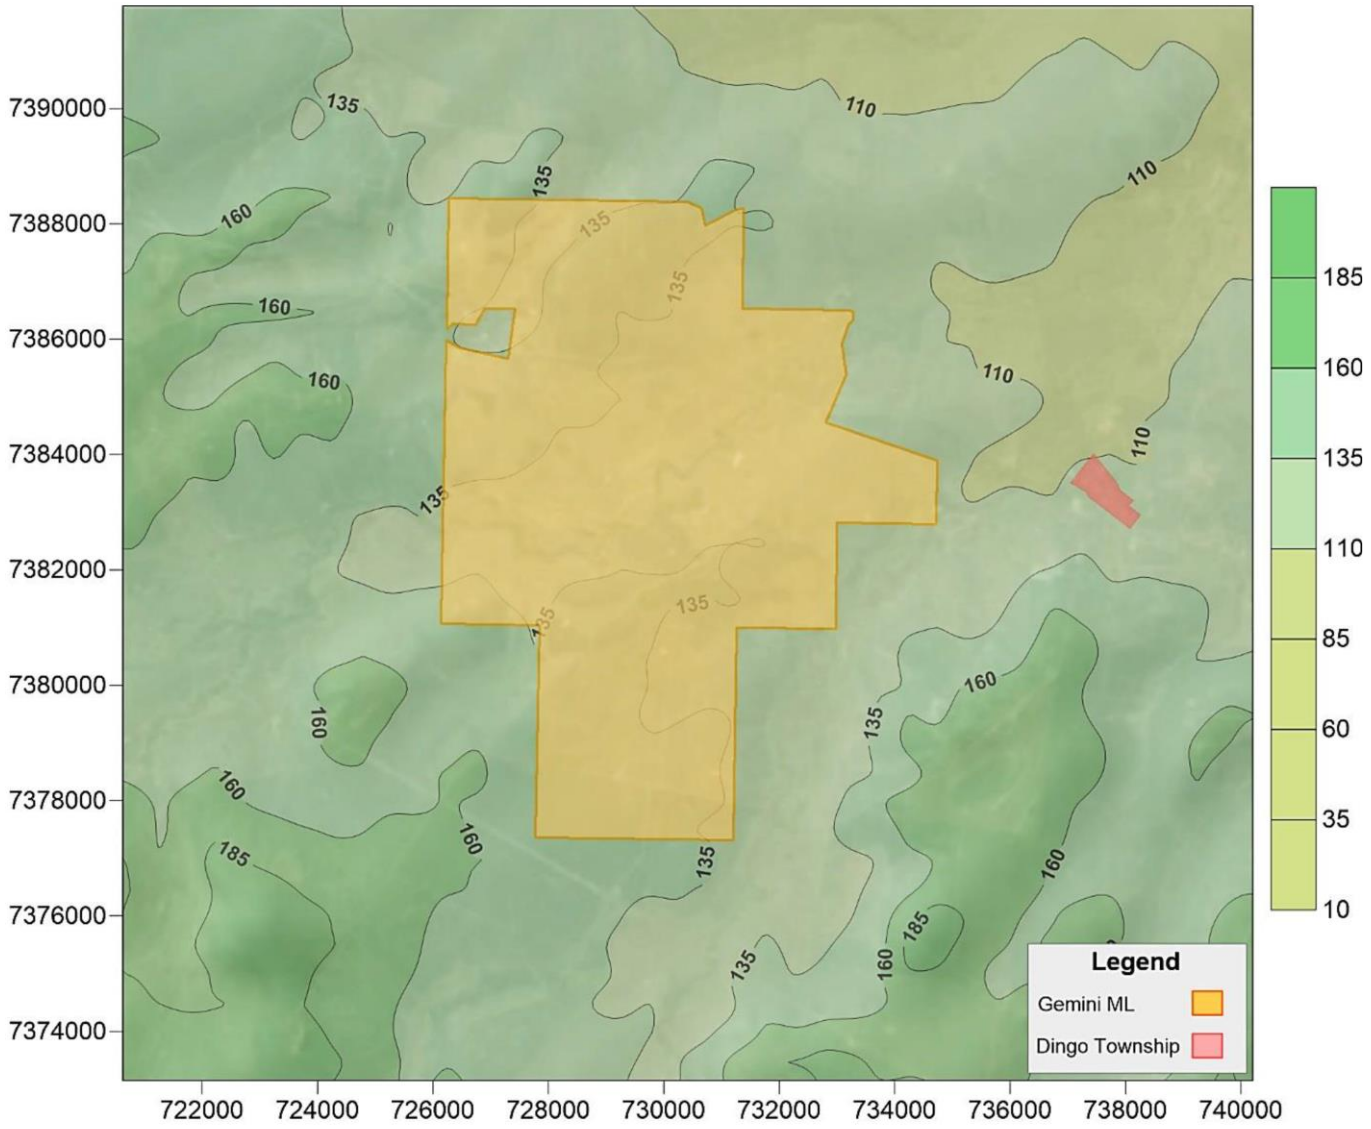

Figure 76 Local Terrain

Table 52 Ambient Background Concentrations Used To Assess Cumulative Impacts

Pollutant	Averaging Period	Concentration	Source
TSP	Annual	45.8 µg/m^3	Calculated from the average PM_{10} data measured at Blackwater using PM_{10}/TSP ratio of 0.5.
PM_{10}	24-hour	23.8 µg/m^3	70th percentile of monitoring data at Blackwater.
	Annual	22.9 µg/m^3	Average of monitoring data at Blackwater.
$PM_{2.5}$	24-hour	7.4 µg/m^3	70th percentile of monitoring data at Blackwater.
	Annual	6.8 µg/m^3	Average of monitoring data at Blackwater.
Dust Deposition	Monthly	50 mg/m²/day	Typical value for rural areas.

9.2.4 Sensitive Receptors

A desktop assessment identified a total of 25 sensitive receptors within 5 km of the Project based on the definition from the EPP (Air). Sensitive receptors considered in the assessment are presented in Figure 77 and Table 53, encompassing residences, businesses, and recreational areas.

At the time of reporting the following sensitive receptors are owned or pending purchase by Magnetic South and have not been considered further in this assessment: SR09, SR14, SR15, SR18, SR19, SR20, SR21, SR23 and SR24.

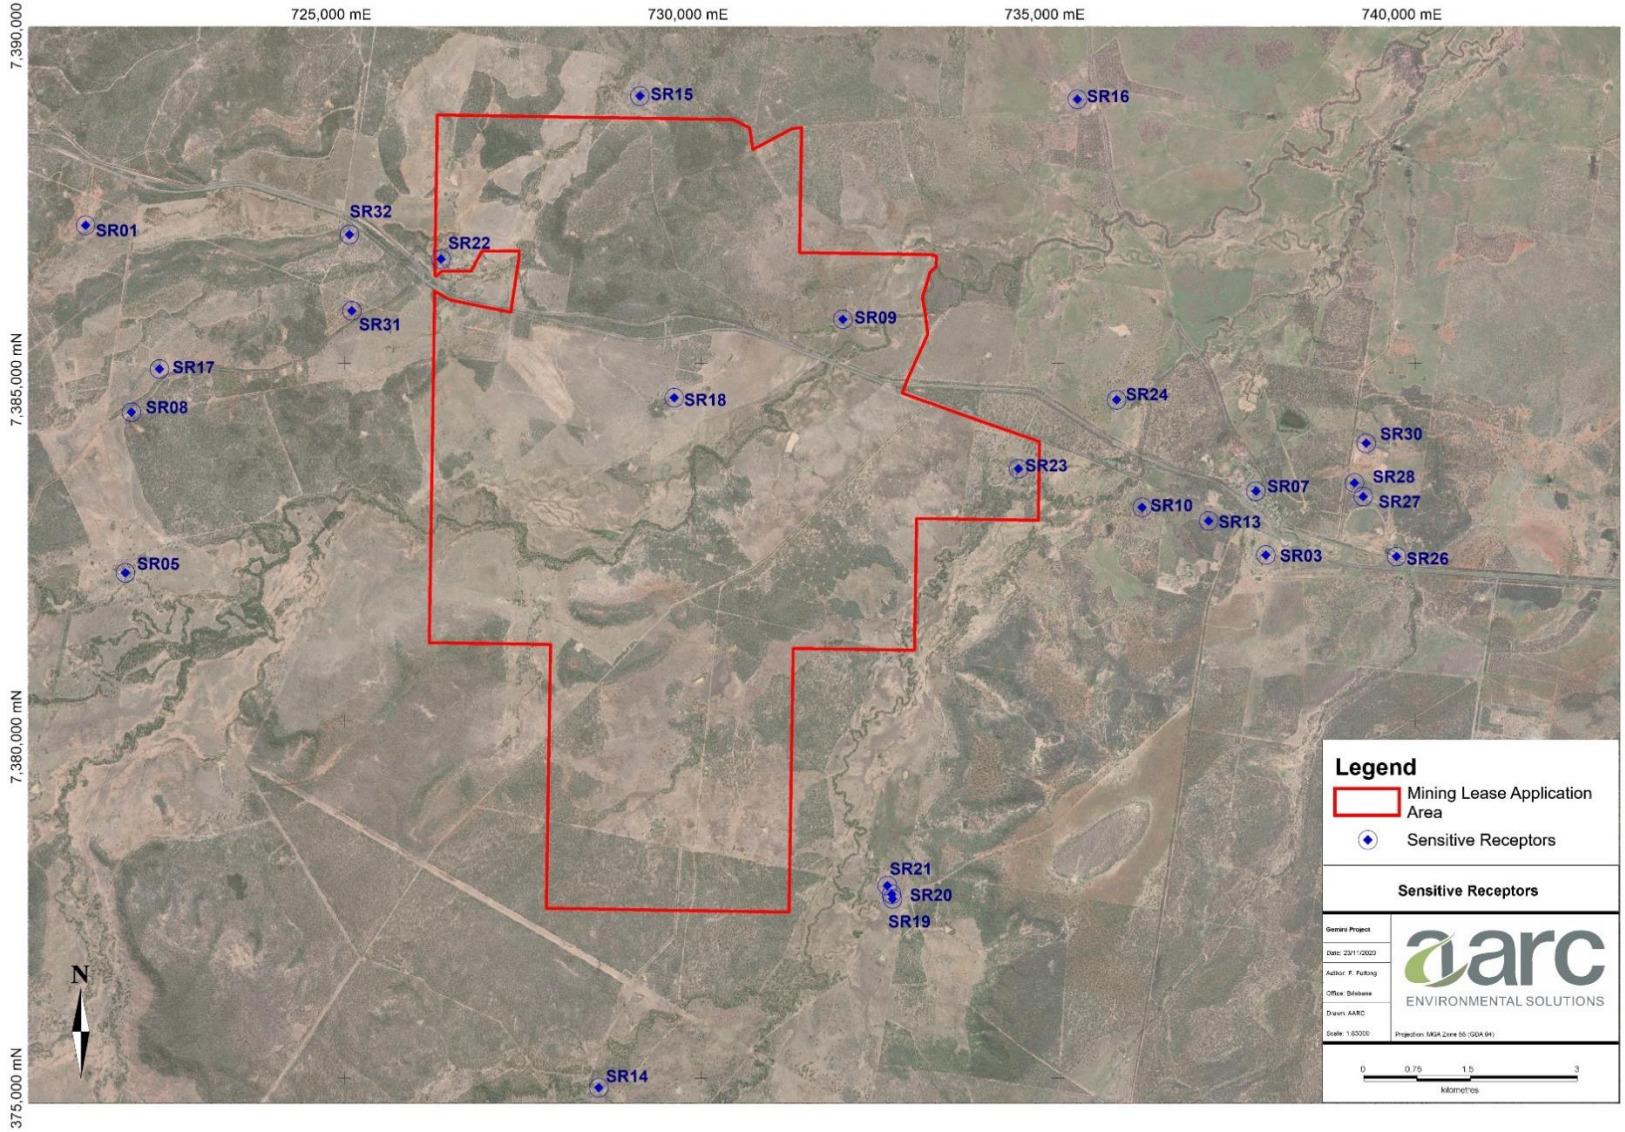

Figure 77 Sensitive Receptors Within 5 km of the Project

Table 53 Sensitive Receptors Within 10 km of the Project

Receptor ID	Receptor Type	Property Name	Easting	Northing	Location
SR01	Residential	3SP165527	721380	7386940	4.8 km W

SR30	Residential	The Lazy H and Hopevale	739319	7383894	4.6 km E
SR31	Residential	Unknown	725109	7385743	1.1 km NW
SR32	Residential	Unknown	725075	7386813	1.2 km NW

Notes: Datum: Map Grid of Australia (MGA) Zone 55.
Green owned or pending purchase by Magnetic South.

9.3 POTENTIAL IMPACTS

Katestone (2020) used standard industry dispersion models suitable for use in Australia and regulatory approved assessment techniques to predict ground-level concentrations of air pollutants in the areas surrounding the Project. Technical details of the methodology and models are provided in Appendix A of the *Air Quality and Greenhouse Gas Assessment* (Katestone 2020) (Appendix L).

9.3.1 Air Quality Objectives and Criteria

The EP Act provides for the management of the air environment in Queensland. The EPP (Air) was made under the EP Act with the objective "*to identify the environmental values of the air environment to be enhanced or protected and to achieve the objective of the EP Act (i.e., ecologically sustainable development)*". The EPP (Air) air quality objectives relevant to key air pollutants that may be generated from the Project are presented in Table 54.

Table 54 EPP (Air) Relevant Air Quality Objectives

Pollutant	Environmental Value	Averaging Period	Air Quality Objective	Number Exceedances Allowed Per Year
TSP	Health and Wellbeing	1 year	90 µg/m^3	None
PM_{10}		24 hours	50 µg/m^3	None
		1 year	25 µg/m^3	None
$PM_{2.5}$		24 hours	25 µg/m^3	None
		1 year	8 µg/m^3	None
Dust Deposition	Amenity	1 month	120 mg/m²/day	None

Notes: Dust deposition value is a DES recommended design objective rather than EPP (Air) objective and applies to total insoluble solids.

9.3.2 Emissions

Dust emissions will be generated over the life of the Project as a result of material extraction, handling, haulage and wind erosion of exposed mine areas. Emissions of oxides of nitrogen, sulphur dioxide and carbon dioxide (CO_2) would also occur due to blasting activities and combustion of fuels onsite. However, these emissions are transient (contained within the haul road corridor and open-cut pits) and low in magnitude compared with dust emissions. For these reasons, dust is the sole pollutant of interest for this assessment. Key dust-generating activities associated with the Project include:

- drilling and blasting;
- material extraction and handling (overburden and ROM coal);
- bulldozer activity;
- material haulage (overburden and ROM coal);
- road grading; and
- wind erosion of exposed mine areas.

Three operational modelling scenarios were used within the assessment as being the worst-case potential for dust emissions over the life of the Project based upon volumes of material extracted, proposed mining schedule and proximity of sensitive receptors. These assessed years include:

- year 2;
- year 8; and
- year 15.

The emissions estimation techniques applied in this assessment were based on standard methods that are applied throughout Australia and in the United States. These methods are consistent with those adopted for other air quality assessments conducted for other coal mines in Australia. Emissions of TSP, PM_{10} and $PM_{2.5}$ from mining activities were estimated using an approximation of emission rates from NPI emissions estimation technique handbook (DSEWPAC 2012a) and the United States Environmental Protection Agency AP42 emission handbooks (EPA 1998; EPA 2006).

Dust emissions from individual mining activities for the modelling scenarios were accounted for and have been explicitly modelled using Project specific activity information. The size distribution of dust particles was derived from the emission rates estimated for TSP, PM_{10} and $PM_{2.5}$.

Emissions have been presented inclusive of standard mitigation control factors to minimise dust emissions from mining activities. Deviation away from the NPI emissions estimation technique handbook has occurred under confidence that standard efficiency factors can be achieved. Standard efficiency factors for these control measures are presented in Table 55. Schematics and a breakdown of dust emission rates estimated for the three assessment scenarios is presented in Table 6, and Figures 7 to 9 of Appendix L.

9.3.3 Modelling Results

The dispersion modelling assessment has erred on the side of caution and selected conservative inputs; therefore, the predicted concentrations of dust are conservative estimates. Results have been presented as ground-level concentrations or deposition rates at the sensitive receptors as well as contours across the modelling domain. Results provided are subject to the standard mitigation measures outlined in Table 55.

Background dust levels have been added to the incremental model predictions in order to estimate the potential cumulative impacts of the Project with existing sources of dust in the region. Results have been assessed by comparing the cumulative concentrations and dust deposition rates with the air quality objectives described in Table 54.

Table 55 Dust Control Measures and Relative Reduction in Emissions

Activity	Control Measure	Reduction Factor
ROM coal haulage	Watering and/or suppressants/vehicle speed reduction	85%
Overburden haulage	Watering and/or suppressants/vehicle speed reduction	85%
Drilling	Drill dust suppression sprays	70%
ROM unloading at CHPP	Water sprays	70%
Crushing	Enclosure	70%
Product stockpile	Wet from CHPP	50%
Train loading	Telescopic chute with water spray	85%
Conveyor	Enclosure	70%
Conveyor	Uncovered	0%

Note: Reduction factors for coal haulage are calculated using '*NSW Coal Mining Benchmarking Study*' (Katestone, 2011) and ACARP report '*Mobile Sampling of Dust Emissions from Unsealed Roads*' (ACARP 2015). A review of both indicates that an 85% control of haul road dust emissions is achievable through a combination of watering level 2 (75% control), use of chemical suppressants (84% control) and reduction of vehicle speeds to 30 km/hr (85% control).

When interpreting the results, it is important to note that the predictions are not contemporaneous. The values presented are the maximum concentration predicted independently at each sensitive receptor or

grid point for the entire modelling period and thus constitute a worst-case or near worst-case result. These values do not necessarily occur at the same time or under the same meteorological conditions.

9.3.3.1 Suspended Particulate Matter (TSP)

Annual average TSP modelling results, inclusive of the estimated annual average background level, show concentrations of TSP comply with the relevant air quality objective at all sensitive receptors in isolation and cumulatively using the standard mitigation measures for all assessed years.

The maximum cumulative annual average TSP concentration predicted at any sensitive receptor over the three scenarios modelled is 58.3 µg/m^3, at SR22 in Year 2. This equates to 64.77% of the relevant objective value of 90 µg/m^3.

Modelled scenarios for TSP concentrations, with standard mitigation measures, have been provided as contour plots for all modelled runs alongside detailed results (Appendix L).

9.3.3.2 Suspended Particulate Matter (PM_{10})

Modelling results for PM_{10} predicted concentrations when using standard mitigation measures exceeded the 24-hour average and annual objective value of 50 µg/m^3 and 25 µg/m^3 respectively for each of the assessed mining years, these exceedances are summarised below:

- year 2:
    - 24-hour average (SR03, SR13, SR22, SR27, SR28, SR31 and SR32); and
    - annual average (SR22, SR31, and SR32).
- year 8:
    - 24-hour average (SR03, SR07, SR10, SR13, SR16, SR22, SR26, SR27, SR28, SR31 and SR32); and
    - annual average (SR22, SR31, and SR32).
- year 15:
    - 24-hour average (SR17, SR22, SR31 and SR32); and
    - annual average (SR17, SR22, SR31, and SR32).
- Further analysis of 24-hour average PM_{10} concentrations identified a time length for exceedances of at most one to three days (year 2), one to five days (year 8) and fifty days (year 15).

Modelling has shown that using standard and, when necessary, additional mitigation measures, predicted 24-hour average concentrations of PM_{10} comply with the relevant air quality objective at all sensitive receptors. Additional mitigation measures used to achieve this compliance may include but are not limited to the modification of activity rate or ceasing of certain operations. Detailed mitigation measures that will be employed are discussed in Section 9.4.

Modelled scenarios for 24-hour average and annual average PM_{10} concentrations with standard mitigation measures and additional measures, when necessary, have been provided as contour plots for all modelled runs alongside detailed results (Appendix L).

9.3.3.3 Suspended Particulate Matter ($PM_{2.5}$)

Modelling results for 24-hour average $PM_{2.5}$ concentrations, inclusive of the estimated background levels, show levels of $PM_{2.5}$ comply with the relevant air quality objective at all sensitive receptors using the standard mitigation measures for years 2, 8 and 15.

Modelling results for annual averages of $PM_{2.5}$ concentrations, inclusive of the estimated background levels, show levels of $PM_{2.5}$ comply with the relevant air quality objective at all sensitive receptors using the standard mitigation measures for years 2 and 8. However, the annual average $PM_{2.5}$ objective of 8 $\mu g/m^3$ was exceeded at SR22, SR31 and SR32 during year 15.

Modelled scenarios for $PM_{2.5}$ concentrations, with standard mitigation measures and additional measures, when necessary, have been provided as contour plots for all modelled runs alongside detailed results (Appendix L).

9.3.3.4 Dust Deposition

Monthly dust deposition modelling results, inclusive of the estimated background level, show dust deposition rates comply with the relevant air quality objective at all sensitive receptors using the standard mitigation measures for all years.

The maximum cumulative monthly dust deposition rates predicted at any sensitive receptor over the three scenarios modelled is 62.5 $mg/m^2/day$, at SR22 in Year 15. This equates to 52.08% of the relevant objective value of 120 $mg/m^2/day$.

Modelled scenarios for dust deposition concentrations, with standard mitigation measures have been provided as contour plots for all modelled runs alongside detailed results (Appendix L).

9.3.4 Impacts and Risks

Modelling shows that with the inclusion of standard and additional mitigation measures, where necessary, the Project can be operated in accordance with the EPP (Air) objectives at all sensitive places. Under these provisions, the Project is unlikely to result in impacts to air quality that could adversely affect:

- human health and wellbeing;
- health and biodiversity of ecosystems including Taunton National Park;
- aesthetics of the environment including odour, dust, visibility reducing particles or light; or
- agriculture activities including crop production.

Additional mitigation measures will be employed on an as required basis during operations to avoid any anticipated exceedances. There is a low risk that the Project would exceed the modelled scenarios with addition measures in place as the modelling has assessed potential worst-case conditions with conservative assumptions.

The management strategies discussed in Section 9.4 demonstrate the feasibility to ensure risk remains low throughout the life of the Project and provides for implementing procedures for monitoring and complaints resolution to control magnitude of risk. Appendix B (*Surface Water Assessment*) demonstrates through the water balance model that adequate amounts of water will be available to meet the water demand for the proposed dust suppression. A water supply pipeline is also proposed to provide make up water during dry periods, if required.

9.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

The management hierarchy for air emissions as set out in the EPP (Air) requires that, to the extent that it is reasonable to do so, air emissions must be dealt with in the following order of preference:

1. avoid (e.g., using technology that avoids air emissions);
2. recycle (e.g., re-using air emissions in another industrial process);
3. minimise (e.g., treating air emissions before release); and
4. manage.

Dust management and mitigation measures will be implemented for the Project. Magnetic South is committed to implementing the following measures:

- Develop and implement a dust and particulate matter monitoring program for three sites representative of surrounding sensitive receptors for early detection of elevated PM_{10} concentrations, refer to Appendix L for approximate monitoring locations. At minimum, monitoring of air quality at these locations will include:
    - continuous monitoring of PM_{10} at one primary location;
    - continuous monitoring of $PM_{2.5}$ at one primary location;
    - dust deposition monitoring at one primary location; and
    - meteorological monitoring (including temperature, wind speed and direction) at a single location representative of the Project.
- Monitoring equipment will be installed in accordance with relevant standards (i.e., dust deposition - *AS/NZS 3580.10.1:2003*, wind speed and direction - *AS/NZS 3580.14:2014*, PM_{10} - *AS3580.9.6* and $PM_{2.5}$ - *AS3580.9.10*) or otherwise approved by the administering authority.
- Ensure mitigation measures are put in place where the dust monitoring indicates a potential exceedance. This may include, increased watering of haul roads and other dust sources, and if required, timing blasts or other high-risk activities to occur outside of high-risk weather conditions.
- Develop an *Air Quality Management Plan* that will include a range of available measures to be implemented as necessary, including the implementation of a *Trigger Action Response Plan* to ensure compliance with approval conditions (refer to section 9.4.1).
- Enter into discussions and, as appropriate, commercial arrangements with affected surrounding landholders which could include:
    a. measures (e.g., purchase or relocation) which result in homesteads no longer being considered a sensitive receptor; or
    b. installation of receptor-side mitigation (e.g., air conditioners / purifiers in affected residences).

9.4.1 Air Quality Management Plan

An example *Air Quality Management Plan* has been developed to assist in the implementation of the monitoring and reporting requirements of the proposed EA and has been provided in Appendix L. The objective of the *Air Quality Management Plan* is to ensure the integrity of the environmental values of the Project site and surrounds to minimise potential impacts to air quality.

The *Air Quality Management Plan* will include the following components:

- a summary of the baseline environment and the potential impacts of the Project on air quality;
- identification of sensitive receivers surrounding the Project;
- use of real-time measurement of dust levels and meteorological conditions;
- details of mitigation measures implemented for mining and ancillary activities;
- implementation of a *Trigger Action Response Plan* as a dust management procedure that aims to investigate and respond to unexpected dust exceedances by:
    - trigger: nomination of air quality trigger values based on complaints and/or real-time dust and meteorological measurement and a range of additional measures which will be implemented, as necessary;
    - alert: an alert occurs as a result of the conditions of a trigger being met. Each alert requires one or more responses;
    - response: a response is a dust management action that may be implemented as a result of an alert being issued; and
    - action: an action is a specific activity that is condition as part of a response.
- an air quality monitoring program detailing the monitoring network, equipment requirements and monitoring, reporting and review procedures;
- a complaints and handling response procedure; and
- details of the roles and responsibilities of personnel.

The *Air Quality Management Plan* will focus on minimising air emissions in accordance with the management hierarchy set out in the EPP (Air) in the order of avoid, recycle, minimise and manage air emissions.

Due to the nature of air emissions associated with the Project, the *Air Quality Management Plan* will implement adaptive management that includes avoidance, minimisation, and management of air quality emissions.

Avoid

Air emission avoidance is defined as the prevention of air emissions. Air emissions will be avoided by:

- the adjustments to activity rates of ceasing of certain operations under adverse meteorological conditions in accordance with a meteorological forecast system and a dust risk forecast system;

- the unauthorised clearing of land and early identification of mitigation requirements through the *Land Disturbance Permit*;
- the seeding of long-term storage topsoil stockpiles; and
- progressive rehabilitation where vegetative cover will be established as soon as possible.

Minimise

A series of mitigation measures will be implemented to minimise air emissions to the receiving environment. Air emissions generated by the Project will be minimised by:

- ensuring mitigation measures are put in place where the dust monitoring or modelling indicates a potential exceedance. This may include increased watering of haul roads and other dust sources;
- the implementation of additional remedial actions for air emissions control in the event of complaints being received, exceedances of criteria being recorded, or other trigger levels in accordance with the *Trigger Action Response Plan* being breached; for example:
    - applying additional at-source and/or at-receptor dust controls under median and high-risk trigger scenarios;
    - increasing the intensity of dust controls under median and high-risk trigger scenarios; and/or
    - modifying certain operations under high-risk trigger scenarios;
- the implementation of a dust and particulate matter monitoring program at sites representative of surrounding sensitive receptors for early detection of elevated PM_{10} concentrations.

Manage

Air emissions produced by the Project will be managed through the following measures;

- entering into discussions and, as appropriate, commercial arrangements with affected surrounding landholders which could include:
    - measures (e.g., purchase or relocation) which result in homesteads no longer being considered a sensitive receptor; and
    - installation of receptor-side mitigation (e.g., air conditioners / purifiers in affected residences).
- a response plan for complaints handling; and
- an annual review program where the performance of air quality mitigation measures is assessed and where necessary, refined.

10.0 GREENHOUSE GAS

Climate change refers to long-term fluctuations in temperature, precipitation, wind, and other elements of the Earth's climate system. The Earth naturally absorbs and reflects incoming solar radiation and emits longer wavelength terrestrial (thermal) radiation back into space. A portion of this terrestrial radiation is absorbed by gases, known as greenhouse gasses (GHGs) in the atmosphere. Changes in the atmospheric concentrations of these GHGs can alter the balance of energy transfers between the atmosphere, space, land, and the oceans. The major GHGs which make the largest contribution to global warming are CO_2, methane (CH_4) and nitrous oxide (N_2O).

The main GHG associated with the Project is CO_2, with smaller contributions from CH_4 and N_2O. These gases vary in effect and longevity in the atmosphere, however identifying the global warming potential of each gas allows them to be described in terms of CO_2 (the most prevalent GHG); called carbon dioxide equivalent (CO_2-e). A unit of one tonne of CO_2-e is the basic unit used in carbon accounting.

The *Air Quality and Greenhouse Gas Assessment* (Katestone 2020) (Appendix L) identifies the potential sources of GHG emissions associated with the Project and quantifies the emissions from each source over the life of the Project. The estimated emissions have then been compared to State and National GHG emission inventory totals to provide an assessment of the potential significance of the Project in relation to Australia's GHG emission inventory.

10.1 REGULATORY FRAMEWORK FOR GREENHOUSE GAS EMISSIONS

The *National Greenhouse and Energy Reporting Act 2007* (NGER Act) establishes a mandatory scheme, the *National Greenhouse and Energy Reporting Scheme* (NGER Scheme) for the reporting of company GHG emissions and energy production and consumption.

The supporting *National Greenhouse and Energy Reporting Technical Guidelines* (NGER Guidelines) (DoEE 2017) are applicable across all industry sectors and cover important concepts under the NGER Act and supporting regulations, including scheme participation, and the determination of corporate, facility and operational control, and registration and reporting obligations. The *National Greenhouse and Energy Reporting (Measurement) Determination 2008* (NGER Determination) provides methods and criteria for calculating GHG emissions and energy data under the NGER Act.

The range of emission sources covered in the NGER Determination includes:

- the combustion of fuels for energy;
- fugitive emissions from the extraction of coal;
- oil and gas;
- industrial processes (such as producing cement and steel); and
- waste management.

Registration and reporting is mandatory for corporations that have an energy consumption or GHG emissions, including Scope 1 and Scope 2, that exceed the thresholds summarised in Table 56.

Scope 1 emissions in relation to a facility refers to the release of GHG into the atmosphere as a direct result of an activity or series of activities (including ancillary activities) that constitute the facility. Scope 2 emissions refers to the release of GHG into the atmosphere as a direct result of one or more activities

that generate electricity, heating, cooling or steam that is consumed by the facility but that do not form part of the facility.

A third classification of emissions, Scope 3, is defined as indirect greenhouse gas emissions other than Scope 2 emissions that are generated in the wider economy. They occur as a consequence of the activities of a company, but from sources not owned or controlled by that company. To limit the potential of double counting of GHG emissions on a national scale, Scope 3 are not included in NGER reporting however for information purposes will be included below (Section 10.3.2).

In addition, GHG emissions associated with land clearing are not covered by the NGER scheme but for information purposes are also detailed below (Section 10.2.1 and Section 10.3.1).

Table 56 Reporting Thresholds for Greenhouse Gas Emissions and Energy Use

Threshold Level	Threshold Type	
	GHG Emissions (kt CO_2-e per year)	Energy Consumption (TJ per year)
Facility	25	100
Corporate	50	200

10.2 EMISSIONS SOURCES

For the purposes of this assessment, Scope 1, 2 and 3 GHG emissions, including land clearing estimates, were calculated on an annual basis for the Project. This includes emissions from:

Scope 1: diesel combustion from heavy machinery and equipment and haulage vehicles, fugitive emissions of CH_4 from mining of coal deposits (i.e., waste mine gas), land clearing and use of explosives;

Scope 2: electricity usage for conveyors, CHPP and other amenities; and

Scope 3: transport of coal, rail transport to coal terminal and use of coal (coking applications).

A complete summary of emission sources associated with Project is documented in Table 15 of Appendix L.

10.2.1 Land Clearing

The GHG emissions associated with land clearing have been estimated and included below (Table 57). Land clearing is considered Scope 1 and emissions were estimated based on the Full Carbon Accounting Model developed by the Australian Government to support the estimation of carbon stock change on forest systems.

Land clearing required for the Project is made up of:

- Eucalyptus woodland – 407.17 ha;
- Acacia woodland – 313.57 ha; and
- Grazing land (previously cleared) – 1,240 ha.

To account for the prolonged nature of emissions from land clearing, total GHG emissions associated with land clearing for the life of the Project have been averaged across each year of the Project. Carbon sequestration associated with land rehabilitation was not included in the assessment due to its delayed impact in the years following the conclusion of the Project.

10.3 EMISSIONS ESTIMATION

10.3.1 Scope 1 and Scope 2

Predicted GHG emissions, exclusive of land clearing, is summarised as reportable emissions (Section 10.3.3). Estimated GHG emissions (Scope 1 and Scope 2) associated with the Project are detailed in Table 57. A complete breakdown of emissions is provided in Appendix L.

The following emissions (Scope 1 and Scope 2), inclusive of land clearing, are predicted:

- total predicted emissions are expected to average 145 kt CO_2-e per year; and
- total predicted emissions range between 12 - 217 kt CO_2-e (peaking at Year 16).

For total Project GHG emissions, the percentage of relative GHG emissions sources is shown below in Figure 78. The most significant source of GHG emissions is attributed to diesel consumption for heavy machinery, mining equipment, haulage and other onsite vehicles. Similarly, fugitive methane emission and electricity usage were also identified as significant sources of GHG emissions. These emission-source trends were frequently observed for most individual years.

Table 57 Summary of Scope 1 and Scope 2 GHG Emissions

Year	GHG Emissions (kt CO_2-e/yr)		Total Scope 1 and 2	
	Scope 1	Scope 2	Incl Land Clearing	Excl Land Clearing
Year 1	22.83	1.62	24.45	18.47
Year 2	184.71	18.25	202.96	196.98
Year 3	153.58	18.25	171.83	165.85
Year 4	163.17	18.25	181.42	175.44
Year 5	175.49	18.25	193.74	187.76
Year 6	155.29	18.25	173.54	167.56
Year 7	184.55	18.25	202.80	196.82
Year 8	191.15	18.25	209.40	203.42
Year 9	157.30	18.25	175.54	169.56
Year 10	155.12	18.25	173.37	167.39
Year 11	152.13	18.25	170.37	164.39
Year 12	161.03	18.25	179.28	173.30
Year 13	168.29	18.25	186.54	180.56
Year 14	175.41	18.25	193.66	187.68
Year 15	172.91	18.25	191.15	185.17
Year 16	198.66	18.25	216.91	210.93
Year 17	171.35	18.25	189.59	183.61
Year 18	198.53	18.25	216.78	210.80
Year 19	114.33	18.25	132.58	126.59
Year 20	28.65	3.98	32.62	32.62
Year 21	29.06	2.65	31.71	31.71

Year	GHG Emissions (kt CO_2-e/yr)		Total Scope 1 and 2	
	Scope 1	Scope 2	Incl Land Clearing	Excl Land Clearing
Year 22	11.26	2.65	13.91	13.91
Year 23	11.06	2.65	13.71	13.71
Year 24	11.06	1.33	12.38	12.38
Total (kt CO_2-e)	**3146.90**	**343.34**	**3490.23**	**3376.59**

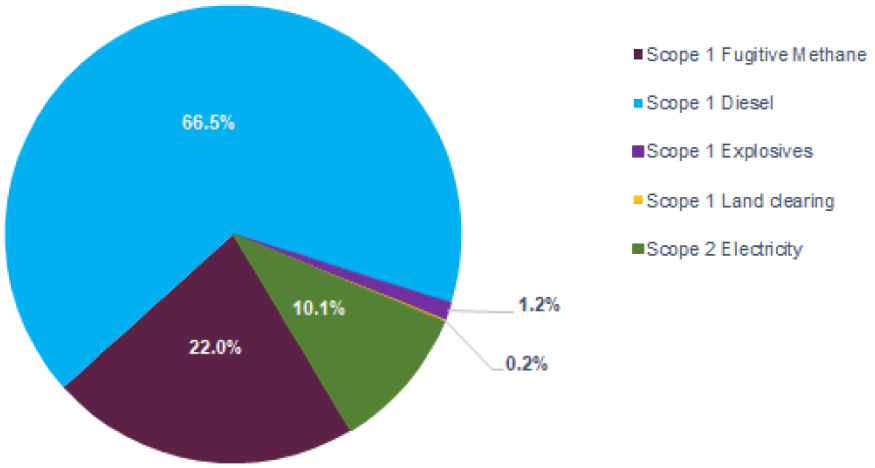

Figure 78 Total Greenhouse Gas Emissions by Scope

For comparative purposes; the latest GHG inventory estimates (excluding emissions from land use, land use change and forestry) is 538 Mt CO_2-e per year for Australia and 162 Mt CO_2-e per year for Queensland (DoEE 2019a; DoEE 2019b). Accounting for the estimated maximum year of annual GHG emissions of 217 kt CO_2-e (Year 16), the Project could contribute up to 0.04% of Australia's emissions and 0.13% of Queensland's emissions.

10.3.2 Scope 3

Total estimated annual scope 3 emissions ranged between 1905 - 3943 kt CO_2-e per year (refer to Appendix L for detailed annual summary).

10.3.3 Reportable Emissions

In accordance with the NGER scheme, the approximate reportable annual GHG emissions of the Project (excluding land clearing), range from:

Scope 1: 11 - 193 kt CO_2-e per year

Scope 2: 2 -18 kt CO_2-e per year

Total: 12 - 211 kt CO_2-e per year

Based on the NGER Act reporting thresholds detailed in Table 56, the Gemini Project will have ongoing reporting obligations including an annual assessment of GHG emissions as set out by the NGER Act and the NGER Determination.

10.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

The following management measures are proposed to minimise GHG emissions and energy use from the Project during operation:

- where practicable, energy efficiency design aspects will be investigated as part of the detailed design process in order to reduce energy and fuel consumption;
- fuel efficiency of the construction plant/equipment will inform equipment selection, and where possible, equipment with the highest fuel efficiency and lower GHG intensive fuel (e.g., biodiesel) requirements will be used;
- minimise vegetation clearing at the Project to the authorised areas required for Project development;
- consideration of renewable energy options for initial design or future improvements, such as solar powered lighting for the MIA, CHPP and accommodation facilities;
- logistical planning to improve efficiency and minimise energy use, including route and load optimisation of mining equipment and production scheduling to reduce idle time;
- maintenance of mining equipment in accordance with manufacturer and supplier guidelines to maximise fuel efficiency;
- on-site power factor correction optimised to minimise the usage of grid electricity;
- where practical, adjust peak electricity demand through production scheduling to allow for optimal and well utilised diesel power generation capacity;
- spontaneous combustion of coal will be managed to avoid unexpected emission through the burial of reactive materials, spoil dump design, temperature monitoring and spoil dump ventilation;
- using appropriately sized equipment; and
- ongoing monitoring and reporting of GHG emissions including an annual review of energy use to identify potential energy efficiency opportunities on a regular and ongoing basis.

11.0 NOISE AND VIBRATION

This section describes the assessment of potential noise, vibration and blasting impacts from the construction, operation, and closure of the Gemini Project.

This section is informed by the *Noise Impact Assessment* (ASK 2020) provided as Appendix M.

11.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objectives relevant to potential noise impacts have been developed in accordance with the *Application requirements for activities with noise impacts [ESR/2015/1838]* (DES 2017d) to ensure:

The activity will be operated in a way that protects the environmental values of the acoustic environment.

The Project would achieve either one of the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

1 *sound from the activity is not audible at a sensitive receptor; and*

2 *the release of sound to the environment from the activity is managed so that adverse effects on environmental values including health and wellbeing and sensitive ecosystems are prevented or minimised.*

11.2 DESCRIPTION OF ENVIRONMENTAL VALUES

11.2.1 Land Use

The Project site and surrounding area is currently used predominately for cattle grazing with most of the area cleared for agricultural purposes. To the east of the Project lies Dingo, a small town of approximately 450 people, and includes residences, sporting facilities (sports oval, tennis courts), a primary school, and local businesses (Post Office, hotel, shops, etc).

11.2.2 Sensitive Receptors

A total of 25 sensitive receptors were identified within 5 km of the Project in parallel with the *Air Quality and Greenhouse Gas Assessment* (Katestone 2020) (Appendix L) based on the definition from the *Environmental Protection (Noise) Policy 2019* (EPP (Noise)). A number of the identified sensitive receptors are located within 1 km of the Capricorn Highway and Blackwater Railway that extends through the northern section of the MLA. Eight sensitive receptors (SR09, SR14, SR15, SR19, SR20, SR21, SR23 and SR24) are located on land owned or under purchase by Magnetic South. Any dwellings situated on these properties will be vacant prior to the commencement of mining activities and therefore have been excluded from the noise assessment.

The same suite of receptors encompassing multiple dwellings and residences, facilities, businesses, and recreational areas, including the Dingo township, was used for both the air quality and noise assessments (refer to Figure 77 and Table 53).

The nearest mining operation to the Gemini Project is Bluff PCI Project, located approximately 12 km west of the Gemini Project's proposed ROM pad. At the time of submission, this mine is in care and maintenance, with no certainty of returning to operations during the life of the Gemini Project.

11.2.3 Climate and Wind Characteristics

The propagation of noise in the outdoor environment can be influenced by the local meteorological conditions. Air temperature, humidity, wind speed, wind direction and stability of the atmosphere can all influence noise either in isolation or as combined weather conditions.

Computer modelling was used to input specific meteorological conditions to predict noise levels under unfavourable 'adverse' day and night meteorological conditions using wind conditions from the southeast and west directions. The meteorological scenarios used in these modelled calculations are provided in further detail below (Table 58).

Table 58 Meteorological Scenarios

Parameter	Day Meteorological Scenarios			Night Meteorological Scenarios		
	Scenario D1	Scenario D2	Scenario D3	Scenario N1	Scenario N2	Scenario N3
Pasquill Stability Class	D	D	D	F	F	F
Temperature (°C)	25	25	25	10	10	10
Wind Speed (m/s)	2	2	2	2	2	2
Wind direction	Towards receivers	SE	W	Towards receivers	SE	W
Relative humidity (%)	40	40	40	70	70	70

11.2.4 Background Noise Levels

The Project is located in a rural area with influences from transport and the agricultural industry. Specifically, the existing acoustic environment is affected by:

- traffic on the Capricorn Highway and other local roads;
- coal trains;
- native birdlife;
- insect noise;
- agricultural equipment; and
- cattle.

A baseline noise monitoring study was conducted to determine baseline background noise prior to the commencement of the Project (Appendix M). Monitoring was undertaken in general accordance with *Australian Standard AS1055: Acoustics – Description and measurement of environmental noise* and the *Noise Measurement Manual* (EHP 2013b).

Noise levels were continuously monitored with noise loggers for up to 13 consecutive days in June 2019, and attended logging was undertaken for two nights for separate 15-minute periods. Noise logging was undertaken at three locations to produce representative modelling outcomes:

Location A: Accommodation facility (the same location as SR22). Located in an open-field, approximately 360 m northeast of the railway line and 440 m northeast of the Capricorn Highway.

Location B: Dingo Roadhouse (approximately the same location as SR03). Located in an open-field location, approximately 220 m southwest of the Capricorn Highway.

Location C: Rural residence (approximately the same location as SR19, SR20 and SR21). Located in an open-field position, approximately 200 m northeast of the homestead.

The existing background noise levels were influenced by a variety of natural sources (insects, birdsong, windblown vegetation, cattle) at all locations. In particular, locations A and B were influenced by transport related sources of background noise including the Capricorn Highway and Blackwater Railway, and locations A and C were influenced by levels of high insect noise. As insect noise is a seasonal influence, the noise level data was filtered to remove the insect noise from Locations A and C. The background noise level results were calculated using the lowest 10th percentile method and have been provided in Table 59.

Table 59 Background Noise Level

Period	Background Noise Level (L_{90} dBA)		
	Location A	Location B	Location C
Day (7am to 6pm)	33	35	25
Evening (6pm to 10pm)	23	37	29
Night (10pm to 7am)	20	27	22

Notes: dBA 'A' weighted decibel.
L_{90} 'A' weighted sound pressure level equalled or exceeded 90% of the time.

11.3 POTENTIAL IMPACTS

To assess impacts and risks of the Project to the existing noise environment, ASK (2020) undertook a noise and vibration assessment. A summary of the impact assessment and modelled results are detailed below.

11.3.1 Noise Quality Objectives and Criteria

ASK (2020) consulted several sources of information in order to propose relevant noise and vibration objectives for the Project:

- EP Act;
- EPP (Noise);
- *Guideline (Noise): Planning for noise control* (EHP 2004);
- *Guideline (Noise): Noise and vibration from blasting [EM2402]* (EHP 2016); and
- *Guideline (Mining): Model mining conditions [ESR/2016/1936]* (DES 2017e).

In accordance with *Model Mining Conditions* (DES 2017e), the EPP (Noise) and the *Planning For Noise Control* guideline (EHP 2004), the following noise criteria provided in Table 60 has been adopted.

Table 60 Proposed Noise Limits

Period	Noise Limit ($L_{Aeq,adj,1hr}$ dBA)
Day (7am to 6pm)	40
Evening (6pm to 10pm)	40
Night (10pm to 7am)	35

Notes: $L_{Aeq,adj,1hr}$ means an 'A' weighted sound pressure level of a continuous steady sound, adjusted for tonal character, that within a 1-hour period has the same mean square sound pressure of a sound that varies with time.

It is noted by the *Planning For Noise Control* (EHP 2004) that the noise reduction provided by a typical residential building façade is 7 dBA with windows open. Based on a façade reduction of 7 dBA (i.e., 7 dBA reduction in noise levels from outside a house to inside a house when windows are fully open), the EPP (Noise) indoor noise objectives could be converted to the proposed noise limits (with windows open) presented in Table 60.

The *Noise and vibration from blasting* and the *Model Mining Conditions* (DES 2017e) contain the same criteria for blasting. ASK (2020) propose that these criteria are adopted for the Project, as outlined in Table 61.

Table 61 Proposed Blasting Vibration and Air-blast Criteria

Issue	Criteria
Airblast overpressure	115 dB (linear) peak for nine out of ten consecutive blasts initiated and not greater than 120 dB (linear) peak at any time.
Ground vibration peak particle velocity	5 mm/s PPV for nine out of ten consecutive blasts and not greater than 10 mm/s PPV at any time.

PPV peak particle velocity

11.3.2 Noise Prediction Model

Mining noise emissions from the Project have been predicted for the three mine year scenarios; Year 2, Year 8, and Year 15. These years were selected to give a representation of mine noise levels near the beginning, middle and end of the project. Modelling of the scenarios has incorporated mine ground elevations, and type, number and location of equipment for each mine year. Mining noise levels at residential receptors can vary significantly depending upon the meteorology and the mine activities. Meteorology has significant effects on noise levels, predominantly due to wind speed and direction, and vertical temperature gradients, including temperature inversions. Detailed information regarding model inputs including noise source emissions, noise source locations, mobile equipment numbers and total scenario power levels is provided in Appendix M.

A SoundPLAN (Version 8.2) computer noise model was used to predict noise levels at sensitive receptors. The computer model calculated the noise levels at sensitive receptors, accounting for noise propagation variables such as distance attenuation, ground absorption, air absorption and shielding attenuation from topography, buildings or barriers.

The CONCAWE industrial noise prediction methodology was utilised within SoundPLAN, which is specially designed for large facilities and incorporates the influence of wind effects and stability of the atmosphere.

11.3.3 Noise Modelling Results

The predicted noise levels at nearby sensitive receptors for the three mining year scenarios are presented for 'adverse' night and day scenarios below (Table 62, Table 63 and Table 64). The results are compared against the proposed noise limits of 35 dBA $L_{Aeq,adj,1hr}$ (night) and 40 dBA $L_{Aeq,adj,1hr}$ (day/evening). From this, potential noise impacts associated with the Project include the following:

- no exceedances are recorded during day/evening operations; and
- night exceedances are limited to:
    - Year 2 (SR10: 2 dBA and SR22: 1 dBA); and
    - Year 8 (SR10: 3 dBA).

Therefore, the maximum exceedance is limited to 3dBA at sensitive receptor SR10 located 1.4 km to the east of the Project.

Model Mining Conditions and the EPP (Noise) for sleep disturbance recommend the assessment of L_{Amax}, L_{A01} and L_{A10}, however these parameters have not been included in this assessment. Most mine noise source data is available in the L_{Aeq} parameter and where noise limits of L_{Amax}, L_{A01} and L_{A10} are specified for the Project, they would be 15, 10 and 5 dBA higher than the L_{Aeq} noise limits, respectively. It is noted that L_{A01} and L_{A10} noise limits cannot be accurately used for compliance during warmer months as noise levels are commonly dominated by insect noise (i.e., removal of insect noise is not strictly possible from these noise parameters). The L_{Amax} parameter can also be challenging for compliance monitoring as extraneous L_{Amax} events (e.g., birds, animals, farm activities) need to be removed from the noise monitoring data.

In this instance, L_{Aeq} is the preferred parameter. If L_{Aeq} noise levels comply with relative limits, no further assessment is proposed for the L_{Amax}, L_{A01} and L_{A10} parameters as they would subsequently comply (refer to Appendix M).

The predicted noise levels are displayed graphically as noise contours below (Figure 79 through to Figure 84).

Table 62 Predicted Noise Levels - Year 2

Receptor	Predicted Noise Emission Levels (L_{eq} dBA)																	
	Day Meteorological Scenarios									Night Meteorological Scenarios								
	Mine Only			Mine & Rail Loadout			Night Criterion Exceedance (35 dBA)			Mine Only			Mine & Rail Loadout			Night Criterion Exceedance (35 dBA)

11.3.4 Background Creep

The EPP (Noise) no longer contains criteria for background creep, but states that background creep should be prevented or minimised, to the extent that it is reasonable to do so. In consideration of the *Noise Measurement Manual (ESR/2016/2195 - formerly EM1107*), background creep is defined as 'a gradual increase in the total amount of background noise in an area or place.' Therefore, consideration of cumulative impacts, including other developments, is required to ensure background creep is minimised in accordance with the EPP (Noise) recommendations.

The nearest existing mine is Bluff Mine to the west of the Project. The sensitive receptors that have the most potential to be impacted by the Project to the west are SR22, SR31 and SR32, with noise levels of up to 36 dBA, 33 dBA and 31 dBA L_{Aeq} respectively. The Bluff Mine is over 12 km from these receptors (SR22, SR31 and SR32) and only 1 km from the township of Bluff. Given the requirement to comply with noise criteria in the township, it would be expected that Bluff mine noise levels at the receptors would be well below the 35 dBA noise limit and would not significantly contribute to exceedances at these locations. In addition to this, cumulative impacts from adverse wind conditions cannot occur for both mines simultaneously at these receptors since they are in opposite directions. Similarly, due to the broadscale consistency of adopted noise limits for the Project with other mining operations such as the Bluff Mine and Jellinbah Mine in the surrounding region (limits detailed above in Section 11.3.1), a 'no wind scenario' is considered to produce the same outcome. Additionally, it is noted that, at the time of submission, Bluff mine is under care and maintenance, with no certainty of returning to operations during the life of the Gemini Project. Therefore, it is unlikely that cumulative noise impacts from surrounding mines would contribute to background creep.

11.3.5 Vibration Assessment

It is anticipated that the existing vibration levels around the Project and at the location of sensitive receptors will generally be negligible, except at locations which are close to roads, rail lines or near major items of fixed plant. The only vibration source of significance from the mining of the Project would be blasting. Blasting activities within the pits have been assessed for both ground vibration and airblast.

Ground vibration and airblast levels caused by blasting activities were predicted based on the formulas and methodology of *Australian Standard AS2187.2: Explosives - Storage Transport and Use - Use of Explosives*, which predicts the PPV in mm/s and the airblast over pressure (peak pressure) in dB. Technical details of assessment methodology and inputs for ground vibration and airblast can be found in Section 7 of the *Noise Impact Assessment* (ASK 2020) (Appendix M).

Based on the ASK (2020) blasting calculations, the ground vibration and airblast levels from the Project are predicted to be acceptable at the nearest sensitive receptors based on the nominated criteria (Table 61).

Table 65 shows that the 10 mm/s PPV criterion would not be exceeded at distances greater than 1.0 km from the blast, whilst the 5 mm/s PPV criterion would not be exceeded at distances greater than 1.5 km from the blast. The nearest sensitive receptor is approximately 1.9 km away from the nearest pit shell area where blasting would occur. Therefore, ground vibration due to blasting is predicted to be compliant with the nominated criteria at all sensitive receptors.

Table 65 Ground Vibration Levels at Various Distances from The Blast

Distance from Blast (km)	Vibration Level (mm/s)	
	K = 800	K = 1600
1.0	2.9	5.9
1.5	1.5	3.1
2.0	1.0	1.9
2.5	0.7	1.4
3.0	0.5	1.0
3.5	0.4	0.8
4.0	0.3	0.6
4.5	0.3	0.5
5.0	0.2	0.4
5.5	0.2	0.4
6.0	0.2	0.3
6.5	0.1	0.3
7.0	0.1	0.3
7.5	0.1	0.2
8.0	0.1	0.2
8.5	0.1	0.2
9.0	0.1	0.2
9.5	0.1	0.2
10.0	0.1	0.1

Notes: K site and rock constant. Assumed to be in the range of 800 to 1600 for the Gemini Project (ASK 2020).

Table 66 contains the separation distances and the reduction of airblast noise levels due to distance. The distance to the airblast criterion contour line of 120 dB (linear) was calculated to be 880 m. The distance to the 115 dB (linear) contour line is calculated to be 1,290 m. Based on these calculations and blast parameters, the airblast criteria would not be exceeded at any sensitive receptors.

Table 66 Airblast Noise Levels At Various Distances From The Blast

Distance from Blast (km)	Airblast Level (dB (linear))
1.0	118.3
1.5	113.0
2.0	109.3
2.5	106.4
3.0	104.0
3.5	102.0
4.0	100.3
4.5	98.8
5.0	97.4
5.5	96.2
6.0	95.0
6.5	94.0
7.0	93.0
7.5	92.2
8.0	91.3
8.5	90.5
9.0	89.8
9.5	89.1
10.0	88.4

11.3.6 Impact Summary

The Project has potential to impact on EVs as a result of Project related noise impacts. Noise criteria was proposed (Table 60) in line with current policy.

From the predicted noise levels in Section 11.3.3, of the properties that are not owned by Magnetic South at the time of submission, exceedances of the 35 dBA night objective is predicted at two receptors:

- SR10 (Year 2 and Year 8);
- SR22 (Year 2).

Compliance is predicted at all other sensitive receptors during both day and night 'averse' conditions.

Of these potentially impact receptors, SR22 is located within the MLA, whilst SR10 is located 1.4 km east of the MLA. Given there is a potential for exceedances, a range of mitigation measures will be implemented, as necessary, to achieve compliance for residual sensitive receptors in the area. These measures are detailed in the subsection below.

11.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

The management hierarchy for noise as set out in the EPP (Noise) requires that for an activity involving noise that affects, or may affect, an EV, to the extent that it is reasonable to do so, noise must be dealt with in the following order of preference:

1. avoid the noise (e.g., locating an activity in an area that is not near a sensitive receptor);
2. minimise the noise by preferably:
    a. orientating an activity to minimise the noise (e.g., facing a part of an activity that makes noise away from a sensitive receptor); or alternatively
    b. using the best available technology to minimise the noise; or
3. manage the noise (e.g., using heavy machinery only during business hours).

The potential requirements for noise mitigation at this time are based solely on noise modelling for the Project. Magnetic South will monitor and verify noise levels before considering the implementation of mitigation measures.

11.4.1 Noise Monitoring

Prior to mining operations, noise level compliance will be undertaken by real time noise monitoring at the most noise affected receptor/s (i.e., SR10 and SR22). A noise monitoring survey will be then conducted at the commencement of operations to verify the noise emissions within the Project and the level of noise impact at sensitive receptors. The verified noise levels will direct the noise limits that will be administered under the EA and subsequent auditing compliance.

The following noise monitoring measures will be undertaken to inform the ongoing design of operations and any noise mitigation requirements:

- Develop and implement a noise monitoring program at sites representative of surrounding sensitive receptors for verification of modelling results. All noise monitoring will be conducted in accordance with *Australian Standard AS1055: Acoustics – Description and measurement of environmental noise* and the *Noise Measurement Manual* (EHP 2013b).
- Operate a real time noise monitoring system that will report one-third octave band noise levels (including L_{eq} ,L_1, L_{10} and L_{90}.) over 15-minute periods and provide audio recording/snapshots and 1 second time period noise levels. The system will have the capability to email, text message, or otherwise transmit alerts to mine operators to enable the mine to react to potential exceedances and may also provide a web portal interface where mine operators can track the noise during night periods.
- A blast monitoring program will be developed to monitor the airblast overpressure and blast vibration levels during all blast events. The blast design details will be the responsibility of the blast contractor and observations before and after blasting will also be recorded.

Where the monitoring programs indicate a potential exceedance, the following mitigation measures below would be implemented, as necessary.

11.4.2 Noise Mitigation Management and Scenarios

Noise and vibration management and mitigation measures will be undertaken for the Project to ensure all noise objectives and limits have been achieved. Magnetic South is committed to implementing the following measures:

- Develop a *Noise and Blast Management Plan* that will detail noise monitoring frequency and a range of available measures to be implemented as necessary to ensure compliance with approval conditions.

  Measures that will be considered for inclusion in the *Noise and Blast Management Plan* as opportunities for noise reduction and additional remedial actions for noise control in the event of complaints being received, exceedances of criteria being recorded, or other trigger levels being breached include:

  - management of mining equipment locations (i.e., moving mine equipment further from the most-affected receptors);
  - where appropriate, ceasing operations at times of the day that are predicted to result in exceedances (i.e., night-time) is considered to minimise effects;
  - where appropriate, ceasing operations under meteorological conditions that are predicted to result in exceedances at highly affected receptors (real time noise monitors can inform reactive operation to meteorological conditions if limits are exceeded);
  - reducing the number of equipment in operation during the night (e.g., halving of equipment numbers would be expected to provide a reduction of 3 dBA, assuming the shutdown equipment was spread around the mine operations);
  - attenuation of equipment, particularly the mobile fleet, could result in noise reductions of the order of 3 to 8 dBA, at $250,000 to $750,000 per item of equipment;
  - construction of bund walls where possible nearest to the noise source (i.e., adjacent a haul road, or sensitive receptors);
  - the requirement that Magnetic South will investigate, if monitoring indicates unexpected exceedances of noise or blast objectives; and/or
  - roles and responsibilities for implementation, monitoring and review of the *Noise and Blast Management Plan*.

- Enter into discussions and, as appropriate, commercial arrangements with any affected surrounding landholders which could include:

  - measures (e.g., purchase or relocation) which results in homesteads no longer being considered a sensitive receptor; or
  - installation of receptor-side mitigation (e.g., air conditioners and glazed windows in affected residences to allow for closed windows).

Based on the modelled noise results in Section 11.3.3, a number of noise mitigation scenarios are outlined below (Table 67). These optional scenarios focus on removing or relocating equipment and should be considered as examples only as other acoustically equivalent scenarios could be developed. The mine could operate compliantly by selecting and operating to one of the optional scenarios below.

Table 67 Example Mitigation Scenarios

Year	Scenario	Example Scenarios and Resulting Noise Levels Under Adverse Conditions for Each Time Period	
		Day and Evening (7am to 10pm)	Night (10pm to 7am)
Year 2	Original	36 dBA at SR10 and 35 dBA at SR22, as per Table 62.	37 dBA at SR10 and 36 dBA at SR22, as per Table 62.
	Option 2A	No change to day/evening operations. Results as per Original scenario already achieve compliance.	35 dBA at SR10 and 35 dBA at SR22, i.e., compliance achieved when 5 of 12 x OB haul trucks removed.
Year 8	Original	37 dBA at SR10, as per Table 63	38 dBA at SR10, as per Table 63.
	Option 8A	No change to day/evening operations. Results as per original scenario already achieve compliance.	35 dBA at SR10, i.e., compliance achieved when 1 of 6 x D11 dozers are removed from dump and 6 of 15 x OB haul trucks are removed.

12.0 WASTE GENERATION

This section provides a description of the waste streams that are likely to be produced over the life of the Project and describes the proposed measures for minimising and managing waste generated. This section refers to general and regulated waste streams to be managed at the Project. Other waste products not addressed here include water, air, GHG and waste rock. These are addressed in the relevant technical sections:

- surface water runoff and wastewater is addressed in Section 7.0;
- groundwater inflows into the open pits is addressed in Section 8.0;
- airborne wastes excluding GHGs is addressed in Section 9.0;
- GHGs and fugitive emissions is addressed in Section 10.0; and
- excavated waste rock and coal rejects is addressed in Section 13.0.

12.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

The environmental objective relevant to waste, as described in the EA guideline for *Application requirements for activities with waste impacts [ESR/2015/1836]* (DES 2019), is:

Any waste generated, transported, or received as part of carrying out the activity is managed in a way that protects all environmental values.

The Project would achieve the following performance outcomes identified in Schedule 8, Part 3, Division 1 of the EP Regulation:

a) waste generated, transported, or received, is managed in accordance with the waste and resource management hierarchy in the Waste Reduction and Recycling Act 2011; and

b) if waste is disposed of, it is disposed of in a way that prevents or minimises adverse effects on environmental values.

12.2 DEFINITION OF WASTE

The EP Act defines 'waste' as anything that is:

a) left over, or an unwanted by-product, from an industrial, commercial, domestic or other activity; or

b) surplus to the industrial, commercial, domestic or other activity generating the waste.

Section 42 of the EP Regulation defines 'regulated waste' as waste that is:

a) commercial waste or industrial waste; and

b) a type, or contains a constituent of a type, mentioned in schedule 9, part 1, column 1.

Classified under 'regulated waste' –

Schedule 2 of the EP Regulation defines 'limited regulated' waste to include –

a) *animal effluent and residues, asbestos, biosecurity waste that has been rendered non-infectious, food processing waste, tyres, and sewage sludge or residue produced in carrying out an activity.*

Schedule 19 of the EP Regulation defines 'commercial waste' as:

a) *waste produced as a result of the ordinary use or occupation of commercial or premises; and*

b) *waste other than green waste, recyclable waste, interceptor waste or waste discharged to a sewer.*

Schedule 19 of the EP Regulation defines 'industrial waste' as:

a) *interceptor waste; or*

b) *waste other than the following—*

i. *domestic waste, domestic clean-up waste, green waste, recyclable waste, recyclable interceptor waste, waste discharged to a sewer.*

Schedule 19 of the EP Regulation defines 'biosecurity waste' as:

a) *waste that is goods subject to biosecurity control under the Biosecurity Act 2015 (Cwlth); or*

b) *goods under the Biosecurity Act 2015 (Cwlth) that are or were in contact with waste mentioned in paragraph (a).*

Schedule 19 of the EP Regulation defines 'general waste' as:

a) *waste other than regulated waste;*

b) *chapter 6, part 2, any of the following –*

i. *commercial waste, other than regulated waste;*

ii. *domestic waste;*

iii. *recyclable waste.*

c) *general waste composition includes –*

i. *putrescibles, paper, cardboard, glass, office waste, industrial waste and construction waste.*

Schedule 19 of the EP Regulation defines 'green waste' as:

a) *organic waste from vegetation (e.g., trees, shrubs, and grass).*

Schedule 19 of the EP Regulation defines 'clinical waste' as:

a) *waste that has the potential to cause disease*

b) *clinical waste composition includes –*

i. *animal waste, discarded sharps, human tissue waste and laboratory waste.*

12.3 IDENTIFIED WASTE TYPES

The primary source of waste from mining operations is excavated waste (overburden and interburden), coarse rejects and fine rejects (tailings) from the CHPP. Other wastes (regulated and non-regulated) expected to be produced from activities pertaining to the Project include:

- general waste;
- recyclable waste;
- refurbishable items;
- green waste;
- scrap metal;
- personal protective equipment (ppe);
- air filters;
- timber and reusable pallets;
- waste oils;
- engine oil/fuel filters;
- waste greases;
- sewage effluent;
- empty waste oil containers;
- paints;
- hydrocarbon contaminated material;
- miscellaneous chemicals;
- batteries;
- E-waste;
- ozone depleting substances; and
- tyres.

Table 68 describes the expected quantity of each generated waste type, stream and disposal locations during the construction and operational phases of the Project based on different waste definitions listed in the EP Regulation.

Table 68 Anticipated Waste Generation From The Construction and Operation of the Project

Waste Type/ Waste Category	Form	Source	Approximate Quantity (per annum)		Management Strategies	Waste Management Hierarchy	Proposed Disposal Location
			Construction	Operation			
General Waste							
General waste *(i.e., food scraps, non-Class 1, 2 and 5 plastics)*	Solid	Kitchenettes, crib rooms, administration areas, workshop, etc.	<130 t	<170 t	General waste will be stored onsite in bins for regular transport offsite by a licensed waste transport contractor to a licensed landfill.	Waste disposal	General waste will be transported offsite by a licenced waste contractor to an approved landfill.
Recyclable waste *(i.e., aluminium, steel cans, Class 1, 2 and 5 plastics, paper towels, paper and cardboard)*	Solid	Kitchenettes, crib rooms, administration areas, workshop, etc.	<40 t	<70 t	Recyclable waste will be stored onsite in bins for regular transport offsite by a licensed waste transport contractor for recycling.	Waste recycling	Recyclable waste will be transported offsite by a licenced recycling contractor to an approved recycling facility.
Timber/reusable pallets	Solid	Workshop and administration areas	<20 t	<20 t	Reusable pallets will be returned to the supplier.	Waste reuse	Return to supplier for reuse.
					Where pallets are unable to be reused, they will be sent to general waste.	Waste disposal	Pallets that are not reusable will be transported offsite by a licenced waste contractor to an approved landfill.
Refurbishable items *(i.e., pipe work and associated components and fittings, wing nuts, conveyor rollers and belt)*	Solid	CHPP and workshops	<10 t	<10 t	Refurbishable items will be stockpiled within a designated area. If condition is acceptable, items will be reused directly.	Waste reuse	Reuse onsite.
					Where items are unable to be reused, they will be collected and disposed by a licensed waste contractor. Where items are contaminated with hydrocarbons, they will be managed as regulated waste.	Waste disposal	Refurbishable items will be disposed of offsite by a licenced waste contractor to an approved waste facility.

Waste Type/ Waste Category	Form	Source	Approximate Quantity (per annum)		Management Strategies	Waste Management Hierarchy	Proposed Disposal Location
			Construction	Operation			
PPE and other small items *(i.e., gloves, hard hats, safety glasses and face masks)*	Solid	Bathhouse and contractor facilities	<100 kg	<200 kg	Equipment that is not damaged will be reused onsite.	Waste reuse	Reuse onsite.
					Equipment that is sufficiently used and/or damaged will be disposed.	Waste disposal	PPE will be transported offsite by a licenced waste contractor to an approved landfill.
Scrap metal *(i.e., stainless steel, aluminium and any item considered to be metal [ferrous or non-ferrous] including machine and vehicle parts)*	Solid	Construction activities, infrastructure maintenance and workshops	<50 t	<100 t	Small scrap metals will be placed in scrap metal skips. All grease and oils will be removed prior to placement in skips. Specific arrangements will be made for the collection of larger scrap metals. A licensed contractor will remove all scrap metals for segregation at a licensed recycling facility.	Waste recycling	Scrap metal will be transported offsite by a licensed contractor to an approved recycling facility.
Air filters *(i.e., engine air filters)*	Solid	Vehicle and machinery maintenance at workshops	<1 t	<7 t	Air filters will be temporarily stored in the appropriate air filter skip and will be disposed of offsite by a licensed waste contractor.	Waste recycling	Air filters will be transported offsite by a licenced waste contractor to be recycled.
Green & Biosecurity							
Green waste *(i.e., grass, cleared timber and weeds)*	Solid	Clearing of vegetation	As per schedule	As per schedule	Green waste will be mulched and/or placed in timber stacks for reuse onsite during rehabilitation.	Waste reuse	Reuse onsite.
Regulated							
Excavated waste *(i.e., overburden, interburden)*	Solid	Mining activities	n/a	Up to 473.4 Mbcm	Excavated waste rock will be placed in an out-of-pit waste rock emplacement and in-pit waste rock emplacements of Pit AB and Pit C when space becomes available behind the advancing mining operations.	Waste disposal	Excavated waste rock will be disposed of within Pit AB and Pit C and out-of-pit waste rock emplacements.

Waste Type/ Waste Category	Form	Source	Approximate Quantity (per annum)		Management Strategies	Waste Management Hierarchy	Proposed Disposal Location
			Construction	Operation			
Coal rejects *(i.e., coarse and fine rejects)*	Solid	Mining activities	n/a	Up to 0.5 Mt	Coal rejects will be disposed of in out-of-pit waste rock emplacements and in-pit waste rock emplacements of Pit AB and Pit C when space becomes available behind the advancing mining operations.	Waste disposal	Coal rejects will be disposed of within Pit AB and Pit C and out-of-pit waste rock emplacements.
Waste oils	Liquid	Machinery and vehicle maintenance and workshop	30 kL	199 kL	Waste oils will be transported offsite by a licensed regulated waste contractor and will be reused or recycled by a licensed regulated waste receiver.	Waste reuse or recycling	Waste oils will be recycled by a licenced regulated waste contractor.
Engine oil/fuel filters	Solid/ Liquid	Vehicle and machinery maintenance at workshop	50 each	780 each	Engine oil filters will be collected and stored in sealed oil filter disposal pod. They will be transported by a licensed regulated waste contractor to a licensed regulated waste receiver for treatment to recover oil for reuse.	Waste reuse	Re-use onsite.
					If filters are unable to be recovered, they will be recycled by a licensed regulated waste contractor.	Waste recycling	Engine oil/fuel filters will be recycled by a licenced regulated waste receiver at an approved recycling facility.
Waste grease *(i.e., from machinery)*	Liquid	Workshop, large machinery maintenance	<0 kL	<0.5 kL	Waste grease will be stored in sealed containers or tanks in a designated bunded area, which will then be transported offsite by a licensed regulated waste contractor. Waste grease will be recycled at a licensed waste facility.	Waste recycling	Waste grease will be recycled at an approved offsite facility by a licenced regulated waste contractor.

Waste Type/ Waste Category	Form	Source	Approximate Quantity (per annum)		Management Strategies	Waste Management Hierarchy	Proposed Disposal Location
			Construction	Operation			
Empty waste oil containers	Solid	Workshop	<1 t	<1 t	All drums will be segregated and sealed prior to collection by a licensed regulated waste contractor and transported to a licensed waste receiver for recycling.	Waste recycling	Empty waste oil containers will be recycled offsite by a licenced regulated waste receiver.
Paints *(i.e., general paint, air dried insulating varnish)*	Liquid /Gas	Industrial area infrastructure and workshop	<1 t	<1 t	Paints will be transported to a designated sealed and bunded area to be collected by a licensed regulated waste contractor and transported to a licensed regulated waste receiver for treatment before disposal.	Treat waste before disposal	Empty waste oil containers will be recycled by a licenced regulated waste contractor.
Hydrocarbon contaminated material *(i.e., oily rags)*	Solid/ Liquid	Workshop servicing trucks and light/heavy vehicles	<1 t	<5 t	Hydrocarbon contaminated material will be stored in temporary storage facilities in the MIA, which will then be collected for offsite disposal.	Waste disposal	Hydrocarbon contaminated material will be disposed of by licenced waste transport operators at an appropriately licensed waste disposal facility.
Miscellaneous chemicals *(i.e., engine coolant, solvents, sealants, etc.)*	Liquid / Gas	Workshop and administration	<1 kL	40 kL	Miscellaneous chemicals will be transported to a designated sealed and bunded area for collection by a licensed regulated waste contractor and transported to a licensed regulated waste receiver for treatment and disposal.	Treat waste before disposal	Miscellaneous chemicals will be disposed offsite by a licenced regulated waste contractor at an approved licenced facility.
Batteries *(i.e., dry cell, gel cell, lead acid)*	Solid	Operation of portable electrical equipment (radios, phones, etc.) within the	<1 t	<2 t	Batteries will be segregated and stored within dedicated containers in the battery storage area, which will then be collected and transported by a licensed regulated waste contractor to a licensed regulated waste facility for recycling.	Waste recycling	Batteries will be recycled by a licensed regulated waste contractor at a licensed regulated waste facility.

Waste Type/ Waste Category	Form	Source	Approximate Quantity (per annum)		Management Strategies	Waste Management Hierarchy	Proposed Disposal Location
			Construction	Operation			
		workshop and other areas			Remaining batteries that are not recyclable will be disposed of by a licensed regulated waste contractor.	Waste disposal	Batteries will be disposed offsite by a licenced regulated waste contractor at a licensed regulated waste facility.
Ozone depleting substance *(i.e., refrigerants and air conditioning substances)*	Liquid / Gas	Air conditioning units, fridges and cars throughout site	<1 kg	<1 kg	Ozone depleting substances will be stored at the source in cylinders and returned to the supplier for reuse and recycling.	Waste reuse and recycling	Ozone depleting substances will be recycled by a licenced regulated waste contractor.
Limited Regulated							
Tyres *(i.e., light and heavy vehicle tyres)*	Solid	Tyres from light and heavy vehicles	20	50	Tyres will be segregated and re-purposed onsite in a designated area where there will be no flammable materials within a 10 m radius. Tyres will then be transported offsite to a supplier for re-treading.	Waste reuse	Reuse onsite for alternate purposes.
					The remainder of tyres that will not be re-purposed will be disposed onsite in a designated tyre disposal area of the backfilled Pit AB and/or Pit C.	Waste disposal	Tyres will be disposed onsite within a designated tyre disposal area of the backfilled Pit AB and/or Pit C.
Sewage	Liquid	Offices, workshops and accommodation facility	<7,665 kL	<7,665 kL	Sewage generated onsite will be pumped to the STP located west of the accommodation facility. Treated effluent will be irrigated with sprinklers to a designated area located at a distance of at least 500 m away from site offices and residences.	Treat waste before disposal	Treated effluent will be irrigated with sprinklers to a designated area.

Waste Type/ Waste Category	Form	Source	Approximate Quantity (per annum)		Management Strategies	Waste Management Hierarchy	Proposed Disposal Location
			Construction	Operation			
			Low	Low	Sewage sludge will be directed to the septic systems and will be removed as required by a certified regulated waste contractor for offsite disposal.	Disposal	Waste sludge will be disposed of by a regulated waste contractor

12.4 REGIONAL WASTE MANAGEMENT FACILITIES

The CHRC provides a network of 18 waste management facilities available for communities and businesses to dispose waste materials (CHRC 2016). The waste management facilities comprise eight small facilities (<2,000 t/a), three with a landfill capacity of 2,000-5,000 t/a, one large facility with a capacity of 10,000-20,000 t/a located in Emerald, and six bulk bin/transfer stations.

CHRC is currently progressing through an infrastructure rationalisation program in order to ensure environmental and licence compliance with DES requirements, while increasing opportunities for recycling, and ultimately, reducing the amount of waste sent to landfill (CHRC 2016).

Regional and local industry in general and the regional coal industry in particular, has created sufficient demand for waste management services such that the region is well serviced by all major waste service providers. Access to these services has resulted in a relatively mature approach by businesses in the area to waste sorting and recycling.

Current bulk bin, landfill and transfer station facilities are indicated in Figure 85.

12.5 WASTE MANAGEMENT

Waste from the Project will be managed in accordance with the waste and resource management hierarchy from the *Waste Reduction and Recycling Act 2011*, which lists waste and resource management strategies in the order of most to least preferred option:

(a) ***avoid*** *unnecessary resource consumption;*

(b) ***reduce*** *waste generation and disposal;*

(c) ***re-use*** *waste resources without further manufacturing;*

(d) ***recycle*** *waste resources to make the same or different products;*

(e) ***recover*** *waste resources, including the recovery of energy;*

(f) ***treat*** *waste before disposal, including reducing the hazardous nature of waste; and*

(g) ***dispose*** *of waste only if there is no viable alternative.*

Appropriate waste management strategy for each waste stream in accordance with the hierarchy is addressed in Table 68.

Wastes that are not able to undergo processes of onsite reuse, recycling or treatment would be able to do so at offsite waste facilities. Where practicable, consumable suppliers will collect and recycle the waste product, and consider off-site recycling services that may be available. Before disposing waste to landfill, Magnetic South will consider the reuse and recycling of the waste within practicable measures.

Avoid or Reduce

Avoiding the production of waste is predominantly achieved through procurement practices, where the expected life and disposal requirements of materials or products are considered during the purchasing process.

Raw materials would be delivered in bulk where feasible. Otherwise, material that is not purchased in bulk will be determined based on minimal packaging and use of biodegradable and compostable

materials. Magnetic South will also consider the use of alternative products, implementation of appropriate technology and procurement processes to ensure that unnecessary waste is not produced.

Magnetic South will aim to reduce the amount of waste produced by limiting the amount of materials being transported to and stored onsite. Waste reduction efforts will also be towards reducing unnecessary consumption of electricity and water resources, along with the use of materials and products such as paper.

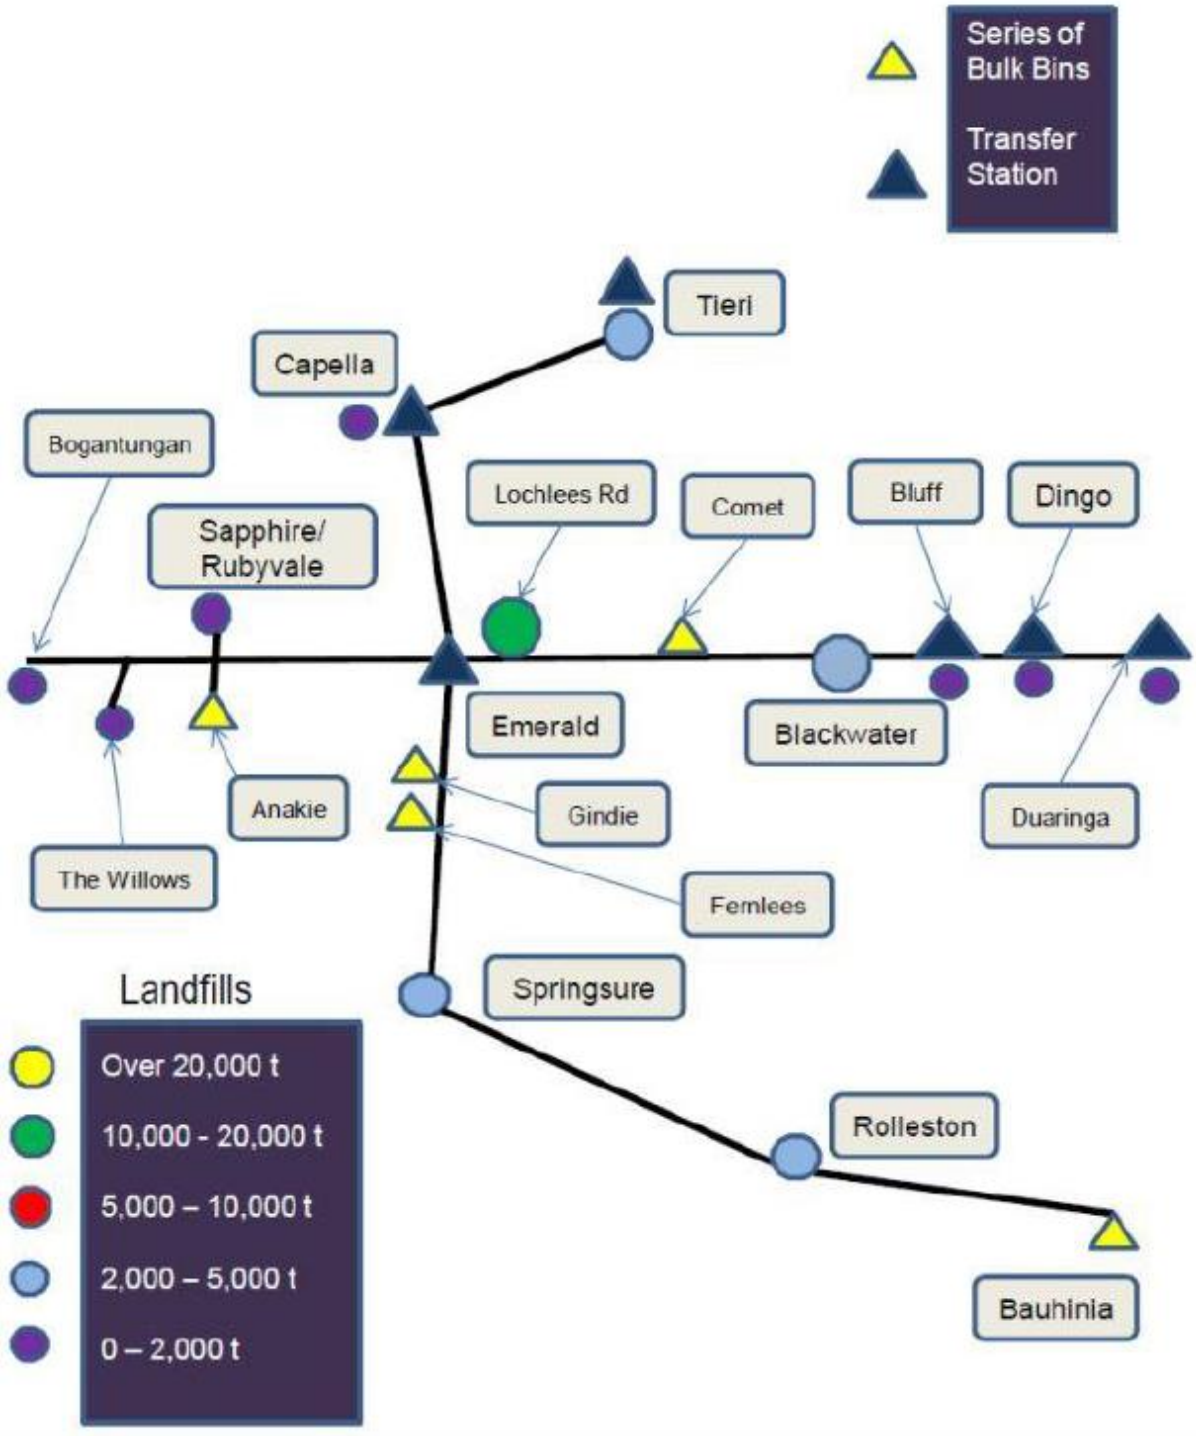

Figure 85 **Current CHRC Waste Infrastructure Plan**

Reuse

Waste streams will be reused wherever ongoing health, safety and reliability can be ensured. Where possible, waste will be reused onsite or will be returned to the suppliers to enable reuse.

Air filters will be collected and cleaned by local facility, Filter Resources Qld, and reused until considered unsuitable where they will be collected and recycled by Filter Resources Qld.

Recycle

The Project will generate a number of waste materials that can be recycled to generate products for a beneficial reuse.

Wastes that are recyclable, including includes aluminium, steel cans, Class 1, 2 and 5 plastics, paper towels, paper and cardboard will be collected and stored in designated bins, sealed containers or bunded areas, which will then be taken offsite by a licensed waste contractor and recycled at a licensed recycling facility.

Recover

Waste recovery is not proposed to be undertaken at the Project.

Treatment

Treatment of waste before disposal can minimise the environmental impact of waste disposal.

Paints and miscellaneous chemicals will be transported offsite by a licensed regulated waste contractor and treated at a licensed waste facility before disposal.

Hydrocarbon contaminated material will be treated and disposed off-site by licenced waste transport operators at an appropriately licensed waste disposal facility. Cleanaway provides contaminated soil remediation services delivering safe, compliant, and environmentally responsible solutions.

Onsite treatment of waste will be limited to the treatment of sewage effluent within a STP at the on-site accommodation facility towards the northwest boundaries of the MLA. Treatment will comprise standard primary, secondary removal of solids alongside nutrient removal and disinfection. Treated effluent will be released for irrigation in accordance with the EA conditions. Sludge will be treated offsite by Cleanaway, where it may be reused to generate energy or alternatively turned into compost and biosolids for non-agriculture purposes (Cleanaway 2019c).

Dispose

Disposal of waste is to be considered when no other economically feasible option for reuse or treatment exists. The disposal method will seek to minimise environmental effects and the potential for land contamination. In most instances, where waste is proposed to be transported to a licenced landfill facility. Magnetic South will arrange for the waste to be transported offsite. This commitment will form part of the contractual arrangements which will be developed with licenced contractors.

Waste that will be disposed of offsite includes general waste, tyres, and wastes that are no longer in reusable or recyclable conditions such as wooden pallets, refurbishable items and PPE. These waste streams are fundamental to daily operations and other waste management avenues (e.g., avoid, reduce, reuse, and treat) were considered unsuitable.

For instance, it is of preference that tyres will be transported offsite to a supplier for re-treading for reuse. Subject to demonstrating to the administering authority that no other use higher in the waste management hierarchy can be practically implemented, waste tyres will be disposed onsite in a designated tyre disposal area of the backfilled Pit AB and/or Pit C. These disposal areas will be managed to avoid any impedance on saturated aquifers, cause contamination or compromise the stability of the final landform. Tyre recycling was considered unsuitable and not economically feasible as the nearest facility for an accredited member of the Australia Tyre-Recycling Association is approximately 700km south-east.

Burial of waste tyres can lead to environmental impacts associated with contamination, fire risk and health risks. There is also a risk that compounds may leach from the tyres and contaminate soil, groundwater and surface water, and a possibility that tyre piles may become breeding grounds for insects, particularly mosquitoes, rodents and other animals. Tyres have also been known to cause fires that release pyrolytic oils and other compounds into the soil and groundwater and through smoke, coupled with contaminated runoff of water used to extinguish the fire. To mitigate these impacts, the storage and disposal of tyres generated by mining activities will be in accordance with *Operational Policy for Disposal and storage of scrap tyres at mine sites* (ESR/2016/2380). Further details of the disposal of scrap tyres will be addressed in a *Non-Mineral Waste Management Plan,* described in Section 12.8.1.

Excavated waste (over-burden and inter-burden) will be disposed of onsite as its unlikely to pose a significant risk to the quality of surface and groundwater when management measures are implemented.

12.6 CLEANER PRODUCTION

Cleaner production refers to the continuous application of an integrated preventative environmental strategy to processes, products and services to increase energy efficiency and reduce risks to people and the environment.

Cleaner production techniques could be implemented during construction, operational or decommissioning phases of the Project through:

- input substitution – Use of process auxiliaries less polluting and/or raw materials;
- product selection – Use non-hazardous products over hazardous materials;
- improved operation and maintenance – Select and use the most appropriate and practicable fixed and mobile equipment for use in coal extraction, transportation and processing, and high levels of maintenance to ensure items are operating efficiently;
- reuse of resources – Reuse resources onsite that would otherwise be classified as wastes;
- technology modifications – Improve process automation, process optimisation, equipment redesign and process substitution through use of available modern technology; and
- closed-loop cycling – Recycle and reuse the product in the same form.

Magnetic South will progressively seek cleaner production to maximise operational efficiency whilst minimising energy consumption and waste generation and disposal. Potential cleaner production techniques include, but not limited to, the following:

- improving operation and maintenance practices to reduce the resource consumption and minimise waste generation (e.g., reuse of water within the mine water management system and CHPP system);

- selecting best available technology for the CHPP, with consideration of the environmental and economic factors to maximise water use and energy efficiency, minimise dust emissions and waste generation;
- site extraction design to minimise the volume of waste rock respective to the excavated coal;
- reusing resources on-site that would be otherwise classified as wastes; and
- closed-loop recycling where a product is recycled and used again in the same form (e.g., wooden pallets, tyres).

Magnetic South seeks to prioritise cleaner production and waste management strategies for all generated waste types, unless it is not feasible.

12.7 REGULATED WASTE MANAGEMENT

The EP Regulation requires that the administering authority be provided with appropriate information to manage the associated environmental risks of 'trackable wastes' listed in Schedule 11 of the EP Regulation.

Trackable waste will only be transported offsite by a licensed transporter (Section 96 of the EP Regulation). Magnetic South will also be required to provide information to the waste transporter in accordance with Schedule 12 of the EP Regulation.

A register will be developed and maintained for all regulated wastes generated on-site, which will include the following details:

- source, type and quantity of waste;
- storage location;
- dates of collection and recycling/disposal; and
- name and details (including licencing details) of transporter and waste disposal facility.

A full list of regulated waste has been identified for the Project based on the definitions listed in the EP Regulation which is detailed in Table 68.

12.7.1 Regulated Waste Treatment and Disposal

Treating and disposing of waste will predominantly occur offsite and will be carried out in a way that causes least harm to the environment and can be achieved through the following methods:

- employing a bio-treatment to degrade material into a compound or mixture;
- employing a physico-chemical treatment (for example, evaporation, drying, calcination, catalytic processing, neutralisation, precipitation, or encapsulation) to obtain a compound or mixture;
- blending or mixing waste to obtain a compound or mixture storing or repackaging waste;
- employing thermal processes, with or without catalysts, to convert waste into a non-hazardous material;
- disposal to a landfill; or

- thermal destruction without recovering heat or another secondary product.

Regulated waste types that will undergo treatment before disposal include sewage, paints, and miscellaneous chemicals.

Magnetic South will use waste management services within the region such as Cleanaway Emerald Liquid Waste Services (Cleanaway). Cleanaway seeks to prioritise the recycling of waste paint and its by-products and processing to be turned from waste to valuable resources before considering disposal. Cleanaway facilities offer services for metal and plastic paint containers to be recycled and turned into new packaging materials. Water-based paint can be processed, with the by-products used in a variety of industrial applications, such as cement mixer, industrial water or in composting (Cleanaway 2019b). Solvent based paint can be recycled and used as an alternative fuel source for local cement and manufacturers (Cleanaway 2019b).

Cleanaway will be responsible for all waste oil and coolant removal and treatment as their facilities operate onsite treatment plants for liquid and hazardous waste (Cleanaway 2019a). Liquid and hazardous waste can undergo a chemical reaction process called Base Catalysed Dechlorination to treat high concentration persistent organic pollutants oils and reduce polychlorinated biphenyls concentrations. The process will be monitored to ensure the reaction continues to completion (Cleanaway 2019a).

12.7.1.1 Sewage Waste Treatment

A *Land-Based Effluent Disposal Assessment* (Cardno 2020) was undertaken in accordance with the current industry standards for wastewater management set out in *AS/NZ 1547:2012 On-site Domestic Wastewater Management* and provided in Appendix N. As described in Section 12.3 (Table 68), sewage generated onsite will be treated at a STP through a standard primary, secondary removal of solids alongside nutrient removal and disinfection.

A MEDLI was used to assess the suitability of dispersal in the surrounding area. Treated effluent will be released within a designated irrigation area on-site and is expected to achieve the water quality parameters set out in the *Eligibility Criteria and Standard Conditions for Sewage Treatment Works (ERA 63) – Version 2)*. These limits also align with the quality which would be expected from a basic sewage treatment plant as per *Table A3.2 of the Australian Guidelines for Water Recycling: Managing Health and Environmental Risks (Phase 1)*. These are detailed below (Table 69).

Table 69 Wastewater Quality Limits

Quality Characteristic	Release Limit	Limit Type
Total Nitrogen	30 mg/L	Maximum
Total Phosphorus	10 mg/L	Maximum
Electric Conductivity	1600 µs/cm	Maximum
pH	5.0 – 8.5	Range
Total Residue Chlorine (if used for disinfection)	1 mg/L	Maximum
E.Coli	<1000 cfu/100mL	Maximum
Total Suspended Solids	20 mg/L	Maximum
Biochemical Oxygen Demand	30 mg/L	Maximum

To ensure sewage effluent does not pose any risks to surrounding environmental values (water logging, surface runoff or excessive deep drainage), the soil profile of the site (category 6 soil) governs the following application parameters and schedules day in accordance with *AS 1547:2012*:

- construction – expected secondary treated effluent generation (56m^3), irrigation area (3.8 ha), rate (2mm/day); and

- operations – expected secondary treated effluent generation (28m^3), irrigation area (1.9 ha), rate (2mm/day);

The designed irrigation rate, area and chosen pasture were sufficient to prevent waterlogging, surface runoff or excessive deep drainage in two extreme soil types (i.e., extremely permeable sand and extremely impermeable clay) without requiring trigger limits. Conservative modelling identified no overflows predicted to occur throughout both construction and operational phases. However, it has been noted that during substantial rain events, irrigation should not occur when the ground is showing signs of saturation (such as surface water pooling).

In order to account for such events, 3 days of wet weather storage (168 m^3 tank capacity) was accounted for in the MEDLI model as recommended by the *QLD Government Technical Guideline for Disposal of Effluent via Irrigation.* Once detailed design information is available, a site-specific contingency plan will be developed to manage the wet weather storage tanks, STP shutdowns and maintenance periods when >3 days storage may be required. As closed tanks will be used instead of ponds, a negligible risk is expected for algae blooms or leaching into the groundwater. All released effluent will be monitored for pH and faecal coliforms to comply with the appropriate limits prescribed by the EA for the Project.

Rhodes grass was assumed to be the pasture which will be irrigated on-site. Modelling using Rhodes Grass (moderately salt-tolerant) indicates the resulting salinity would be too low to impact upon the health of the grass. The proportion of years that crop yields would be expected to fall below 90% of potential due to salinity (fraction) was 0% for both construction and operations. The MEDLI model indicates that mowing (with removal of clippings) would only be required approximately 3 times per year to maintain sufficient growth and subsequent nutrient uptake. Modelling of design irrigation rate, area and chosen pasture resulted in negligible concentrations of nutrient leaching to groundwater in either extreme soil type.

The MEDLI model confirms the suitability of the proposed wet weather storage and effluent irrigation areas to cater for the expected volume of wastewater generated, inclusive of climatic conditions, vegetation being irrigated and effluent quality (total nitrogen, total phosphorous, TDS, EC and soil properties). It concludes that no runoff from the effluent irrigation management area and wet weather storage will occur under the proposed irrigation regime with minimal irrigation-induced deep drainage (Appendix N). When combined with the setback distances discussed above (section 3.5.3.1), the risk of aerosol drift and odour is considered negligible.

12.7.1.2 Sludge Treatment

Sludge will be dewatered on site and the resulting dried sludge will be removed via a licensed regulated waste contractor. No waste residues are anticipated, and tank system sludge accumulation is expected to be 0.0 kg dwt/year.

12.7.2 Regulated Waste Transport

All regulated waste generated onsite will be arranged by the Magnetic South to be transported offsite for recycling, treatment, or disposal at a licensed facility. Regulated waste must only be removed and transported from the site by a person who holds a current licence to transport such waste under the EP Act.

Contractors within the region such as JJ Richards & Sons will be responsible for collection of regulated waste bins as well as collection of recyclable wastes (e.g., cardboard). Waste handlers are required to

submit waste tracking information to DES as part of the system for tracking waste listed in Schedule 9 Part 1 of the EP Regulation (i.e., regulated wastes). Waste handlers are defined as generators, transporters and receivers of wastes. Waste Transport Certificates are to be completed by waste handlers (i.e., generators, transporters, and receivers of waste) and submitted to DES as part of the process for tracking wastes in Queensland.

The transport of regulated wastes from the Project will be conducted in compliance the system requirements outlined by DES in *Waste tracking guideline – Overview of managing waste tracking in Queensland (ESR/2016/2425) Version 2.01* (DES 2018e).

Skip bulk or lift trucks will be used for heavier and/or bulkier waste materials such as empty waste oil containers, scrap metals and timber pallets. Mine affected water may be piped, trucked via liquid tankers or transferred in compliance with EA conditions.

Further information regarding the machinery and proposed method of regulated waste transportation will be detailed in a *Non-Mineral Waste Management Plan*, which will be developed at a later stage (refer to Section 12.8.1 for further details). The commitment will form part of the contractual arrangements and will be developed with licenced contractors.

12.8 WASTE AUDITING, MONITORING AND REPORTING

The waste streams and quantities produced would be recorded by Magnetic South over the life of the Project. Audits of the waste management activities will include:

- assessing actual generated wastes against the predicted waste quantities;
- monitoring the actual and potential impacts from wastes;
- reviewing the waste transportation records to ensure compliance; and
- identifying potential improvements in waste management practices, including establishment of waste reduction targets, where practicable.

Magnetic South will also monitor the implementation and effectiveness of the *Non-Mineral Waste Management Plan* and its compliance with relevant Commonwealth and Queensland legislation detailed below.

12.8.1 Non-Mineral Waste Management Plan

A *Non-Mineral Waste Management Plan* will be developed for all non-mining wastes prior to the construction of the Project. The plan will be developed in consideration of the waste hierarchy outlined in Section 12.5 to identify all waste streams and volumes, baseline data, compliance protocols, set measurable waste reduction targets, describe management controls and related environmental impacts. The following principles will be incorporated into the proposed plan:

- waste will be segregated into general waste, various recyclable wastes and regulated waste;
- the collection of general waste will be in clearly designated bins;
- recyclable waste will be separated and stored for collection into streams, including paper and cardboard, metals and recyclable plastics;

- all used tyres will be managed in accordance with the operational policy '*Disposal and storage of scrap tyres at mine sites*' (DES, 2014b). This may result in used heavy machinery tyres being disposed of within spoil dumps if other higher order options are not feasible. In this case, the locations of spoil dumps containing used tyres will be recorded on the Environmental Management Register;

- different forms of waste (e.g., metals, paper, oils, batteries, general waste, etc) will be stored on-site according to their corresponding waste stream. The design of the waste storage facility will consider public health, hygiene and safety standards. For example, flammable material or combustible liquid wastes will be stored in facilities designed to meet '*AS 1940:2017, The storage and handling of flammable and combustible liquids*' (Standards Australia 2017);

- waste oils, chemicals, batteries and other hazardous and/or regulated substances will be stored in bunded areas or on bunded pallets within the waste collection area;

- bins located within offices and workshops will be appropriately labelled to avoid cross-contamination and provide for separation of different waste streams. Bins will be emptied regularly to minimise vermin and pests; and

- regulated and/or hazardous waste will be stored in a separate storage area to ensure that the potential for environmental harm is minimised.

The *Non-Mineral Waste Management Plan* will include procedures and programs that detail monitoring frequency, collection methodologies, performance indicators and reporting requirements to ensure compliance with regulatory frameworks.

13.0 WASTE ROCK AND COAL REJECT GEOCHEMISTRY

This section discusses the characterisation of waste rock and coal rejects for the Gemini Project. The *Geochemical Assessment of Mining Waste Materials* (RGS 2019) (Appendix G) and *Geochemical Assessment of Coal Reject Material* (RGS 2020) (Appendix H) were undertaken with the aim of understanding any potential geochemical risks. The assessments provide a geochemical characterisation of samples representative of the mining wastes (overburden and interburden materials) and coal reject materials.

Both static and kinetic testing methods were utilised to indicate the presence and degree of risk from the oxidation of reactive sulfides, and the potential for acid generation and leaching of soluble metals/metalloids and salts. The assessments also included characterisation of chemical parameters related to sodicity and material stability. The assessments were completed in accordance with relevant industry guidelines:

- *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland* (DME 1995);
- *Application requirements for activities with impacts to water [ESR/2015/1837]* (DES 2017c);
- *Leading Practice Sustainable Development Program for the Mining Industry: Mine Closure* (DFAT 2016a);
- *Leading Practice Sustainable Development Program for the Mining Industry: Mine Rehabilitation* (DFAT 2016b);
- *Leading Practice Sustainable Development Program for the Mining Industry: Preventing Acid and Metalliferous Drainage* (DFAT 2016c); and
- *Global Acid Rock Drainage Guide (GARD Guide)* (INAP 2009).

13.1 ENVIRONMENTAL OBJECTIVES AND PERFORMANCE OUTCOMES

Surface waters and groundwaters could potentially be impacted from any adverse geochemical by-product associated with waste rock and coal rejects. The EVs have been determined given that waste rock is being disturbed, placed and rehabilitated, and that coal rejects are a waste stream from coal processing that need to be managed. The relevant environmental objectives were therefore determined to be associated with potential impacts to water.

The environmental objective relevant to water, as described in the EA guideline for *Application requirements for activities with impacts to water [ESR/2015/1837]* (DES 2017c); are:

- *the activity will be operated in a way that protects environmental values of waters; and*
- *the activity will be operated in a way that protects the environmental values of groundwater and any associated surface ecological systems.*

The Project would generally achieve these performance outcomes through implementation of the following measures as outlined in Part 3, Schedule 8, Division 1 of the EP Regulation:

a) the storage and handling of contaminants will include effective means of secondary containment to prevent or minimise releases to the environment from spillage or leaks.

b) contingency measures will prevent or minimise adverse effects on the environment due to unplanned releases or discharges of contaminants to water.

c) the activity will be managed so that stormwater contaminated by the activity that may cause an adverse effect on an environmental value will not leave the site without prior treatment.

d) the disturbance of any acid sulphate soil, or potential acid sulphate soil, will be managed to prevent or minimise adverse effects on environmental values.

e) acid producing rock will be managed to ensure that the production and release of acidic waste is prevented or minimised, including impacts during operation and after the environmental authority has been surrendered.

f) any discharge to water or a watercourse or wetland will be managed so that there will be no adverse effects due to the altering of existing flow regimes for water or a watercourse or wetland.

g) the activity will be managed so that adverse effects on environmental values are prevented or minimised.

With respect to the groundwater-related objective, the following measures apply (DES 2017c):

a) there will be no direct or indirect release of contaminants to groundwater from the operation of the activity; and

b) there will be no actual or potential adverse effect on groundwater from the operation of the activity.

In addition, the activity will be managed to prevent or minimise adverse effects on groundwater or any associated surface ecological systems.

13.2 DESCRIPTION OF ENVIRONMENTAL VALUES

From a geochemical perspective, the EPP (WWB) is the primary instrument for protecting Queensland waters to achieve the object of the EP Act in relation to water. The EPP (WWB) establishes EVs and management goals for waters and wetlands.

A key relevant document for the Project is the *Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin* (EHP 2011a). The document is made pursuant to the provisions of the EPP (WWB). It contains EVs and WQOs for waters in the Mackenzie River sub-basin. The WQOs and EVs are detailed Section 7.0 and Section 8.0.

13.2.1 Surface Water and Groundwater Resources

A description of surface water resources is provided in Section 7.2.1, including several illustrative figures.

All waterways of the Project area are ephemeral and experience flow only after sustained or intense rainfall in the catchment. Stream flows are highly variable, with most channels drying out during winter to early spring when rainfall and runoff is historically low, although some pools hold water for extended periods. Therefore, physical attributes, water quality, and the composition of aquatic flora and fauna communities are expected to be highly variable over time.

The land within the Project boundary is currently used for low intensity cattle grazing and resource exploration activities. The reaches of Springton Creek and Charlevue Creek in the proposed mining area have well-defined channels, typically with alluvial clay beds and well established in-channel vegetation.

Further details regarding the surface water management of the Project have been included in Section 3.4 and Section 7.4.

Groundwater resources are described in detail in Section 8.2.1and Section 8.2.2, including several illustrative figures.

13.3 POTENTIAL IMPACTS

Detailed geochemical assessments were undertaken of waste rock material (RGS 2019) (Appendix G) and coal reject material (RGS 2020) (Appendix H) associated with the Project. Geochemical test work undertaken was based on industry recognised procedures for the geochemical characterisation and assessment of mine materials. Refer to the relevant appendix report for technical details of the methodology and results of each assessment.

13.3.1 Coal Reject Geochemistry

A total of 80 coal reject samples from coal quality washability tests were provided from 14 different drill holes, comprising 52 coarse reject and 28 fine reject samples.

The $pH_{(1:5)}$ of the 22 composite coal reject samples from the Project ranged from 5.1 to 8.3 with a median value of 7.4 indicating that coal reject materials are typically in the pH neutral range. There does not appear to be any significant correlation between pH and reject type or coal seam.

$EC_{(1:5)}$ ranges from 398 to 1,062 µS/cm (median 774 µS/cm), with no apparent correlation between EC and reject type or coal seam. Based on the median pH and EC values, the coal reject samples tested are generally regarded as having ‘high’ soil pH and ‘medium’ salinity values with respect to the criteria for mining waste materials as defined by the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland* (DME 1995).

The total sulphur content (measure as total sulphur concentration - %S) of the samples ranges from 0.23-4.20 %S with a median value of 1.03 %S. This compares to a median crustal abundance value of 0.07 %S in unmineralised soils (Bowen 1979; INAP 2009). Materials with a total sulphur content less than or equal to 0.1 %S have negligible capacity to generate acidity. The reject samples used in the kinetic leach column (KLC) tests retained at least about 95.6% of their inherent total sulphur content after three months of exposure to idealised oxidising conditions. This reflects a relatively slow rate of sulfide oxidation (and potential acid generation) for these materials.

The results of the multi-element analysis were assessed against the geochemical abundance index in accordance with relevant guidelines and practices (Bowen 1979; INAP 2009). The geochemical abundance index results indicate that of the metals/metalloids measured, none are significantly enriched compared to median crustal abundance. The main findings of the coal reject geochemical assessment (RGS 2020) (Appendix H) are:

- the coal reject samples represent materials with a variety of geochemical characteristics ranging from non-acid forming (NAF) to PAF. As a bulk material, coal reject is expected to be NAF with excess acid neutralising capacity. Overall, most coal reject materials have a relatively low risk of acid generation and an increased factor of safety with respect to potential for AMD;

- initial and ongoing surface runoff and seepage from coal reject materials is expected to be pH neutral and have a moderate level of salinity. The salinity of leachate from higher sulphur coal reject materials could increase over time if exposed to atmospheric conditions, due to the release of sulphate through sulphide oxidation;

- comparison with guideline values and median crustal abundance in unmineralised soils indicates that the coal reject materials are not significantly enriched with metals/metalloids; and

- most metals/metalloids are sparingly soluble at the current pH of the leachate from coal reject materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk coal reject materials are expected to be relatively low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities.

13.3.2 Waste Rock Geochemistry

A total of 70 waste samples were collected from three drill holes within the Project area; representative of the main overburden, interburden and potential coal reject materials likely to be encountered during development of the Project. Samples were collected from the surface down through the stratigraphic profile (including economic and uneconomic coal seams) to the base of the open pit. The number of samples was selected to provide a good statistical representation of the amount and types of mining waste materials expected to be generated at the Project.

The $pH_{(1:5)}$ of samples across all sample types, ranged from 5.0 to 9.7 with a median value of 9.2. The samples with the lowest pH values (pH 5.0 to 5.5) represent clay and soil materials.

$EC_{(1:5)}$ ranges from 270 to 1,440 µS/cm with a median of 646 µS/cm, considered to be moderate. The weathered material tends to have a higher EC value than the fresh material.

Total sulphur content ranges from less than 0.01-0.60 %S (median 0.06 %S). Compared to the median crustal abundance of sulphur (0.07%) (INAP 2009), the median value of the mining waste materials is relatively low. The sulphur content of carbonaceous siltstone and coal are both higher than natural background values and both lithologies show greater variation in sulphur content than the weathered material, sandstone and siltstone.

The results of the multi-element analysis were assessed against the geochemical abundance index in accordance with relevant guidelines and practices (Bowen 1979; INAP 2009). The geochemical abundance index results indicate that, compared to median crustal abundance, only one of the 10 selected samples was enriched and then only with respect to cobalt. It should be noted that the nature of a coal deposit means some metals/metalloids are expected to be slightly elevated in various minerals.

Sample analysis indicated that the CEC of the materials varies between 4.2-18 meq/100g with a mean value of 10 meq/100g. The resulting effective CEC rating for the materials is from very low to moderate.

The ESP of the 10 selected samples ranged from low (4.5%) to very high (31.5%) with a median of 19.3%, indicating that some of the sample materials are likely to be sodic.

The findings of the geochemical assessment of waste rock samples (RGS 2019) (Appendix G) can be summarised as follows:

- all of the mining waste samples tested are NAF, have excess acid neutralising capacity and typically have low sulphur content. The sulphur content of coal and carbonaceous siltstone can be elevated compared to typical background concentrations, but is mainly present in a non-

sulfidic form, which does not contribute to acid generation. Overall, these materials have a low risk of acid generation and a high factor of safety with respect to potential for AMD;

- initial and ongoing surface runoff and seepage from mining waste materials is expected to be moderately alkaline and have a moderate level of salinity;
- KLC test results indicate that mining waste materials are unlikely to generate acid conditions and more likely to generate pH neutral to alkaline conditions;
- metal/metalloid enrichment in mining wastes, compared to median crustal abundance in unmineralised soils, is limited to cobalt in a single carbonaceous siltstone sample;
- most metals/metalloids are sparingly soluble at the neutral to alkaline pH of leachate expected from bulk mining waste materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk mining waste materials are therefore expected to be low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities;
- mining waste materials should be amenable to revegetation as part of rehabilitation activities, although, gypsum and fertiliser will be used as necessary for sodic materials to limit dispersion and erosion and to provide a reasonable growth medium for revegetation and rehabilitation; and
- as most mining materials appear to be susceptible to dispersion and erosion, additional testing including field trials, may be needed when the mine is operational and bulk materials are being generated. Such tests would help to determine the most appropriate management option for progressive rehabilitation of these materials during operations at mine closure.

13.3.3 Potential Impacts on Surface and Groundwater Resources

The potential impacts which may arise as a result of adverse mineral waste characteristics are primarily related to acid and saline leachate production and landform stability. With respect to acid and saline leachate potential, the majority of both the coal reject and waste rock material to be produced is classified as NAF, with excess acid neutralising capacity, and essentially devoid of sulphur. These materials have a very low risk of acid generation and a high factor of safety with respect to potential acid generation in leachate from waste dumps and storage facilities.

The static and kinetic geochemical test results indicate that surface runoff and seepage from both coal reject and waste rock materials is likely to be pH neutral and have a moderate salinity value. The pH of surface runoff and seepage from these materials is likely to fall within the range for 95% species protection in freshwater aquatic ecosystems as set out in ANZG (2018).

The major ion concentrations in surface runoff and seepage from both coal reject and the leachate from NAF mining materials are relatively low. The major ions from coal reject are dominated by calcium, magnesium, sodium, sulphate, chloride (and bicarbonate), and the leachate from NAF mining waste materials are dominated by bicarbonate, sodium, chloride and to a lesser extent sulphate. The sulphate concentration in leachate from all mining waste samples tested is well below the applied ANZG (2018) livestock water quality guideline criterion (1,000 mg/L).

The concentration of most trace metals/metalloids tested for water in contact with both coal reject and mining waste materials is low, typically below the LOR for the laboratory analysis, and below the applied water quality guideline criteria. KLC tests exhibit a LOR of below applied water quality guideline criteria. As a result, for these course reject dissolved metal concentrations of Se, Zn, Cr, Cu and Cd exceeded the trigger values for freshwater aquatic ecosystems (95 % species protection). Additionally, Se

exceeded trigger values for livestock drinking water guideline values. Similar results were observed for fine reject dissolved concentrations.

Whilst there are no specific regulatory criteria for metal/metalloid concentrations in leachate from mining waste material on mine sites in Queensland. The Australian guideline values for livestock drinking water and aquatic freshwater eco-systems are provided for context are not intended to be interpreted as "maximum permissible levels" for site water storage or discharge" (ANZG 2018).

These trace metals/metalloids are sparingly soluble at the expected pH of coal reject materials. All of the metals/metalloid concentrations are less than the applied livestock drinking water guideline trigger values.

For water in contact with mining waste materials, the static water extract results for a few samples. suggest that the concentrations of arsenic and selenium can be above applied aquatic freshwater ecosystem water quality guideline concentrations for 95 % species protection (ANZG 2018). However, the concentration of these metals/metalloids in surface runoff and seepage from bulk mining waste materials is likely to be much lower and within the applied guideline concentrations described. Whilst one carbonaceous siltstone water extract sample had a selenium concentration marginally above the applied livestock drinking water guideline value, all other water extract samples displayed trace metal/metalloid concentrations at or below the applied livestock drinking water guideline values.

Overall, the static geochemical test results indicate that dissolved metal/metalloid concentrations in initial surface runoff and seepage from coal reject materials are unlikely to significantly impact upon the quality of surface and groundwater resources. However, some coal reject materials, if left exposed to oxidising conditions, may have the potential to generate brackish leachate containing elevated concentrations of sulphate and some metals/metalloids, in comparison to applied water quality guideline values. Therefore, coal reject materials should be encapsulated within spoil storage areas, well away from the outside surface of the final rehabilitated landforms. If coal reject materials are left exposed to oxidising conditions for an extended period of time prior to encapsulation, dosing with agricultural limestone (e.g., fine limestone) could be considered as a contingency measure.

In addition, the results of the CEC and ESP tests on the selected mining waste samples indicate that most of the materials represented by these samples are likely to have elevated sodicity levels and may be susceptible to dispersion and erosion, although these characteristics may be improved to some extent by the addition of gypsum. In addition, fertiliser addition will need to be considered for some mining waste materials to provide a reasonable growth medium for revegetation and rehabilitation.

The management strategies discussed in Section 13.4, will ensure the risk of impact to waters remains low throughout the life of the Project, and will provide for water monitoring activities appropriate to assess any potential adverse effects.

13.3.4 Spontaneous Coal Combustion Potential

The geochemical properties of the Gemini coal deposit are considered high rank for the Project and therefore of lower propensity for spontaneous combustion. Intrinsic factors such the presence of pyrite, moisture, mineral matter, and particle size are known to influence the risk of combustion (Kaymakci, E and Didari 2002). The presence of pyrite within the coal reject materials can generally increase the risks, however the identified qualities within both geochemical assessments (Appendix G; Appendix H) are noted to be relatively low risk of acid generation and below 0.1% (nonsulfide sulfur (ie., non-acid generating). Further to this, the moderate content of ash known to occur in the Rangal measures negatively correlates with the propensity for coal to self-heat and lowers risk based on coal quality (Beamish and Blazak 2005).

The potential for spontaneous combustion of stockpiles is driven by the oxidation of coal and other carbonaceous materials. The reactivity of material contained within spoil dumps is known to vary considerably and therefore assessing combustion risk is often based on external factors (temperature, oxygen concentration, barometric pressure, ventilation, and surrounding strata). Most strategies for control and prevention of spontaneous combustion focus on removing oxygen, or rather, preventing its access to the reactive material.

If not managed, spontaneous combustion in open-cut coal mines poses a number of potentially serious impacts on the receiving environment, of which include:

- toxic emissions such as particulates and trace elements, carbon monoxide, sulfur dioxide, hydrogen sulfide, polynuclear aromatic hydrocarbons and volatile organic compounds;
- greenhouse gas emissions of CO_2 and CH_4;
- destabilisation of spoil piles and long-term problems with rehabilitation; and
- damage of the nearby ecosystems, vegetation loss, windblown dust, and pollution of surface and ground water.

13.4 MITIGATION MEASURES, MANAGEMENT AND MONITORING

13.4.1 Coal Reject Materials

As a result of the geochemical assessment work completed on coal reject materials (RGS 2020) (Appendix H) at the Project, the following management strategies are proposed for all coal reject material to minimise the risk of any significant environmental harm to the immediate and downstream environment:

- operational sampling and geochemical testing of representative samples of all coal reject material (coarse rejects and tailings) will be strategically undertaken at the CHPP to verify and extend the findings of the assessment for management;
- coal reject materials will be transferred from the CHPP and encapsulated within a much larger volume of NAF overburden material in spoil emplacements with excess neutralising capacity well away from the outside surface of the final rehabilitated landforms.
- coal reject material will be placed where there is a lower risk of connectivity to surface water or groundwater resources;
- if coal reject materials are left exposed to oxidising conditions for an extended period of time prior to encapsulation, dosing with agricultural limestone would be considered as a contingency measure; and
- surface water and seepage from the coal reject storage areas will be monitored to ensure that key water quality parameters remain within appropriate criteria.

13.4.2 Mining Waste Materials

As a result of the geochemical assessment work completed on mining waste materials (RGS 2019) (Appendix G) at the Project, a number of management strategies are proposed for these materials to minimise the risk of any significant environmental harm to the immediate and downstream environment.

- placement of any carbonaceous mining waste material encountered during mining at the surface and outer batters of waste rock emplacement areas will be avoided;

- additional overburden/interburden testing and rehabilitation field trials will be completed during operations when bulk materials become available on an as needed basis to confirm the most appropriate management option for progressive rehabilitation of these materials during operations and at mine closure; and

- surface water and seepage from the proposed mining and mining waste storage areas will be monitored to ensure that key water quality parameters remain within appropriate criteria. Water quality monitoring parameters will include pH, EC and total suspended solids on a quarterly basis and the suite of water quality analyses described in Appendix G (refer to Table B4 – Multi-element test results for water extracts from mining waste from the Project).

13.4.3 Spontaneous Combustion

The following prevention and control measures will be adopted to maintain a low risk of spontaneous combustion:

- dispersal and burying of reactive materials within the spoil;

- controlling ventilation through compaction and capping;

- design of spoil dumps to minimize erosion & cracking of capping material avoiding the risk of air ingress;

- firefighting equipment readily available at appropriate locations;

- regular inspections and maintenance of firefighting equipment; and

- operator training.

Magnetic South will develop a *Spontaneous Combustion Management Plan* to ensure long-term management is maintained to:

- identify the source, quantity and timing of potentially reactive carbonaceous material that will be stockpiled;

- identify the main inert materials within the spoil;

- identify availability of local capping material (clays); and

- on-going gas and temperature monitoring around spoil piles.

13.4.4 Waste Rock Emplacement Rehabilitation

Progressive rehabilitation of all waste rock emplacements will be carried out when final placement has been attained and areas are no longer required for mining operations. The geochemical assessment (Appendix G) and soil and land suitability assessment (Appendix I) identified no significant risks for rehabilitation and waste rock materials were considered suitable.

As areas progressively become available, they will be classified as ‘available for rehabilitation’ (illustrated in Figure 23). The sequence of rehabilitation activities as described in section 4.0 will then commence, staring behind Pit AB and progress systematically north-east (Figure 23 – Figure 32). Three

waste rock emplacements (one temporary) will be progressively constructed throughout the course of the operations and be designed to have externally draining slopes of a maximum of 6°, elevation 175-190 mAHD and slope length 530 m – 540 m. The design of waste rock emplacements is detailed in Table 18.

Overburden placement will be undertaken using rear dump trucks in accordance with mine planning schedules. Standard mine survey controls will be utilised to ensure that disturbance footprints are not exceeded and that design slopes will be attained. Regrading to final landform will be undertaken using bulldozers to push to grade utilising standard survey controls. Final trimming of reshaped areas will be undertaken as required to remove excess rock and ensure correct graded bank slopes.

Where highly sodic and/or dispersive spoil are identified, this material would not be placed in final landform surfaces and would not be used in construction activities. As described in section 5, subsoils of the Geoffrey and Kosh SMUs are considered strongly sodic (ESP > 14%). Furthermore, physical assessment of soils within the Project area reveal the medium to medium-heavy clay texture (>45% clay) of subsoils of the Geoffrey and Kosh SMU. Clay rich soils may be more susceptible to erosion due to the small size (<0.002 mm) of clay-sized particles, particularly if soils are dispersive. However, the topsoil layers are not considered sodic. Stripping depths have accounted for this and have been determined to exclude any sodic subsoil material from the topsoil resource.

Coal reject materials and any potentially acid forming waste rock materials identified will be selectively handled and encapsulated within waste rock emplacements and well away from the outside surface of rehabilitated landforms, where there is a low risk of connectivity to surface water or groundwater resources.

Surface drainage will be managed using graded banks and rock-protected spine drains to allow drainage from long rehabilitated slopes to be conveyed to natural ground level. Ongoing monitoring of climate, geotechnical properties of materials, revegetation progress and surface water runoff quality throughout all rehabilitation phases will provide systematic feedback for assessment of the rehabilitation measures to be used.

Topsoil resources have been characterised as suitable for rehabilitation and sufficient material will be available to ensure the recommended respreading depth of 0.3m. A growth medium 0.3m will provide sufficient depth to hold water and support revegetation. Topsoil will be deep ripped into the underlying spoil surface, to encourage surface water infiltration and minimise soil loss due to erosion. Seeding will typically be scheduled to occur prior to wet season to maximise the benefits of subsequent rainfall.

On-going rehabilitation maintenance and monitoring including earthworks repairs, re-seeding supplementary tube-stock planting, fertiliser application and drainage repairs will occur, as necessary.

Low intensity grazing has been determined the preferred PMLU for waste rock emplacements. This PMLU has been determined on the basis of pre-mining land suitability, landholder/stakeholder preferences, the existing land use and EVs of the surrounding landscape. Other rehabilitation management options such as dryland cropping, improved pastures and native pastures were considered, however on the basis of economic value, deemed unsuitable due to limited soil nutrient deficiencies, soil water availability, soil wetness, erosion and surface condition. A conceptual layout for the PMLU is illustrated in Figure 36.

A progressive rehabilitation schedule, including the rehabilitation of waste rock emplacements is provided within schedule calculations (Section 4.6).

13.4.5 Erosion and Sediment Run-Off

Erosion and sediment from waste rock dumps will be managed in accordance with an ESCP that has been designed for the Project by a suitably qualified person. The plan has been designed to address the construction, operational and rehabilitation/closure phases of the Project to prevent adverse impacts from waste rock dumps to nearby local environmental values (i.e., Charlevue Creek and Springton Creek). Management measures to address the risks associated with waste rock dumps will include the following:

- limit land clearing to the minimum required for safe operations of the Project;
- retention of riparian vegetation where possible along Charlevue Creek and Springton Creek;
- diversion of clean overland flow/runoff from the upper reaches of Springton Creek and Charlevue Creek around the out-of-pit waste rock emplacement associated with Pit C and Pit AB;
- rapid revegetation of disturbed areas and hydromulching of areas subject to short term exposure;
- waste rock emplacements have been designed to a slope of 1V:10H (adhering to a maximum slope of 6°) and a maximum height of 190 mAHD;
- installation of sediment entrapment devices and infrastructure between receiving waters and disturbed areas, including:
    - silt fences, coir logs, hay bales or other flow reduction devices;
    - pit protection levees & diversion channels;
    - sediment traps and dams;
    - cleaning protocols of sediment drains and entrapment devices; and
    - traffic control measures and haul route bunding.
- flood protection levee and clean water drains to minimise flood water interaction with waste rock emplacements.

Erosion and sediment control structures will be designed and installed in accordance with *Best Practice Erosion and Sediment Control* (IECA Australasia 2008) and *Soil Erosion and Sediment Control: Engineering Guidelines for Queensland Construction Sites* (Witheridge & Walker 1996), as appropriate.

As described in Section 13.4.2, surface water and seepage from mining waste storage areas will be monitored to ensure that key water quality parameters remain within the appropriate criteria. Sediment and water quality monitoring will be undertaken in accordance with a REMP to ensure the effectiveness of employed control measures, including the enforcement of sediment quality trigger values (refer to Section 7.4.4.1).

13.4.6 Monitoring Program

Environmental monitoring to identify and assess any impacts arising from seepage or contamination associated with the geochemistry of waste rock and coal rejects will comprise the following components:

- Ongoing groundwater monitoring to verify baseline groundwater information. It should be noted that groundwater data collected to date has indicated high EC groundwater associated with all groundwater units (refer to Section 8.0).

- Ongoing surface water monitoring will be undertaken principally to validate water management system performance against the design assumptions, both in terms of water quality and water quantity, so that adaptive management decisions can be undertaken where necessary to protect the surface water environment. Surface runoff and seepage water collection in the mine water dams and process water dam will be monitored for standard water quality parameters including, but not limited to pH, EC, major anions (sulphate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS and a broad suite of soluble metals/metalloids.

- Validation test work will be undertaken on potential spoil materials as the Project develops to enable appropriate spoil management measures to be planned and implemented as required. Where highly sodic and/or dispersive spoil is identified, this material would not be placed in final landform surfaces and would not be used in construction activities. Regardless of the spoil type, especially where engineering or geotechnical stability is required, testing would be undertaken during construction to determine the propensity of such materials to erode. Surface runoff and seepage from spoil piles, including any rehabilitated areas, would be monitored for 'standard' water quality parameters including, but not limited to, pH, EC, major anions (sulphate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS and a broad suite of soluble metals/metalloids.

- A REMP will also be developed and implemented in accordance with the *Model Mining Conditions* (DES 2017e). The REMP would be implemented to monitor, identify and describe any adverse impacts to surface water EVs, quality and flows due to the authorised mining activity. Water quality monitoring will be undertaken upstream and downstream of the Project to detect downstream water quality impacts and to demonstrate compliance with the EA release conditions. Further details of the REMP are provided in Section 7.4.4.1, including the location of proposed receiving water monitoring points (Table 45).

14.0 RISK ASESSMENT

14.1 RISK ASSESSMENT REQUIREMENTS

A preliminary risk assessment has been undertaken for the Project, to address the potential or actual impacts on environmental values during the construction, operation, decommissioning and rehabilitation stages.

The risk assessment has been carried out in accordance with the following objectives to identify and address associated Project risks, these include:

- the likelihood of an impact occurring;
- the management/mitigation measures proposed;
- the consequence of the managed impact;
- potential levels of residual impacts on environmental and community values; and
- the cumulative impacts on environmental values.

The risk assessment was carried out in accordance with *AS ISO 31000:2018 Risk management – guidelines.* The corresponding management of environmental risk was informed by both expert opinion and the Project specific technical studies detailed within this EA application.

14.2 RISK IDENTIFICATION

For this assessment, a risk assessment was undertaken by a panel of environmental consultants. In accordance with *Section 6.4.2 of AS ISO 31000:2018,* hazards and risks were considered from three different perspectives (environmental impact, impacted receptors and introduced/exacerbated hazards).

The cohort of risks, segregated by each perspective, can be summarised as:

- environmental impact -
    - land impacts (e.g., loss of land resources and constraints on future land use);
    - noise and air blast related impacts;
    - visual impacts (e.g., landscape and lighting);
    - surface water (e.g., hydrology and water quality);
    - groundwater (e.g., geohydrology and groundwater quality);
    - air quality (e.g., dust and other contaminants);
    - occupational health and safety impacts (e.g., impacts on personnel);
    - impacts arising from pests and diseases (either exacerbated or introduced by the Project);
    - socio-economic impacts; and

  - exacerbation of impacts from natural events (e.g., fire, flood, cyclone/ extreme weather, landslide, climate change);

- impacted receptor -
  - impacts on important environmental receptors (e.g., identified MSES, nature refuges, national parks); and
  - impacts on local, regional and state residents;
- introduced or exacerbated hazard -
  - workplace occupational and health risks and hazards;
  - mining-related hazards including:
    - heavy earthmoving equipment;
    - light vehicles;
    - hazardous materials and dangerous goods; and
    - geochemical and geotechnical hazards (e.g., waste rock materials, carbonaceous materials, waste rock dumps and final void).

The identified set of risks and hazards were transferred to a risk assessment template designed for the specific purpose of assessing environmental risks, identifying associated causes, potential impacts and the expected base level of controls.

14.3 RISK ASSESSMENT PROCESS

Any risk assessment needs to be undertaken in consideration of the scope, context and criteria relevant to the assessment. For this risk assessment, the following scope and purpose was discussed and agreed to:

- The purpose of this risk assessment is to identify and analyse any risks arising because of the Project that may impact on environmental aspects, including socioeconomic aspects; at the local, regional and state levels and across the construction, operational and closure stages of the Project.

Several important assumptions and/or criteria have also been identified, including:

- Occupational Health and Safety hazards are assumed to be assessed and managed at an operational level in accordance with legislated requirements and contemporary mining industry practice.
- The risk assessment is a preliminary and high-level assessment set at the overall project level. Therefore, while some risk scenarios may be viewed as being generic, the assessment process interrogates the risk scenarios sufficiently to focus on project and site-specific aspects in assessing hazards and risks.
- Risks are assessed on the basis that expected, contemporary operational controls will be in place on the assumption that the proponent's view of legal and constructive obligations,

statutory controls and management systems are in line with current industry standards and expectations.

The risk assessment was undertaken to analyse and evaluate the risks and hazards identified with the following process steps established:

- The basis and purpose of the risk identification was agreed on, as well as the process used to develop the risk scenarios, causes and impacts proposed in the risk assessment template.
- The risk assessment scheme, including the consequence descriptors for each consequence type, the likelihood classifications and the control effectiveness rankings were evaluated and agreed on.
- Each of the identified risk scenarios or descriptions was then considered in turn. In most cases, one or more of the 'risk/hazard title', 'causes' and 'impacts' proposed were refined as a result.
- The likelihood of each risk/hazard, subject to the expected control level, was then considered and a ranking was provided in accordance with the consensus view.
- The consequence category for the relevant impact or impacts was similarly assessed and ranked.
- The risk class was then determined based on the risk matrix (Table 72).
- For risks and hazards determined as being of Class III and IV, additional control measures were discussed and assessed and, where effective and appropriate, proposed.

A summary of the complete risk assessment outcomes is provided at Table 74.

14.3.1 Risk Assessment Scheme

The risk assessment scheme used is representative of risk schemes used widely within the mining industry. For this risk assessment, the scheme comprised the following components:

- a likelihood classification table (Table 70);
- a severity and consequence classification table (Table 71); and

Table 70 Likelihood of Exposure

Likelihood	Description	Frequency	Probability
Almost certain	The event will occur often.	More than once a year	> 95%
Likely	The event could easily happen.	At least once in 1 year	60%–95%
Possible	The event could happen and has happened elsewhere.	At least once in 3 years	30%–60%
Unlikely	The event has not happened but could.	At least once in 10 years	5%–30%
Rare	Conceivable but only in extreme circumstances.	Less than once in 30 years	< 5%

Table 71 Severity and Consequence Classification

Severity level	Consequence		
	Human Health and Safety	Natural Environment	Community/ Cultural Heritage
Catastrophic	Multiple fatalities, significant irreversible impairment to multiple persons	Very serious, long-term environmental impairment of ecosystem functions	N/A
Major	Single fatality, significant irreversible impairment to a person	Very serious, long-term environmental impairment of ecosystem functions	Ongoing serious social issues. Significant damage to structures/items of cultural significance
Moderate	Significant reversible impairment to one or more persons (lost time injury, disabling injury)	Serious medium-term environmental effects	Ongoing serious social issues. Significant damage to structures/items of cultural significance
Minor	Reversible impairment requiring medical treatment (medical treatment injury)	Moderate, short-term effects but not affecting ecosystem functions	Ongoing social issues. Permanent damage to items of cultural significance
Insignificant	No treatment or first aid treatment	Negligible/minor effects on biological or physical environment	Minor medium-term social impacts on local population. Mostly repairable

Following the hazard identification, and assessment of likelihood and consequence criteria, the risk level was determined using Table 72, which then defines the assessed risk level. Table 73 describes the appropriate level of action required for each assessed risk level.

Table 72 Risk Level Matrix

Likelihood	Consequence				
	Insignificant	Minor	Moderate	Major	Catastrophic
Almost Certain	II	III	III	IV	IV
Likely	II	II	III	III	IV
Possible	I	II	III	III	III
Unlikely	I	I	II	II	III
Rare	I	I	II	II	III

Table 73 Risk Level Actions

Risk Level Actions	
Very High Risk	Board and/or board level committee attention required; action plans and management responsibility specified.
High Risk	Senior executive management attention required; action plans and management responsibility specified.
Medium Risk	Manage by specific monitoring or response procedures, with management responsibility specified.
Low Risk	Manage by routine procedures, unlikely to need specific application of resources.

14.4 RISK ASSESSMENT OUTCOMES

In total, 47 risks and/or hazards were identified and assessed. There are a number of risks identified where the risk or hazard impacts on more than one environmental aspect or category, resulting in 68 discrete risk assessments in total. Unnecessary duplication was avoided by only including a duplicate scenario where it was felt that there was a legitimate reason to assess both risk scenarios by virtue of either a significantly different environmental impact outcome or, for a high ranked risk, where significantly different mitigation measures might be required. The risk profile for the Project and the risk profile by consequence area are illustrated at Figure 86 and Figure 87 respectively, and the summary of identified risks and mitigation measures is presented in Table 74.

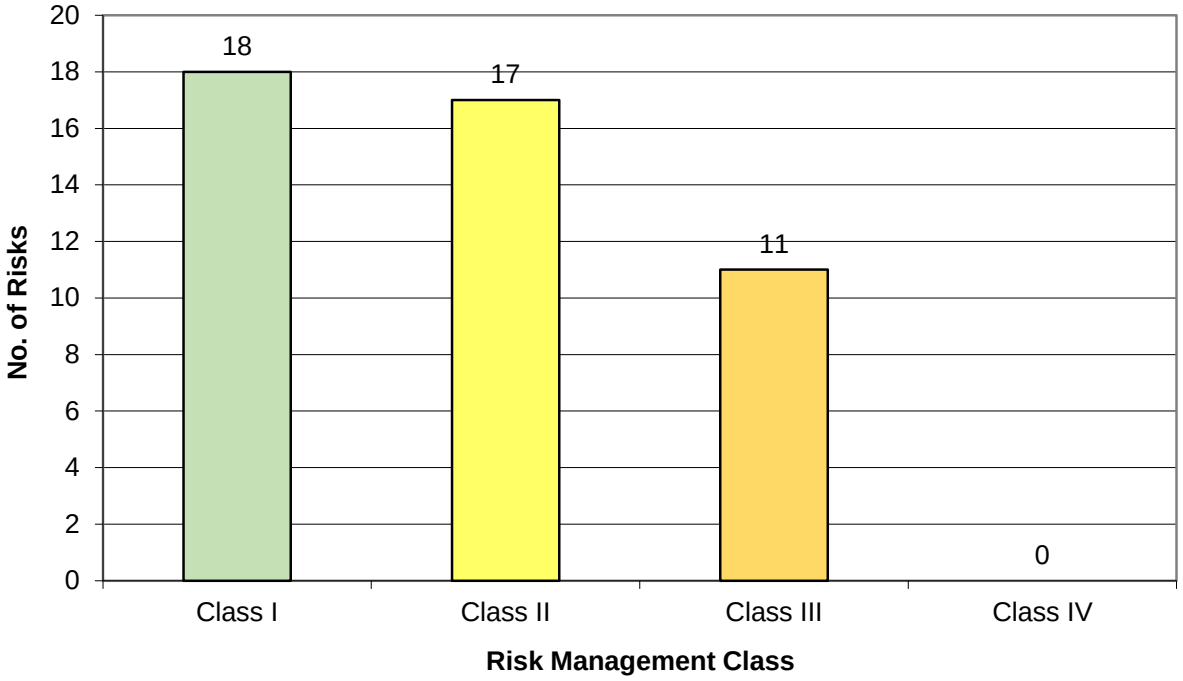

Figure 86 Risk Profile

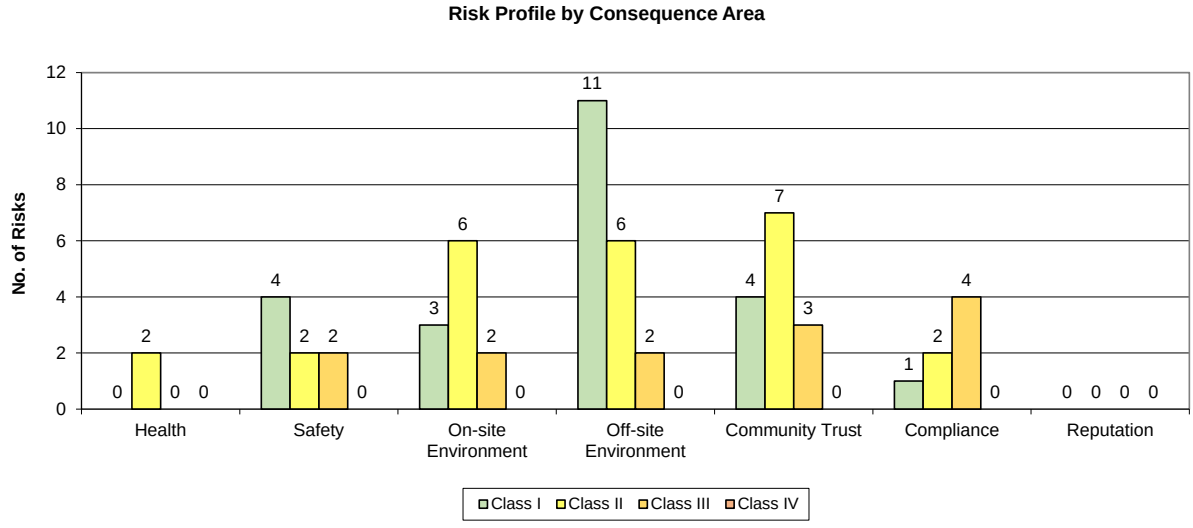

Figure 87 Risk Profile by Consequence Area

14.5 RISK MITIGATION

The following processes and measures will be implemented in addition to expected and standard controls to reduce the risk of impacts on health, safety and the environment associated with the Project:

- Fatigue management/fitness for work, alcohol and drug testing and road safety awareness training to manage the increased risk of motor vehicle incidents.
- Occupational health and safety performance to be closely monitored and assessed and, where required, individual issue specific risk assessments to be undertaken to identify fit-for-purpose safety initiatives.
- Long term monitoring of noise and dust impacts at sensitive receptors.
- Active management of equipment locations and operating hours if required to reduce the likelihood of noise and air quality impacts on sensitive receptors.
- Geochemical characterisation of topsoils and waste rock materials and amelioration measures as appropriate to manage impacts to the environment (downstream watercourses) from erosion of rehabilitated areas.
- Cultural heritage surveys to be undertaken prior to site clearing, and implementation of procedures for the management of any identified cultural heritage values or artefacts.

Table 74 Summary of Identified Risks and Mitigation Measures

Risk Description				Risk Evaluation										Risk Ranking								Risk Management	
Risk /Hazard Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Expected/Standard Controls	Likelihood / Probability	Greenhouse	Health	Safety	Environment On-site	Environment Off-site	Community Trust	Compliance	Stakeholders	Cultural Heritage	Greenhouse	Health	Safety	On-site Environment	Off-site Environment	Community Trust	Compliance	Stakeholders	Cultural Heritage	Risk Management Class	Additional Risk Mitigation
Amenity																								
Amenity of local residents																								
Increased risk of motor vehicle incidents	Increase light and heavy vehicle movements associated with the Project	Ranges from inconvenience to fatality	Road access design (subject to regulatory controls) and public road controls	R			H									III							III	Fatigue management/fitness for work, alcohol and drug testing, road safety awareness training
Impacts to local farmers	Construction phase specific Impeding access to properties	Inconvenience	Road access design (subject to regulatory controls)	p						L									II				II	
Increased rail movements	Increase in production	Annoyance, amenity	Restricted TLO operating hours to reduce noise impacts	p						L	M								II	III			III	
Increased heavy vehicle movements	Operational phase only	Impacts limited largely to north of site at intersection with Capricorn Hwy	Road access design (subject to regulatory controls) and public road controls. Road approved for required capacity.	L						L									III				III	
Increased activism associated with coal mining impacts on environmental values	Existence of operation	Inconvenience, worker safety	Media monitoring, community/ stakeholder engagement program	P		L				L					II				II					
Bushfire																								
Impacts to surrounding properties and existing mine rehabilitation	Project-related activities Surrounding land management activities Natural causes	Destruction to surrounding properties, operational cost and rehabilitation failure	Distance from source, firebreaks, ERT with fire-fighting capacity	R			M			M						II			II				II	
Flood																								
Detrimental flooding impacts within Project area	Altered flood regimes due to project	Flooding of project operations and infrasructure	Site Water Management System design to minimise flooding to operations Levee and clean water dams to contain and redirect flows	R				L				VL					I				I		I	REMP, groundwater and surface water monitoring, water management plan, progressive rehabilitation to limit disturbance, flood protection levee surveillance, communications/ consultation with stakeholders
Detrimental flooding impacts to neighbouring residents	Altered flood regimes due to project	Flood depth afflux, velocity, inundation 1% to 10% AEP range	Flood study indicates negligible increase to the extent of inundation up to 0.1% AEP, and duration increases up to 48 hours	R					L			L						I			I		I	REMP, groundwater and surface water monitoring, water management plan, progressive rehabilitation to limit disturbance, flood protection levee surveillance, communications/ consultation with stakeholders
Detrimental flooding impacts to neighbouring residents	Project location and extents (floodplain extents defined by levee location)	Stream power and shear stress	Modelling indicates minimal increase in flow velocities	R					L		L							I		I			I	
Flooding impacts to Dingo township	Project location and extents (floodplain extents defined by levee location)	Increase in flood inundation duration and extent	Modelling shows no significant change at Dingo township	R			VL		VL			VL				I		I			I		I	
Flooding impacts to mine / final void	Project location and extents (floodplain extents defined by levee location)	Pit/ final void flooding, loss of access, property damage	Levee and final landforms designed to provide flood protection to 0.1% AEP and PMF event	R				H									III						III	Effective rehabilitation and final landform design. Ongoing maintenance of water management infrastructure. Business Continuity Plan

Risk Description				Risk Evaluation										Risk Ranking								Risk Management	
Risk /Hazard Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Expected/Standard Controls	Likelihood / Probability	Greenhouse	Health	Safety	Environment On-site	Environment Off-site	Community Trust	Compliance	Stakeholders	Cultural Heritage	Greenhouse	Health	Safety	On-site Environment	Off-site Environment	Community Trust	Compliance	Stakeholders	Cultural Heritage	Risk Management Class	Additional Risk Mitigation
Hazards																							
OHS																							
OHS consequences	Construction, mining and industrial activities	Health, safety, operational cost	Staff awareness and training, safety management system	R		M	VH								II	III							III	OHS performance to be closely monitored and assessed and, where required individual, issue-specific risk assessments to be undertaken to identify fit-for purpose safety initiatives
Hazardous chemicals																							
Impacts on emergency services	Significant incident involving major hazardous facility	Health, safety, operational cost	Emergency Response Plan, staff awareness and training	U			L			VL						I			I				I	
Physical Environment																							
Noise																							
Noise impacts to sensitive receptors (residents)	Noise emissions from plant, equipment and processes, road haulage	Annoyance, amenity, harm to wildlife	Distance from source, positioning of equipment for evening shift, attenuation packages for equipment, construction of noise bunds	L						L	L								III	III			III	Implementation of Noise Management Plan Noie Monitoring Management of equipment locations and operating hours
Air quality																							
Dust impacts to sensitive receptors	Equipment, processes and vehicle movements on unsealed roads, and increased bare areas (waste rock dumps, TSF)	Annoyance, amenity (sensitive receptors), harm to wildlife, crop impact, contamination of water tanks	Distance from source, routine haul road watering, progressive rehabilitation, speed limits	L						L	L								III	III			III	Implementation of Air Quality Management Plan Dust Monitoring Management of equipment locations and operating hours
Impacts to air quality (bushfire) - see 'Bushfire'	Project-related activities	Health, safety, amenity, harm to wildlife, annoyance	Onsite containment and control measures, staff training	R						M										II			II	
Visual amenity																							
Visual impact to sensitive receptors	Changed landforms and prominent plant and equipment	Annoyance, amenity	Progressive revegetation of waste rock dumps, visual impact assessment	U						VL									I				I	

Risk Description				Risk Evaluation											Risk Ranking										Risk Management
Risk /Hazard Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Expected/Standard Controls	Likelihood / Probability	Greenhouse	Health	Safety	Environment On-site	Environment Off-site	Community Trust	Compliance	Stakeholders	Cultural Heritage		Greenhouse	Health	Safety	On-site Environment	Off-site Environment	Community Trust	Compliance	Stakeholders	Cultural Heritage	Risk Management Class	Additional Risk Mitigation
Land																									
Impacts to the environment arising from geotechnical instability	Blasting, wet weather, or a combination of both	Health, safety, rehabilitation landform failure and rehabiliation scheduling delays	Geotechnical advice on levee, landforms, low-walls and high-walls	R				M										II						II	Engineering and blasting design to consider geotechnical stability
Impacts to the environment (downstream watercourses) from erosion of rehabilitated areas	Dispersive soil characteristics, rehabilitated landform (slope, surface preparation, revegetation success, climate)	Downstream water quality, operational cost, compliance	Rehabilitation practices, ESC practices	P					M		L								III		II			III	Geochemical characteriation of topsoils and amelioration if necessary
Impacts to the environment (surface water and groundwater)	Waste rock inherent geochemical issues	Downstream water quality, flora, fauna, aquatic fauna, operational cost, compliance	Waste rock characterisations, short residence time on stockpiles, mining schedule	U					M										II					II	Waste rock characterisation program scaled to match findings and identified geochemical risk
Impacts to the environment (land contamination)	Presence of contaminants or potential for acid mine drainage from overburden	Localised land contamination and potential delay in rehabilitation remediation works	Decontamination works, appropriate storage of hazardous chemicals and fuels, training, emergency spill procedures and registers.	R				L										I						I	
Impacts to the environment (revegetation and rehabilitation success)	Unfavourable soil characteristics, climate, inappropriate or unavailable seed mix, weeds and premature grazing	Insufficient tree canopy, poor seedling survival, unfavourable plant community species composition, erosion due to lack of vegetation cover, poor pasture productivity and diversity leading to failure in achieving PMLU	Soil ameliorants and/or fertilisers, seed requirements determined early and purchased to be maintained on site, unavailable seeds planted as tubestocks in the following wet season, weed management, fencing and vegetation monitoring	U				M										II						II	
Impacts to the environment and workforce health	Presence of carbonaceous materials (spontaneous combustion)	Air quality, safety	Appropriate storage and handling of carbonaceous materials, staff training	R			L		L								I		I					I	
Surface water																									
Impacts to local/regional surface water quality	Overtopping of mine pit/ final void	Adverse changes water quality in receiving waterways	Site Water Management System designed to contain mine affected water on site, with releases only under favourable conditions	R					M										II					II	Water management plan, REMP and water quality monitoring, flood protection levee/ landform, progressive rehabilitation to limit disturbance
Impacts to local/regional surface water quality	Catchment disturbance, release of sediment laden waters	Adverse changes to TSS, turbidity, water quality in receiving waterways, HES wetland	Provision of engineered sedimentation structures and ESC measures	U					L										I					I	ESC Plan, SWMS, REMP and water quality monitoring, progressive rehabilitation to limit disturbance
Impacts to local/regional surface water quality	Releases of mine affected water	Adverse changes to salinity, water quality in receiving waterways	Water balance, engineered water management system, licensed release conditions	U					L										I					I	Water management plan, REMP and water quality monitoring, water management system, progressive rehabilitation to limit disturbance
Impacts on surface water resources	Loss of catchment reporting to receiving waterways and wetlands	Impacts to local and regional surface water quality, aquatic ecology and other uses	Water efficiency programs, water management plan	L						VL										II				II	Water management plan, REMP and water quality monitoring, flood protection levee/ landform, progressive rehabilitation to limit disturbance

Risk Description				Risk Evaluation											Risk Ranking										Risk Management
Risk /Hazard Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Expected/Standard Controls	Likelihood / Probability	Greenhouse	Health	Safety	Environment On-site	Environment Off-site	Community Trust	Compliance	Stakeholders	Cultural Heritage	Greenhouse	Health	Safety	On-site Environment	Off-site Environment	Community Trust	Compliance	Stakeholders	Cultural Heritage	Risk Management Class	Additional Risk Mitigation
Groundwater																								
Impacts to groundwater quality	Seepage from MAW water storages	Contamination of groundwater	Engineered MAW water storages	U				M	M								II	II					II	Groundwater and surface water monitoring, REMP, groundwater model validation, make good agreements where required, regular site inspections and housekeeping checklists
Impacts to groundwater resources	Leakage to mine/ final void	Aquifer drawdown	Modelling indicates limited extent of impact	U					M									II					II	Groundwater and surface water monitoring, REMP, groundwater model validation, make good agreements where required
Impacts to groundwater resources	Aquifer disturbance, leakage to mine/ final void	Diminished resource for other users	Modelling indicates limited extent of impact	U					L									I					I	Groundwater and surface water monitoring, REMP, groundwater model validation, make good agreements where required
Impacts to groundwater dependent ecosystems	Aquifer disturbance, leakage to mine/ final void	Impacts to stygofauna habitat	Modelling indicates limited extent of impact	U					L									I					I	Groundwater and surface water monitoring, REMP, groundwater model validation, make good agreements where required
Impacts to groundwater/ surface water	Aquifer disturbance, leakage to mine/ final void	Diminished watercourse baseflow	Modelling indicates limited extent of impact	U					L									I					I	Groundwater and surface water monitoring, REMP, groundwater model validation
Safety																								
Increased safety risk	Steeper landforms, rougher surfaces	Safety, community trust	Relinquishment, exclusion areas and barriers	P			VL	M		L						I	III		II				III	Modify landform design and surface preparation regime to reduce risk
Increased incidence of pests	Introduction of, or creation of conditions to promote, potentially dangerous pest species	Safety	Pest management program, monitoring, raising awareness	R			M									II							II	
Socio-economic																								
Negative impacts to the local and regional economy	Equity of economic contribution	Community trust	DIDO with limited FIFO, local employment opportunities	P						VL									I				I	
Negative impacts to the local and regional economy	Changes associated with closure	Community trust	Wind-down of operations into closure	P						L									II				II	
Cultural Heritage																								
Impacts to cultural heritage values	Planned and/or unplanned disturbance	Degradation of cultural heritage values, compliance	CHMP (presence of CH has not currently been surveyed).	P									L									II	II	Cultural Heritage surveys prior to site clearance Implementation of procedures if cultural heritage values or artefacts are identified
Incident																								
Impacts to the environment (Surface water, groundwater, land contamination, flora, fauna, air quality)	Significant operational/process incident occurring on site (spill, fire, explosion)	Physical environment (soil, landforms, water source), harm to wildlife, compliance	Emergency Response Planning and Training, staff training, awareness, spill control, bunding, containment practices	U				M	H		H						II	III		III			III	Systematic implementation of identified controls
Flora																								
Impacts to flora	Land disturbance, increase in pest species	Loss of native flora outside of approved disturbance area	Land Disturbance Permit System Weed management plan (staff training, equipment/vehicle wash-downs)	P				L	L								II	II					II	
Impacts to flora from bushfire	Project-related activities	Loss of native flora	Containment and control measures, Distance from source, firebreaks, ERT with fire-fighting capacity	R					L									I					I	

Risk Description				Risk Evaluation											Risk Ranking										Risk Management
Risk /Hazard Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Expected/Standard Controls	Likelihood / Probability	Greenhouse	Health	Safety	Environment On-site	Environment Off-site	Community Trust	Compliance	Stakeholders	Cultural Heritage		Greenhouse	Health	Safety	On-site Environment	Off-site Environment	Community Trust	Compliance	Stakeholders	Cultural Heritage	Risk Management Class	Additional Risk Mitigation
Fauna																									
Impacts to fauna	Land disturbance, presence of introduced pests and/or disease	Fauna	Pest management program, habitat offset strategy	P					L										II					II	
Impacts to fauna from bushfire	Project-related activities	Fauna, fauna habitat	Containment and control measures, staff training	R					L										I					I	
Climate change																									
Impacts to climate change	Direct and indirect greenhouse gas emissions from the Project	Localised and regional air quality, extreme weather events (droughts, cyclones and heat waves) with subsquent rehabilitation or mine scheduling delays	Annual review program, efficient and minimal energy use, fuel efficient equipment, equipment maintenance	AC	VL										II									II	
Essential services																									
Impacts on essential services (power, telecoms, potable water)	Additional pressure from the Project	Wearing out of service infrastructure, economic (repair and maintenance)	Annual review, efficient and minimal energy use, audit and monitoring	P						VL										I				I	
Future land use																									
Loss of land resource value	Construction and operation of the Project	Loss of lands having agricultural value	Rehab and closure plan to ensure post mining land use returned to equivalent value and use as pre-mining	L								L										III		III	
Scheduled infrastructure decomissioning and removal delayed or inadequately communicated	Mine planning or changes in the market	Rehab milestones not achieved and failure to remove infrastucture for rehabilitation	Mine scheduling meetings and additonal workforce employed if anticipated that the completion of works in accordance with mine schedule is unlikely	P				L				L						II				II		II	• Infrastructure decommission schedule to be incorporated into annual mine planning. • A register of infrastructure to track which structures exist in each rehabilitation area and which have been removed.
Restrictions on possible future land uses in and around the project area	Post-closure of the Project	Land suitability	Rehabilitation practices, land use assessments, alternative post mining land uses	U				VL										I						I	

15.0 DRAFT EA CONDITIONS

The presentation of the following EA conditions is intended to assist with the process of developing appropriate EA conditions for the Project in consultation with DES. This section does not intend to replace or replicate the Notice of Decision stage of the EA application process under Chapter 5, Division 3, subdivision 2 of the EP Act.

The *Guideline (Mining): Model mining conditions [ESR/2016/1936]* (DES 2017e) provide a basis for proposing environmental protection commitments in EA application documents. The guideline allows for modification of the *Model Mining Conditions* to address the site-specific conditions and circumstances of the Project.

The conditions proposed within this section have been developed to address the anticipated impacts of the Project as described within the EA application, and to be measurable and auditable. Where alternative conditioning has been proposed, an explanatory box is provided beneath the condition. For ease of application and review, the proposed EA conditions have been structured as per the guidelines.

15.1 ENVIRONMENTALLY RELEVANT ACTIVITIES

ERAs include resource activities or specific agricultural activities, or other activities prescribed by the EP Act. Current prescribed ERAs and resource activities are defined in Schedules 2 and 3 respectively of the EP Regulation. The Project will include the resource activity of 'Mining Black Coal' as well as the ancillary activities outlined in Table 75.

Table 75 Environmentally Relevant Activities

Environmentally Relevant Activity	Description
Schedule 2 (Prescribed ERAs)	
8 (1) (c) Chemical storage	Chemical storage (the relevant activity) consists of storing more than 500 m^3 of class C1 or C2 combustible liquids under AS1940 or dangerous goods class 3. Threshold 3) Storing more than 500 m^3 of chemicals of class C1 or C2 combustible liquids under AS1940 or dangerous goods class 3 under subsection (1)(c). *Aggregate Environmental Score: 85*
31 (1) Mineral processing	Mineral processing (the relevant activity) consists of processing, in a year, a total of 1,000t or more of coke or mineral products. Threshold 2) Processing, in a year, the following quantities of mineral products, other than coke (b) more than 100,000 t. *Aggregate Environmental Score: 280*
33 (1) Crushing, milling, grinding or screening	Crushing, milling, grinding or screening (the relevant activity) consists of crushing, grinding, milling or screening more than 5,000 t of material in a year. Threshold Crushing, grinding, milling or screening more than 5,000 t of material in a year. *Aggregate Environmental Score: no score*
60 (1)(ii)(A) Waste disposal	Waste disposal (the relevant activity) consists of operating a facility for disposing of general waste and a quantity of limited regulated waste that is no more than 10% of the total amount of waste received at the facility in a year. Threshold 2) Operating a facility for disposing of, in a year, (h) more than 200,000 t. *Aggregate Environmental Score: 107*
63 (1)(b) (i) Sewage treatment	Sewage treatment (the relevant activity) consists of operating 1 or more sewage treatment works at a site that have a total daily peak design capacity of at least 21EP. Threshold 1) Operating sewage treatment works, other than no-release works, with a total daily peak design capacity of (b) more than 100 but not more than 1500 EP (i) if treated effluent is discharged from the works to an infiltration trench or through an irrigation scheme. *Aggregate Environmental Score: 27*
Schedule 3 (Resource Activity)	
13 Mining black coal	*Aggregate Environmental Score: 128*

15.2 PROPOSED CONDITIONS

Schedule A – General Conditions

General

A1 This environmental authority authorises environmental harm referred to in the conditions. Where there is no condition or this environmental authority is silent on a matter, the lack of a condition or silence does not authorise environmental harm.

A2 In carrying out the mining activity, the holder of this EA must not exceed the allowed disturbance area as detailed in **Schedule 1 – Figure A2 (Approved Plan)**.

A3 This environmental authority authorises the mining of 1.9 million tonnes per annum (Mtpa) ROM (run-of-mine) coal.

A4 The holder of this environmental authority must:

a) install all measures, plant and equipment necessary to ensure compliance with the conditions of this environmental authority;

b) maintain such measures, plant and equipment in a proper and efficient condition;

c) operate such measures, plant and equipment in a proper and efficient manner; and

d) ensure all instruments and devices used for the measurement or monitoring of any parameter under any condition of this environmental authority are properly calibrated.

Monitoring and Records

A5 Except where specified otherwise in another condition of this environmental authority, all monitoring records or reports required by this environmental authority must be kept for a period of no less than five years.

A6 Where monitoring is a requirement of this environmental authority, ensure that a competent person conducts all monitoring in accordance with:

a) the most recent *Monitoring and Sampling Manual* released by the administering authority, or

b) an appropriate method described in Australian Standards (AS), or;

c) any other document approved by the administering authority.

A7 All analyses and tests required to be conducted under this environmental authority must be carried out by a laboratory that has National Association of Testing Authorities (NATA) certification for such analyses and tests, expect as otherwise authorised by the administering authority.

A8 All instruments, equipment and measuring devices used for measuring or monitoring in accordance with any condition of this authority must be:

a) appropriately and competently calibrated, operated and maintained; and

b) calibration reports must be supplied upon request to the administering authority, in accordance with Condition A19.

Estimated Rehabilitation Calculation

A9 The activity must not be carried out until the environmental authority holder has given surety or paid a contribution to the scheme fund, as required by section 297 of the Act.

Risk Management

A10 The holder of this environmental authority must develop and implement a risk management system for mining activities which mirrors the content requirement of the *Standard for Risk Management (ISO31000:2009),* or the latest edition of an Australian standard for risk management, to the extent relevant to environmental management, by 3 months from date of issue.

Notification of Emergencies, Incidents and Exceptions

A11 The holder of this environmental authority must notify the administering authority by written notification within 24 hours, after becoming aware of any emergency or incident which results in the release of contaminants not in accordance, or reasonably expected to be not in accordance with, the conditions of this environmental authority.

A12 Within 10 business days following the initial notification of an emergency or incident, or receipt of monitoring results, whichever is the latter, further written advice must be provided to the administering authority, including the following:

a) results and interpretation of any samples taken and analysed;

b) outcomes of actions taken at the time to prevent or minimise unlawful environmental harm; and

c) proposed actions to prevent a recurrence of the emergency or incident.

Complaints

A13 The holder of this environmental authority must record all environmental complaints received about the mining activities including:

a) name, address and contact number for of the complainant;

b) time and date of complaint;

c) reasons for the complaint;

d) investigations undertaken;

e) conclusions formed;

f) actions taken to resolve the complaint;

g) any abatement measures implemented; and

h) person responsible for resolving the complaint.

A14 The holder of this environmental authority must, when requested by the administering authority, undertake relevant specified monitoring within a reasonable timeframe nominated or agreed to by the administering authority to investigate any complaint of environmental harm. The results of the investigation (including an analysis and interpretation of the monitoring results) and abatement measures, where implemented, must be provided to the administering authority within 10 business days of completion of the investigation, or no later than 10 business days after the end of the timeframe nominated by the administering authority to undertake the investigation.

Third-Party Reporting

A15 The holder of this environmental authority must:

a) within one year of the commencement of this environmental authority, obtain from an appropriately qualified person a report on compliance with the conditions of this environmental authority;

b) obtain further such reports at regular intervals, not exceeding three-yearly intervals, from the completion of the report referred to above; and

c) provide each report to the administering authority within 90 days of its completion.

A16 Where a condition of this environmental authority requires compliance with a standard, policy or guideline published externally to this environmental authority and the standard is amended or changed subsequent to the issue of this environmental authority, the holder of this environmental authority must:

a) comply with the amended or changed standard, policy or guideline within two years of the amendment or change being made, unless a different period is specified in the amended standard or relevant legislation, or where the amendment or change relates specifically to regulated structures referred to in a condition, the time specified in that condition; and

b) until compliance with the amended or changed standard, policy or guideline is achieved, continue to remain in compliance with the corresponding provision that was current immediately prior to the relevant amendment or change.

Schedule B – Air

Dust and Particulate Matter Monitoring

B1 The environmental authority holder shall ensure that all reasonable and feasible avoidance and mitigation measures are employed so that the dust and particulate matter emissions generated by the mining activities do not cause exceedances of the following levels when measured at any sensitive or commercial place:

a) dust deposition of 120 milligrams per square metre per day (mg/m^2/day), averaged over one month, when monitored in accordance with the most recent version of *AS3580.10.1: Methods for sampling and analysis of ambient air - Method 10.1: Determination of particulate matter - Deposited matter - Gravimetric method*;

b) a concentration of particulate matter with an aerodynamic diameter of less than 10 micrometres (PM_{10}) suspended in the atmosphere of 50 micrograms per cubic metre over a 24-hour averaging time, when monitored in accordance with the most recent version of either:

i) *AS3580.9.6 Methods for sampling and analysis of ambient air Part 9.6: Determination of suspended particulate matter - PM_{10} high volume sampler with size-selective inlet - Gravimetric method;* or

ii) *AS3580.9.9 Methods for sampling and analysis of ambient air Part 9.9: Determination of suspended particulate matter - PM_{10} low volume sampler - Gravimetric method.*

c) a concentration of particulate matter with an aerodynamic diameter of less than 2.5 micrometres ($PM_{2.5}$) suspended in the atmosphere of 25 micrograms per cubic metre over a 24-hour averaging time, when monitored in accordance with the most recent version of *AS3580.9.10 Methods for sampling and analysis of ambient air - Determination of suspended particulate matter - $PM_{2.5}$ low volume sampler—Gravimetric method*; and

d) a concentration of particulate matter suspended in the atmosphere of 90 micrograms per cubic metre over a 1-year averaging time, when monitored in accordance with the most recent version of *AS3580.9.3 Methods for sampling and analysis of ambient air – Method 9.3: Determination of suspended particulate matter - Total suspended particulate matter (TSP) - High volume sampler gravimetric method*.

B2 The holder of this environmental authority must undertake monitoring of air quality at the locations specified in **Table B1 – Air Quality Monitoring** in accordance with the standards listed above in Condition B1, which must include:

a) continuous real-time monitoring of PM_{10} at one location;

b) continuous real-time monitoring of dust deposition at one location;

c) meteorological monitoring (including temperature, wind speed and direction) at one location;

d) each location listed in **Table B1 – Air Quality Monitoring** is monitored for a continuous month each year; and

e) regular reporting of the measured PM_{10} and dust deposition concentrations, including investigations into any possible exceedances, must occur.

B3 When requested by the administering authority or as a result of a complaint, dust and particulate monitoring (including dust deposition, TSP, PM_{10} and $PM_{2.5}$) must be undertaken, and the results thereof notified to the administering authority within 14 days following completion of monitoring.

B4 If the monitoring, which is carried out in accordance with Condition B3, indicates an exceedance of the relevant limits in Condition B1, then the environmental authority holder must investigate whether the exceedance is due to emissions from the activity. If the mining activity is found to be the cause of the exceedance, then the environmental authority holder must:

a) notify the administering authority within seven days of an exceedance of the relevant limits in Condition B3.

b) address the complaint including the use of appropriate dispute resolution if required; and

c) implement dust abatement measures so that emissions of dust from the activity do not result in further environmental nuisance.

Table B1 – Air Quality Monitoring Locations

Monitoring Site ID	Monitoring Location		Air Quality Indicator	Frequency
	Monitoring Point (Eastings)	Monitoring Point (Northings)		
Northwest Primary Site	TBC	TBC	PM_{10}	Continuous
			Dust Deposition	Continuous monthly period as per AS
			Meteorological Conditions	Hourly
Dingo Township	TBC	TBC	PM_{10}	Continuous
			Dust Deposition	Continuous monthly period as per AS
			Meteorological Conditions	Hourly
South Secondary Site	TBC	TBC	PM_{10}	Continuous
			Dust Deposition	Continuous monthly period as per AS
			Meteorological Conditions	Hourly

Schedule C – Waste Management

C1 All general and regulated waste (except tyres) must be removed from site to a facility that is lawfully able to accept the waste under the *Environmental Protection Act 1994*.

C2 An effective firebreak must be installed and maintained around all waste laydown and tyre storage areas.

C3 Subject to demonstrating to the administering authority that no other use higher in the waste management hierarchy can be practicably implemented, waste tyres generated from mining activities may be disposed of onsite in waste rock emplacements.

C4 Scrap tyres resulting from mining activities disposed within the operational land must not impede saturated aquifers, cause contamination or compromise the stability of the consolidated landform.

C5 Unless otherwise permitted by the conditions of this environmental authority or with prior approval from the administering authority and in accordance with a relevant standard operating procedure, waste must not be burnt.

C6 Coarse and fine rejects from the CHPP must be managed in accordance with management plan that provides for:

a) containment of tailings;

b) the management of seepage and leachates both during operation and the foreseeable future;

c) the control of fugitive emissions to air;

d) a program of progressive sampling and characterisation to verify the effective containment of rejects within spoil; and

e) maintaining records of the relative locations of rejects disposed of in spoil.

Schedule D – Noise

D1 The holder of this environmental authority must ensure that noise generated by the mining activities does not cause the criteria in **Table D1 – Noise Limits** to be exceeded at a sensitive place or commercial place.

Table D1 – Noise Limits

Noise Level dBA Measured As:	Sensitive or Commercial Place		
	7:00 am to 6:00 pm	6:00 pm to 10:00 pm	10:00 pm to 7:00 am
$L_{Aeq,adj,1hr}$	40	40	35

In accordance with Note 6 of the Model Mining Conditions, criteria were developed in accordance with the EPP (Noise) and the Planning For Noise Control guideline (EHP 2004).

Airblast Overpressure Nuisance

D2 The holder of this environmental authority must ensure that blasting does not cause the limits for peak particle velocity and air blast overpressure in **Table D2 – Blasting Limits** to be exceeded at a sensitive place or commercial place.

Table D2 – Blasting Limits

Blasting Parameter	Sensitive or Commercial Place Limits	
	7:00 am to 6:00 pm	6:00 pm to 7:00 am
Airblast overpressure	115 dBZ peak for 4 out of 5 consecutive blasts initiated; or Not greater than 120 dBZ peak at any time.	No blasting is allowed during these times.
Ground vibration peak particle velocity	For vibrations of more than 35 Hz – more than 25 mm per second ground vibration, peak particle velocity, or For vibrations of no more than 35 Hz – more than 10 mm of second peak particle velocity.	No blasting is allowed during these times.

D3 Every explosive blast for the mining activity shall be designed by a competent person and be in accordance with a blast monitoring and management program, to achieve the criteria specified in **Table D2 – Blasting Limits**.

Monitoring and Reporting

D4 Noise monitoring and recording must include the following descriptor characteristics and matters:

a) the level and frequency of occurrence of impulsive or tonal noise and any adjustment and penalties to statistical levels;

b) atmospheric conditions including temperature, relative humidity and wind speed and directions;

c) effects due to any extraneous factors such as traffic noise; and

d) location, date and time of monitoring.

D5 The holder of this environmental authority must develop and implement a blast monitoring and management program to monitor compliance with **Table D2 – Blasting Limits** for:

a) at least 50% of all blasts undertaken on this site in each month at the nearest sensitive place or commercial place; and

b) all blasts conducted during any time period specified by the administering authority at the nearest and most affected sensitive place(s) or commercial place(s) or another such place to investigate an allegation of environmental nuisance caused by blasting.

Schedule E – Groundwater

E1 The holder of this environmental authority must not release contaminants to groundwater.

E2 All determinations of groundwater quality must be performed by an appropriately qualified person.

E3 Groundwater quality and levels must be monitored at the locations and frequencies defined in **Table E1 – Groundwater Monitoring Locations and Frequency** for quality characteristics identified in **Table E2 - Groundwater Quality**

Bore Construction and Maintenance and Decommissioning

E4 The construction, maintenance and management of groundwater bores (including groundwater monitoring bores) must be undertaken in a manner that prevents or minimises impacts to the environment and ensures the integrity of the bores to obtain accurate monitoring.

Table E1 – Groundwater Monitoring Locations and Frequency

Site	Bore ID	Easting	Northing	Type	Bore Depth (m)	Unit Monitored	Monitoring Frequency
1	DW7065W	730860	7382307	SP	77.27	Permian Coal Seams (Aries 3)	Quarterly
	DW7066W	730863	7382304	SP	17.35	Tertiary sediments	Quarterly
3	DW7069W	730397	7382699	SP	71.38	Permian Coal Seams (Pollux Upper Seam)	Quarterly
	DW7071W	730394	7382703	SP	31.59	Permian Coal Seams (Aries 3)	Quarterly

Schedule F – Water (Fitzroy Model Conditions)

F1 A *Water Management Plan* must be developed by an appropriately qualified person and implemented for all stages of mining activities on the site.

F2 The *Water Management Plan* must:

a) Provide for the effective management of actual and potential environmental impacts result from water management associated with the mining activities carried out under this environmental authority.

b) Be developed by an appropriately qualified person and in accordance with administering authority's current guideline for preparation of a water management plan for mining activities, and include:

i) a study of the source of contaminants;

ii) a water balance model for the site;

iii) a water management system for the site;

iv) measures to manage and prevent and/or minimise saline drainage;

v) measures to manage and prevent and/or minimise acid mine drainage; and

vi) contingency procedures for emergencies.

F3 The *Water Management Plan* must be reviewed each calendar year and a report prepared by an appropriately qualified person. The report must:

a) assess the plan against the requirements under Condition F2;

b) include recommended actions to ensure actual and potential environmental impacts are effectively managed for the coming year; and

c) identify any amendments made to the water management plan following the review.

F4 The holder of this environmental authority must attach to the review a report required by Condition F3, a written response to the report and recommended actions, detailing the actions take or to be taken by the environmental authority holder on stated dates:

a) to ensure compliance with this environmental authority; and

b) to prevent a recurrence of any non-compliance issues identified.

F5 A copy of the *Water Management Plan* must be provided to the administering authority on request.

Contamination Release

F6 Contaminants that will, or have the potential to, cause environmental harm must not be released directly or indirectly to any waters as a result of the authorised mining activities, except as permitted under the conditions of this environmental authority.

F7 Unless otherwise permitted under the conditions of this environmental authority, the release of mine affected water to waters must only occur from the release points specified in **Table F1 – Mine Affected Water Release Points and Sources** and depicted in **Schedule 2 – Figure H1 (Post-mining Land Use Areas)** attached to this environmental authority.

Table F1 – Mine Affected Water Release Points and Sources

Release Point	Easting (MGA94 Zone 55)	Northing (MGA94 Zone 55)	Mine Affected Water Source and Location
Mine Water Dam	731,377	7,383,379	Mine affected water system

F8 The release of mine affected water to internal water management infrastructure installed and operated in accordance with a water management plan that complies with Condition F1 - F4 is permitted.

F9 The release of mine affected water to waters in accordance with Condition F7 must not exceed the release limits stated in **Table F2 – Mine Affected Water Release Limits** when measured at the monitoring points specified in **Table F1 – Mine Affected Water Release Points and Sources** for each quality characteristic.

Table F2 – Mine Affected Water Release Limits

Quality Characteristic	Release Limits	Monitoring Frequency
Electrical conductivity (EC) (µS/cm)	Release limits specified in **Table F4 – Mine Affected Water Release During Flow Events**.	Daily during release (the first sample must be taken within two hours of commencement of release).

pH (pH Unit)	6.5 (minimum) 9.0 (maximum)	Daily during release (the first sample must be taken within two hours of commencement of release).
Turbidity (NTU)	TBA	Daily during release (first sample within two hours of commencement of release).

F10 The release of mine affected water to waters from the release points must be monitored at the locations specified in **Table F1 – Mine Affected Water Release Points and Sources** for each quality characteristic and at the frequency specified in **Table F2 – Mine Affected Water Release Limits** and **Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants**.

Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants

Quality Characteristic	Trigger Levels (µg/L)	Comment on Trigger Level	Monitoring Frequency
Aluminium	55	For aquatic ecosystem protection, based on SMD guideline.	Commencement of release and thereafter weekly during release.
Arsenic	13	For aquatic ecosystem protection, based on SMD guideline.	
Cadmium	0.2	For aquatic ecosystem protection, based on SMD guideline.	
Chromium	1	For aquatic ecosystem protection, based on SMD guideline.	
Copper	2	For aquatic ecosystem protection, based on LOR for ICPMS.	
Iron	300	For aquatic ecosystem protection, based on low reliability guideline.	
Lead	4	For aquatic ecosystem protection, based on SMD guideline.	
Mercury	0.2	For aquatic ecosystem protection, based on LOR for ICPMS.	
Nickel	11	For aquatic ecosystem protection, based on SMD guideline.	
Zinc	8	For aquatic ecosystem protection, based on SMD guideline.	
Boron	370	For aquatic ecosystem protection, based on SMD guideline.	
Cobalt	90	For aquatic ecosystem protection, based on low reliability guideline.	
Manganese	1,900	For aquatic ecosystem protection, based on SMD guideline.	
Molybdenum	34	For aquatic ecosystem protection, based on low reliability guideline.	
Selenium	10	For aquatic ecosystem protection, based on LOR for ICPMS.	
Silver	1	For aquatic ecosystem protection, based on LOR for ICPMS.	
Uranium	1	For aquatic ecosystem protection, based on LOR for ICPMS.	

Quality Characteristic	Trigger Levels (µg/L)	Comment on Trigger Level	Monitoring Frequency
Vanadium	10	For aquatic ecosystem protection, based on LOR for ICPMS.	
Ammonia	900	For aquatic ecosystem protection, based on SMD guideline.	
Nitrate	1,100	For aquatic ecosystem protection, based on ambient Qld WQ Guidelines (2006) for TN.	
Petroleum Hydrocarbon (C6 – C9)	20		
Petroleum Hydrocarbon (C10 – C36)	100		
Fluoride (total)	2,000	Protection of livestock and short-term irrigation guideline.	

ICPMS inductively coupled plasma mass spectrometry

*The quality characteristics required to be monitored as per **Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants** can be reviewed once the results of two years monitoring data is available, or if sufficient data is available adequately demonstrate negligible risk, and it may be determined that a reduced monitoring frequency is appropriate or that certain quality characteristics can be removed from **Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants** by amendment.*

F11 If quality characteristics of the release exceed any of the trigger levels specified in **Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants** during a release event, the environmental authority holder must compare the downstream results in the receiving waters to the trigger values specified in Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants and:

a) Where the trigger values are not exceeded then no action is to be taken; or

b) Where the downstream results exceed the trigger, values specified **Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants** for any quality characteristic, compare the results of the downstream site to the data from background monitoring sites and:

i) if the result is less than the background monitoring site data, then no action is to be taken; or

ii) if the result is greater than the background monitoring site data, complete an investigation into the potential for environmental harm and provide a written report to the administering authority in the next annual return, outlining:

1. details of the investigations carried out; and

2. actions taken to prevent environmental harm.

Note: *Where an exceedance of a trigger level has occurred and is being investigated, in accordance with Condition F11 (b)(i) of this condition, no further reporting is required for subsequent trigger events for that quality characteristic.*

F12 If an exceedance in accordance with Condition F11 (b)(ii) is identified, the holder of the environmental authority must notify the administering authority in writing within 24 hours of receiving the result.

Mine Affected Water Release Events

F13 The holder must ensure a stream flow gauging station/s is installed, operated and maintained to determine and record stream flows at the locations and flow recording frequency specified in **Table F4 – Mine Affected Water Release During Flow Events**.

Table F4 – Mine Affected Water Release During Flow Events

Receiving Water	Release Points	Gauging Station	Easting	Northing	Minimum flow
Charlevue Creek	Mine Water Dam	Downstream Charlevue Creek	TBA	TBA	TBA

*No mine affected waters will be released from site until a stream flow gauging, station as required under **Table F4 – Mine Affected Water Release During Flow Events**.*

F14 Notwithstanding any other condition of this environmental authority, the release of mine affected water to waters in accordance with Condition F7 must only take place during periods of natural flow in accordance with the receiving water flow criteria for discharge specified in **Table F4 – Mine Affected Water Release During Flow Events** for the release point(s) specified in **Table F1 – Mine Affected Water Release Points and Sources**.

F15 The 80th percentile of electrical conductivity (EC) values recorded at the downstream monitoring points listed in **Table F4 – Mine Affected Water Release During Flow Events** must not exceed 310 µS/cm over the duration of the release influence period and have a maximum value of no greater than 20 per cent of 310 µS/cm. The 80th percentile must be calculated using all EC values recorded by the monitoring station during the release influence period.

F16 The daily quantity of mine affected water released from each release point must be measured and recorded.

F17 Releases to waters must be undertaken so as not to cause erosion of the bed and banks of the receiving waters or cause a material build-up of sediment in such waters.

Notification of Release Event

F18 The environmental authority holder must notify the administering authority as soon as practicable and no later than 24 hours after commencing to release mine affected water to the receiving environment. Notification must include the submission of written advice to the administering authority of the following information:

a) release commencement date / time;

b) details regarding the compliance of the release with the conditions of department interest: water of this environmental authority (that is, contaminant limits, natural flow, discharge volume);

c) release point/s;

d) release rate;

e) release salinity; and

f) receiving water/s including the natural flow rate.

***Note**: Notification to the administering authority must be addressed to the Manager and Project Manager of the local Administering Authority via email or facsimile.*

F19 The environmental authority holder must notify the administering authority as soon as practicable and nominally no later than 24 hours after cessation of a release event of the cessation of a release notified under Condition F13 and within 28 days provide the following information in writing:

a) release cessation date/time;

b) natural flow rate in receiving water;

c) volume of water released;

d) details regarding the compliance of the release with the conditions of department interest; water of this environmental authority (i.e., contaminant limits, natural flow, discharge volume);

e) all in-situ water quality monitoring results; and

f) any other matters pertinent to the water release event.

***Note**: Successive or intermittent releases occurring within 24 hours of the cessation of any individual release can be considered part of a single release event and do not require individual notification for the purpose of compliance with Conditions F14 and F15, provided the relevant details of the release are included within the notification provided in accordance with Conditions F14 and F15.*

Notification of Release Event Exceedance

F20 If the release limits defined in **Table F2 – Mine Affected Water Release Limits** are exceeded, the holder of the environmental authority must notify the administering authority within 24 hours of receiving the results.

F21 The environmental authority holder must, within 28 days of a release that is not compliant with the conditions of this environmental authority, provide a report to the administering authority detailing:

a) the reason for the release;

b) the location of the release;

c) the total volume of the release and which (if any) part of this volume was non-compliant;

d) the total duration of the release and which (if any) part of this period was non-compliant;

e) all water quality monitoring results (including all laboratory analyses);

f) identification of any environmental harm as a result of the non-compliance;

g) all calculations; and

h) any other matters pertinent to the water release event.

Receiving Environment Monitoring and Contaminant Trigger Levels

F22 The quality of the receiving waters must be monitored at the locations specified in **Table F6 – Receiving Water Upstream Background Sites and Downstream Monitoring Sites** for each quality characteristic and at the monitoring frequency stated in **Table F5 – Receiving Waters Contaminant Trigger Levels**.

Table F5 – Receiving Waters Contaminant Trigger Levels

Quality Characteristic	Trigger Level	Monitoring Frequency
pH (pH Units)	6.5-8.5	Daily during the release
Electrical conductivity (EC) (µS/cm)	310	
Sulphate (SO_4^{2-}) (mg/L)	10	

Table F6 – Receiving Water Upstream Background Sites and Downstream Monitoring Sites

Description	Latitude (decimal degree, GDA94)	Longitude (decimal degree, GDA94)
Upstream Background Monitoring Points		
Springton Ck Upstream (SC1)	-23.6976	149.2738
Charlevue Ck Upstream (CC1)	-23.6305	149.2715
Downstream Monitoring Points		
Springton Ck Downstream (SC2)	-23.6434	149.3145
Charlevue Ck Downstream (CC2)	-23.6469	149.2104

F23 If quality characteristics of the receiving water at the downstream monitoring points exceed any of the trigger levels specified in **Table F5 – Receiving Waters Contaminant Trigger Levels** during a release event the environmental authority holder must compare the downstream results to the upstream results in the receiving waters and:

a) Where the downstream result is the same or a lower value than the upstream value for the quality characteristic, then no action is to be taken; or

b) Where the downstream results exceed the upstream results, complete an investigation into the potential for environmental harm and provide a written report to the administering authority in the next annual return, outlining:

i) details of the investigations carried out; and

ii) actions taken to prevent environmental harm.

Note: *Where an exceedance of a trigger level has occurred and is being investigated, in accordance with Condition F18 (b) of this condition, no further reporting is required for subsequent trigger events for that quality characteristic.*

F24 All determinations of water quality monitoring must be performed by suitably experienced and qualified person.

Receiving Environment Monitoring Program (REMP)

F25 The environmental authority holder must develop and implement a Receiving Environment Monitoring Program (REMP) to monitor, identify and describe any adverse impacts to surface water environmental values, quality and flows due to the authorised mining activity. This must include monitoring the effects of the mine on the receiving environment periodically (under natural flow conditions) and while mine affected water is being discharged from the site.

For the purposes of the REMP, the receiving environment is the waters of Creek and connected or surrounding waterways within 15 km downstream of the release. The REMP should encompass any sensitive receiving waters or environmental values downstream of the authorised mining activity that will potentially be directly affected by an authorised release of mine affected water.

F26 The REMP must:

a) assess the condition or state of receiving waters, including upstream conditions, spatially within the REMP area, considering background water quality characteristics based on accurate and reliable monitoring data that takes into consideration temporal variation (e.g., seasonality);

b) be designed to facilitate assessment against water quality objectives for the relevant environmental values that need to be protected;

c) include monitoring from background reference sites (e.g., upstream or background) and downstream sites from the release (as a minimum, the locations specified in **Table F6 – Receiving Water Upstream Background Sites and Downstream Monitoring Sites**);

d) specify the frequency and timing of sampling required in order to reliably assess ambient conditions and to provide sufficient data to derive site-specific background reference values in accordance with the *Queensland Water Quality Guidelines 2009*. This should include monitoring during periods of natural flow irrespective of mine or other discharges;

e) include monitoring and assessment of dissolved oxygen saturation, temperature and all water quality parameters listed in **Table F5 – Receiving Waters Contaminant Trigger Levels** and **Table F3 - Release Contaminant Trigger Investigation Levels, Potential Contaminants**;

f) include, where appropriate, monitoring of metals/metalloids in sediments (in accordance with ANZG (2018). BATLEY and/or the most recent version of *AS5667.1 Water quality - Sampling - Guidance on the design of sampling programs, sampling techniques and the preservation and handling of samples*);

g) include, where appropriate, monitoring of macroinvertebrates in accordance with the AusRivAS methodology;

h) apply procedures and/or guidelines from ANZG (2018) and other relevant guideline documents;

i) describe sampling and analysis methods and quality assurance and control; and

j) incorporate stream flow and hydrological information in the interpretations of water quality and biological data.

F27 A REMP Design Document that addresses the requirements of the REMP must be prepared and made available to the administrating authority upon request.

F28 A report outlining the findings of the REMP, including all monitoring results and interpretations must be prepared annually and made available on request to the administrating authority. This must include an assessment of background reference water quality, the condition of downstream water quality compared against water quality objectives, and the suitability of current discharge limits to protect downstream environmental values.

Water Reuse

F29 Mine affected water may be piped or trucked or transferred by some other means that does not contravene the conditions of this environmental authority and deposited into artificial water storage structures, such as farm dams or tanks, or used directly at properties owned by the environmental authority holder or a third party (with the consent of the third party).

Annual Water Monitoring Report

F30 The following information must be recorded in relation to all water monitoring required under the conditions of this environmental authority and submitted to the administering authority in the specified format:

a) the date on which the sample was taken;

b) the time at which the sample was taken;

c) the monitoring point at which the sample was taken;

d) the measured or estimated daily quantity of mine affected water released from all release points;

e) the release flow rate at the time of sampling for each release point;

f) the results of all monitoring and details of any exceedances of the conditions of this environmental authority; and

g) water quality monitoring data must be provided to the administering authority in the specified electronic format upon request.

Stormwater and Water Sediment Controls

F31 An *Erosion and Sediment Control Plan* must be developed by an appropriately qualified person and implemented for all stages of the mining activities on the site to minimise erosion and the release of sediment to receiving waters and contamination of stormwater.

F32 Stormwater, other than mine affected water, is permitted to be released to waters from:

a) Erosion and sediment control structures that are installed and operated in accordance with the *Erosion and Sediment Control Plan* required by Condition F31; and

b) Water management infrastructure that is installed and operated, in accordance with a *Water Management Plan* that complies with Conditions F2-F4 for the purpose of ensuring water does not become mine affected water.

Schedule G – Sewage Treatment

G1 The only contaminant permitted to be released to land is treated sewage effluent in compliance with the release limits stated in **Table G1 – Contaminant Release Limits To Land**.

Table G1 – Contaminant Release Limits To Land

Contaminant	Unit	Release Limit	Limit Type	Frequency
5-day biochemical oxygen demand	mg/L	20	Maximum	Monthly
total suspended solids	mg/L	30	Maximum	Monthly
Nitrogen	mg/L	30	Maximum	Monthly
Phosphorus	mg/L	15	Maximum	Monthly
E-coli	Organisms/100ml	1,000	Maximum	Monthly
pH	pH units	6.0 – 9.0	Range	Monthly

G2 Treated sewage effluent may only be released to land in accordance with the conditions of this approval.

G3 The application of treated effluent to land must be carried out in a manner such that:

a) vegetation is not damaged;

b) there is no surface ponding of effluent; and

c) there is no run-off of effluent.

G4 If areas irrigated with effluent are accessible to employees or the general public, prominent signage must be provided advising that effluent is present, and care should be taken to avoid consuming or otherwise coming into unprotected contact with the effluent.

G5 All sewage effluent released to land must be monitored at the frequency and for the parameters specified in **Table G1 – Contaminant Release Limits To Land**.

G6 The daily volume of effluent release to land must be measured and records kept of the volumes of effluent released.

G7 When circumstances prevent the irrigation or beneficial reuse of treated sewage effluent such as during or following rain events, waters must be directed to a wet weather storage or alternative measures must be taken to store/lawfully dispose of effluent.

G8 Treated sewage effluent must only be supplied to another person or organisation that has a written plan detailing how the user of the treated sewage effluent will comply with their general environmental duty under section 319 of the *Environmental Protection Act 1994* whilst using the treated sewage effluent.

Schedule H – Land and Rehabilitation

H1 Land disturbed by mining must be rehabilitated in accordance with **Table H1 – Rehabilitation Areas and Post-Mining Land Use** and **Schedule 2 – Figure H1 (Post-mining Land Use Areas)**.

Table H1 – Rehabilitation Areas and Post-Mining Land Use

Rehabilitation Area	Post-mining Land Use	Approximate Footprint Area (ha)	Approximate Proportion of Total Disturbance
In-pit and out-of-pit waste emplacements, including dry rejects disposal areas	Grazing	722.4	37%
Temporary waste emplacements	Grazing	17.54	1%
Residual void lakes	Fauna habitat	76.5	4%
Residual void high walls	Native vegetation supporting fauna habitat	133.1	7%
Residual void low walls	Grazing	187.2	9%
Water management infrastructure	Grazing/native vegetation	85	4%
Mine infrastructure areas	Grazing	731.8	38%

Impacts to Prescribed Environmental Matters

H2 The significant residual impacts to prescribed environmental matters are not authorised under this environmental authority or the *Environmental Offsets Act 2014* unless the impact(s) is specified in **Table H2 – Significant Residual Impacts To Prescribed Environmental Matters**.

H3 Records demonstrating that each impact to a prescribed environmental matter not listed in **Table H2 – Significant Residual Impacts To Prescribed Environmental Matters** did not, or is not likely to, result in a significant residual impact to that matter must be:

a) Completed by an appropriately qualified person; and

b) Kept for the life of the environmental authority.

Table H2 – Significant Residual Impacts To Prescribed Environmental Matters

Prescribed Environmental Matter	Description		Maximum Extent of Impact (ha)
Regulated Vegetation	Of concern regional ecosystem	RE 11.3.2	2.57
	Regional ecosystems within a defined distance of a vegetation management watercourse (RE 11.3.25, 11.5.2, 11.3.2 and 11.7.2)		58.32
Connectivity Areas			710.72

H4 An environmental offset made in accordance with the *Environmental Offsets Act 2014* and the *Queensland Environmental Offsets Policy*, as amended from time to time, must be undertaken for the maximum extent of impact to each prescribed environmental matter authorised in **Table H2 – Significant Residual Impacts To Prescribed Environmental Matters**, unless a lesser extent of the impact has been approved in accordance with Condition H8.

H5 The significant residual impacts to a prescribed environmental matter authorised in Condition H2 for which an environmental offset is required by Condition H2 may be carried out in stages. An environmental offset can be delivered for each stage of the impacts to prescribed environmental matters.

Staged Impacts

H6 The significant residual impacts to a prescribed environmental matter authorised in Condition H2 for which an environmental offset is required by Condition H11 may be carried out in stages. An environmental offset can be delivered for each stage of the impacts to prescribed environmental matters.

H7 Prior to the commencement of each stage, a report completed by an appropriately qualified person, that includes an analysis of the following must be provided to the administering authority:

a) For the forthcoming stage—the estimated significant residual impacts to each prescribed environmental matter; and

b) For the previous stage, if applicable—the actual significant residual impacts to each prescribed environmental matter, to date.

H8 The report required by Condition H7 must be approved by the administering authority before a notice of election for the forthcoming stage, if applicable, is given to the administering authority.

H9 A notice of election for the staged environmental offset referred to in Condition H8, if applicable, must be provided to the administering authority no less than three months before the proposed commencement of that stage, unless a lesser timeframe has been agreed to by the administering authority.

H10 Within six months from the completion of the final stage of the project, a report completed by an appropriately qualified person, that includes the following matters must be provided to the administering authority:

a) An analysis of the actual impacts on prescribed environmental matters resulting from the final stage; and

b) If applicable, a notice of election to address any outstanding offset debits for the authorised impacts.

Chemical and Flammable or Combustible Liquids

H11 All flammable and combustible liquids must be contained within an onsite containment system and controlled in a manner that prevents environmental harm and maintained in accordance with the current edition of *AS1940 The storage and handling of flammable and combustible liquids*.

H12 All explosive, corrosive substances, toxic substances, gases and dangerous goods must be stored and handled in accordance with the relevant Australian Standards.

H13 All chemicals and flammable or combustible liquids stored onsite that have the potential to cause environmental harm must be stored in, or serviced by, an effective containment system that is impervious to the materials stored and managed to prevent the release of liquids to water or land. Where no relevant Australian Standard is available, the following must be applied:

a) Storage tanks must be bunded so that the capacity and construction of the bund is sufficient to contain at least 110% of a single storage tank or 100% of the largest storage tank plus 10% of the second largest storage tank in multiple storage areas; and

b) Drum storage must be bunded so that the capacity and construction of the bund is sufficient to contain at least 25% of the maximum design storage volume within the bund.

Spills

H14 Any spills or release of flammable and combustible liquids; or chemicals, must be controlled in a manner that prevents environmental harm.

H15 An appropriate spill kit, personal protective equipment and relevant operator instructions/emergency procedure guides for the management of wastes, chemicals and flammable and combustible liquids associated with the activity must be kept at the site.

H16 Anyone operating with wastes, chemicals or flammable and combustible liquids under this approval must be trained in the use of the spill kit.

Infrastructure

H17 All infrastructure constructed by, or for, the environmental authority holder during the licensed activities include water storages, must be removed from the site prior to surrender, except where agreed in writing by the post mining landowner.

Note: *This is not applicable where the landowner/holder is also the environmental authority holder.*

Schedule I - Regulated Structures

Assessment of consequence category

I1 The consequence category of any structure must be assessed by a suitably qualified and experienced person in accordance with the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016) at the following times:

a) prior to the design and construction of the structure, if it is not an existing structure; or

b) prior to any change in its purpose or the nature of its stored contents.

I2 A consequence assessment report and certification must be prepared for each structure assessed and the report may include a consequence assessment for more than one structure.

I3 Certification must be provided by the suitably qualified and experienced person who undertook the assessment, in the form set out in the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016).

I4 Conditions I5 to I9 inclusive do not apply to existing structures.

I5 All regulated structures must be designed by, and constructed under the supervision of, a suitably qualified and experienced person in accordance with the requirements of the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016).

I6 Construction of a regulated structure is prohibited unless:

a) the holder has submitted a consequence category assessment report and certification to the administering authority; and

b) certification for the design, design plan and the associated operating procedures has been certified by a suitably qualified and experienced person in compliance with the relevant condition of this authority.

I7 Certification must be provided by the suitably qualified and experienced person who oversees the preparation of the design plan in the form set out in the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016) and must be recorded in the Register of Regulated Structures.

I8 Regulated structures must:

a) be designed and constructed in compliance with the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016).

b) be designed and constructed with due consideration given to ensuring that the design integrity would not be compromised on account of:

i) floodwaters from entering the regulated dam from any watercourse or drainage line; and

ii) wall failure due to erosion by floodwaters arising from any watercourse or drainage line.

I9 Certification by the suitably qualified and experienced person who supervises the construction must be submitted to the administering authority on the completion of construction of the regulated structure, and state that:

a) the 'as constructed' drawings and specifications meet the original intent of the design plan for that regulated structure; and

b) construction of the regulated structure is in accordance with the design plan.

Notification of affected persons

I10 All affected persons must be provided with a copy of the emergency action plan in place for each regulated structure:

a) for existing structures that are regulated structures, within 10 business days of this condition taking effect;

b) prior to the operation of the new regulated structure; and

c) if the emergency action plan is amended, within 5 business days of it being amended.

Operation of a regulated structure

I11 Operation of a regulated structure, except for an existing structure, is prohibited unless the holder has submitted to the administering authority in respect of regulated structure, all of the following:

a) one paper copy and one electronic copy of the design plan and certification of the 'design plan' in accordance with Condition I6;

b) a set of 'as constructed' drawings and specifications;

c) certification of the 'as constructed drawings and specifications' in accordance with Condition I9;

d) where the regulated structure is to be managed as part of an integrated containment system for the purpose of sharing the design storage allowance (DSA) volume across the system, a copy of the certified system design plan;

e) the requirements of this authority relating to the construction of the regulated structure have been met;

f) the holder has entered the details required under this authority, into a Register of Regulated Structures; and

g) there is a current operational plan for the regulated structure.

Mandatory reporting level

I12 Conditions I13 to I16 inclusive only apply to Regulated Structures which have not been certified as low consequence category for 'failure to contain – overtopping'.

I13 The mandatory reporting level (the MRL) must be marked on a regulated dam in such a way that during routine inspections of that dam, it is clearly observable.

I14 The holder must, as soon as practicable but within forty-eight (48) hours of becoming aware, notify the administering authority when the level of the contents of a regulated dam reaches the MRL.

I15 The holder must, immediately on becoming aware that the MRL has been reached, act to prevent the occurrence of any unauthorised discharge from the regulated dam.

I16 The holder must record any changes to the MRL in the Register of Regulated Structures.

Design storage allowance

I17 The holder must assess the performance of each regulated dam or linked containment system over the preceding November to May period based on actual observations of the available storage in each regulated dam or linked containment system taken prior to 1 July of each year.

I18 By 1 November of each year, storage capacity must be available in each regulated dam (or network of linked containment systems with a shared DSA volume), to meet the DSA volume for the dam (or network of linked containment systems).

I19 The holder must, as soon as practicable but within forty-eight (48) hours of becoming aware that the regulated dam (or network of linked containment systems) will not have the available storage to meet the DSA volume on 1 November of any year, notify the administering authority.

I20 The holder must, immediately on becoming aware that a regulated dam (or network of linked containment systems) will not have the available storage to meet the DSA volume on 1

November of any year, act to prevent the occurrence of any unauthorised discharge from the regulated dam or linked containment systems.

Annual inspection report

I21 Each regulated structure must be inspected each calendar year by a suitably qualified and experienced person.

I22 At each annual inspection, the condition and adequacy of all components of the regulated structure must be assessed and a suitably qualified and experienced person must prepare an annual inspection report containing details of the assessment and include a recommendations section, with any recommended actions to ensure the integrity of the regulated structure or a positive statement that no recommendations are required**.**

I23 The suitably qualified and experienced person who prepared the annual inspection report must certify the report in accordance with the *Manual for assessing consequence categories and hydraulic performance of structures [ESR/2016/1933]* (DES 2016).

I24 The holder must within 20 business days of receipt of the annual inspection report, provide to the administering authority:

a) the recommendations section of the annual inspection report;

b) if applicable, any actions being taken in response to those recommendations; and

c) if, following receipt of the recommendations and (if applicable) recommended actions, the administering authority requests a copy of the annual inspection report from the holder, provide this to the administering authority within 10 business days11 of receipt of the request.

Transfer arrangements

I25 The holder must provide a copy of any reports, documentation and certifications prepared under this authority, including but not limited to any Register of Regulated Structures, consequence assessment, design plan and other supporting documentation, to a new holder on transfer of this authority.

Decommissioning and rehabilitation

I26 Regulated structures must not be abandoned but be either:

a) decommissioned and rehabilitated to achieve compliance with Condition I27; or

b) be left in-situ for a use by the landholder provided that:

i) it no longer contains contaminants that will migrate into the environment; and

ii) it contains water of a quality that is demonstrated to be suitable for its intended use(s); and

c) the holder of the environmental authority and the landholder agree in writing that the;

i) dam will be used by the landholder following the cessation of the environmentally relevant activity(ies); and

ii) landholder is responsible for the dam, on and from an agreed date.

I27 Before surrendering this environmental authority the site must be rehabilitated to achieve a safe, stable, non-polluting landform and grazing.

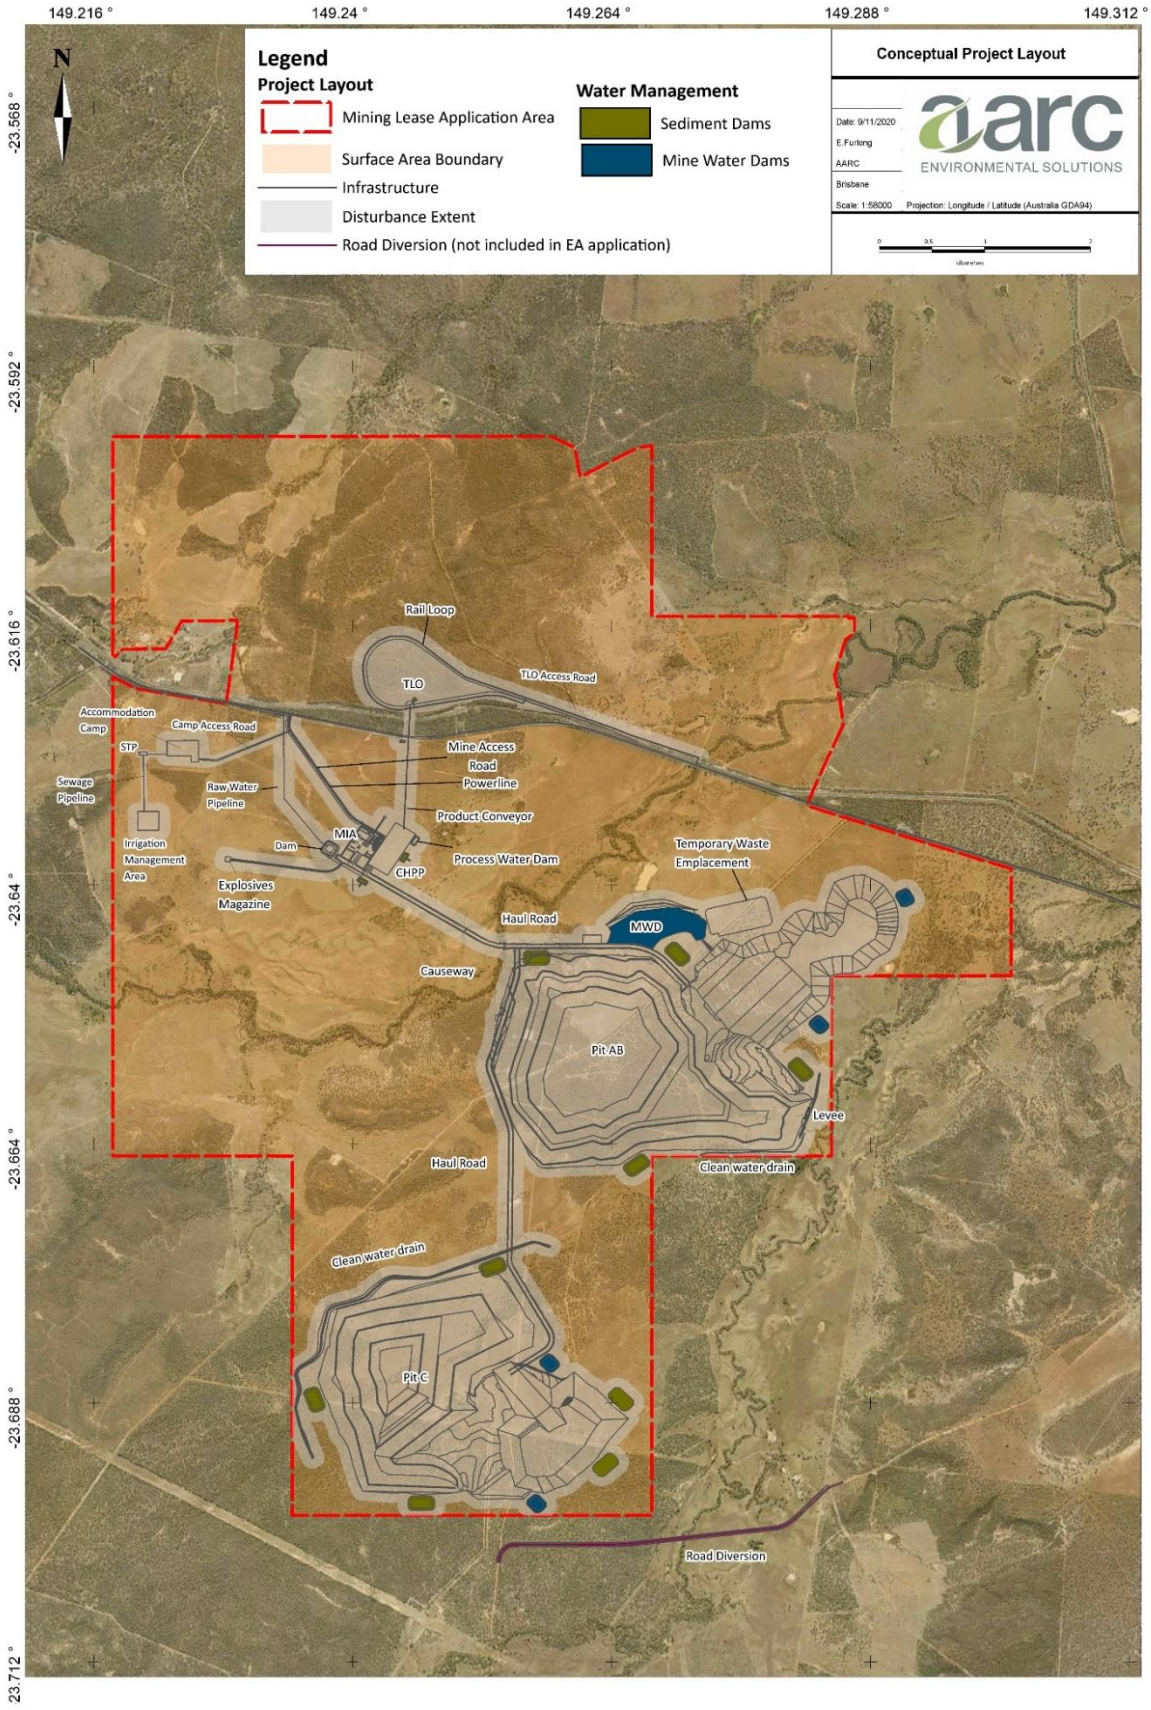
Register of Regulated Structures

I28 A Register of Regulated Structures must be established and maintained by the holder for each regulated structure:

I29 The holder must provisionally enter the required information in the Register of Regulated Structures when a design plan for a regulated dam is submitted to the administering authority.

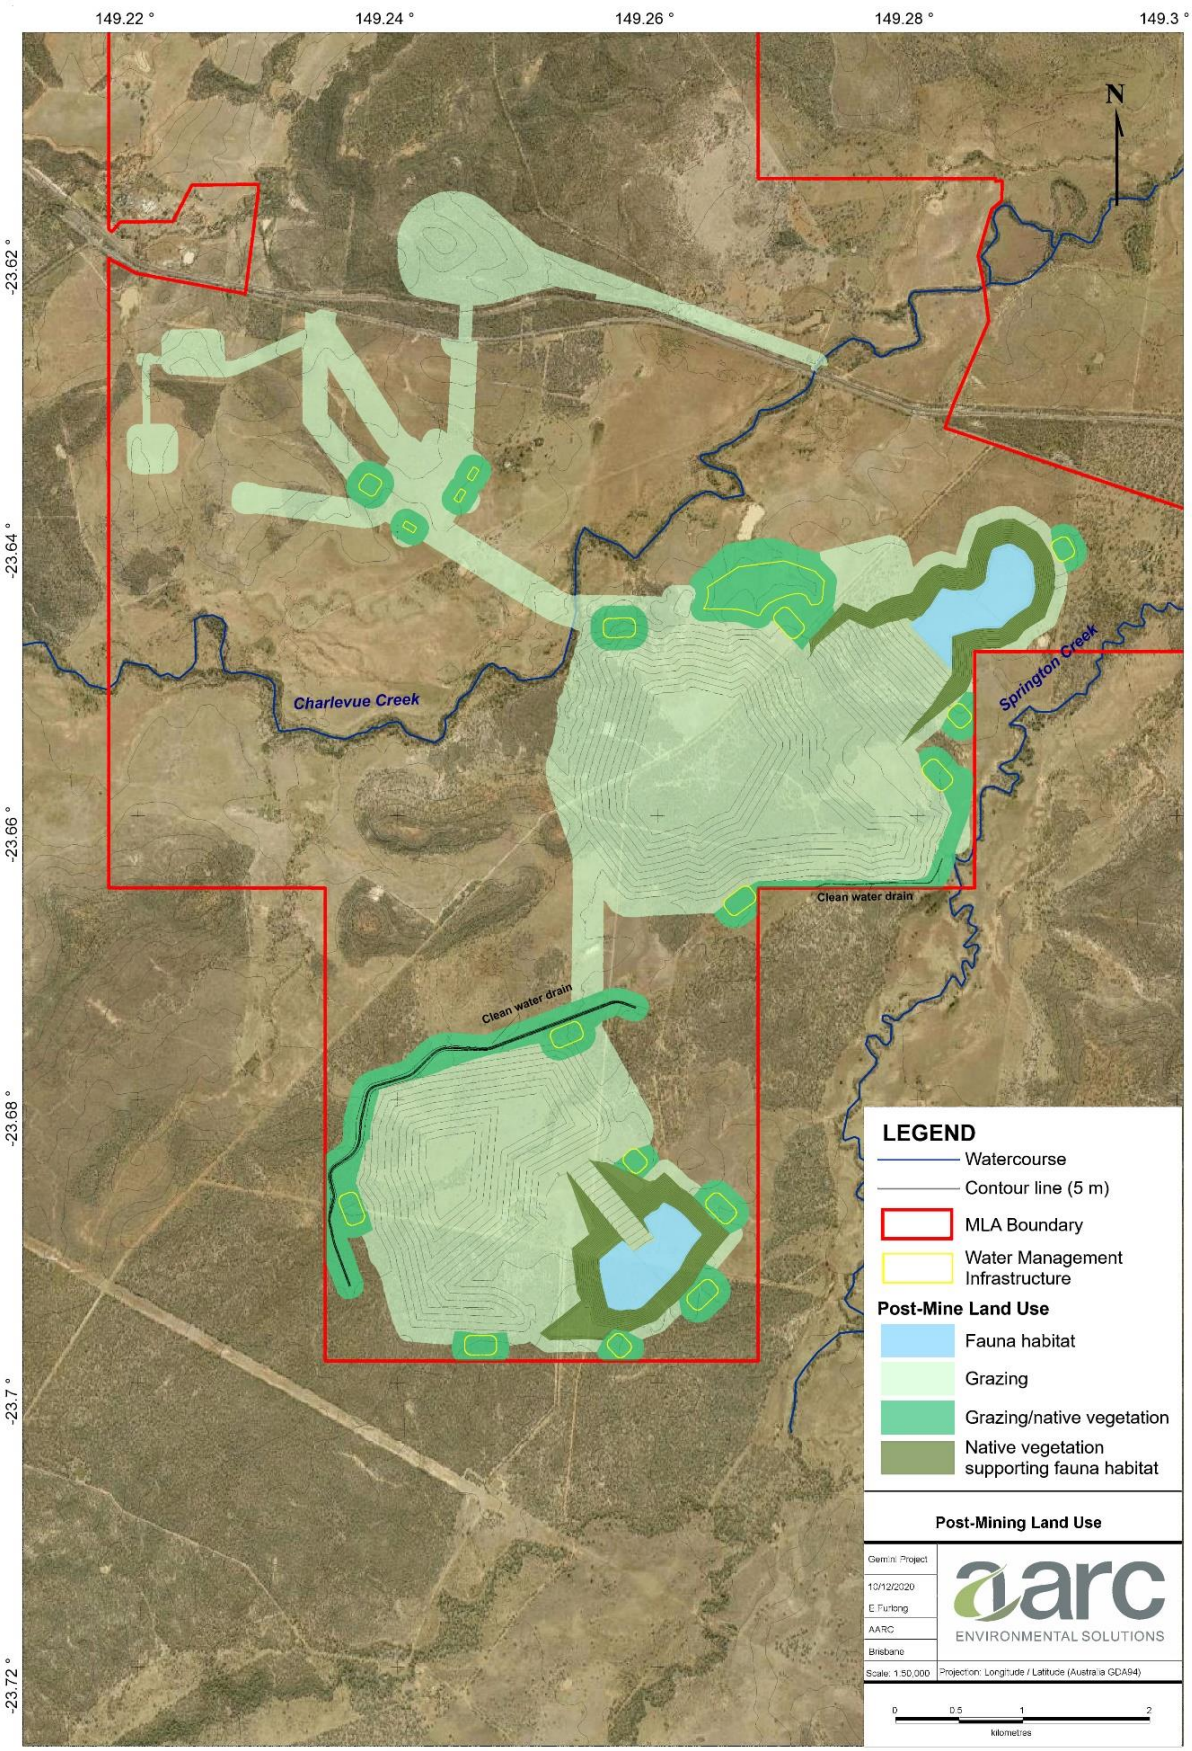
I30 The holder must make a final entry of the required information in the Register of Regulated Structures once compliance with Condition I11 and I12 has been achieved.

I31 The holder must ensure that the information contained in the Register of Regulated Structures is current and complete on any given day.



I32 All entries in the Register of Regulated Structures must be approved by the chief executive officer for the holder of this authority, or their delegate, as being accurate and correct.

I33 The holder must, at the same time as providing the annual return, supply to the administering authority a copy of the records contained in the Register of Regulated Structures, in the electronic format required by the administering authority.



Definitions

The words and phrases used throughout this proposed EA are as per the *Model Mining Conditions* (DES 2017e). Where a definition for a term used in this environmental authority is not provided by the *Model Mining Conditions* but is provided in the EP Act 1994 or subordinate legislation, the definition in the EP Act or subordinate legislation must be used.

1.0 INTRODUCTION

AARC Environmental Solutions Pty Ltd (AARC) was commissioned by Magnetic South Pty Ltd (Magnetic South) to conduct a Soil and Land Suitability Assessment (SLSA) for the Gemini Project (the Project).

An assessment of the Project's soil and land suitability values was conducted within Exploration Permit Coal (EPC) 881 near Dingo in Central Queensland. This assessment forms part of the supporting studies required for the Project's Environmental Authority (EA) Application.

The Project is a greenfield, open-cut metallurgical mine approval, proposing production of Pulverised Coal Injection (PCI) coal for export to the international steel making industry.

This SLSA documents the nature and distribution of major soil types in the target area and assesses their suitability for land uses such as cattle grazing and cropping. This assessment establishes baseline environmental characteristics and values relating to land use and suitability and makes recommendations for the management of soil resources.

1.1 SCOPE OF STUDY

The objectives of the SLSA were to:

- Describe the agricultural use of the land of the Project and the surrounding area, including any crop rotations;
- Describe, map and illustrate soil types and profiles according to the *Australian Soil and Land Survey Field Handbook* (NCST 2009), *Guidelines for Surveying Soil and Land Resources* (McKenzie et. al. 2008) and *Australian Soil Classification* (Isbell 2002);
- Identify soils that would require specialised management due to wetness, erosivity, depth, acidity, salinity or other features;
- Identify soil management units from representative samples down the soil profile, based on their physical and chemical properties;
- Describe and map land suitability classes of the potentially affected area in accordance with the *Guidelines for Agricultural Land Evaluation in Queensland – Second Edition (Draft)* (DSITI & DNRM 2015), and the *Regional Land Suitability Frameworks for Queensland Guidelines for Agricultural Land Evaluation in Queensland – Second Edition (Draft)* (DSITI & DNRM 2013);
- Assess the potential impacts of the Project on the soil and land use values and provide recommended mitigation measures to minimise negative impacts; and
- Include the findings in a stand-alone report suitable for reference in the Project's EA Application.

1.2 PROJECT BACKGROUND

The Project is situated in the Bowen Basin, Central Queensland, approximately 3 kilometres (km) west of the township of Dingo, 110 km east of Emerald, and 125 km south-west of Rockhampton (Figure 1). The study area is contained within the bounds of EPC 881.

The Project is proposed to be an open-cut coal mine with an anticipated life of 25 years from grant of the mining lease (ML); with this term including initial construction, mine operation and rehabilitation activities.

1.3 LOCAL WATERWAYS AND TOPOGRAPHY

The Project lies within the Fitzroy River Basin, which encompasses an area of 142,545 square kilometres (km^2) and contains the Comet, Connors, Dawson, Don, Nogoa and Mackenzie Rivers, which make up its six sub-catchment areas (BoM 2018; DES 2018).

The Project lies within the Mackenzie River sub-catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River catchment. The major water body associated with the Project site is Charlevue Creek, which dissects the EPC in a north-easterly direction. This creek begins within the boundaries of Blackdown Tablelands National Park, flowing north-east before joining with Springton Creek and the Fitzroy River, eventually reaching the Pacific Ocean approximately 46 km north of Gladstone. Two significantly smaller creeks, Stanley and Springton, cross the Project boundaries in the north-west and south-east respectively. These two creeks also eventually converge with the Mackenzie River. Associated tributaries, dams and drainage features also appear across the site. Figure 2 displays the extent of the watercourses associated with the study area.

Topography of the land varies from flat to undulating hills, with elevation within the study area ranging between 120 metres (m) and 150 m above sea level. The landscape is influenced by the presence of Charlevue Creek and its associated flood plains, which have relatively lower elevations than the surrounding landscape of undulating hills. The topography of the Project is representative of the surrounding region.

1.4 CURRENT LAND USE

The land within the Project boundary is currently used for low intensity cattle grazing and resource exploration activities. There is one highway (Capricorn) and five publicly gazetted roads (Charlevue, Cooinda, Red Hill, Normanby, and Ellesmere) dissecting the area.

.

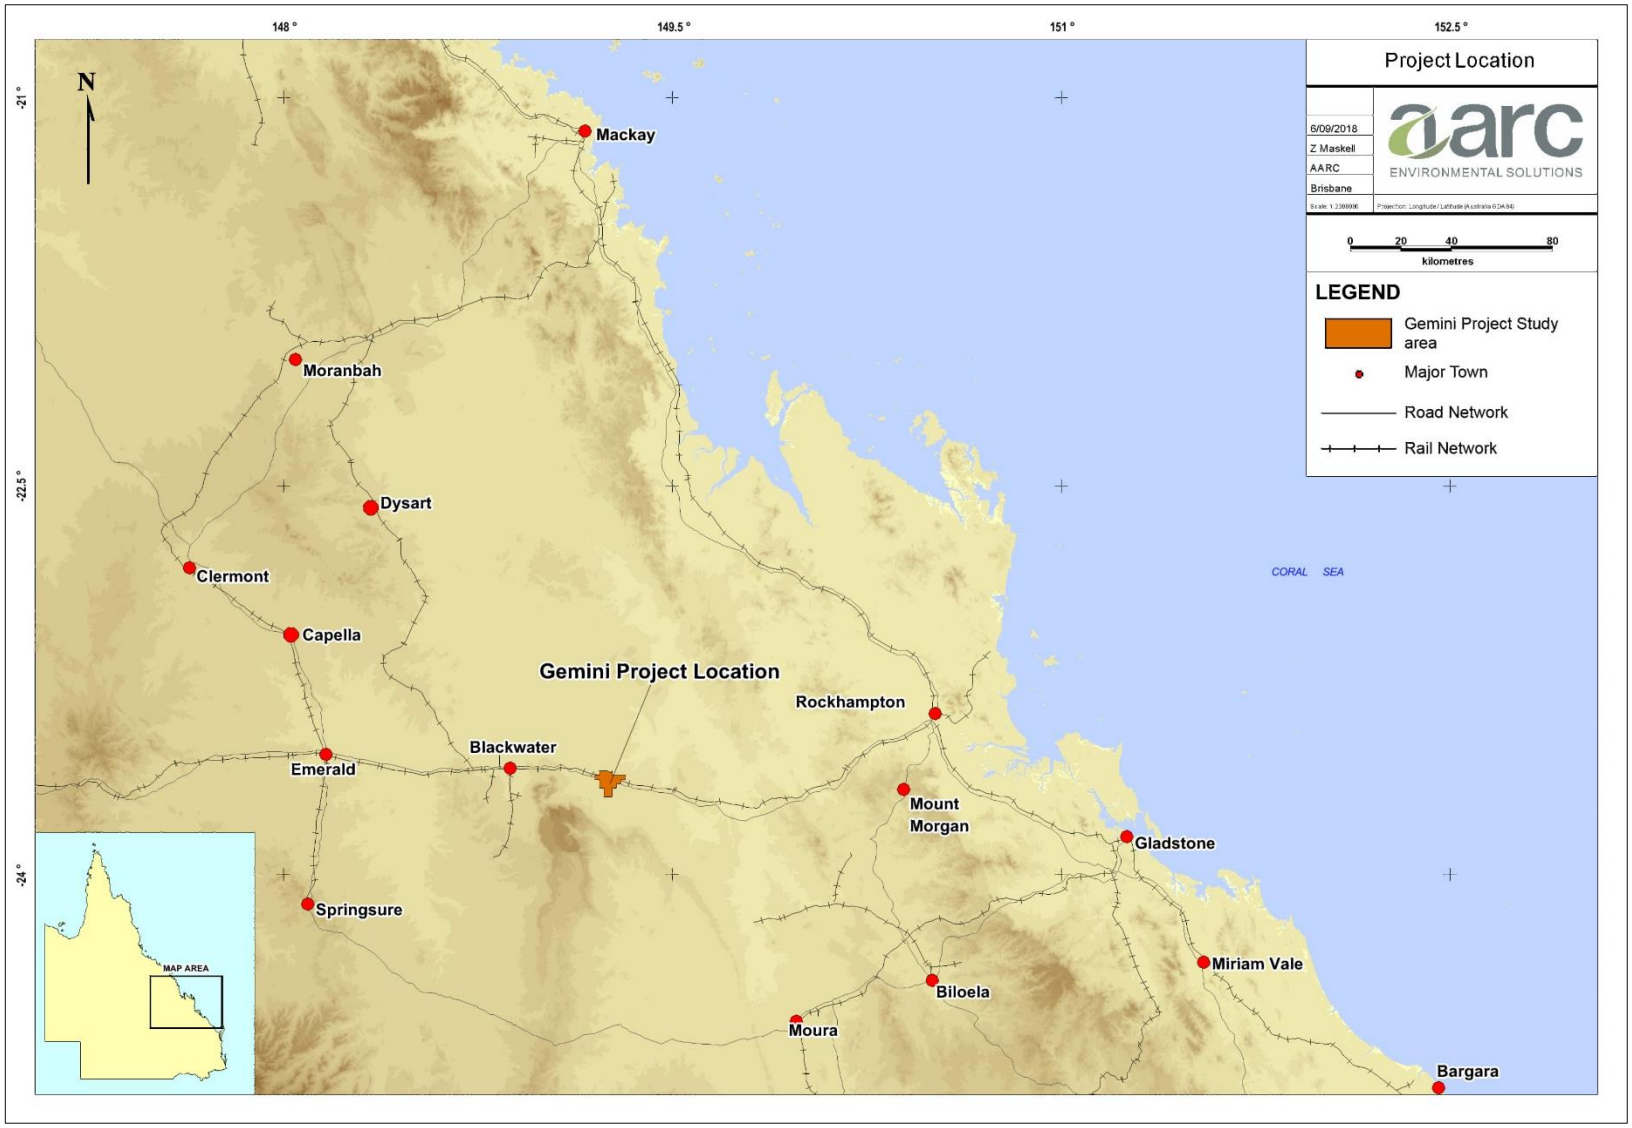

Figure 1 Project Location

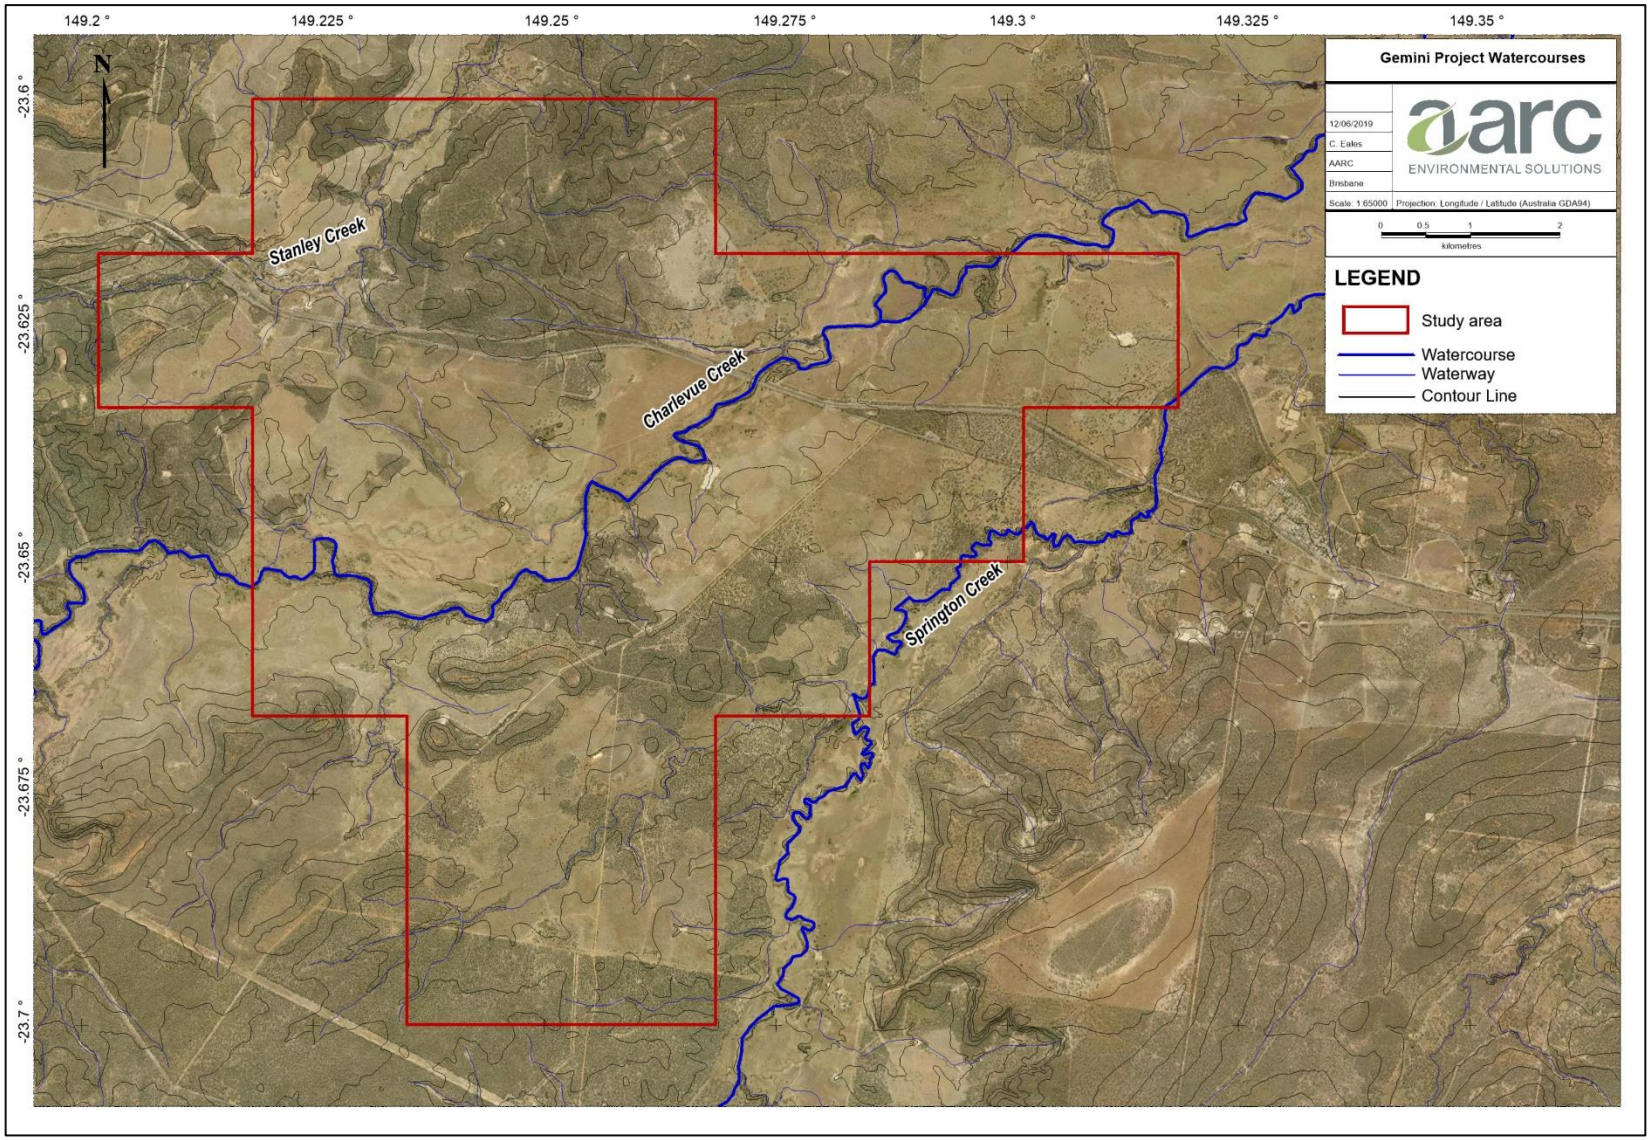

Figure 2 Waterways and Topography associated with the Project

1.5 REGIONAL GEOLOGY

The geology of the Dingo area is dominated by its position within the Bowen Basin. The Bowen Basin is one of Queensland's largest depositional zones, forming through a period of rifting and subsidence lasting from the Early Permian to Mid-Triassic. The area surrounding the Project is dominated by clastic sedimentary rocks of marine and lacustrine origin, including sandstones, conglomerates, mudstones, siltstones and coal (Geoscience Australia 2018).

The coastal and inland depositional environments which created these deposits allowed for the formation of extensive coal seams throughout the Bowen Basin, with the anoxic deposition of organic matter subsequently compacted and de-volatised through compression and increased temperatures (Brooks & Smith 1969).

Generally, coal seams found in the east-central part of the basin contain higher quality coking coal deposits, with rank falling below coking range farther south and west (Hutton 2009). The high-quality coal measures found at within the Gemini Project are of Permian age, and are generally located less than 60 m from the surface (Mutton 2003).

1.5.1 Solid Geology

The following solid geology map units were identified within the Project area.

- Rangal Coal Measures (Pwj) – Late Permian sedimentary unit comprised of sandstone, siltstone, mudstone, coal, tuff and conglomerate;
- Gyranda Subgroup (Pwy) – Late Permian sedimentary unit comprised of siltstone and shale with minor tuff and volcanilithic sandstone and rare coal (lower part - Banana Formation); calcareous sandstone, mudstone and siltstone (upper part - Wiseman Formation); and
- Rewan Group (Rr) – Early Triassic – Middle Triassic sedimentary unit comprised of lithic sandstone, pebbly lithic sandstone, green to reddish brown mudstone and minor volcanilithic pebble conglomerate (at base).

These map units are displayed below in Figure 3.

1.5.2 Surface Geology

The following surface geology map units were identified within the Project area.

- Qa-QLD (Qa) – Quaternary clay, silt, sand and gravel; flood-plain alluvium
- Td-QLD (Td) – Tertiary duricrusted palaeosols at the top of deep weathering profiles, including ferricrete and silcrete; duricrusted old land surfaces.
- Duaringa Formation (Tu) – Eocene-Oligocene mudstone, sandstone, conglomerate, siltstone, oil shale, lignite and basalt.
- Gyranda Subgroup (Pwy) – Late Permian sedimentary unit comprised of siltstone and shale with minor tuff and volcanilithic sandstone and rare coal (lower part - Banana Formation); calcareous sandstone, mudstone and siltstone (upper part - Wiseman Formation);

These map units are displayed below in Figure 4.

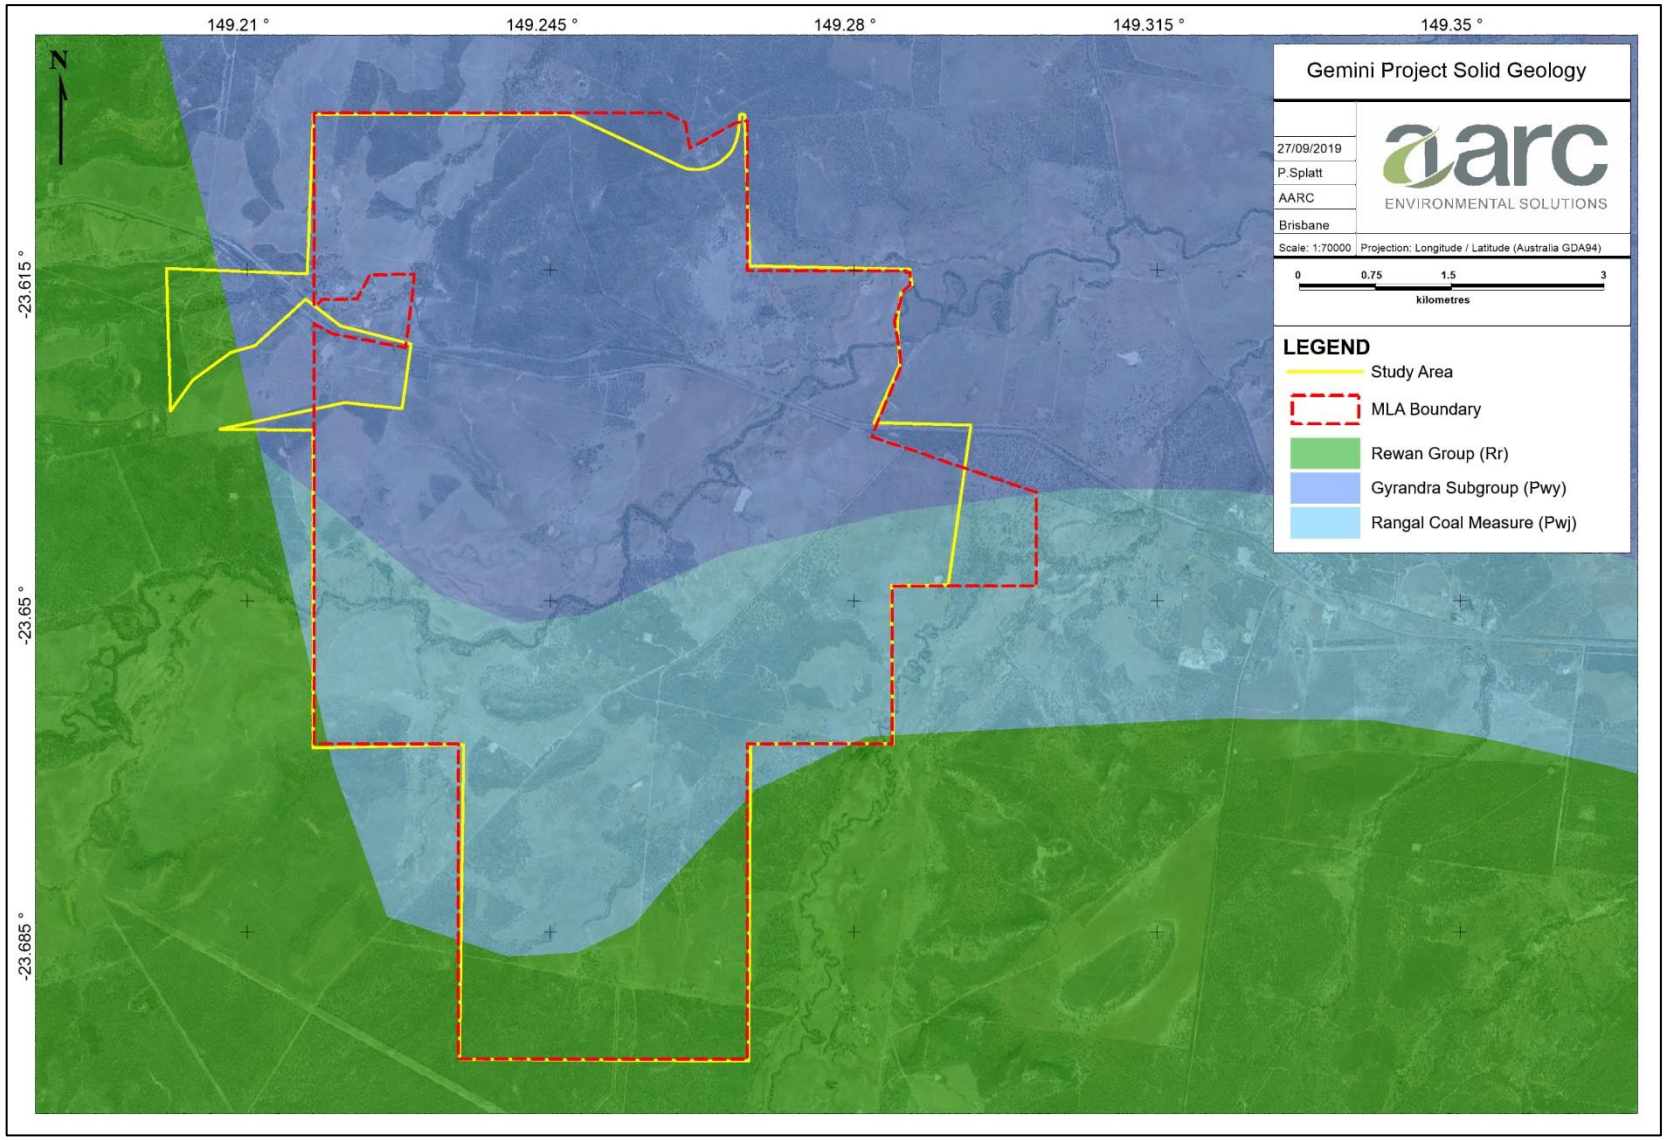

Figure 3 Solid Geology

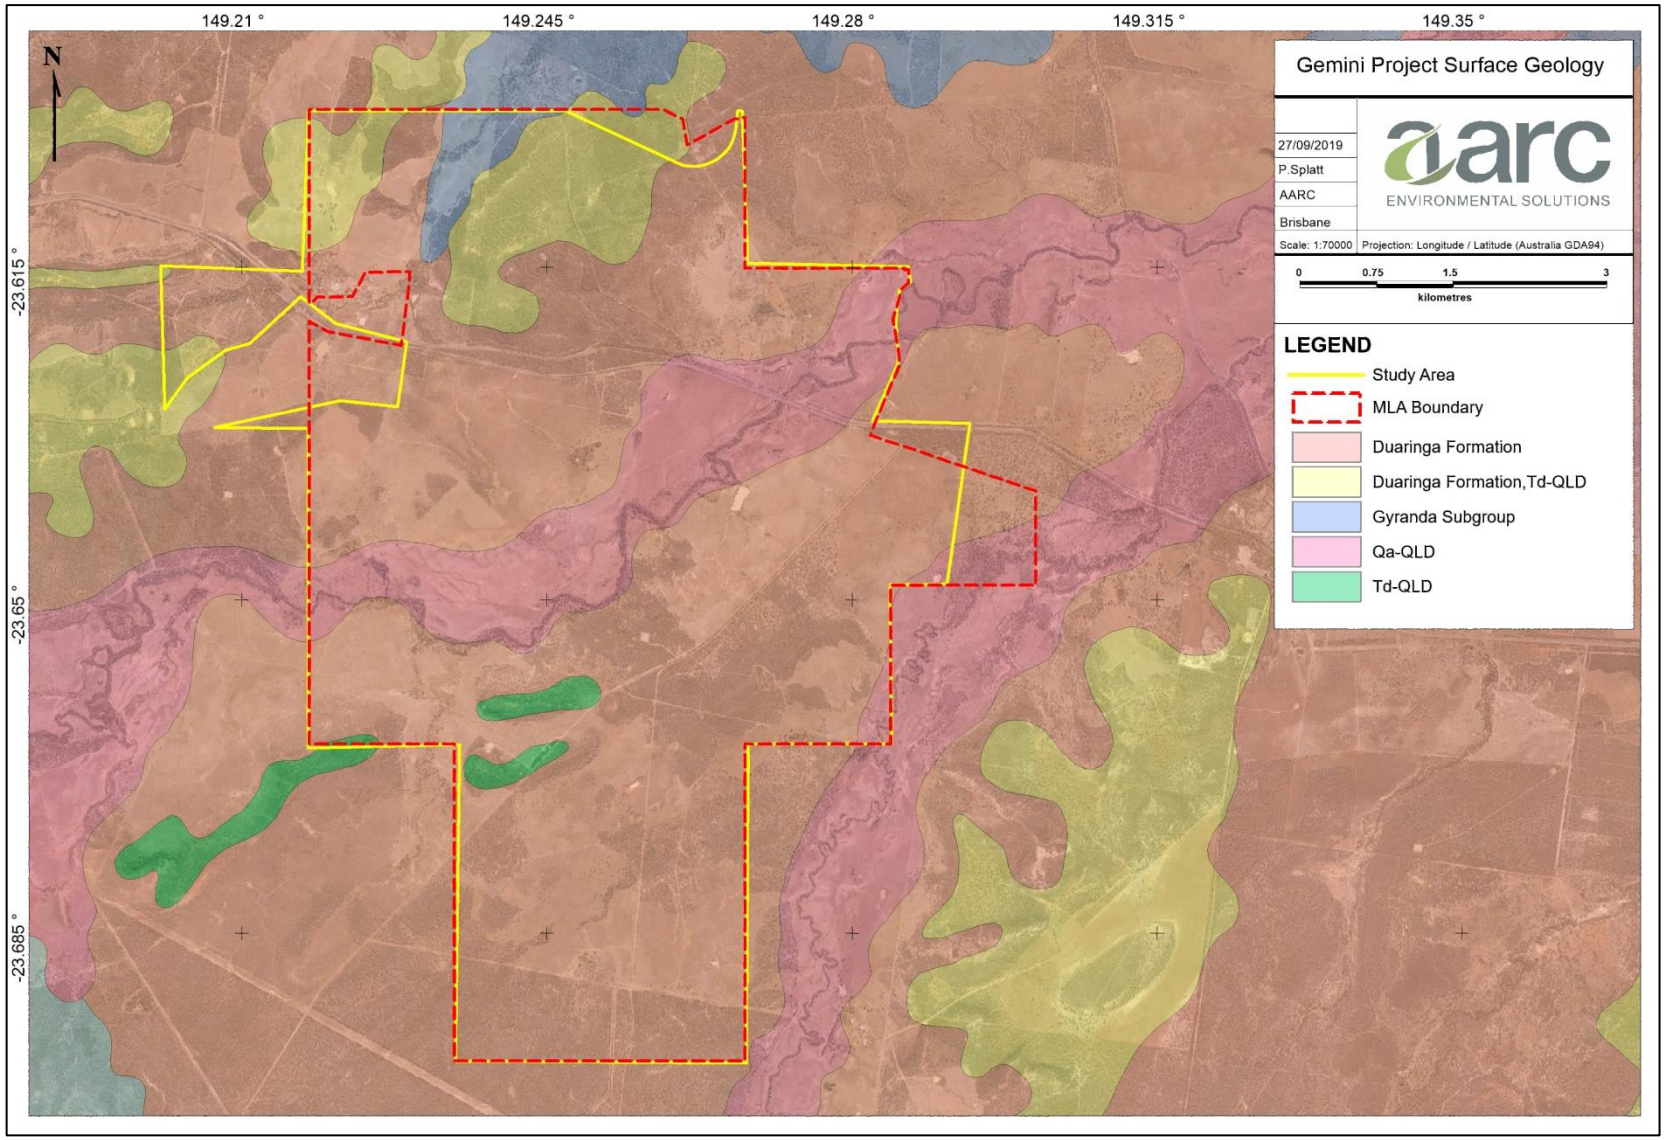

Figure 4 Surface Geology

1.6 REGIONAL CLIMATE

The regional climate is classified as semi-arid, characterised with warm dry summers and warm winters. Climate data for the Project has been sourced from Scientific Information for Land Owners (SILO) climate database (Queensland Government), which operates by interpolating data from the Commonwealth Bureau of Meteorology (BoM) into a single point data drill. SILO was selected to obtain the data, instead of weather station data from BoM, due to the significant distance between the Project and the closest weather station located in Blackwater Water Treatment Plant weather station approximately 50 km away, which only recorded weather data between 1995 and 2008.

Figure 5 shows average temperature and rainfall registered in the area from January 1999, to present. The data indicates the annual mean rainfall for the region is highest between December and March with the maximum average registering in December (111.5 millimetres (mm)).

The hottest months typically occur between October and March while the coldest months occur between May and September. The highest mean maximum temperature typically occurs in December (34.2 degrees Celsius (°C)) and the lowest mean minimum temperature in July (8.5°C). The mean annual maximum temperature for the region is 29.8°C and the mean annual minimum temperature is 16 °C.

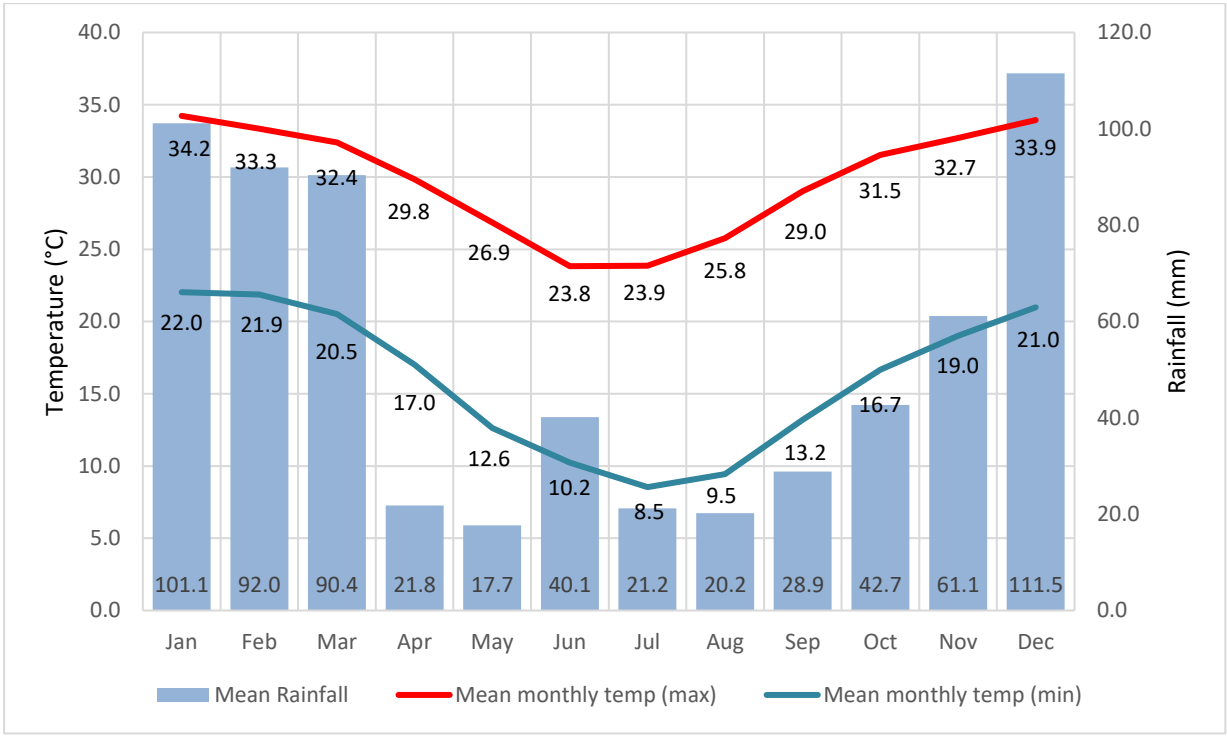

Figure 5 Mean temperature and rainfall data for the region

1.7 LAND SYSTEMS

The General Report on Lands of the Dawson-Fitzroy Area (Speck et. al. 1967) mapped at a scale of 1:80,000 indicated the study area contains the Dingo Land System and the Melbadale Land System.

1.7.1 Dingo Land System

The Dingo Land System is characterised by fluvial plains surrounding significant waterways. It is mostly composed of stable flood plains traversed by a branching pattern of drainage floors. The majority of deposits are weathered alluvium, with slopes of coarser or finer textured alluvium (depending on flow patterns). Channels can be up to 30 m wide and 3 m deep, with fringing riparian vegetation. Main drainage floors can then extend 800 m outwards, with deep texture contrast sandy loams over mottled clays, and open spaces of *Eucalyptus tereticornis* (Blue gum) and *Eucalyptus crebra* (Narrow-leaved ironbark) with sparse shrubs. Large plains surround drainage features (up to 3 km wide) which can contain either deep texture contrast soils with *Eucalyptus populnea* (Poplar box) woodlands, or deep layered soils on alluvium with woodlands of Blue gum and Narrow-leaved ironbark. Slopes within this land unit are usually the result of strongly gilgaied shrink-swell clays, forming depressions of finer soil textures with *Acacia harpophylla* (Brigalow) scrub.

Geology in this unit is comprised of weathered Quaternary alluvium.

1.7.2 Melbadale

The Melbadale Land System in characterised by the shallow dissection of weathered tertiary land surfaces, forming undulating plains dominated by complex depositional mid and lower slopes, with minor lateritic upper slopes in some places. This land system features moderately dense branching drainage patterns, with local relief usually less than 15 m. Depending on the steepness of terrain, upper slopes are often dominated by deep loamy red earths (gentle slopes) with *Eucalyptus crebra*, or shallow fine sandy loams (steep terrain) with *Acacia shirleyi* (lancewood) forests. Mid to lower slopes are often associated with deep texture contrast soils of loamy sands overlying mottled sandy clays, with grassy woodlands of open-spaced narrow-leaved ironbark and shrubs. Lower slopes are often associated with deep light to medium clays, with tall forests of narrow-leaved ironbark. Tributaries have variable soil textures depending on slope, though stratified loams and texture contrast soils are common.

Geology in this land system is comprised of Quaternary to Late Tertiary colluvial/alluvium, laterised tertiary sandstone, conglomerate, and shale.

2.0 RELEVANT LEGISLATION, POLICY AND GUIDELINES

Relevant legislation, and supporting policy and guidelines, relevant to the assessment of soil and land suitability values on the Project are discussed below.

2.1 REGIONAL PLANNING INTERESTS ACT 2014 (QLD)

The *Regional Planning Interests Act 2014 (Qld)* (RPI Act) aims to identify areas of Queensland that are of regional interests because they contribute, or are likely to contribute, to Queensland's economic, social and environmental prosperity. The RPI Act also aims to give effect to the policies about matters of State interest stated in regional plans and effectively manage impact of resource activities on the areas of regional interest and the coexistence of the two and other regulated activities such as highly productive agricultural activities.

Areas of regional interest that the RPI Act aims to protect are classified as:

- Living areas in regional communities (Priority Living Areas);
- High-quality agricultural areas from dislocation (Priority Agricultural Areas);
- Strategic cropping areas; and
- Regionally important environmental areas (Strategic Environmental Areas).

Detailed description of what constitutes each type of area of regional interest are addressed in Section 8 – 11 of the Act and the Regional Planning Interests Regulation 2014 (RPI Regulation). The RPI Act and RPI Regulation seeks to strike an appropriate balance between protecting priority land uses and delivering a diverse and prosperous economic future for our regions.

There are no areas of regional interest within the study area. Bluff is located just over 6 km to the west is mapped as a Priority Living Area and the nearest SCAs are about 5 km to the north and north-east.

2.2 GUIDELINES

Below is a summary of all relevant guidelines and resources pertaining to the assessment of soil and land suitability for the Project. These guidelines form the basis of the methodology and requirements around these assessments.

- *Australian Soil and Land Survey Field Handbook* (NCST 2009),
- *The Australian Soil Classification Revised Edition* (Isbell 2002);
- *Guidelines for Agricultural Land Evaluation in Queensland – Second Edition* (DSITI & DNRM 2015);
- *Guidelines for Surveying Soil and Land Resources* (McKenzie et al. 2008);
- *Regional Land Suitability Frameworks for Queensland Guidelines for Agricultural Land Evaluation in Queensland – Second Edition* (DSITI & DNRM 2013); and
- *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995).

3.0 SOIL SURVEY METHODOLOGY

3.1 DESKTOP ANALYSIS

Desktop analysis was conducted prior to field sampling. This analysis was comprised of background research and evaluation of available information for the study area. Resources used included:

- The Digital Atlas of Australian Soils (BRS, 1991). Australian soils were mapped at a scale of 1:2,000,000. Although this scale is broad it provided a good foundation for understanding the soils that may be present in the Project region.
- Government maps featuring regional topography, geology, contour data, and watercourse locations was used to help refine mapping boundaries, particularly where soil types were a function of gradient.
- Reference information for land systems: *Lands of the Dawson-Fitzroy Area, Queensland* (Speck et al. 1967).
- Reference Information for regional geology: *Geology of the Bowen Basin, Queensland* (Dickins & Malone 1973).
- Reference information for land management: *Understanding and Managing Soils in the Central Highlands* (DPI, 1993).

3.2 SURVEY DESIGN

Methodologies employed throughout this study followed procedures detailed in the *Australian Soil and Land Survey Field Handbook* (NCST, 2009) and the *Guidelines for Surveying Soil and Land Resources* (McKenzie et. al. 2008). The soil survey was based on a free-survey technique with soil profile and observation sites located to best represent all soil types present in the Project.

For this site, a scale between 1:25,000 to 1:100,000 was deemed most appropriate. This scale was selected based on information contained within the *Guidelines for Surveying Soil and Land Resources* (McKenzie et. al. 2008). The final mapping scale for the Project site fell within the specified range.

To achieve a mapping scale of 1:25,000 to 1:100,000, McKenzie et. al. (2008) suggest a minimum recommended sampling density of 1 site per 25 ha with data collection comprising detailed soil profile descriptions (15 to 35 percent (%) of sites), representative profile sampling for lab analysis (1 to 5%) and mapping observations sites (55 to 83%).

The number of sites surveyed for the SLSA (Table 1) exceeded these minimum requirements.

Table 1 Survey Site Numbers for SLSA 2018

Survey Site	Scale	Detailed Soil Profiles	Representative Profiles for Analysis	Mapping Observations	Total
Gemini (6,240 ha)	1:70,000	60	12	180	252

3.3 FIELD INVESTIGATIONS

Field sampling at the Project was undertaken from 20th to 29th of June 2018, consisting of both primary sampling sites (profiles) and secondary visual assessments (observations).

During the survey, sampling site locations were determined using desktop analysis, land management units, landform and vehicle access. Visual assessments were conducted continually whilst traversing the landscape to confirm major soil types and boundaries between soil units. Each site location was recorded using a Global Positioning System (GPS).

Detailed soil profiles were undertaken at 60 sites within the Project boundaries. A jack hammer operated soil corer was used to excavate cores to a maximum depth of 120 centimetres (cm). Soil samples were collected from profiles at standard depths of 0-10, 20-30, 50-60, 80-90, and 110-120 cm where possible. Samples were sealed in clean, plastic zip-lock bags and labelled with the site number, date, depth of sampling, and the initials of the sampler.

Parameters recorded included micro-relief, permeability, drainage, substrate, site disturbance, landform (slope %, relief, elevation, morphological type, landform element and landform pattern), runoff, erosion, SC fragments, rock outcrops, surface condition and dominant vegetation type. Soil profile morphology was described in the field in terms of horizon type, horizon depth, boundary, colour, mottles, texture, coarse fragments, structure, segregations, consistency, and field pH.

3.4 LABORATORY ANALYSIS

Soil profiles from 12 representative sites were selected for analysis through Australian Laboratory Services (ALS) for National Association of Testing Authorities (NATA) approved physical and chemical analyses. All standard depths at the chosen sites were utilised in chemical analysis. Samples were analysed to:

- Confirm the classification of the described soil profile;
- Assist in the description of soil characteristics;
- Assist in the determination of land suitability classes;
- Assist in the determination of topsoil and subsoil as a suitable topdressing media; and
- Assist in the identification of soils that would require specialised management.

Physical and chemical parameters analysed for all samples included:

- pH;
- Electrical Conductivity (EC);
- Moisture Content;
- Chloride (Soluble);
- Exchangeable Cations (Calcium(Ca), Magnesium (Mg), Sodium (Na), Potassium (K));
- Cation Exchange Capacity (CEC); and
- Exchangeable Sodium Percentage (ESP).

Additional physical and chemical parameters analysed for topsoil samples included:

- Organic Matter (%);
- Particle Size Analysis (PSA);
- Extractable Trace Elements/Metals (Iron (Fe), Copper (Cu), Zinc (Zn), Manganese (Mn));
- Boron ($CaCl_2$ extractable);
- N as Nitrate;
- Sulphate (water soluble S as SO_4);
- Phosphorus and Potassium (Colwell); and
- Emerson Class.

3.5 CHARACTERISATION OF SOIL MANAGEMENT UNITS

Soil classification was undertaken using the methodologies specified in *The Australian Soil Classification* (Isbell 2002). Soil Management Units (SMUs) were then described based on the soils' physical and chemical attributes, and land attributes in accordance with the *Guidelines for Surveying Soil and Land Resources* (McKenzie et. al. 2008).

Typically, each SMU was described in terms of its soil profile class, defined as a group of similar soils, having soil profile properties in common. The soils' attributes/limitations were then interpreted using the *Guidelines for Agricultural Land Evaluation in Queensland – Second Edition* (DSITI & DNRM, 2015) to determine their suitability for cattle grazing and broadacre cropping. SMUs were mapped at a scale of 1:70,000 across the Project.

4.0 SOIL SURVEY RESULTS

Within the Project, a total of 12 SMUs were described. Table 2 provides an overview of each SMU and its extent within the Project. The spatial distribution of the SMUs is depicted in Figure 6.

Ratings and categories outlined in the CSIRO publications *Interpreting Soil Test Results – Third Edition* (Hazelton & Murphy 2016) and *Soil Chemical Methods of Australasia* (Rayment & Lyons 2011) were used to assist in interpretation of the SMU physical and chemical properties.

Table 2 Area of Soil Management Units

SMU	Surface Area (ha)	Percent of Study Area (%)
Anderson	37.8	0.61
Barry	156.5	2.54
Charlevue	232.9	3.77

Wallace	32.0	0.52
Total Area	**6,171.3**	**100**

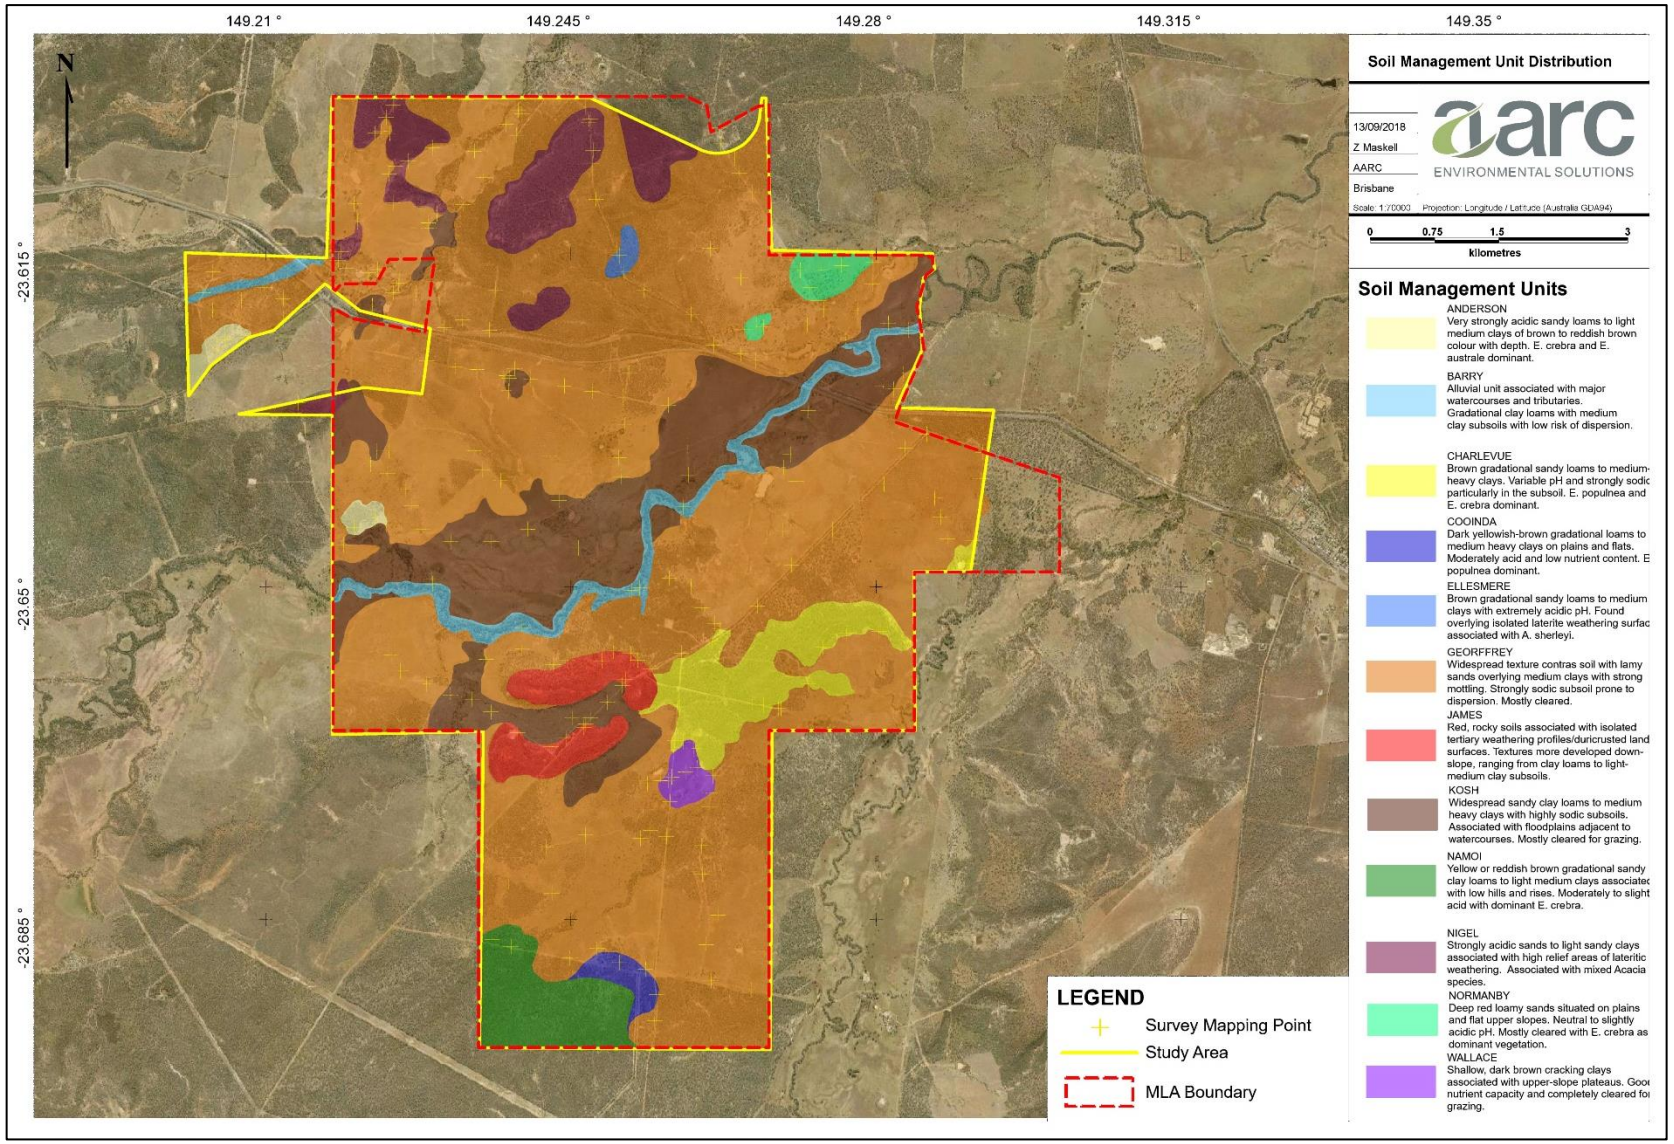

Figure 6 Distribution of Soil Management Units

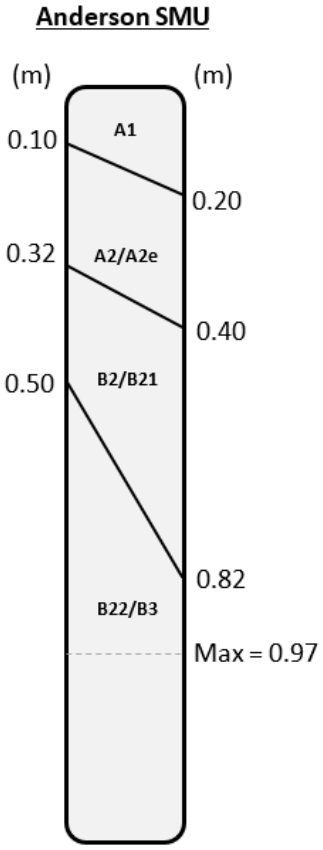
4.1 ANDERSON SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil unit associated with isolated hills. Soil textures grade from loams at the surface, to light medium clays with depth, sometimes exhibiting red mottling. Vegetation associated with this unit includes *Eucalyptus crebra*, *Corymbia clarksoniana*, and *Acacia rhodoxylon* with *Erythroxylum australe* in the shrub layer.

Australian Soil Classification: Red Kurosol.

Photo Plate 1 Anderson SMU Vegetation

Table 3 Anderson Soil Unit Description



Parameter	Soil Unit Description
Profile Site Numbers	DP37, DP26
Observation Site Numbers	DO55, DO75
Landform	Isolated hills
Land System	Melbadale
Slope	1 to 6%
Geology	Rewan Group (Rr) – Early Triassic – Middle Triassic sedimentary unit comprised of lithic sandstone, pebbly lithic sandstone, green to reddish brown mudstone and minor volcanilithic pebble conglomerate (at base)
Vegetation	*Eucalyptus crebra, Corymbia clarksoniana,* and *Acacia rhodoxylon* with *Erythroxylon australe* in the shrub layer.
Runoff	Moderate to Rapid
Permeability	Slowly to moderately permeable
Drainage	Imperfectly to moderately well drained

Profile Description Representative Sites: DP37 and DP26.

The **surface soil** (A1) is a reddish brown to dark greyish brown (5YR4/4, 10YR3/2) sandy loam to clay loam with massive structure. It has a field pH of 4.5, demonstrating a gradual change to;

The **lower surface soil** (A2/A2e) is a reddish brown (5YR4/4) sandy loam to light medium clay with some profiles exhibiting conspicuous bleaching. It has massive to weak polyhedral structure and a field pH of 4.5 to 5.0. Sub-rounded to rounded coarse fragments make up 1 to 20% of this soil horizon. Clear or gradual change to;

The **subsoil** (B2/B21) is a brown to yellowish red (10YR5/3, 5YR4/6) light to light medium clay with weak lenticular to moderate polyhedral structure. It can exhibit red mottles, and has angular course fragments making up to 20% of the horizon. This horizon has a field pH of 5.5, with a gradual change to;

The **lower subsoil** can present as two different horizons depending on slope. B22 is a light brownish grey (10YR6/2) medium clay with strong angular blocky structure with red mottles. B3 is a yellowish red (5YR4/6) light clay with massive structure, and a small amount of 2-6 mm diameter rounded coarse fragments. The pH in these horizons ranges from 5.5 to 5.8.

Key: meq/100g milliequivalent per 100 grams
dS/m deciSiemens per metre
mg/kg milligrams per kilogram

The Anderson SMU has a very strongly acidic pH throughout the profile, ranging from 4.6 in the topsoil, to 4.8 in the lower subsoil. EC and chloride results indicate that at all depths, salinity is very low, with EC ranging from 0.064 deciSiemens per metre (dS/m) in the topsoil, to 0.02 dS/m in the subsoil layer. Chloride concentrations reflected this result, decreasing with depth from 30 milligrams per kilogram (mg/kg) to 10 mg/kg, both well below toxic limits.

CEC is considered very low throughout the profile, though increases from 2.7 milliequivalent per 100 grams (meq/100g) in the topsoil, to 4.2 meq/100g in the subsoil layer. This may be attributed to the high amount of sand in this Exchangeable cation concentrations reflect the low CEC, with calcium (Ca), magnesium (Mg), potassium (K) and sodium (Na) presenting with <1.0 meq/100g) at all depths. Cation percentages are also below appropriate levels, except potassium, which presents within the appropriate range.

The Ca/Mg ratio in the topsoil is between 1 and 4 (low calcium), though this is considered appropriate for sandy soils. This ratio falls to 0.2 in the lower subsoil (Ca deficient). Due to the low clay content of this soil, the low Ca/Mg ratio seen here isn't likely to increase the risk of dispersion in this soil unit.

Table 5 Surface Soil (0-10 cm) Properties of the Anderson SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
10	66	13	11	3	10.2	20	3.3
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
11	<200	0.6		<1.00	296	5.46	<1.00

Key: < less than

The surface soil (A1) was dominated by sand (66%), with 10% gravel, 13% silt, and 11% clay. It lacks true structure (massive), and is non-sodic, with a Ca/Mg ratio of 3.5, and an organic matter content of 3.3%. This information paired with the topsoil's Emerson Class Number of 3, indicates that this soil has favourable chemistry, and is unlikely to suffer from dispersion. The high concentration of coarse particles (sand and gravel) may mean this SMU has the tendency to slump under pressure, as it lacks the binding capacity provided by higher clay percentages.

Nutrient levels are variable, with nitrate concentration (10.2 mg/kg) within the guideline range for supporting plant life, while phosphorous (11 mg/kg) and potassium (<200 mg/kg) are not. Boron (0.6 mg/kg) and sulphate (20 mg/kg) concentrations are acceptable, though extractable metals are generally too low (copper and zinc) or too high (iron), with only manganese within the appropriate range for plant life. Acidic pH values in the topsoil will limit the availability of these nutrients to plants, by impacting solubility and speciation. In addition to this, high iron levels can lead to plant toxicity and inefficiency in photosynthesis (Connolly & Guerinot, 2002).

4.2 BARRY SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with rivers, drainage lines and levees. Surface soils in this unit are comprised of clay loams to medium clays, grading into light or medium clays at variable depths. Dominant vegetation includes *Eucalyptus tessellaris, Eucalyptus populnea* and *Eucalyptus tereticornis,* with *Lysiphyllum hookeri*, *Cassia spinarum* and *Cassia brewsteri* in the shrub layer.

Australian Soil Classification: Brown Dermosol.

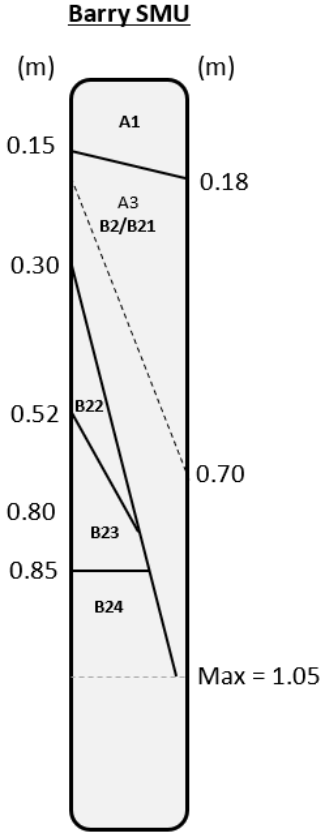

Photo Plate 2 Barry SMU Vegetation

Table 6 Barry Soil Unit Description

Parameter	Soil Unit Description
Profile Site Numbers	DP14, DP29, DP36
Observation Site Numbers	DO45, DO79, DO203
Landform	Alluvial plains and levees
Land System	Dingo
Slope	2 to 3%
Geology	Qa-QLD (Qa) – Quaternary clay, silt, sand and gravel; flood-plain alluvium
Vegetation	*Eucalyptus tessellaris, Eucalyptus populnea* and *Eucalyptus tereticornis*, with *Lysiphyllum hookeri, Cassia spinarum* and *Cassia brewsteri* in the shrub layer.
Runoff	Moderate to Rapid
Permeability	Moderately to highly permeable
Drainage	Moderately well drained

Profile Description – Representative Sites: DP14, DP29 and DP36

The **surface soil** (A/A1) is a dark reddish brown (5YR3/4, 7.5YR4/3) clay loam to medium clay with weak to moderate polyhedral or platy structure. It has a field pH of 6.0 to 6.5, with a gradual change to either A3 or B2;

The **lower surface soil** (A3) was not present at all profile sites. It is a reddish brown (5YR4/4) sandy clay loam with massive structure and a field pH of 6.5. Gradual change to;

The **upper subsoil** (B2/B21) is a dark reddish brown to brown (5YR3/3, 7.5YR4/4) sandy light medium clay to medium heavy clay, with weak to moderate structure. It has a field pH of 6.0 to 6.5, with a gradual change to;

The **subsoil** (B22) is a brown to dark brown (7.5YR4/4, 7.5YR3/2) clay loam to medium clay, which can either extend to great depths in the profile, or grade into the subsoil horizons. It has moderate polyhedral structure and a field pH of 6.0 to 6.5. Gradual change to;

The **mid-subsoil** (B23) is a brown (7.5YR4/4) light clay with moderate platy structure and a field pH of 6.5. Clear change to;

The **lower-subsoil** (B24) is a dark brown (7.5YR3/3) light medium clay with moderate polyhedral structure and a field pH of 6.5.

0.8-0.9	18	Moderate	10	7.5	0.3	0.2	1.3

Percentage in Topsoil	51.20%	41.60%	7.20%	0.30%	-

The Barry SMU has a slightly acidic pH (6.5) which increases gradually with depth, becoming neutral at 0.2 m (6.8), and increasing to pH 7.2 with depth. EC is very low throughout the profile, ranging from 0.063 dS/m in the topsoil, to 0.012 dS/m in the lower subsoil. Chloride concentrations reflect this result, ranging from 20 mg/kg to <10 mg/kg mg/kg with depth.

CEC varies with depth from moderate in the topsoil, to low in the mid-stratum, to moderate in the lower subsoil. This result is reflected in the concentrations of exchangeable cations, which are higher in the topsoil and lower subsoil than they are in the mid-level horizons. Ca, Mg, K and Na are all within the desirable range for plant growth, at all depths. Throughout the profile, calcium dominates magnesium, with a Ca/Mg ratio of 1.2 to 1.3 at all depths. This assists in decreasing any risk of dispersion in the soil, though plants could benefit from additional calcium.

ESP is considered non-sodic at all depths, ranging from 0.3% in the topsoil layer to 1.0% in the lower subsoil. This is beneficial for plant life and ensures that the unit should remain relatively stable when wet. This conclusion is supported by the unit's Emerson Class Numbers, which vary from 3 to 4 throughout the profile, suggesting that if left undisturbed, this unit should not become dispersive.

Table 8 Surface Soil (0-10cm) Properties of the Barry SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	**Sand**	**Silt**	**Clay**				
2	42	42	14	3	1.7	<10	3.3
Extractable Nutrients (mg/kg)				**Extractable Metals (mg/kg)**			
P	**K**	**B**		**Cu**	**Fe**	**Mn**	**Zn**
64	596	0.4		<1.00	53.4	37.2	2.88

The surface soil (A/A1) is dominated by sand (42%) and silt (42%), with 14% clay and 2% gravel. It has weak to moderate structure and is hard setting. The surface soil is non-sodic, with a Ca/Mg ratio of 1.2, and a high organic matter content of 3.3%. This information paired with the topsoil's Emerson Class Number of 3 suggests that the surface soil is unlikely to suffer from dispersion when wetted. The water-holding capacity of the topsoil is relatively good, due to the organic matter content and presence of clay sized particles. This is evidenced by the increase in moisture content with depth (as seen in Table 7).

Nutrient levels are variable, with deficient nitrate (1.7 mg/kg), and adequate concentrations of phosphorous (64 mg/kg) and potassium (569 mg/kg). Boron (0.4 mg/kg) and sulphate (<10 mg/kg) are both below guideline levels for supporting plant life. Extractable metal concentrations also vary in their suitability. While zinc is at an appropriate concentration (2.88 mg/kg), manganese (37.2 mg/kg) and iron (53.4 mg/kg) are both slightly higher than desirable, while copper is below detectable concentration (<1.0 mg/kg). These variable nutrient and metals concentrations are likely to limit the types of vegetation supported by the Barry SMU.

4.3 CHARLEVUE SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with plains and rises. Textures within this unit grade from sandy clay loams or light clays in the surface soil, to medium heavy clays in the subsoil horizons. Dominant vegetation includes *Eucalyptus populnea* and *Eucalyptus crebra,* with *Flindersia dissosperma* (sometimes dominant) and *Cassia spinarum* in the shrub layer.

Australian Soil Classification: Red or Brown Dermosol

Vegetation	*Eucalyptus populnea* and *Eucalyptus crebra*, with *Flindersia dissosperma* and *Cassia spinarum* in the shrub layer.
Runoff	Very slow to rapid
Permeability	Slowly permeable
Drainage	Poorly drained

Profile Description – Representative Sites: DP6, DP10 and DP11

Charlevue SMU

The **surface soil** (A1/A1e) is a dark brown to brown (7.5YR3/3, 7.5YR4/3, 10YR3/3) sandy clay loam to light medium clay, with weak to moderate structure. It may exhibit conspicuous bleaching, and has a field pH of 5.5 to 5.8. Clear or sharp change to;

The **lower surface soil** (A2e/A3) was not present as all profile sites. It is a light to medium clay with moderate structure, sometimes exhibiting conspicuous bleaching. Field pH is 5.5 to 6.0, with a sharp or abrupt change to;

The **upper subsoil** (B21) was only present at one profile site. It is a dark brown (7.5YR3/4) medium clay with weak lenticular structure and a field pH of 6.5. Clear change to;

The **lower subsoil** (B2/B22) is a reddish or yellowish brown (5YR4/4, 10YR4/6) medium heavy clay with weak to moderate structure. It has a field pH of 6.5 to 7.0.

Chemical and Physical Analysis

Table 10 Chemical Properties of the Charlevue SMU

Representative site: DP6									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**
	#	**Rate**	**dS/m**	**Rate**	**mg/kg**	**%**	**Rate**		
0-0.1	5.4	Strongly acid	0.28	Medium	420	19.8	Strongly sodic	9.1	4
0.2-0.3	6.4	Slightly acid	0.43	Medium	680	15.1	Strongly sodic	11.8	2
0.5-0.6	7.9	Moderately alkaline	0.46	High	630	29.4	Strongly sodic	10.7	1

Depth (m)	**CEC**		**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**
	meq / 100g	**Rate**	**Ca**	**Mg**	**K**	**Na**	
0-0.1	6.3	Low	1.7	3.1	0.1	1.2	0.5
0.2-0.3	11.4	Low	3.2	6.4	<0.1	1.7	0.5
0.5-0.6	13.1	Moderate	2.7	6.5	<0.2	3.8	0.4
Percentage in Topsoil			26.98%	49.21%	1.59%	19.80%	-

The Charlevue SMU has a variable pH, ranging from 5.4 (strongly acid) in the topsoil to 7.9 (moderately alkaline) in the lower subsoil. EC is medium in the surface soil (0.28 to 0.43 dS/m), and increases to high in the subsoil (0.46 dS/m). Chloride is considered to be high from 0.2 m depth downwards (>600 mg/kg), which can cause toxicity by interfering with plants' osmotic capacity.

CEC increases with depth, ranging from low (6.3 meq/100g) in the topsoil, to moderate (13.1 meq/100g) in the subsoil layer. This result is reflected in the concentrations of exchangeable cations, which also generally increase with depth. Potassium concentrations were lower than desirable, and though calcium and magnesium fell within the appropriate concentration ranges, necessary percentages were unbalanced throughout the profile. In the topsoil, exchangeable cations are dominated by magnesium at 49.21%, which translates to a Ca/Mg ratio of 0.5. Subsoil layers see a decrease in this ratio, with magnesium (6.5 meq/100g) dominating over calcium (2.7 meq/100g). Due to the high clay content of this soil, this is likely to increase the risk of dispersion in this soil unit.

ESP is considered strongly sodic throughout the profile, ranging from 19.8% in the topsoil layer to 29.4% in the lower subsoil. Due to the high clay content in this soil, this is likely to increase the dispersive tendencies of the unit with depth. This result is reflected in the unit's Emerson Class Numbers, which range from 4 in the surface soil (non-dispersive) to 1 in the lower subsoil (highly dispersive).

Table 11 Surface Soil (0-10 cm) Properties of the Charlevue SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
5	54	38	3	4	0.4	20	1
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K		B	Cu	Fe	Mn	Zn
12	<200		0.8	<1.00	29.7	5.45	<1.00

The surface soil (A1/A1e) for the Charlevue SMU is dominated by sand (54%) and silt (38%), with 5% gravel and 3% clay. It has weak to moderate structure, and a hard setting surface condition. The topsoil is strongly sodic, with a Ca/Mg ratio of 0.5, and an organic matter content of 1.0%. This information would usually suggest that dispersion would be a considerable risk for the topsoil, though chemical results presented an Emerson Class Number of 4 (non-dispersive). This is likely due to the high sand content in the topsoil layer, which decreases with depth as clay content (and dispersive tendency) increases.

Nutrient levels in the topsoil layer are generally poor, with nitrate (0.4 mg/kg), phosphorous (12 mg/kg) and potassium (<200 mg/kg) below suitable levels. Sulphate (20 mg/kg) and boron (0.8 mg/kg) are within acceptable ranges for supporting plant life. Extractable metals vary in their suitability. Both copper and zinc are below reportable amounts, while manganese (5.45 mg/kg) and iron (29.7 mg/kg) are present in suitable concentrations.

Strongly acidic soils such as these can limit the availability of these nutrients to plants, by affecting their solubility, speciation, and toxicity.

4.4 COOINDA SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with plains. Texture development within this unit is gradual, changing from a sandy clay loam in the topsoil, to a sandy light clay at mid-depth, and a medium heavy clay in the deeper subsoil. Dominant vegetation includes *Eucalyptus populnea* and *Flindersia dissosperma* (sometimes dominant), with *Cassia spinarum* in the shrub layer.

Australian Soil Classification: Brown Dermosol

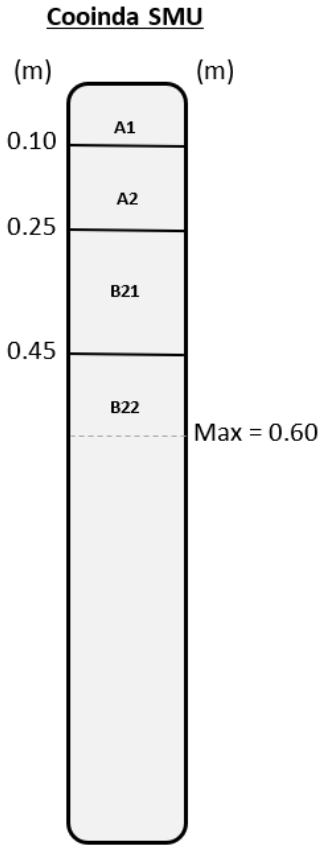

Photo Plate 4 Cooinda SMU Vegetation

Table 12 Cooinda Soil Unit Description

Parameter	Soil Unit Description
Profile Site Numbers	DP2
Observation Site Numbers	N/A
Landform	Plains and flats
Land System	Melbadale

Geology	Qa-QLD (Qa) – Quaternary clay, silt, sand and gravel; flood-plain alluvium
Vegetation	Eucalyptus populnea and Flindersia dissosperma (sometimes dominant), with Cassia spinarum in the shrub layer.
Runoff	Moderate
Permeability	Slowly permeable
Drainage	Imperfectly drained

Profile Description – Representative Sites: DP2

The **surface soil** (A1) is a dark yellowish brown (10YR3/6) sandy clay loam with strong play structure. It has a small percentage (<2%) of small sub-rounded coarse fragments. The field pH is 6.0. Clear change to;

The **lower surface soil** (A2) is a dark brown (7.5YR3/4) sandy light clay with moderate polyhedral structure. It also has a small percentage (<2%) of small sub-rounded coarse fragments, with a field pH of 5.5. Gradual change to;

The **upper subsoil** (B21) is a dark yellowish brown (10YR4/4) sandy light clay with moderate polyhedral structure. It has a small percentage (<2%) of small sub-rounded coarse fragments (these are consistent throughout the entire profile), with a field pH of 6.0. Sharp change to;

The **lower subsoil** (B22) is a dark yellowish brown (10YR4/6) medium heavy clay with moderate lenticular structure. It has a small percentage (<2%) of small sub-rounded coarse fragments, with a field pH of 7.0.

Chemical and Physical Analysis

Table 13 Chemical Properties of the Cooinda SMU

Representative site: DP2									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**
	#	**Rate**	**dS/m**	**Rate**	**mg/kg**	**%**	**Rate**		
0-0.1	5.6	Moderately acid	0.015	Very low	<10	0.9	Non-sodic	4.2	3
0.2-0.3	5.7	Moderately acid	0.013	Very low	10	2.1	Non-sodic	6.0	3
0.5-0.6	6.8	Neutral	0.043	Very low	40	10.9	Sodic	10.0	3

Depth (m)	**CEC**		**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**
	meq / 100g	**Rate**	**Ca**	**Mg**	**K**	**Na**	
0-0.1	4.4	Very low	1.9	2.0	0.4	<0.1	1.0
0.2-0.3	4.6	Very low	1.5	2.6	0.2	<0.1	0.6
0.5-0.6	9.8	Low	1.9	6.7	0.1	1.1	0.3
Percentage in Topsoil			43.18%	45.45%	9.09%	0.9%	-

The pH of the Cooinda SMU ranges from moderately acid (5.6) in the topsoil, to neutral (6.8) in the lower subsoil. EC is very low throughout the profile, with topsoil values of 0.015 dS/m, increasing to 0.043 dS/m in the subsoil. Chloride levels reflect EC, increasing from less than 10 mg/kg to 40 mg/kg with depth.

CEC increases down the soil profile, ranging from very low (4.4 meq/100g) in the topsoil to low (9.8 meq/100g) in the subsoil. An increase in clay content with depth likely contributes to this increase in CEC. Exchangeable cations are dominated by magnesium and calcium in the topsoil, then magnesium in the subsoil, resulting in a Ca/Mg ratio that decreases with depth from 1.0 to 0.3. Magnesium concentrations (meq/100g) are within acceptable ranges at all depths, though all other cations are either too low (calcium and potassium) or too high (sodium) to be considered appropriate for healthy plant growth.

ESP ranges from non-sodic (0.9%) in the topsoil layer, to sodic (10.9%) in the lower subsoil. Due to the moderate clay content within this soil, this ESP may impact the dispersive tendencies of the soil unit. This result is reflected in the unit's Emerson Class Numbers, which remain at the same level throughout the profile (3), suggesting that the soil unit may become dispersive if physically disturbed.

Table 14 Surface Soil (0-10cm) Properties of the Cooinda SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
7	51	30	12	3	1.2	<10	1
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
15	<200	0.4		<1.00	76.9	61.6	1.82

The surface soil (A1) for the Cooinda SMU is dominated by sand (51%), with 30% silt, 12% clay, and 7% gravel. It has a strong platy structure and is hard setting. The topsoil is non-sodic, with a Ca/Mg ratio of 1.0, and an organic matter content of 1.0%. This information paired with the topsoil's Emerson Class Number of 3 suggests that the soil may suffer from dispersion if physically disturbed. The mixture of particle sizes seen here will assist in stabilising the topsoil horizon, as pore spaces between sand grains may be infilled with the sand and silt fractions.

Nutrient levels are low, with nitrate (1.2 mg/kg), phosphorous (15 mg/kg) and potassium (<200 mg/kg) all below the guideline levels for plant life. Boron (0.4 mg/kg) and sulphate (<10 mg/kg) were also lower than desired. Extractable metals were found below suitable concentrations with zinc (1.82 mg/kg) the only trace element detected within the desirable range. Iron (76.9 mg/kg) and manganese (61.6 mg/kg) were both high enough to potentially impact plant health, while copper (<1.0 mg/kg) was below the desirable concentration.

4.5 ELLESMERE SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with isolated hills of weathered tertiary surfaces (laterite). Textures within this unit grade from fine sandy loams in the surface soil to medium clays in the subsoil horizons. Dominant vegetation is *Acacia shirleyi*, with *Erythroxylon australe* in the shrub layer.

Australian Soil Classification: Red Dermosol.

Photo Plate 5 Ellesmere SMU Vegetation

0.8-0.9	6.9	Low	<0.1	3.4	0.1	0.6	<0.1
Percentage in Topsoil			17.39%	8.70%	8.70%	<0.1	-

The Ellesmere SMU is a highly acidic soil unit, ranging from 4.6 (very strongly acid) in the topsoil to 5.5 (strongly acid) in the lower subsoil layer. EC is very low throughout the profile, changing from 0.02 dS/m in the topsoil, to 0.026 dS/m in the lower subsoil. Chloride concentrations are very low, consistently presenting at <10 mg/kg.

CEC increases progressively with depth, ranging from very low in the topsoil (2.3 meq/100g) to low in the subsoil (6.9 meq/100g). Corresponding exchangeable cation concentrations are also low, the only values within the appropriate range being magnesium in the bottom two horizons, and potassium in the topsoil. Calcium dominated magnesium in the surface soil layer (Ca/Mg = 2.0), though this was reversed in the subsoil (Ca/Mg = <0.1), where Mg comprises 49.28% of the exchangeable cations, with Ca below reportable levels. These low levels of exchangeable cations may be limiting plant growth.

While sodium concentrations are within the commonly measured levels at all depths, ESP ranges from <0.1% (non-sodic) in the topsoil layer to 13.8% (sodic) in the lower subsoil, becoming sodic at 0.2 m depth. This unit has a moderate clay content in the subsoil layers, though has a very low/low CEC. For this reason, the impact of sodicity is less pronounced than it would be in a soil with high CEC, as sodium atoms cannot effectively separate the clay particles within the soil. This interpretation is reflected in the unit's Emerson Class Numbers, which range from 3 in the surface soil (dispersive if disturbed) to 4 in the subsoil layers (non-dispersive).

Table 17 Surface Soil (0-10 cm) Properties of the Ellesmere SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
3	68	19	10	3	1.6	<10	5
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
6	532	0.4		<1.00	327	3.13	<1.00

The surface soil (A1) is dominated by sand (68%), with 19% silt, 10% clay, and 3% gravel. It has a moderate, platy structure and is hard setting. The topsoil is non-sodic, with a Ca/Mg ratio of 2.0, and a high organic matter content of 5%. This information paired with the topsoil's Emerson Class Number of 3, suggests that the surface soil is unlikely to suffer from dispersion if it is not physically disturbed.

Nutrient levels for this SMU are variable. Nitrate (1.6 mg/kg) and phosphorous (6 mg/kg) were both below desirable levels, while potassium (535 mg/kg) was extremely high for both grazing and cropping land uses. Both sulphate (<10 mg/kg) and boron (0.4 mg/kg) were lower than desired. Extractable metals were generally unsuitable, with only manganese (3.13 mg/kg) within the appropriate range. Copper and zinc were both below reportable levels, while iron (327 mg/kg) concentrations were significantly elevated.

Elevated iron levels such as these can cause toxicity to plants and limit their photosynthetic efficiency. They can also limit the uptake of phosphorous, which is already below the ideal concentration. In addition to this, acidic pH values such as those seen in this SMU can limit the availability of all metals and nutrients to plants, by increasing toxicity, reducing solubility and altering elemental speciation.

4.6 GEOFFREY SOIL MANAGEMENT UNIT

Soil Unit Description: This unit consists of texture contrast soils with soft surface conditions, associated with undulating plains and rises. Textures range from loamy sands to sandy light clays, overlying sandy medium clays with conspicuous orange or red mottling. Where these soils were exposed due to insufficient groundcover, extensive washouts and large erosion gullies were observed. In these areas, overland flow had removed coarse sandy material, leaving the easily eroded clays exposed to surface runoff. The Geoffrey SMU was often cleared, though when present dominant vegetation included *Eucalyptus crebra*, *Melaleuca leucadendra*, *Casuarina cunninghamiana* and *Corymbia clarksoniana*, with *Alphitonia excelsa*, *Petalostigma pubecens*, and *Acacia rhodoxylon* in the shrub layer.

Australian Soil Classification: Brown Sodosol.

Profile Description – Representative Sites: DP1, DP5, DP7, DP30, DP32

Geoffrey SMU

The **surface soil** (A1) is a pale brown to brown (10YR6/3, 7.5YR4/4, 7.5YR4/3) sand to fine sandy loam with massive or grainy structure. This horizon has a field pH of 5.5 to 6.0, with a gradual change to;

The **mid-surface soil** (A2j/A2e) is a brown (7.5YR4/3, 7.5YR5/4, 10YR5/3) sand to fine sandy clay loam with sporadic or conspicuous bleaching. It has a massive to grainy structure and a field pH of 5.5 to 6.0. At some sites, this horizon had an abrupt change to B2, though at other sites had a gradual change to;

The **lower surface soil** (A3j/A3e) was not present at all sites. It is a sporadically or conspicuously bleached pale brown to pink (10YR6/3, 5YR7/3) sand to light sand. It has a grainy structure with a field pH of 6.0 to 6.5. Where present, this horizon has an abrupt change to;

The **subsoil** (B2) is very easy to differentiate from the overlying horizons. It is a yellowish brown to greyish brown (10YR6/4, 10YR5/2, 10YR4/6) medium clay, with moderate lenticular structure. Field pH is 6.0 to 7.5. This horizon continues to great depths, and exhibits distinct yellow, orange and red mottles.

Chemical and Physical Analysis

0.8-0.9	8.8	Low		0.9	5.9	<0.2	2.0	<0.2	
Percentage in Topsoil				41.18%	41.18%	17.65%	1.00%	-	

Due to the stark difference in textures between the topsoil and subsoil layers, pH for the Geoffrey SMU changes quite dramatically down the soil profile. Sandy, massive horizons (0.0 to 0.6 m) are moderately acid, with pH increasing with depth from 5.8 to 6.0. The clay B2 horizon has a pH value over two units higher (8.1) and is classified as 'moderately alkaline'. This is likely due to the increased CEC of the clay in the B2 horizon compared with the sand in the upper horizons (A1, A2 and A3). In addition to this, salts are held in the subsoil layers, resulting in an increase in EC, chloride, and sodicity (evidenced by the ESP) in the B2 layer.

The clay-rich subsoil present a higher CEC, due to its elevated clay content. It is likely that if exposed, the subsoil (B2) would become dispersive, while the surface soil horizons (A1, A2 and A3) would remain non-dispersive. This interpretation is supported by the unit's Emerson Class numbers, which change from 4 (non-dispersive) for the topsoil layers, to 1 (extremely dispersive) for the subsoil. The dispersive tendencies of the B2 horizon may be further exacerbated by the low Ca/Mg ratio in this layer (<0.2).

Low concentrations of exchangeable cations were observed in this unit. In the surface soil, calcium and magnesium were relatively equally represented, though concentrations of these cations were extremely limited. Increased levels of some of the major cations were observed in the subsoil, these were dominated by magnesium (67.1%) and sodium (22.1%), with calcium and potassium at similar levels to observed levels in the A horizons. These low levels of calcium in comparison to magnesium in the B2 horizon further increases the susceptibility of this layer to dispersion upon wetting.

The Geoffrey soil unit also lends itself to storage of water above the B2 horizon due to the low permeability of the clay sub-soil layers..

Table 20 Surface Soil (0-10cm) Properties of the Geoffrey SMU

Particle Size Analysis %	Emerson	Nitrate	Sulphate	Organic

Gravel	Sand	Silt	Clay	Class No.	(mg/kg)	(mg/kg)	Matter (%)
1	65	25	9	4	3	<10	1.8
Extractable Nutrients (mg/kg)				**Extractable Metals (mg/kg)**			
P	**K**	**B**		**Cu**	**Fe**	**Mn**	**Zn**
8	<200	0.2		<1.00	166	16.0	2.16

The surface soil (A1) is dominated by sand (65%) with 25% silt, 9% clay, and 1% gravel. It has grainy texture, and a soft surface condition. The topsoil is non-sodic, with a Ca/Mg ratio of 1.0, and an organic matter content of 1.8%. The soil has an Emerson Class of 4, indicating that the topsoil unit is unlikely to become dispersive when wetted. Sandy soils such as these are often less susceptible to erosion, due to the large particle size of the sand grains, and their low CEC.

Topsoil nutrients for the Geoffrey SMU are generally quite limited, with nitrate (3 mg/kg), phosphorous (8 mg/kg) and potassium (<200 mg/kg) below desirable levels. Boron (0.2 mg/kg) and sulphate (<10 mg/kg) are also lower than guideline recommendations for suitable plant growth medium. For extractable metals, manganese (16.0 mg/kg) and zinc (2.16 mg/kg) are within the desirable range, though iron (166 mg/kg) is elevated, and copper (<1.0 mg/kg) is below reportable levels. These low levels of nutrients are likely due to the low CEC and leaching capacity of sand, paired with the nutrient content of the parent material.

4.7 JAMES SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting red soils associated with hills and rises. Textures within this unit vary depending on slope, with lesser developed soils found on crests (sandy clay loams to clay loams) and more developed/deeper soils found on mid slopes (clay loams to light medium clays). Dominant vegetation includes *Acacia rhodoxylon, Eucalyptus crebra,* and *Corymbia clarksoniana.*

Australian Soil Classification: Red Dermosol.

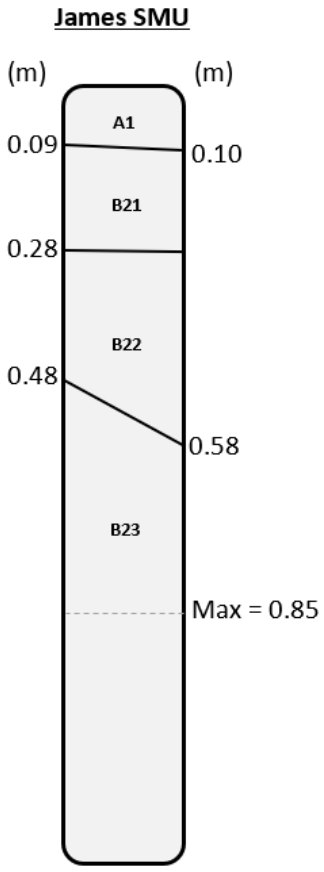

Photo Plate 7 James SMU Vegetation

Table 21 James Soil Unit Description

Parameter	Soil Unit Description
Profile Site Numbers	DP17, DP16.1
Observation Site Numbers	DO39, DO40, DO42, DO253
Landform	Hills and rises
Land System	Melbadale
Slope	4 to 6%
Geology	Td-QLD (Td) – Tertiary duricrusted palaeosols at the top of deep weathering profiles, including ferricrete and silcrete; duricrusted old land surfaces.
Vegetation	*Acacia rhodoxylon, Eucalyptus crebra,* and *Corymbia clarksoniana*.
Runoff	Moderate to rapid
Permeability	Moderately permeable
Drainage	Moderately to well drained

Profile Description – Representative Sites: DP17 & DP16.1

The **surface soil** (A1) is a dark reddish brown (5YR3/4) sandy clay loam to clay loam with weak to moderate platy structure. Profiles with higher relief may have a small number of sub-rounded coarse fragments. This horizon has a pH of 6.0, with a gradual change to;

The **upper subsoil** (B21) varies in texture depending on relief within the landscape. Profiles with high relief (crests) exhibit a dark red (2.5YR3/6) clay loam, with a grainy structure and a significant amount (10-20%) of small sub-rounded coarse fragments. Lower relief profiles (slopes) are a dark reddish-brown (5YR3/4) light medium clay with weak angular blocky structure and no coarse fragments. Both variations of this horizon have a pH of 6.0, with a gradual change to;

The **mid-subsoil** (B22) is also variable in texture depending on relief. High relief (crest) examples are dark red in colour (2.5YR3/6) with a clay loam texture and a large amount (50-90%) of small sub-rounded coarse fragments. Lower relief profiles (slopes) are also dark red in colour (2.5YR3/6) with light clay texture, and no coarse fragments. Both versions of this horizon have a pH of 6.0, and moderate structure, with lower relief profiles gradually changing to;

The **lower subsoil** (B23) is only present on the lower slopes of the James SMU, where deeper clays have had the opportunity to develop. It is dark red in colour (2.5YR3/6), with a light medium clay texture, moderate lenticular structure and no coarse fragments. Field pH is 6.5.

Chemical and Physical Analysis

Table 22 Chemical Properties of the James SMU

Representative site: DP17									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**
	#	**Rate**	**dS/m**	**Rate**	**mg/kg**	**%**	**Rate**		
0-0.1	6.2	Slightly acid	0.013	Very low	<10	0.4	Non-sodic	1.5	8
0.2-0.3	6.1	Slightly acid	0.006	Very low	<10	0.7	Non-sodic	7.0	3
0.5-0.6	6.4	Slightly acid	0.015	Very low	<10	1.4	Non-sodic	10.2	4

Depth (m)	**CEC**		**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**
	meq / 100g	**Rate**	**Ca**	**Mg**	**K**	**Na**	
0-0.1	4.3	Very low	2.0	1.8	0.4	<0.1	1.1
0.2-0.3	5.9	Very low	3.1	2.4	0.3	<0.1	1.3
0.5-0.6	5.8	Very low	2.4	3.2	<0.1	<0.1	0.8
Percentage in Topsoil			46.51%	41.86%	9.30%	0.40%	-

pH in the James SMU is slightly acidic throughout the profile, with very little variation. It increases gradually with depth from 6.2 in the topsoil, to 6.4 in the lower subsoil. EC is very low at all depths, ranging from 0.013 dS/m in the topsoil to 0.015 dS/m in the subsoil. Chloride levels reflect this result, presenting at <10 mg/kg throughout the profile.

CEC remains fairly consistent with depth, ranging from 4.3 meq/100g (very low) in the topsoil to 5.8 meq/100g (very low) in the subsoil. Despite this, concentrations of available cations are within the acceptable ranges, with the exception of potassium in the lower subsoil, which is below reportable levels. In the topsoil, exchangeable cations are dominated by calcium (46.51%) and magnesium (41.86%) in roughly equal amounts (Ca/Mg = 1.1). The mid-stratum layer sees this ratio increase to 1.3, before dropping in the subsoil layer to 0.8.

ESP is considered non-sodic throughout the profile, ranging from 0.4% in the topsoil layer to 1.4% in the lower subsoil. This ESP isn't likely to impact the dispersive tendencies of the soil unit. This interpretation is confirmed by the unit's Emerson Class Numbers, which range from 8 (non-dispersive) in the surface soil, to 3 (dispersive if disturbed) in the mid-stratum, to 4 (non-dispersive) in the subsoil layer.

Table 23 Surface Soil (0-10 cm) Properties of the James SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
6	56	21	17	8	1.1	<10	2.8
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
14	<200	0.3		<1.00	21.4	18.7	<1.00

The surface soil (A1) is dominated by sand (56%) with 21% silt, 17% clay, and 6% gravel. It has moderate, platy structure, and a hard setting surface. The topsoil is non-sodic, with a Ca/Mg ratio of 1.1, and an organic matter content of 2.8%. This favourable chemistry combination, paired with the topsoil's Emerson Class Number of 8, suggests that the surface soil is unlikely to suffer from dispersion. The water-holding capacity of the topsoil is relatively poor, due to the lack of clay sized particles. This is evidenced by the increase in moisture content with depth (as seen in Table 22).

Nutrient availability within the James SMU is generally limited. Nitrate (1.1 mg/kg), phosphorous (14 mg/kg) and potassium (<200 mg/kg) are all well below the desirable concentrations, with sulphate (<10 mg/kg) and boron (0.3 mg/kg) also low. Extractable metals vary in concentration. While, iron (21.4 mg/kg) and manganese (18.7 mg/kg) are both within the suitable range for plant life, copper and zinc are below reportable levels.

It is noted that the soil profile examined here represents a mid-slope site on the James SMU, with profiles higher in the landscape (e.g. hill crests) typically possessing shallower subsoils, lower CECs and reduced nutrient concentrations.

4.8 KOSH SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with alluvial plains, plains and low rises. Textures within this unit are gradational, changing from sandy clay loams and light clays in the topsoil, to medium heavy clays in the lower subsoil. Commonly, this unit was cleared for grazing, with regrowth consisting of scrub species including *Vachellia nilotica*, *Cassia spinarum, Capparis lasiantha, Cassia brewsteri*, and various Eucalyptus shrubs. When present, vegetation included *Eucalyptus tereticornis, Acacia hemiglauca, Acacia salicina, Lysiphyllum hookeri, Eucalyptus crebra* and *Eucalyptus populnea*.

Australian Soil Classification: Brown Dermosol

Slope	1 to 4%
Geology	Qa-QLD (Qa) – Quaternary clay, silt, sand and gravel; flood-plain alluvium
Vegetation	Cleared - *Vachellia nilotica, Cassia spinarum, Capparis lasiantha, Cassia brewsteri* Vegetated - *Eucalyptus tereticornis, Acacia hemiglauca, Acacia salicina, Lysiphyllum hookeri, Eucalyptus crebra* and *Eucalyptus populnea*.
Runoff	Very slow to rapid
Permeability	Slowly permeable
Drainage	Poorly drained

Profile Description – Representative Sites: DP23, DP34, DP35, DP47

The **surface soil** (A1) is a brown to dark reddish brown (7.5YR4/3, 10YR3/3, 5YR3/3) sandy clay-loam to medium clay with weak to massive structure. Field pH of 6.0 to 6.5, with clear/gradual change to;

The **lower surface soil** (A2e/A2j) is a sporadically or conspicuously bleached horizon present at approximately half of the profile sites. It is a pale brown to brown (10YR6/3, 7.5YR4/3) sandy clay-loam to medium clay that usually has massive structure (though can be weak angular blocky), with a field pH of 6.0 to 7.0. When present, this layer has a clear or gradual change to;

The **upper subsoil** (B21/B21j) was not present at all sites. When present this horizon can exhibit sporadic bleaching. It is a brown to dark reddish brown (7.5YR4/4, 5YR3/2) medium heavy clay with weak to moderate angular blocky structure. This horizon has a field pH of 6.0 to 7.0, with a clear or gradual change to;

The **subsoil** (B2/B22) is variable in colour, presenting as a dark brown, dark reddish, or yellowish brown colour (7.5YR3/3, 5YR3/3, 10YR5/6). Soil texture is a medium heavy clay, with moderate lenticular structure. pH gradually increased with depth at all sites, ranging from 7.0 to 9.0, sometimes within the same soil profile. This layer can extend to great depths, otherwise exhibiting a gradual change to;

The l**ower subsoil** (B23) was only observed at two sites. It is a dark brown (7.5YR3/4) medium heavy clay with moderate lenticular structure, and a field pH ranging from 6.5 to 7.5 (increasing with depth).

	meq / 100g	**Rate**		**Ca**	**Mg**	**K**	**Na**		
0-0.1	6.8	Low		4.4	1.7	0.6	<0.1	2.6	
0.2-0.3	13.3	Moderate		4.4	6.9	0.2	1.8	0.6	
0.5-0.6	17.4	Moderate		4.1	9.7	<0.2	3.4	0.4	
Percentage in Topsoil				64.71%	25.00%	8.82%	0.60%	-	

The pH within the Kosh SMU is highly variable, changing from 6.3 (slightly acid) in the topsoil to 8.5 (strongly alkaline) in the lower subsoil. EC follows a similar pattern, changing from very low between 0.0 and 0.3 m depth, to medium in the subsoil. Chloride concentration also increases significantly with depth, ranging from <10 mg/kg in the topsoil, to 490 mg/kg in the subsoil layer. High chloride concentrations such as these can impact a plant's osmotic capacity, impacting its ability to access water and nutrients.

CEC increases with depth from low (6.8 meq/100g) to moderate (17.4 meq/100g), likely due to the increased clay content in the subsoil layers. Exchangeable cations within the topsoil are dominated by calcium (64.71%) and magnesium (25.00%), with potassium at 8.82%. These concentrations and ratios are considered appropriate for plant growth, though become less so with depth. While calcium remains relatively consistent throughout the profile, magnesium and sodium concentrations continue to increase, eventually contributing to 55.75% and 19.5% of the total CEC, respectively. The Ca/Mg ratio drops from 2.6 in the topsoil, to 0.4 in the lower subsoil layer. This is detrimental to the ability of the soil to maintain its integrity upon exposure, significantly increasing the subsoil's potential erodibility.

ESP for this SMU increases progressively with depth, changing from non-sodic (0.6%) in the topsoil to strongly sodic (19.5%) in the lower subsoil. Due to the high clay content in the lower horizons, the elevated ESP observed here is likely to impact the dispersive tendencies of the soil unit. This interpretation is reflected in the sample's Emerson Class Numbers, which range from 4 in the surface soil (non-dispersive) to 2 in the subsoil (moderately dispersive).

It is likely that subsoils in this unit would be considerably erosive.

Table 26 Surface Soil (0-10 cm) Properties of the Kosh SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
4	63	24	9	4	2.5	<10	4
Extractable Nutrients (mg/kg)				**Extractable Metals (mg/kg)**			
P	K	B		Cu	Fe	Mn	Zn
13	<200	0.4		<1.00	32.4	17.5	1.20

The topsoil layer (A1) for the Kosh SMU is dominated by sand-sized particles (63%), with 24% silt, 9% clay, and 4% gravel. It has a weak structure, with a hard setting surface. The surface soil is non-sodic, with a Ca/Mg ratio of 2.6, and an organic matter content of 4%. This means the topsoil has favourable chemistry in terms of dispersion, evidenced by the unit's Emerson Class of 4 (non-dispersive). This topsoil is particularly significant for this SMU, as it protects the underlying sodic clay from erosion.

Nutrient content within this topsoil is quite poor. Nitrate (2.5 mg/kg), phosphorous (13 mg/kg) and potassium (<200 mg/kg) are all below suitable levels, as are sulphate (<10 mg/kg) and boron (0.4 mg/kg). Extractable metal concentrations are adequate, with only copper below the required concentration.

4.9 NAMOI SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with hills and rises. Textures within this unit are gradational, changing from a sandy clay loam in the topsoil to a light medium clay in the subsoil. Dominant vegetation includes *Eucalyptus crebra,* with *Heteropogon contortus* and juvenile Acacia species.

Australian Soil Classification: Red Dermosol

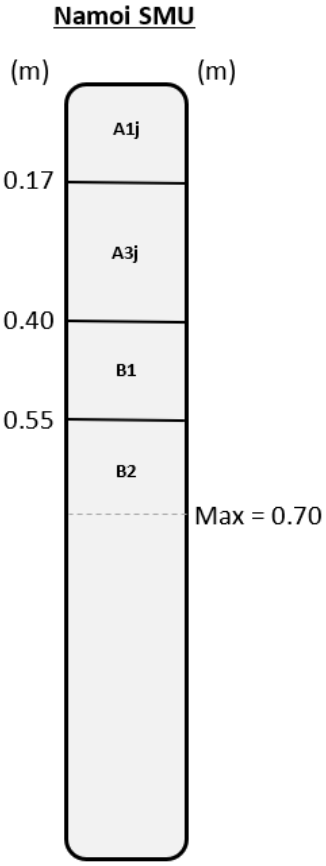

Photo Plate 9 Namoi SMU Vegetation

Table 27 Namoi Soil Unit Description

Parameter	Soil Unit Description
Profile Site Numbers	DP3
Observation Site Numbers	DO1
Landform	Hills and rises
Land System	Melbadale
Slope	4%
Geology	Rewan Group (Rr) – Early Triassic – Middle Triassic sedimentary unit comprised of lithic sandstone, pebbly lithic sandstone, green to reddish brown mudstone and minor volcanilithic pebble conglomerate (at base)
Vegetation	*Eucalyptus crebra*, with *Heteropogon contortus* and juvenile Acacia species.
Runoff	Rapid
Permeability	Slowly permeable
Drainage	Moderately well drained

Profile Description – Representative Sites: DP3.

The **surface soil** (A1j) is a dark brown (7.5YR3/4) sandy clay-loam with sporadic bleaching. It has a moderate lenticular structure, and a field pH of 5.0. Clear change to;

The **lower surface soil** (A3j) is a reddish brown (5YR4/4) sandy clay-loam+ with sporadic bleaching. It has a weak angular blocky structure, and a field pH of 5.5. Gradual change to;

The **upper subsoil** (B1) is a yellowish red (5YR4/6) light clay with weak angular blocky structure, and a field pH of 6.0. Gradual change to;

The **lower subsoil** (B2) is a yellowish red (5YR5/8) light medium clay with moderate polyhedral structure, and a field pH of 6.5. It may contain a small number (<2%) of subangular coarse fragments and faint red mottling.

Chemical and Physical Analysis

Table 28 Chemical Properties of the Namoi SMU

Representative site: DP3									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**

0.2-0.3	5.5	Strongly acid	0.008	Very Low	<10	1.8	Non-sodic	3.2	3
0.5-0.6	6.1	Slightly acid	0.007	Very Low	<10	4.1	Non-sodic	6.6	3
Depth (m)	**CEC**			**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**	
	meq / 100g	**Rate**		**Ca**	**Mg**	**K**	**Na**		
0-0.1	2.0	Very low		1.0	0.6	0.2	<0.1	1.7	
0.2-0.3	1.9	Very low		0.8	0.8	<0.1	<0.1	1.0	
0.5-0.6	3.0	Very low		0.7	2.1	<0.1	0.1	0.3	
Percentage in Topsoil				50.00%	30.00%	10.00%	0.60%	-	

The Namoi SMU has a pH that is most acidic in the upper subsoil (5.5), with a moderately acidic topsoil (5.7), and a slightly acidic lower subsoil (6.1). EC is very low at all depths, ranging from 0.01 dS/m in the topsoil, to 0.007 dS/m in the subsoil horizon. Chloride concentration reflects this result, presenting at <10 mg/kg at all depths.

CEC is also very low throughout the profile, changing from 2.0 meq/100g in the surface horizons, to 3.0 meq/100g in the subsoil layer. Exchangeable cations were found at concentrations below desirable, with calcium at 1.0 mg/kg, and magnesium at 0.6 mg/kg. Topsoil potassium however (0.2 mg/kg), meets the required concentration. Calcium levels decrease with depth, while magnesium increases, such that the lower subsoil has a Ca/Mg ratio of 0.3. This could exacerbate soil dispersion if ESP was high, though in this case should not reduce soil cohesion. Overall, exchangeable cation concentrations do not reflect the optimal ranges expected of a healthy soil, which may be affecting plant health within this SMU.

ESP is considered non-sodic throughout the profile, ranging from 0.6 to 4.1% with depth. The entire profile has an Emerson Class of 3, meaning that the soil should remain non-dispersive unless it is physically disturbed.

Table 29 Surface Soil (0-10 cm) Properties of the Namoi SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
3	64	21	12	3	1.7	<10	0.8
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
7	<200	0.2		<1.00	86.3	43.7	2.09

The surface soil (A1j) has a high concentration of sand (64%), with 21% silt, 12% clay, and 3% gravel. It has moderate, lenticular structure, and is hard setting. The topsoil is non-sodic, with a Ca/Mg ratio of 1.7, and an organic matter content of 0.8%. Low organic matter levels combined with high sand percentages, means that the topsoil for Namoi is likely to have a low water holding capacity. The Emerson Class Number is 3, meaning that the surface soil horizon may become dispersive when wetted, if physically disturbed through stripping or tillage.

Nutrient levels are generally low, with nitrate (1.7 mg/kg), phosphorous (7 mg/kg) and potassium (<200 mg/kg) all below the desirable concentrations. Sulphate (<10 mg/kg) and boron (0.2 mg/kg) are also lower than expected for soils supporting plant growth. Extractable metals are generally unsuitable, with only zinc (2.09 mg/kg) within the acceptable range. Variable concentrations of nutrients and metals could limit vegetation type and plant growth within the Namoi SMU.

4.10 NIGEL SOIL MANAGEMENT UNIT

Soil Unit Description: Hard setting soil associated with isolated high relief areas of tertiary land surface. Textures within this unit are rudimentary, grading from sands to sandy light clays. Vegetation is variable between sites, but includes *Acacia shirleyi, Acacia rhodoxylon, Eucalyptus crebra, Melaleuca leucadendra, Corymbia clarksoniana,* and *Eucalyptus tessellaris.*

Australian Soil Classification: Brown Kandosol

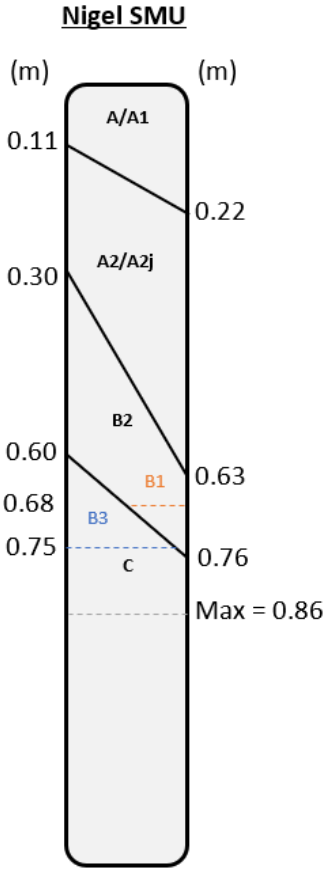

Photo Plate 10 Nigel SMU Vegetation

Table 30 Nigel Soil Unit Description

Parameter	Soil Unit Description
Profile Site Numbers	DP43, DP51, DP52
Observation Site Numbers	DO83, DO101, DO107
Landform	Hills and rises
Land System	Melbadale
Slope	3 to 5%
Geology	Gyranda Subgroup (Pwy) – Late Permian sedimentary unit comprised of siltstone and shale with minor tuff and volcanilithic sandstone and rare coal (lower part - Banana Formation) (weathered to laterite)
Vegetation	*Acacia shirleyi, Acacia rhodoxylon, Eucalyptus crebra, Melaleuca leucadendra, Corymbia clarksoniana,* and *Eucalyptus tessellaris.*
Runoff	Very slow to rapid
Permeability	Slowly permeable
Drainage	Poorly drained

Profile Description – Representative Sites: DP43, DP51 & DP52

The **surface soil** (A/A1) is a dark brown to greyish brown (10YR3/3, 7.5YR3/4, 10YR4/4) sand to loamy sand with massive structure. It has a field pH of 4.8 to 5.5, with a clear or gradual change to;

The **lower surface soil** (A2/A2j) is a dark red to yellowish-red (2.5YR3/6, 5YR4/6, 5YR3/3) sand to clayey sand, which often demonstrates sporadic bleaching. It has a massive/grainy structure and a field pH ranging from 5.0 to 5.5. This horizon exhibits a clear or gradual change to;

The **upper subsoil** (B1) was only present at one profile site. It is a red (2.5YR4/6) loamy sand with grainy structure and a field pH of 5.5. When present, this horizon has a clear change to the C horizon, though when absent, A2/A2j grades gradually to;

The **subsoil** (B2) is a yellowish brown (10YR4/6, 10YR5/6) soil with a clayey sand to sandy light clay texture. Structure in this horizon is weak to massive, with field pH values of 5.5. This unit can have a clear or gradual change to the C horizon, or;

The **lower subsoil** (B3) was only present at one site. It was a dark yellowish brown (10YR4/6) clayey sand with massive structure and a field pH of 6.0. It contained a small amount (<2%) of manganiferous nodules.

The **parent material** (C) was comprised of laterite pebbles with a pH ranging from 5.5 to 6.0.

Chemical and Physical Analysis

Table 31 Chemical Properties of the Nigel SMU

Representative site: DP52									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**
	#	**Rate**	**dS/m**	**Rate**	**mg/kg**	**%**	**Rate**

0.2-0.3	4.6	Very strongly acid	0.01	Very Low	<10	<0.1	Non-sodic	2.3	4
0.5-0.6	4.6	Very strongly acid	0.01	Very Low	<10	<0.1	Non-sodic	2.3	4

Depth (m)	**CEC**		**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**
	meq / 100g	**Rate**	**Ca**	**Mg**	**K**	**Na**	
0-0.1	2.8	Very low	0.8	0.4	0.2	<0.1	2.0
0.2-0.3	1.7	Very low	<0.1	<0.1	0.1	<0.1	<0.1
0.5-0.6	1.6	Very low	<0.1	<0.1	<0.1	<0.1	<0.1
Percentage in Topsoil			28.57%	14.29%	7.14%	1.30%	-

The Nigel SMU has an extremely low pH throughout the profile, ranging from 4.4 (extremely acidic) in the topsoil to 4.6 (strongly acidic) in the subsoil layers. EC is very low at all depths, a result reflected in chloride results, which are consistently less than or equal to 10 mg/kg.

CEC is also very low, ranging from 2.8 mg/kg in the topsoil to 1.6 mg/kg in the subsoil. This has resulted in very low concentrations of exchangeable cations. Calcium ranges from 0.8 in the topsoil, to <0.1 in the subsoil layers. Magnesium was measured at 0.4 meq/100g in the topsoil, and 0.1 meq/100g in the lower subsoil. Optimal potassium levels should be >0.2 meq/100g, and though this level was met in the topsoil, the concentration dropped to <0.1 meq/100g in the subsoil horizons.

ESP is considered non-sodic at all depths, ranging from 1.3 % in the topsoil layer to <0.1% in the lower subsoil. Therefore, the unit is unlikely to become dispersive when wetted. This interpretation is reflected in the unit's Emerson Class Numbers, which were calculated at 4 for all horizons (non-dispersive).

In addition to this, low pH values can reduce the CEC of the soil, and affect the solubility, availability, and potential toxicity of various macro and micronutrients to plant roots. This means that even if they are present in the soil, some elements (such as calcium, magnesium, and potassium) will become less available to plant roots below a pH of 5.0 and may even become damaging to vegetation (Hazelton & Murphy, 2016).

Table 32 Surface Soil (0-10 cm) Properties of the Nigel SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
1	76	17	6	4	11.2	<10	4.6
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
7	<200	0.2		<1.00	331	3.21	<1.00

The surface soil (A/A1) for the Nigel SMU is dominated by sand (76%) with 17% silt, 6% clay and 1% gravel. It is hard setting and has a massive structure. The topsoil is non-sodic, with a Ca/Mg ratio of 2.0, and a relatively high organic matter content of 4.6%. This indicates that the soil is unlikely to disperse upon wetting, shown by the surface soil's Emerson Class Number of 4 (non-dispersive). Although dispersion is not likely to become an issue, this structureless topsoil indicates that the soil may slake upon wetting, losing air filled porosity and allowing it to collapse under its own weight.

Nutrient levels are generally poor, with nitrate present at optimum levels (11.2 mg/kg), while phosphorous (7 mg/kg) and potassium (<200 mg/kg) outside of the guideline levels for supporting plant life. Boron (0.2 mg/kg) and sulphate (<10 mg/kg) are also lower than desired and may be causing nutrient deficiency.

Extractable metals are quite unbalanced, with copper and zinc at <1.00 mg/kg, and iron much higher than expected in a healthy soil. At 3.21 mg/kg, manganese is the only trace element within the desirable range.

This SMU is characterised by extremely low nutrient levels, exacerbated by limited availability to plant roots caused by the extremely acidic pH throughout the profile. The physical characteristics of this soil, however, are considered suitable in terms of stability.

4.11 NORMANBY SOIL MANAGEMENT UNIT

Soil Unit Description: Deep red earth with soft surface condition, associated with plains, and the flat areas of upper slopes. Textures within this unit are relatively consistent throughout the profile, ranging from loamy sands to sandy light medium clays. Vegetation is mostly cleared, but when present includes *Eucalyptus crebra* and *Alectryon oleifolius.*

Australian Soil Classification: Red Kandosol

Photo Plate 11 Normanby SMU Vegetation

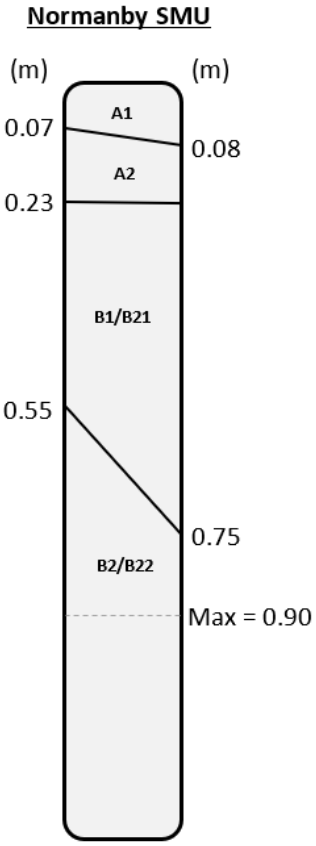

Table 33 Normanby Soil Unit Description

Parameter	Soil Unit Description
Profile Site Numbers	DP48, DP50
Observation Site Numbers	DO208
Landform	Plains and upper slopes
Land System	Melbadale
Slope	2 to 3%
Geology	Duaringa Formation (Tu) – Eocene-Oligocene mudstone, sandstone, conglomerate, siltstone, oil shale, lignite and basalt (iron-rich)
Vegetation	Cleared with *Eucalyptus crebra* and *Alectryon oleifolius.*
Runoff	Slow
Permeability	Moderately to highly permeable

Drainage	Moderately to well drained

Profile Description – Representative Sites: DP48 & DP50

The **surface soil** (A1) is a reddish brown (2.5YR4/4, 5YR4/3) loamy sand to sandy loam, with grainy structure. It has a field pH of 6.0 to 6.5 and a clear or gradual change to;

The **lower surface soil** (A2) is a reddish brown to dark reddish brown (2.5YR3/3, 2.5YR4/3) loamy sand to sandy loam with a grainy/massive structure. It has a field pH of 6.0 to 6.5, and a gradual change to;

The **upper subsoil** (B1/B21) is a red (10R4/6, 2.5YR4/6) loamy sand to sandy loam. It has massive/grainy structure and a pH ranging from 6.0 to 6.5. Gradual change to;

The **lower subsoil** (B2/B22) is a red to dark red (10YR4/6, 2.5YR3/6) sandy loam to sandy light medium clay. It has weak lenticular structure and a field pH ranging from 6.0 to 7.0.

Chemical and Physical Analysis

Table 34 Chemical Properties of the Normanby SMU

Representative site: DP50									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**
	#	**Rate**	**dS/m**	**Rate**	**mg/kg**	**%**	**Rate**		
0-0.1	6.7	Neutral	0.036	Very Low	<10	<0.1	Non-Sodic	6.1	4
0.2-0.3	6.6	Neutral	0.006	Very Low	<10	<0.1	Non-Sodic	1.7	4
0.5-0.6	6.1	Slightly Acid	0.003	Very Low	<10	<0.1	Non-Sodic	1.5	4

Depth (m)	**CEC**		**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**
	meq / 100g	**Rate**	**Ca**	**Mg**	**K**	**Na**	
0-0.1	2.4	Very Low	1.3	0.6	0.4	<0.1	2.2

0.2-0.3	2.1	Very Low	1.4	0.4	0.3	<0.1	3.5
0.5-0.6	1.6	Very Low	0.9	0.5	<0.1	<0.1	1.8
Percentage in Topsoil			54.17%	25.00%	16.67%	4.17%	-

The Normanby soil unit has a neutral to slightly acidic pH throughout the soil profile, decreasing with depth from 6.7 to 6.1. EC is very low throughout the profile, ranging from 0.036 dS/m in the topsoil to 0.003 dS/m in the subsoil. Chloride levels reflect this result, presenting at less than 10 mg/kg at all depths.

CEC measurements are considered very low, ranging from 2.4 meq/100g to 1.6 meq/100g with depth. Exchangeable cation concentrations reflected this result, with calcium, magnesium and potassium concentrations below the desirable level at all depths. The ratios between each cation, however, were appropriate. In addition to this, calcium dominated magnesium at all depths, the Ca/Mg ratio ranging from 2.2 in the topsoil, to 3.5 in the mid-stratum, to 1.8 in the lower subsoil, further reducing the likelihood that this SMU will suffer from dispersion

Of the exchangeable cations, very little was sodium, with ESP values consistently below reportable levels (<0.1%), indicating that the soil is likely to be non-dispersive. This interpretation is supported by the unit's Emerson Class Numbers, which are considered non-dispersive (4) at all depths.

Although this soil is non-dispersive and suitable in terms of pH and salinity, the low levels of exchangeable cations limit the soil in terms of its ability to provide a suitable medium for plant growth. In addition to this, the high sand content within this SMU puts it at risk of slumping if the slope angle is too high.

Table 35 Surface Soil (0-10 cm) Properties of the Normanby SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
1	83	9	7	4	10.3	<10	1.1
Extractable Nutrients (mg/kg)				**Extractable Metals (mg/kg)**			
P	**K**	**B**		**Cu**	**Fe**	**Mn**	**Zn**
6	275	<0.2		<1.00	29.1	13.0	<1.00

The surface soil (A1) for the Normanby unit is dominated by sand (83%) with 9% silt, 7% clay and 1% gravel. It had a grainy structure, and a soft surface condition. The topsoil is non-sodic, with a Ca/Mg ratio of 2.2, and an organic matter content of 1.1%. This information, paired with the topsoil's Emerson Class Number of 4, suggests that the surface soil is unlikely to become dispersive when wetted. The red colour of the soil indicates that drainage and permeability are both highly active in this soil unit.

Nutrient levels within this soil are generally low. Nitrate concentration is within the acceptable bounds at 10.3 mg/kg, as is potassium at 275 mg/kg. Phosphorous, boron and sulphate, however, are all below the desirable level, potentially causing nutrient deficiency. Extractable metal concentrations vary in their suitability, with copper and zinc below reportable levels, and iron and manganese within the appropriate range for plant life.

The limited nutrient holding capacity of this soil can be attributed to its low clay content and low organic matter levels.

4.12 WALLACE SOIL MANAGEMENT UNIT

Soil Unit Description: Shallow, self-mulching, cracking clay associated with upper slope flats. Textures within this unit grade from medium heavy clays to heavy clays, with the B3/C horizon met at approximately 0.24 m depth. The Wallace SMU is extensively cleared, with the boundary of the unit corresponding to an increase in standing vegetation. The dominant grass species is likely *Aristida latifolia*, with confirmation required during the wet season when an accurate identification can be made.

Australian Soil Classification: Black Vertosol.

Profile Description – Representative Sites: DP4

Wallace SMU

The **surface soil** (A) is a very dark brown (7.5YR2.5/2) medium heavy clay with weak lenticular structure and a pH of 6.5. Gradual change to;

The **subsoil** (B2) is a very dark brown (7.5YR2.5/2) heavy clay with moderate sub-angular blocky structure. It has a small amount (<2%) of sub-angular coarse fragments, and a field pH of 6.5. Clear change to;

The **parent material** (C) is a dark grey (7.5YR4/1) rocky material of sedimentary origin, with a field pH of 6.5.

Chemical and Physical Analysis

Table 37 Chemical Properties of the Wallace SMU

Representative site: DP4									
Depth (m)	**pH**		**EC**		**Cl**	**ESP%**		**Moisture (%)**	**Emerson Class No.**
	#	**Rate**	**dS/m**	**Rate**	**mg/kg**	**%**	**Rate**		
0-0.1	6.8	Neutral	0.09	Low	30	0.3	Non-sodic	5.4	3
0.2-0.3	7.4	Slightly alkaline	0.038	Very Low	10	0.6	Non-sodic	13.8	4
Depth (m)	**CEC**			**Exchangeable Cations (meq/100g)**				**Ca/Mg Ratio**	
	meq / 100g		**Rate**	**Ca**	**Mg**	**K**	**Na**		
0-0.1	39		High	18.7	18.3	1.8	0.1	1.0	
0.2-0.3	44		Very high	27.3	16.1	0.3	0.3	1.7	
Percentage in Topsoil				47.95%	46.92%	4.62%	0.30%	-	

The Wallace SMU is a well-rounded soil unit, which would be appropriate for an agricultural land use, but for its shallow soil depth. Soil pH ranges from 6.8 in the topsoil (neutral) to 7.4 in the subsoil (slightly alkaline). Salinity in this soil is not a concern, with EC ranging from low (0.09 dS/m) to very low (0.038 dS/m), with chloride well below toxic levels.

The high clay content and organic matter in this soil is associated with an elevated CEC, ranging from high in the topsoil (39 meq/100g) to very high in the subsoil (44 meq/100g). This has resulted in relatively high concentrations of available cations, dominated by calcium (18.7 to 27.3 meq/100g) and magnesium (18.3 to 16.1 meq/100g), with suitable levels of potassium (1.8 to 0.3 meq/100g). Calcium was present in higher quantities than magnesium at all depths, with the Ca/Mg ratio ranging from 1.0 to 1.7. This reduces the likelihood of any dispersive tendencies within the soil.

ESP is extremely low and considered non-sodic throughout the profile, ranging from 0.3% to 0.6%, meaning that this soil in unlikely to become dispersive upon wetting. Emerson Class numbers support this fact, ranging from 3 in the surface soil (dispersive if physically disturbed) to 4 in the subsoil (non-dispersive).

Water-holding capacity appears to increase with depth and clay content, as evidenced by the increase in moisture % with depth seen in Table 37.

Table 38 Surface Soil (0-10 cm) Properties of the Wallace SMU

Particle Size Analysis %				Emerson Class No.	Nitrate (mg/kg)	Sulphate (mg/kg)	Organic Matter (%)
Gravel	Sand	Silt	Clay				
4	14	52	30	3	6.6	10	4.1
Extractable Nutrients (mg/kg)				Extractable Metals (mg/kg)			
P	K	B		Cu	Fe	Mn	Zn
169	652	0.5		1.61	63.4	53.4	1.02

The surface soil (A) for the Wallace SMU is dominated by silt sized particles (52%), with 30% clay, 14% sand, and 4% gravel. It has a weak lenticular structure, and a fine, self-mulching surface. The topsoil is non-sodic, with a Ca/Mg ratio of 1.0, and an organic matter content of 4.1%. This information paired with the soil's Emerson Class Number of 3, suggests that is will remain non-dispersive unless physically disturbed. This potential dispersion is likely influenced by the relatively low Ca/Mg ratio of the topsoil unit.

Nutrient levels in this topsoil are generally good. Nitrate (6.6 mg/kg) was outside of the acceptable bounds for agriculture, though phosphorous (169 mg/kg), potassium (652 mg/kg), boron (0.5 mg/kg) and sulphate (10 mg/kg) were well within the desired concentrations. For the extractable metals, only zinc (1.02 mg/kg) was found to be at an appropriate level, with copper (1.61 mg/kg) lower than desired, and iron (63.4 mg/kg) and manganese (53.4 mg/kg) higher than necessary.

High clay content, low sodicity, and desirable nutrient concentrations make this unit one of the best growth mediums in the survey area. This fact is observable in the field as the SMU area supports a healthy sward of highly palatable grass species that are rare or absent in most other SMUs. The shallow soil depth and low nitrate concentration are both limiting factors for agricultural use of this soil, though as grazing land it is highly suitable.

5.0 LAND SUITABILITY

The aim of this land suitability assessment is to evaluate the suitability of the Project for agricultural land uses including cattle grazing and dryland cropping, prior to the development of the mine. Land suitability assessment considers environmental factors including climate, soils, geology, geomorphology, erosion, topography and the effects of past land use. The classification does not always represent the current land use. Rather, it indicates the potential of the land to be used for a range of agricultural activities.

The assessment for land suitability (cattle grazing and dryland cropping) has been carried out in accordance with the methodologies described in:

- DSITI & DNRM (2015). *Guidelines for Agricultural Land Evaluation in Queensland* (2nd edition). Queensland Government, Brisbane, Queensland; and
- DSITI & DNRM (2013). *Regional Land Suitability Frameworks for Queensland*, Chapter 10 – Suitability Framework for the Inland Fitzroy and Southern Burdekin area. Queensland Government. Brisbane, Queensland.

The five land suitability classes used for assessing the land are defined in Table 39. Land is considered less suitable as the severity of limitations for a land use increase. The land suitability class reflects the score of the most limiting attribute for a given SMU. An increase in limitations may reflect either:

- Reduced potential for production; and/or
- Increased inputs to achieve and acceptable level of production;
- Increased inputs to prepare the land for successful production; and/or
- Increased inputs required to prevent land degradation.

Table 39 Agricultural and Conservation Land Classes

Agricultural Land Class	Type	Description
Class 1	Agricultural	**Suitable land** with negligible limitations. This is highly productive land requiring only simple management practices to maintain economic production.
Class 2	Agricultural	**Suitable land** with minor limitations which either reduce production or require more than the simple management practices of class 1 land to maintain economic production.
Class 3	Agricultural	**Suitable land** with moderate limitations which either further lower production or require more than those management practices of class 2 land to maintain economic production.
Class 4	Agricultural	**Marginal land**, which is presently considered unsuitable due to severe limitations. The long-term significance of these limitations on the proposed land use is unknown or not quantified. The use of this land is dependent upon undertaking additional studies to determine whether the effect of the limitation(s) can be reduced to achieve sustained economic production.
Class 5	Agricultural	**Unsuitable land** with extreme limitations that preclude its use.

Key: green shading suitable
red shading unsuitable

5.1 CATTLE GRAZING

Limitations for the assessment of grazing land suitability on improved pastures as outlined in the *Land Suitability Assessment Technique* (DME 1995) Guidelines (Table 2.2 and 2.3) are:

- Water availability;
- Nutrient deficiency;
- Soil physical factors;
- Salinity;
- Rockiness;
- Micro relief;
- pH;
- ESP;
- Wetness;
- Topography;
- Water erosion;
- Flooding; and
- Vegetation

Numerous parameters outlined in this assessment require calculation of the 'rootzone'. The rootzone is the depth to hard or weathered rock, or the depth to a significant salt bulge within the soil profile. A depth of 0.6 m has been assumed as the rootzone for any profile in which weathered rock, and/or a salt bulge was absent as outlined in the guidelines (DME 1995).

Class 1 and **class 2** land is considered suitable for grazing improved pastures with maximum grazing productivity achieved in most seasons. **Class 3** land is considered suitable for grazing improved pastures however it is less productive than **Classes 1** and **2**. **Class 4** land is categorised as marginal for grazing improved pastures although it is largely considered suitable for grazing native pastures of variable quality. **Class 5** land is unsuitable for any form of pasture improvement and is limited to low productivity grazing of native pastures. Due to the poor soil quality **Class 5** land may require destocking in poor seasons.

5.1.1 Water Availability

Plant available water capacity (PAWC) for each soil management unit was calculated with reference to Table 2.3 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995). PAWC cut-off levels for each of the land suitability classes are as follows:

Class 1: >125 mm

Class 2: 100-125 mm

Class 3: 75-100 mm

Class 4: 50-75 mm

Class 5: <50 mm

These cut-off levels are not based on a specific species of pasture, but on pasture as a general land use. The soils are assessed on the depth to weathered rock, or other root inhibiting factor such as a salt bulge or significant sodicity. The availability of water in soils is vital for both plants and soil organisms as they require water to survive.

Table 40 Plant Available Water Capacity

Soil Management Unit	Limiting Features	PAWC (mm)	Land Suitability Class
Anderson	Gradational earth reaching 75-125 cm depth with no weathered rock/salt bulge (no rock/salt layer reached at 97cm).	100-125	2
Barry	Gradational earths reaching >125 cm depth with no weathered rock/salt layer (no rock/salt layer reached at 105 cm – alluvial units typically deep and non-sodic).	125-150	1
Charlevue	Gradational earth reaching 50-75 cm depth with no weathered rock/salt layer (EC >0.9 dS/m or Cl >900 mg/kg) (max core depth 70 cm).	75-100	3
Cooinda	Gradational earth reaching 50-75cm depth with no weathered rock/salt layer (EC >0.9 dS/m or Cl >900 mg/kg) (max core depth 60 cm).	75-100	3
Ellesmere	Gradational earth reaching 75-125cm depth with no weathered rock/salt layer (EC >0.9 dS/m or Cl >900 mg/kg) (max core depth 60 cm).	100-125	2
Geoffrey	Sands and sandy loams 45-90 cm deep	75-100	3
James	Gradational earths reaching 75-125 cm depth with no weathered rock/salt layer (EC >0.9 dS/m or Cl >900 mg/kg) (max core depth 85 cm).	100-125	2
Kosh	Non-cracking clay reaching 75-125 cm depth with no weathered rock/salt layer (EC >0.9 dS/m or Cl >900 mg/kg) (max core depth 85 cm).	100-125	2
Namoi	Non-cracking clay reaching 75-125cm depth with no weathered rock/salt layer (EC >0.9 dS/m or Cl >900 mg/kg) (max core depth 70cm).	100-125	2
Nigel	Clayey sands with 75-125 cm depth to weathered rock (parent material at 76 cm).	100-125	2
Normanby	Loamy sands >90 cm deep.	75-100	3
Wallace	Cracking clays with alkaline pH, and 20-40 cm depth to weathered or hard rock.	75-100	3

Key: > greater than

5.1.2 Nutrient Deficiency

The nutrient status of each Soil Management Unit identified has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995). The land suitability classes identified for each Soil Management Unit are presented in Table 41. Note that bicarbonate P was only analysed within the topsoil layer (0-10 cm). Soil nutrients are vital for plant and animal growth and metabolism.

Table 41 Land Suitability Classes for Cattle Grazing based on Nutrient Status

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Eucalypt vegetation and downs with bicarbonate P >10 mg/kg.	2
Barry	Eucalypt vegetation and downs with bicarbonate P >10 mg/kg.	2
Charlevue	Eucalypt vegetation and downs with bicarbonate P >10 mg/kg.	2
Cooinda	Eucalypt vegetation and downs with bicarbonate P >10 mg/kg.	2
Ellesmere	Other soils with Bicarbonate P 5-10 mg/kg.	3
Geoffrey	Other soils with Bicarbonate P 5-10 mg/kg.	3
James	Eucalypt vegetation and downs with bicarbonate P >10 mg/kg.	2
Kosh	Eucalypt vegetation and downs with bicarbonate P >10 mg/kg.	2
Namoi	Other soils with Bicarbonate P 5-10 mg/kg.	3
Nigel	Soil overlying rock at shallow depth, with bicarbonate P 5-10 mg/kg.	4
Normanby	Sands and loams at least 0.75 m deep with bicarbonate P 5-10 ppm.	4
Wallace	Former scrub soils with bicarbonate P >10 mg/kg.	1

Key: ppm parts per million

5.1.3 Soil Physical Factors

Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995) has been used to assess the physical factors of each Soil Management Unit identified. Results are presented in Table 42. The physical condition of soils plays a direct role with seed germination and emergence. Adverse conditions such as hard setting or crusting of surface soils reduces plant establishment through creating a barrier, reducing seed soil contact.

Table 42 Land Suitability Classes for Cattle Grazing based on Soil Physical Factors

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Rigid soils with a hard setting surface when dry	2
Barry	Rigid soils with a hard setting surface when dry	2
Charlevue	Rigid soils with a hard setting surface when dry	2
Cooinda	Rigid soils with a hard setting surface when dry	2
Ellesmere	Rigid soils with a hard setting surface when dry	2
Geoffrey	Rigid soils with a loose, soft or firm surface when dry.	1
James	Rigid soils with a hard setting surface when dry	2
Kosh	Rigid soils with a hard setting surface when dry	2
Namoi	Rigid soils with a hard setting surface when dry	2

Soil Management Unit	Limiting Features	Land Suitability Class
Nigel	Rigid soils with a hard setting surface when dry	2
Normanby	Rigid soils with a loose, soft or firm surface when dry.	1
Wallace	Cracking clays with coarse peds (>10 mm)	3

5.1.4 Salinity

Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995) has been used to determine the land suitability class against salinity parameters. Given salinity can inhibit plant growth; the highest EC recorded is considered the most limiting factor and dictates the rating given to each Soil Management Unit. The results are provided in Table 43. Significant levels of salinity present in the rootzone can negatively impact plant growth and production.

Table 43 Land Suitability Classes for Cattle Grazing based on Salinity

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Barry	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Charlevue	Rootzone EC 0.15-0.3 mS/cm, and rootzone Cl 300-600 mg/kg	2
Cooinda	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Ellesmere	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Geoffrey	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
James	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Kosh	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Namoi	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Nigel	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Normanby	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1
Wallace	Rootzone EC <0.15 mS/cm, Rootzone Cl <300 ppm	1

5.1.5 Rockiness

The land suitability for each Soil Management Unit based on rockiness was assessed in regard to Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995). Results are presented in Table 44. The impacts of rockiness are more extreme for cropping than for grazing. In regard to grazing, rock outcrops reduce the area available to grow pasture, indirectly impacting the carrying capacity of the land.

Table 44 Land Suitability Classes for Cattle Grazing

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	<20% course surface gravel and rock outcrop	1
Barry	<20% course surface gravel and rock outcrop	1
Charlevue	<20% course surface gravel and rock outcrop	1
Cooinda	<20% course surface gravel and rock outcrop	1
Ellesmere	<20% course surface gravel and rock outcrop	1
Geoffrey	<20% course surface gravel and rock outcrop	1
James	20 to 50% course surface gravel and rock outcrop	2
Kosh	<20% course surface gravel and rock outcrop	1
Namoi	<20% course surface gravel and rock outcrop	1
Nigel	<20% course surface gravel and rock outcrop	1
Normanby	<20% course surface gravel and rock outcrop	1
Wallace	<20% course surface gravel and rock outcrop	1

5.1.6 Microrelief

The microrelief for each Soil Management Unit identified has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995), presented in Table 45. Microrelief refers to local relief (up to several metres) around the plane of the land (NCST 2009). Impacts of microrelief on the suitability of land for cattle grazing are only experienced when soil is severely melon holed. Ponding of water in the depressions can reduce pasture yield, indirectly impacting the land's carrying capacity.

Table 45 Land Suitability Classes for Cattle Grazing based on microrelief

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Melon holes cover <20% surface area	1
Barry	Melon holes cover <20% surface area	1
Charlevue	Melon holes cover <20% surface area	1
Cooinda	Melon holes cover <20% surface area	1
Ellesmere	Melon holes cover <20% surface area	1
Geoffrey	Melon holes cover <20% surface area	1
James	Melon holes cover <20% surface area	1
Kosh	Melon holes cover <20% surface area	1
Namoi	Melon holes cover <20% surface area	1
Nigel	Melon holes cover <20% surface area	1
Normanby	Melon holes cover <20% surface area	1
Wallace	Melon holes cover <20% surface area	1

5.1.7 pH

The land suitability class for pH has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995), and presented in Table 46. Soil pH determines the availability of nutrients for plant intake. Where the soil material is strongly acidic, problems with aluminium and manganese toxicity may occur, limiting root growth and plant productivity. Strongly acidic soils may require input of lime or dolomite to increase soil pH. Strongly alkaline soils will restrict the availability of some elements (Fe, Cu, Zn) and may be an indicator of sodicity. Ameliorates may be added to the soil to correct pH and increase nutrient availability.

Table 46 Land Suitability Classes for Cattle Grazing based on pH

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	pH 4.5-5.0	3
Barry	pH 6.6-8.0	2
Charlevue	pH 5.6-6.6	1
Cooinda	pH 5.6-6.6	1
Ellesmere	pH 4.5-5.0	3
Geoffrey	pH 5.6-6.6	1
James	pH 5.6-6.6	1
Kosh	pH 6.6-8.0	2
Namoi	pH 5.6-6.6	1
Nigel	pH 4.5-5.0	3
Normanby	pH 5.6-6.6	1
Wallace	pH 6.6-8.0	2

5.1.8 Exchangeable Sodium Percentage (ESP)

The ESP of each Soil Management Unit identified has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995). ESP is used to determine the erosion potential of soils. The land suitability class identified for each Soil Management Unit based on ESP in the upper 100 mm of soil is presented in Table 47.

Table 47 Land Suitability Classes for Cattle Grazing based on ESP

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	ESP (10 cm) <5%	1
Barry	ESP (10 cm) <5%	1
Charlevue	ESP (10 cm) 15-30%	4
Cooinda	ESP (10 cm) <5%	1
Ellesmere	ESP (10 cm) <5%	1
Geoffrey	ESP (10 cm) <5%	1
James	ESP (10 cm) <5%	1

Soil Management Unit	Limiting Features	Land Suitability Class
Kosh	ESP (10 cm) <5%	1
Namoi	ESP (10 cm) <5%	1
Nigel	ESP (10 cm) <5%	1
Normanby	ESP (10 cm) <5%	1
Wallace	ESP (10 cm) <5%	1

5.1.9 Wetness

The land suitability class identified for each Soil Management Unit based on wetness has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995), and is presented in Table 48. The wetness limitation refers to any excess water both in or on the soil profile. The adverse effects of excess water include reducing plant growth, impeding oxygen supply to plant roots (possibly leading to denitrification) and increased risk of plant disease.

Table 48 Land Suitability Classes for Cattle Grazing based on Wetness

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Elevated plains	1
Barry	Undulating terrain	1
Charlevue	Rigid soils with strongly sodic subsoil (ESP≥15) within 60 cm of the surface	2
Cooinda	Elevated plains	1
Ellesmere	Undulating terrain	1
Geoffrey	Undulating terrain	1
James	Undulating terrain	1
Kosh	Rigid soils with strongly sodic subsoil (ESP≥15) within 60 cm of the surface	2
Namoi	Elevated plains	1
Nigel	Elevated plains	1
Normanby	Elevated plains	1
Wallace	Elevated plains	1

5.1.10 Water Erosion

The land suitability class identified for each Soil Management Unit based on water erosion has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995), and presented in Table 49. Erosion of topsoil reduces the productivity of the land through the loss of key nutrients in the soil's upper horizons.

Table 49 Land Suitability Classes for Cattle Grazing based on Water Erosion

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Slopes 3-12% on non-sodic rigid soils	2
Barry	Slopes <3% on non-sodic rigid soils	1
Charlevue	Slopes 1-3% on sodic rigid soils	2
Cooinda	Slopes <3% on non-sodic rigid soils	1
Ellesmere	Slopes 3-12% on non-sodic rigid soils	2
Geoffrey	Slopes 3-12% on non-sodic rigid soils	2
James	Slopes 3-12% on non-sodic rigid soils	2
Kosh	Slopes 3-12% on non-sodic rigid soils	2
Namoi	Slopes 3-12% on non-sodic rigid soils	2
Nigel	Slopes 3-12% on non-sodic rigid soils	2
Normanby	Slopes <3% on non-sodic rigid soils	1
Wallace	Slopes <3% on non-sodic rigid soils	1

5.1.11 Flooding

The land suitability class identified for each Soil Management Unit based on flooding risk has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995), and is presented in Table 50. Flooding may result in plant death or reduced growth. In severe cases were land is inundated for a prolonged period stock loss and loss of grazing production may also occur.

Table 50 Land Suitability Classes for Cattle Grazing based on Flooding

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	No flooding	1
Barry	Periodic flooding	2
Charlevue	No flooding	1
Cooinda	No flooding	1
Ellesmere	No flooding	1
Geoffrey	Periodic flooding	2
James	No flooding	1
Kosh	Periodic flooding	2
Namoi	No flooding	1
Nigel	No flooding	1
Normanby	No flooding	1
Wallace	No flooding	1

5.1.12 Vegetation Regrowth (management limitation)

The land suitability class identified for each Soil Management Unit based on vegetation regrowth has been assessed against Table 2.2 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995), and is presented in Table 51. Vegetation communities may contain poisonous species or woody weeds that will limit the productivity of grazing pastures to varying degrees and increase the need for land management. The density of tree species and presence of a woody shrub layer may also limit the carrying capacity of the land.

Table 51 Land Suitability Classes for Cattle Grazing based on Vegetation

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Eucalypt woodlands with wattle understorey	4
Barry	Mountain coolabah and ironbark open woodlands	1
Charlevue	Box and ironbark woodlands without wattle understorey	2
Cooinda	Box woodlands without wattle understorey	2
Ellesmere	Acacia scrub without melonholes	1
Geoffrey	Bloodwood and ironbark open woodlands	1
James	Box and ironbark woodlands with wattle understorey	4
Kosh	Box and ironbark woodlands without wattle understorey (cleared)	2
Namoi	Ironbark open woodlands	1
Nigel	Acacia scrub without melonholes	1
Normanby	Ironbark open woodlands	1
Wallace	(cleared)	-

5.1.13 Summary of Land suitability for Cattle Grazing

Table 52 Summary of Land Suitability Limitations for Cattle Grazing

Limitation	Anderson	Barry	Charlevue	Cooinda	Ellesmere	Geoffrey	James	Kosh	Namoi	Nigel	Normanby	Wallace

Key: green shading suitable
red shading unsuitable

On the Project, the suitability of land for cattle grazing is most limited by nutrient deficiency, ESP, and vegetation. Low nutrient levels and high sodicity in the soils may limit livestock production through a reduction in pasture growth and nutritive value of pasture species. Vegetation regrowth species can also impact the suitability of the land if they contain woody or poisonous species. In addition to this, high density regrowth and a woody shrub layer may reduce the carrying capacity of the land, making it unsuitable for grazing.

While no Class 1 land was identified for the Project, examination of the land suitability limitations for cattle grazing (Table 52) indicate 1084.1 ha of the Project is suitable for cattle grazing with minor limitations (Class 2), while 4338 ha is suitable for cattle grazing with moderate limitations (Class 3). The remaining area (750.8 ha) was comprised of Class 4 land, with no Class 5 land identified.

SMUs Barry and Kosh are classified as Class 2 land which is suitable for cattle grazing with minor limitations. In most seasons, younger cattle on Class 2 land will perform well, with minimal inputs required (e.g. fertiliser, land preparation or maintenance) to achieve a weight grade similar to cattle raised on Class 1 land. Land graded as Class 3 (SMUs Cooinda, Ellesmere, Geoffrey, Namoi and Wallace) may require some inputs to achieve this same weight grade, with emphasis on remediating nutrient deficiency and hard setting soil surfaces.

SMUs Anderson, Charlevue, James, Nigel and Normanby are classified as Class 4 land, which is considered suitable for improved pastures (though with severe limitations). Class 4 land will generally require significant inputs in the form of fertiliser or land management, which may not be justified given the limited benefits this land can offer. Given changes to knowledge, economics or technology this land could be sustainably managed, though does not currently hold significant economic value for improved pastures. These areas may be suitable for grazing native pastures of variable quality, though would likely have a reduced output when compared with land Classes 1, 2 and 3.

Figure 7 shows the distribution of land suitability classes for cattle grazing across the Project.

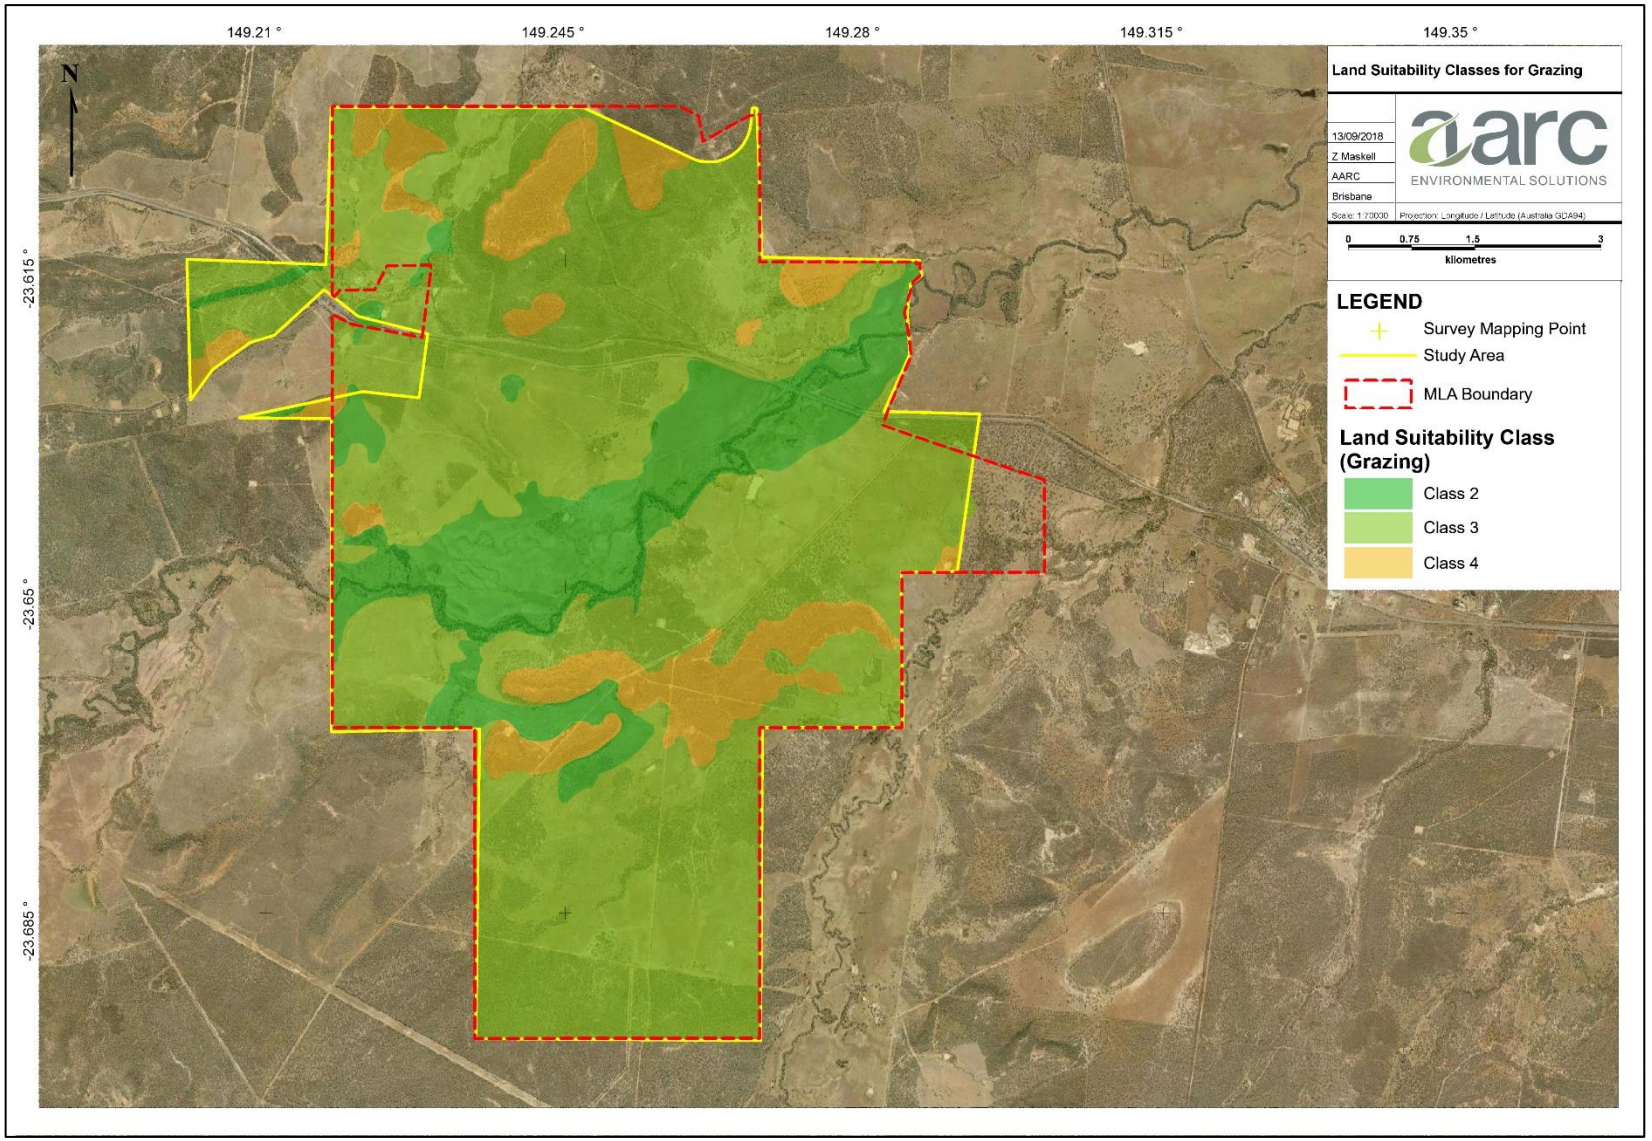

Figure 7 Cattle Grazing Land Suitability Classes

5.2 DRYLAND CROPPING

The Project lies within the Inland Fitzroy and Southern Burdekin area. Limitations for the assessment of dryland cropping suitability are specific to the Projects region and include:

- Water Erosion;
- Erosion hazard, subsoil erodibility;
- Soil water availability;
- Narrow moisture range;
- Surface conditions;
- Rockiness;
- Microrelief; and
- Wetness.

Several of these limitations contain subclasses based on the varying land management practices required for different crops. This suitability assessment will present findings based on the lowest land suitability rating returned across all of the suitability subclasses.

Assessment of the SMUs suitability for dryland cropping has been conducted in accordance with the methodology described within the *Guidelines for Agricultural Land Evaluation in Queensland* (DSITIA & DNRM 2015) and the *Regional Land Suitability Frameworks for Queensland* – Chapter 10 (DSITIA & DNRM 2013). The Suitability framework for the Inland Fitzroy and Southern Burdekin area focusses on assessing the potential for cultivating twelve specific crops including:

- Barley;
- Chickpea;
- Maize;
- Millet;
- Mungbean;
- Oats;
- Safflower;
- Sorghum;
- Soybean;
- Sunflower;
- Triticale; and
- Wheat.

Numerous parameters outlined in this assessment require calculation of the 'rootzone'. The rootzone is the depth to hard or weathered rock, or the depth to a significant salt bulge within the soil profile. A depth of 0.6 m has been assumed as the rootzone for any profile in which weathered rock, and/or a salt bulge was absent as outlined in the guidelines (DME 1995).

5.2.1 Water Erosion

The land suitability class identified for each SMU based on water erosion was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table E, and is presented in Table 53. Dispersive properties were allocated based on Emerson Class Number and sodicity for each SMU. Erosion of topsoil reduces the productivity of the land through the loss of key nutrients in the soil's upper horizons.

Table 53 Land Suitability Classes for Dryland Cropping based on Water Erosion

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Slopes of 5-8% with non-dispersive weakly coherent soil in the surface 200 mm	4
Barry	Slope of 1-3% with non-dispersive weakly coherent soil in the surface 200 mm	3
Charlevue	Slope of 1-3% with dispersive soil in the surface 200 mm	5
Cooinda	Slope of 1-3% with non-dispersive weakly coherent soil in the surface 200 mm	3

Soil Management Unit	Limiting Features	Land Suitability Class
Ellesmere	Slope of 3-5% with non-dispersive weakly coherent soil in the surface 200 mm	4
Geoffrey	Slopes of 3-5% with non-dispersive moderate to strongly coherent soil in the surface 200 mm	3
James	Slopes of 5-8% with non-dispersive moderate to strongly coherent soil in the surface 200 mm	3
Kosh	Slope of 1-3% with non-dispersive moderate to strongly coherent soil in the surface 200 mm	2
Namoi	Slopes of 3-5% with non-dispersive weakly coherent soil in the surface 200 mm	4
Nigel	Slopes of 3-5% with non-dispersive moderate to strongly coherent soil in the surface 200 mm	3
Normanby	1-3% with non-dispersive moderate to strongly coherent soil in the surface 200 mm	2
Wallace	Slopes of 0.5-1% with non-dispersive weakly coherent soil in the surface 200 mm	2

5.2.2 Erosion hazard, Subsoil Erodibility

The land suitability class identified for each Soil Management Unit based on erosion hazard and subsoil erodibility was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table Es, and is presented in Table 54. Subsoil was assessed based on soils ESP, EC, CEC and Ca/Mg ratio. Soils with high ESP and low EC have a tendency to disperse (DME 1995). Low Ca/Mg ratios also indicate dispersive properties of soil. CEC is required to interpreting the ESP value as the lower the CEC value, the less significant the role of the ESP.

Table 54 Land Suitability Classes for Dryland Cropping based on Erosion Hazard and Subsoil Erodibility

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Slopes of 5-8% with no subsoil (200-1000 mm) dispersion	3
Barry	Slope of 1-3% with low to moderate dispersive subsoil (200-1000 mm) and clay content greater than 20%	3
Charlevue	Slope of 1-3% with strongly dispersive subsoil (200-1000 mm) on 2 or more tests and clay content greater than 20%	4
Cooinda	Slope of 1-3% with low to moderate dispersive subsoil (200-1000 mm) and clay content greater than 20%	3
Ellesmere	Slope of 3-5% with strongly dispersive subsoil (200-1000 mm) on 2 or more tests and clay content greater than 20%	5
Geoffrey	Slopes of 3-5% with strongly dispersive subsoil (200-1000 mm) on 2 or more tests and clay content greater than 20%	5
James	Slopes of 5-8% with no subsoil (200-1000 mm) dispersion	3
Kosh	Slope of 1-3% with strongly dispersive subsoil (200-1000 mm) on 2 or more tests and clay content greater than 20%	4
Namoi	Slopes of 3-5% with low to moderate dispersive subsoil (200-1000 mm) and clay content greater than 20%	3
Nigel	Slopes of 3-5% with no subsoil (200-1000 mm) dispersion	3
Normanby	1-3% with no subsoil (200-1000 mm) dispersion	1
Wallace	Slopes of 0.5-1% with no subsoil (200-1000 mm) dispersion	1

5.2.3 Soil Water Availability

The land suitability class identified for each Soil Management Unit based on soil water availability was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table M, and is presented in Table 55. PAWC values were estimated with reference to Table 2.3 of the *Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland – Land Suitability Assessment Techniques* (DME 1995). These cut-off levels are not based on a particular cropping species, but on cropping as a general land use. The soils are assessed on the depth to weathered rock, or other root inhibiting factors such as a salt bulge or significant sodicity. PAWC cut-off levels for each of the land suitability classes are as follows:

Class 1: >125 mm

Class 2: 100-125 mm

Class 3: 75-100 mm

Class 4: 50-75 mm

Class 5: <50 mm

These values were used to delegate land suitability classes for different groups of crop species, as outlined in *Regional Land Suitability Frameworks for Queensland* - Chapter 10, Table M.

Table 55 Land Suitability Classes for Dryland Cropping based on Soil Water Availability

Soil Management Unit	PAWC (mm)	Land Suitability Class (Group A)	Land Suitability Class (Group B)	Land Suitability Class (Group C)
Anderson	100-125	3	3	4
Barry	125-150	2	2	3
Charlevue	75-100	3	4	5
Cooinda	75-100	3	4	5
Ellesmere	100-125	3	3	4
Geoffrey	75-100	3	4	5
James	100-125	3	3	4
Kosh	100-125	3	3	4
Namoi	100-125	3	3	4
Nigel	100-125	3	3	4
Normanby	100-125	3	3	4
Wallace	75-100	3	4	5

5.2.4 Narrow Moisture Range

The land suitability class identified for each SMU based on narrow moisture range was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table Pm, and is presented in Table 56. The narrow moisture range of a soil plays a role in determining the soil's capacity for cultivation within the restraints of machinery.

Table 56 Land Suitability Classes for Dryland Cropping based on Narrow Moisture Range

Soil Management Unit	Limiting Features	Land Suitability Class
Anderson	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting when dry and not 'spewy' when wet.	3
Barry	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting when dry and not 'spewy' when wet. Hard setting pedal clays.	3
Charlevue	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting when dry and not 'spewy' when wet. Hard setting pedal clays.	3
Cooinda	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting when dry and not 'spewy' when wet. Hard setting pedal clays.	3
Ellesmere	Moderate moisture range for cultivation – moderately well drained to rapidly drained; predominantly hard setting when dry and not 'spewy' when wet. Moderately well drained hard setting loamy surfaced soils.	2
Geoffrey	Wide moisture range for cultivation – moderately well drained to rapidly drained; not hard setting when dry and not 'spewy' (i.e. boggy) when wet. Deep sands and thick sandy surfaced texture contrast soils	1
James	Moderate moisture range for cultivation – moderately well drained to rapidly drained; predominantly hard setting when dry and not 'spewy' when wet. Moderately well drained hard setting loamy surfaced soils.	2
Kosh	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting when dry and not 'spewy' when wet. Hard setting pedal clays.	3
Namoi	Moderate moisture range for cultivation – moderately well drained to rapidly drained; predominantly hard setting when dry and not 'spewy' when wet. Moderately well drained hard setting loamy surfaced soils.	2
Nigel	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting when dry and 'spewy' when wet. Loamy surfaced (less than 0.4 m).	3
Normanby	Moderate moisture range for cultivation – moderately well drained to rapidly drained; not hard setting when dry and not 'spewy' when wet. Well drained earths.	2
Wallace	Narrow moisture range for cultivation – imperfectly drained to moderately well drained; hard setting, firm or weakly self-mulching when dry and not 'spewy' when wet. Hard setting or weakly self-mulching, pedal clays.	3

5.2.5 Surface Condition

The land suitability class identified for each SMU based on surface condition was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table Ps, and is presented Table 57. The physical condition of soils plays a direct role with seed germination and emergence. Adverse conditions such as hard setting or crusting of surface soils reduces plant establishment through creating a barrier, reducing seed soil contact.

Table 57 Land Suitability Classes for Dryland Cropping based on Surface Condition

Soil Management Unit	Limiting Features	Land Suitability Class

Anderson	Loamy, fine sand, silty or clayey surface soils that are hard setting, massive or crusting.	4
Barry	Clay soils with hard setting, firm pedal or weakly self-mulching surface horizons.	3
Charlevue	Clay soils with hard setting, firm pedal or weakly self-mulching surface horizons.	3
Cooinda	Clay soils with hard setting, firm pedal or weakly self-mulching surface horizons.	3
Ellesmere	Soils with soft, firm or only weakly hard setting, sandy to loamy surface horizons	2
Geoffrey	Soils with soft, firm or only weakly hard setting, sandy to sandy loam surface horizons	2
James	Clay soils with hard setting, firm pedal or weakly self-mulching surface horizons.	3
Kosh	Loamy, fine sand, silty or clayey surface soils that are hard setting, massive or crusting.	4
Namoi	Clay soils with hard setting, firm pedal or weakly self-mulching surface horizons.	3
Nigel	Loamy, fine sand, silty or clayey surface soils that are hard setting, massive or crusting.	4
Normanby	Soils with soft or loose sandy to sandy loam surface horizons	1
Wallace	Coarse self-mulching clays (peds greater than 5–10 mm); poor seed soil contact due to separation of large peds with drying	3

5.2.6 Rockiness

The land suitability class identified for each SMU based on rockiness was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table R, and is presented in Table 58. Rocky outcrops and soils containing coarse fragments hinder cultivation of crops and may damage harvesting machinery.

Table 58 Land Suitability Classes for Dryland Cropping based on Rockiness

Soil Management Unit	Limiting Features	Land Suitability Class (Group A)	Land Suitability Class (Group B)
Anderson	Gravels less than 20 mm and abundance less than 10%	1	1
Barry	Gravels less than 20 mm and abundance less than 10%	1	1
Charlevue	Gravels less than 20 mm and abundance less than 10%	1	1
Cooinda	Gravels less than 20 mm and abundance less than 10%	1	1
Ellesmere	Gravels less than 20 mm and abundance less than 10%	1	1
Geoffrey	Gravels less than 20 mm and abundance less than 10%	1	1
James	Gravels less than 20 mm and abundance 20-50%	2	3
Kosh	Gravels less than 20 mm and abundance less than 10%	1	1
Namoi	Gravels less than 20 mm and abundance less than 10%	1	1
Nigel	Gravels less than 20 mm and abundance less than 10%	1	1

Soil Management Unit	Limiting Features	Land Suitability Class (Group A)	Land Suitability Class (Group B)
Normanby	Gravels less than 20 mm and abundance less than 10%	1	1
Wallace	Gravels less than 20 mm and abundance less than 10%	1	1

5.2.7 Microrelief

The land suitability class identified for each SMU based on microrelief was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table Tm, and is presented in Table 59. Suitability classes for microrelief are based on the degree to which land needs to be levelled for dryland cropping.

Table 59 Land Suitability Classes for Dryland Cropping based on Microrelief

Soil Management Unit	Limiting Features	Land Suitability Class (Group A)
Anderson	No microrelief across the majority (greater than 70%) of the land surface	1
Barry	No microrelief across the majority (greater than 70%) of the land surface	1
Charlevue	No microrelief across the majority (greater than 70%) of the land surface	1
Cooinda	No microrelief across the majority (greater than 70%) of the land surface	1
Ellesmere	No microrelief across the majority (greater than 70%) of the land surface	1
Geoffrey	No microrelief across the majority (greater than 70%) of the land surface	1
James	No microrelief across the majority (greater than 70%) of the land surface	1
Kosh	No microrelief across the majority (greater than 70%) of the land surface	1
Namoi	No microrelief across the majority (greater than 70%) of the land surface	1
Nigel	No microrelief across the majority (greater than 70%) of the land surface	1
Normanby	No microrelief across the majority (greater than 70%) of the land surface	1
Wallace	No microrelief across the majority (greater than 70%) of the land surface	1

5.2.8 Wetness

The land suitability class identified for each Soil Management Unit based on wetness was determined using the *Regional Land Suitability Frameworks for Queensland* – Chapter 10, Table W, and is presented in Table 60. Soil that becomes waterlogged due to poor permeability and drainage may reduce plant growth, oxygen supply to roots and cause plants to become more susceptible to disease.

Table 60 Land Suitability Classed for Dryland Cropping based on Wetness

Soil Management	Limiting Features	Land Suitability Class (Group A)	Land Suitability Class (Group B)	Land Suitability Class (Group C)

Unit				
Anderson	Moderately well drained and moderately permeable	1	1	2
Barry	Moderately well drained and highly permeable	1	1	2
Charlevue	Poorly drained	5	5	5
Cooinda	Imperfectly drained and slowly permeable	4	4	4
Ellesmere	Moderately well drained and slowly permeable	2	2	2
Geoffrey	Imperfectly drained and slowly permeable	4	4	4
James	Moderately well drained and moderately permeable	1	1	2
Kosh	Poorly drained	5	5	5
Namoi	Moderately well drained and slowly permeable	2	2	2
Nigel	Poorly drained	5	5	5
Normanby	Moderately well drained and highly permeable	1	1	2
Wallace	Moderately well drained and moderately permeable	1	1	2

5.2.9 Summary of Land Suitability for Dryland Cropping

Key: green shading suitable
red shading unsuitable

Land suitability for dryland cropping on the Project is most limited by soil water availability, soil wetness, erosion, and surface condition. Plants require suitable quantities of water to reach optimum production, and therefore maximum rooting depth, with the ability of the soil to take in water (wetness) playing a large part in crop survival. Topsoil and subsoil erosion also limit the ability of the soil to support crops. Soil preparation for sowing in the form of tillage may increase the risk of soil dispersion through slaking caused by the manipulation of soil aggregates by machinery. Surface condition also limits the soil classes, with hard setting soils found across most SMUs. Surface condition directly impacts seedling emergence and establishment by reducing seed-soil contact.

In Central Queensland, Class 1, 2 and 3 lands for dryland cropping are required to have the capacity to store sufficient levels of moisture to sustain a crop cycle from planting to harvesting with minimal rainfall. Class 4 lands are considered marginal for dryland cropping, requiring significant levels of rainfall for crop success. Class 5 lands are unsuitable for dryland cropping due to severe limitations.

Examination of the land suitability limitations for dryland cropping (Table 61) indicates that 156.5 ha of the Project is suitable for cropping with moderate limitations (Class 3), and 409.1 ha of land is marginally suitable for cropping (Class 4). The remaining 5607 ha of land is unsuitable (Class 5) due to land and soil limitations.

Only the Barry SMU is classified as Class 3, presenting soil characteristics suitable for cropping with moderate limitations. Although listed above as Class 3, it is not genuinely expected that this landform would be suitable for dryland cropping on the Project site. This is due to its presence being limited to a narrow corridor along associated with Charlevue Creek.

SMUs Anderson, James, Namoi, and Normanby are listed as Class 4 and therefore marginally suitable for broadacre cropping. The major limitations for these SMUs are associated with soil water availability, erosion, wetness and surface condition.

SMUs Charlevue, Cooinda, Ellesmere, Geoffrey, Kosh, Nigel, and Wallace are classified as Class 5 land which is considered unsuitable for broadacre cropping. This is due to their vulnerability to subsoil erodibility, the soil water holding capacity, and the impact these limitations would have on potential crops.

Figure 8 shows the distribution of land suitability classes for broadacre cropping across the Project.

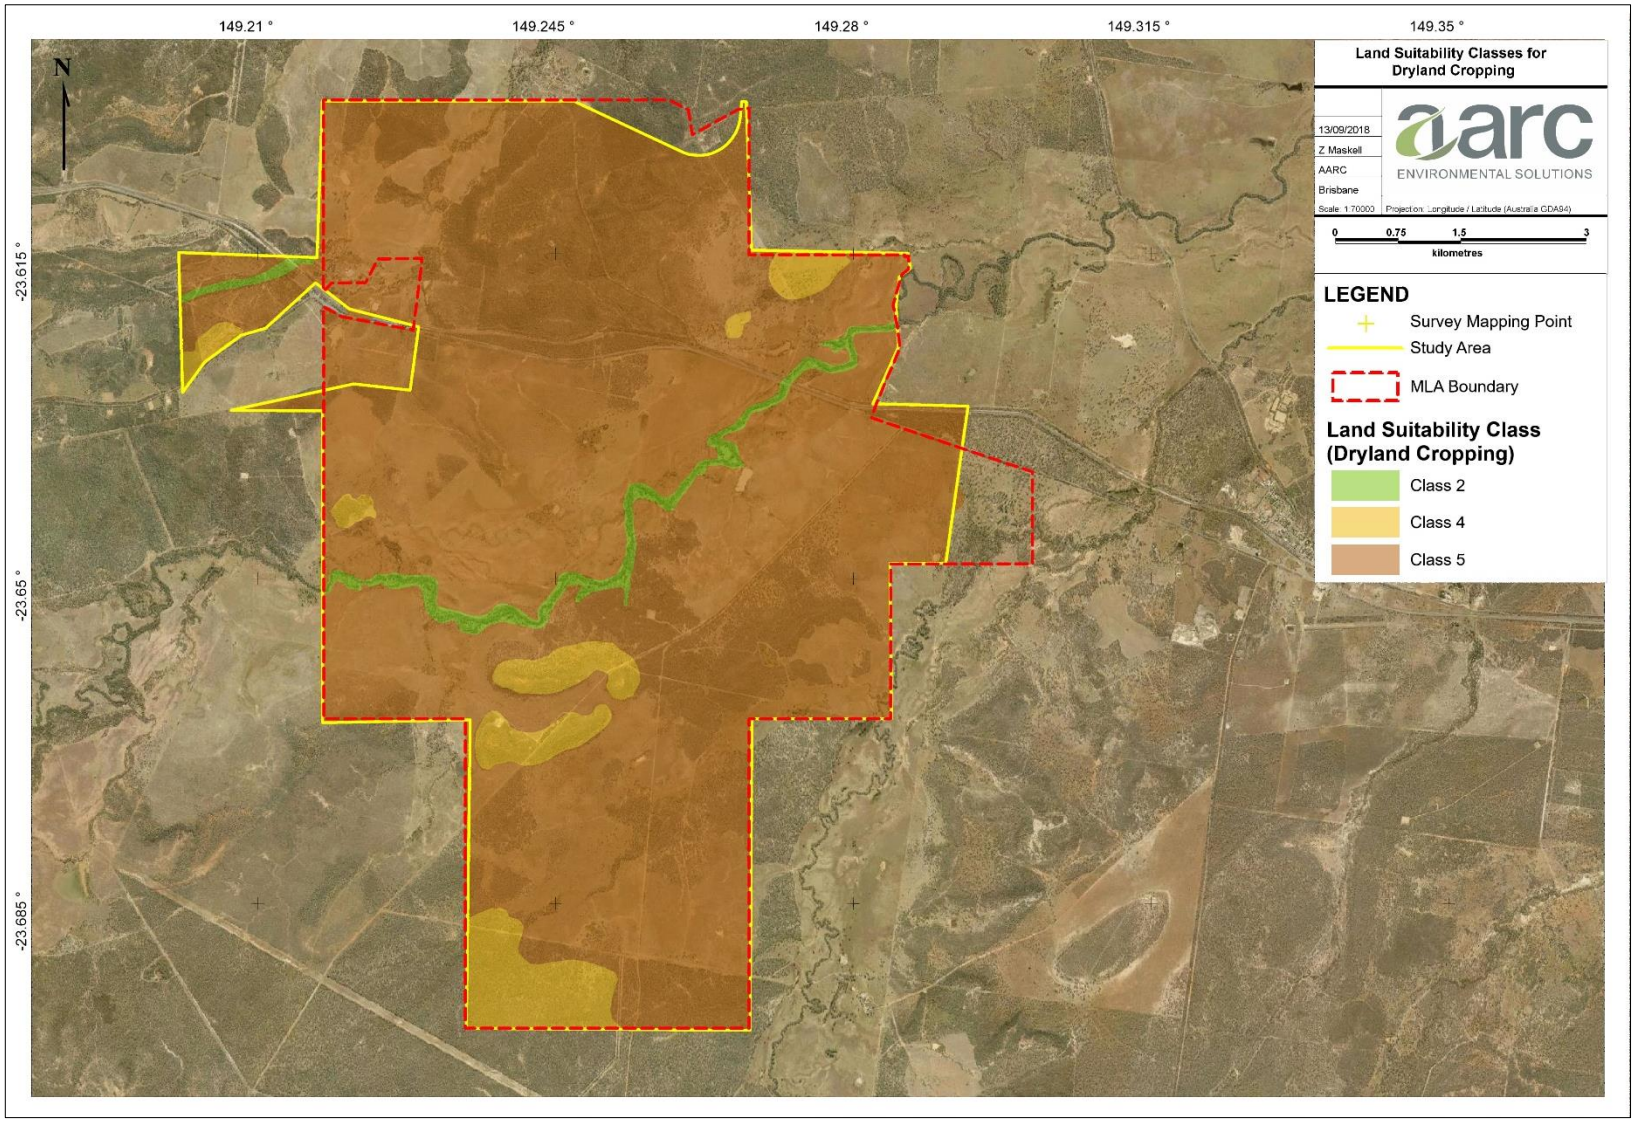

Figure 8 Dryland Cropping Land Suitability Classes

6.0 SOIL HANDLING RECOMMENDATIONS

6.1 TOPSOIL SUITABILITY AND STRIPPING

Useable soil resources are mainly confined to the surface horizons, with the upper part of the surface horizons containing seedstock, micro-organisms, and nutrients necessary for plant growth. Soil microbial activity, organic matter, and other parameters affecting soil fertility, generally decrease with depth. The following section lists a suitable topsoil stripping depth for each SMU and the maximum depth to which suitable subsoil material may be stripped for stockpiling and future rehabilitation. Stripping recommendations were determined based on SMU characteristics and the presence of inherent limitations (such as pH, salinity and sodicity).

Generally, stripping should be timed to occur in conjunction with favourable climatic conditions to reduce compaction and erosion issues. Stripping should generally occur in a single stage, however, where stripping depths exceed 0.30 m it is recommended that two-stage stripping methods are employed to reduce mixing between topsoil and subsoils. Where possible, topsoil will be directly placed in prepared rehabilitation areas and used immediately rather than stockpiled.

Table 62 summarises the maximum recommended depths to which each SMU should be stripped, a detailed discussion of each unit's stripping depth is outlined in the following sections.

Table 62 Maximum Topsoil Stripping Depths for all Soil Management Units

SMU	Topsoil Stripping Depth (m)	Maximum Subsoil Stripping Depth (m)
Anderson	0.0	0.0
Barry	0.2	0.9
Charlevue	0.0	0.0
Cooinda	0.3	0.6*
Ellesmere	0.0	0.0
Geoffrey	0.3	0.5*
James	0.3	0.6
Kosh	0.2	0.5*
Namoi	0.2	0.6*
Nigel	0.0	0.0
Normanby	0.3	0.9*
Wallace	Surface → C Horizon	-

Note: Stripping depths with as asterisk (*) may require nutrient supplements or soil ameliorants for successful use in rehabilitation.

Anderson Soil Management Unit **(Stripping Depth 0.0 m)**

The Anderson SMU is unsuitable for rehabilitation use. This soil is very strongly acid at the surface (pH 4.6) remaining so with depth, where it increases slightly to 4.8. pH values such as these would restrict plant growth and productivity, by reducing the availability of plant nutrients and causing root damage. The addition of lime would neutralise the acidic pH, though this SMU would require vast amounts to accommodate healthy plant growth. The cost of such an exercise would be high, and therefore this SMU is not recommended for use during rehabilitation.

Barry Soil Management Unit **(Stripping Depth 0.9 m)**

The Barry SMU presents no chemical limitations to stripping in the top 0.9 m of the profile. CEC is moderate to low throughout the profile, and exchangeable sodium is below critical values at all depths. The pH ranges from slightly acid to neutral, with Ca/Mg ratios >1.0 in all horizons (further reducing risk of dispersion). Although deficient in nitrate and sulphate (which could be applied as a fertiliser or foliar spray), this soil contains adequate concentrations of most macro and micronutrients. Organic matter is also above 2%. Overall, this SMU is considered a good soil resource for rehabilitation. It is however, associated with Charlevue Creek – a major waterway within the Project. Disturbance of this soil type should be avoided where possible, with the exception of required road crossings where erosion should be closely managed in the disturbed landform.

Charlevue Soil Management Unit **(Stripping Depth 0.0 m)**

The Charlevue SMU has severe chemical limitations that prevent it from becoming an adequate soil resource. pH for this unit is strongly acid in the topsoil (5.4), and though this increases to moderately alkaline with depth (7.9), mixing the horizons to make it usable would be a futile effort, due to the sodicity of the soil. The unit has strongly sodic soil at all depths, ranging from 15.1 to 29.4%. This paired with very low Ca/Mg ratios has resulted in a soil that is prone to dispersion, particularly below 0.2 m where the Emerson Class Number changes from 4, to 2, to 1. The evidence shows that the soil is in fact non-dispersive in the topsoil horizon, though this is where pH is most acidic (and therefore unusable).

The soil could be improved through the use of lime, which would increase the pH and replace some of the sodium with calcium (reducing ESP), but this would be a costly procedure. In addition to this, the unit is low in nutrients, and fertilisers would also need to be added to make it a viable soil resource. It is recommended that this soil should not be utilised in rehabilitation.

Cooinda Soil Management Unit **(Stripping Depth 0.6 m)**

The Cooinda SMU has some limitations in terms of its usability as a soil resource. The pH ranges from moderately acid in the surface soil (5.6 to 5.7) to neutral in the subsoil (6.8). Sodicity also changes from non-sodic (0.9 to 2.1%) in the topsoil, to sodic (10.9%) in the subsoil layer. The actual concentration of sodium in the subsoil layer is quite low (1.1%), though sodicity is presented as high due to the low CEC, giving an Emerson Class number of 3 (dispersive if disturbed) for all layers. Adequate mixing of the A and B horizons from 0.0 to 0.6 m could balance out these inconsistencies in pH and sodicity, creating a soil that is a better growth medium. In addition to this, nutrient levels for this SMU are particularly low. The addition of fertiliser would benefit this soil greatly. Any ameliorated soils should be tested for pH, sodicity, and nutrient content before use.

Ellesmere Soil Management Unit **(Stripping Depth 0.0 m)**

The Ellesmere SMU has severe chemical limitations in terms of pH, which ranges from very strongly acid in the surface soil (4.6) to strongly acid in the lower subsoil (5.5). pH levels such as these will

reduce the availability of some plant nutrients, and increase the toxicity of other elements to plants. This could be amended through the addition of liming agents, though the pH is so low that uneconomic quantities would be required to remediate the problem. In addition to this, nutrient levels are so low in this unit that the incorporation of fertilizers is not likely to be economically viable. This SMU should not be utilised as a soil resource in rehabilitation.

Geoffrey Soil Management Unit **(Stripping Depth 0.5 m)**

The Geoffrey SMU is the largest soil unit within the mapping area. Comprised of deep sands overlying sodic, dispersive clays (Emerson Class of 1), this soil is prone to erosion if subsoils are exposed. In addition to this, nutrient levels in the sandier horizons are somewhat limited in terms of their capacity to support plant life.

Topsoil stripping should aim to segregate the A and B horizons of this soil unit, which are easily distinguishable to trained operators. Where possible, stockpiling of the B horizon should be avoided (i.e. directly placed), or closely managed, due to the dispersive nature of the subsoil.

Due to the sandy nature of the A horizons, it is recommended that soil horizons in the natural landscape are restored during rehabilitation. The clay rich subsoils should be placed first on the rehabilitated landform, followed by the sandy A horizon over the top to recreate the A and B horizons. Placement of the subsoil layer is expected to retain soil moisture necessary for successful revegetation.

Furthermore, it is recommended that where possible this SMU is used in flatter areas of the final landform to limit potential erosion issues.

James Soil Management Unit **(Stripping Depth 0.6 m)**

This SMU presents no chemical limitations to stripping in the top 0.6 m of the profile. CEC is very low throughout the profile, and ESP is classified as non-sodic at all depths. The pH is slightly acid, though should not present a problem for plant establishment. Although the Ca/Mg ratio is >1.0 until 0.5 m, as the sodicity is so low, this should not enhance dispersion. As nutrient availability is quite limited, this SMU would benefit from the addition of fertilisers or foliar applications.

Kosh Soil Management Unit **(Stripping Depth 0.5 m)**

The Kosh SMU is one of the larger soil units in the study area, and given its size, the best unit for grazing cattle. It presents a challenge due to the ESP unit, which although non-sodic in the topsoil (0.6%), becomes strongly sodic (19.5%) and erosive in the subsoil horizon. Paired with a reduction in Ca/Mg ratios, the subsoil is likely to become highly dispersive at depth. If utilised in rehabilitation, care will need to be taken to ensure that only the top 0.5 m of soil is stripped for reuse. In addition to this, this SMU could benefit from the addition of fertilisers, particularly those containing NPK. The addition of organic matter (potentially sourced from mulched vegetation removed prior to stripping) would act in increasing the CEC and water holding capacity of the soil.

Left undisturbed, this SMU remains the best area for grazing cattle within the Project. It also presents a significant challenge in stripping, and removing soils. Where possible, it should be left undisturbed.

Namoi Soil Management Unit **(Stripping Depth 0.6 m)**

The Namoi SMU has chemical limitations related to soil pH, which fluctuates from slightly acid (6.1) to strongly acid (5.5) throughout the soil profile. However, it is non-dispersive, and therefore may benefit from mixing with other soil units and/or the addition of lime to reduce pH. Adding lime to this soil would

also assist in improving the Ca/Mg ratio of the soil, encouraging increased plant growth. Topsoil could also benefit from the addition of fertiliser.

Nigel Soil Management Unit **(Stripping Depth 0.0 m)**

The Nigel SMU is not recommended to be used in rehabilitation, due to severe limitations related to soil pH. The surface horizon is extremely acidic (4.4), becoming very strongly acidic with depth (4.6). Values such as these are likely to decrease the availability of nutrients to plants, and damage plant roots. Although pH may be amended using liming agents, the size of this unit paired with the cost of such a venture makes the use of lime unsuitable for this unit. The Nigel SMU also has low nutrient levels, and is not considered suitable for use in rehabilitation.

Normanby Soil Management Unit **(Stripping Depth 0.9 m)**

The Normanby SMU has no chemical limitations in terms of stripping and rehabilitation. pH in the surface soil is neutral, and although it becomes slightly acidic at 0.5 m depth, the subsoil is still considered within the suitable range for plant life. Salinity is not an issue in this soil, with EC and chloride values both exceedingly low. Dispersion is also not a likely risk in this SMU, which has non-sodic sandy loams extending to great depths in the profile. Nutrient content in this soil however, is generally low, and the soil may be augmented with fertilisers if used in rehabilitation. In addition to this, the high sand content in this soil means that rehabilitated surfaces should not exceed a 3% slope, to reduce the risk of slumping.

Wallace Soil Management Unit **(Stripping Depth Surface → C Horizon)**

The Wallace SMU is a high-quality soil with excellent potential as a topdressing medium. pH ranges from neutral (6.8) to slightly alkaline (7.4), salinity and sodicity are low, and exchangeable cations are within suitable limits for plant growth. Nutrient content is also quite robust, particularly the unit's NPK concentrations. The main limiting factor for this soil is the shallow depth, which was 0.2 m at the sampled location for this SMU. At this depth, the solum grades abruptly into pale grey parent material (C horizon). Identification of this demarcation is easy due to the stark contrast in colour between the black clay soil and the underlying parent material. As the depth to the C horizon may vary slightly across this unit, the stripping depth of 0.2 m may be an underestimate. Stripping depths are better defined within this SMU as the depth of media that exists above the C horizon, rather than a static depth.

The Wallace SMU would be an excellent resource to use when improving the quality of topsoil within other units, by mixing this material with others that may have limited nutrient/water holding capacity or nutrient content (such as those seen in the Geoffrey SMU).

6.2 TOPSOIL STOCKPILING

Stockpiling of topsoil for extended periods can lead to physiochemical changes in the soil and impact on the viability of the soil seed bank. Management recommendations to reduce the risk of soil degradation and improve the chances of rehabilitation success include the following:

- Where possible, topsoil should be directly placed in prepared rehabilitation areas rather than stockpiled. This will assist in maintaining a viable seedbank and will promote revegetation, thus, reducing potential for erosion;

- Topsoil should also be planted over as soon as possible after being placed in prepared rehabilitation areas. This will assist in preventing erosion of the topsoil, and making the best use of the soil's available nutrients;

- If soil is stored, stockpiles should generally be less than 2 m high and be contoured and positioned to encourage water to drain, and discourage erosion;

- If the stockpiles require grass cover, they will need to be ripped and seeded with a quick establishment pasture, to limit erosion, and maintain a viable seed bank. This should be done if the period of stockpiling is greater than one growing season or six months. Topsoil should ideally be stockpiled for the minimum time, with studies in the Hunter Valley having shown that the majority of deterioration occurs in the first year (Keipert et al. 2005). Establishment of weeds on the stockpiles will also need to be monitored and controlled;

- Where soil has been stockpiled for extended periods, soil testing is recommended. If required, fertilizers, soil ameliorants, and seeding is recommended.

Table 63 shows the estimated volumes of soil per SMU for the whole Project area, given the stripping depths outlined in section 6.1, and areas listed in section 4.0.

Table 63 Estimated Soil Volumes

SMU	Topsoil Stripping Depth (m)	Maximum Subsoil Stripping Depth (m)	SMU Area (m^2)	Potential Topsoil Volume (m^3)	Potential Subsoil Volume (m^3)
Anderson	0.0	0.0	377,800	0	0
Barry	0.2	0.9	1,565,000	313,000	1,095,500
Charlevue	0.0	0.0	2,329,000	0	0
Cooinda	0.3	0.6	349,400	104,820	104,820
Ellesmere	0.0	0.0	145,900	0	0
Geoffrey	0.3	0.5	40,790,000	12,237,000	8,158,000
James	0.3	0.6	1,452,000	435,600	435,600
Kosh	0.2	0.5	9,276,480	1,855,296	2,782,944
Namoi	0.2	0.6	1,758,000	351,600	703,200
Nigel	0.0	0.0	2,864,180	0	0
Normanby	0.3	0.9	484,960	145,488	290,976
Wallace	Minimum 0.2 (Surface → C Horizon)	-	320,400	64,080	-

Key: m^2 metres squared
M^3 metres cubed

6.3 TOPSOIL PLACEMENT

Where possible, placement of topsoil at a thickness of approximately 0.3 m is recommended across the rehabilitated area to create a growth medium of sufficient depth to hold water and support revegetation. If available, subsoils that have been identified as having a high clay content with low erosivity risk can be returned first at a depth of up to 0.5 m, prior to the addition of sandier topsoil. This may assist in providing a more suitable growth medium that holds water for long periods of time.

It is recommended that topsoil is deep ripped, into the underlying spoil surface, to encourage surface water infiltration and minimise soil loss due to erosions. On slopes of spoil dumps, ripping should be undertaken along the contour.

For the Geoffrey SMU, it is recommended that soil horizons in the natural landscape are restored during rehabilitation. The clay rich subsoils should be placed first on the rehabilitated landform, followed by the sandy A horizon over the top to recreate the A and B horizons. Placement of the subsoil layer is expected to retain soil moisture necessary for successful revegetation.

Grass and woody vegetation remaining after land clearing can be incorporated into the rehabilitation design at strategic locations to help limit runoff/erosion (by slowing down overland flow), retain active biological activity, and provide habitat for returning fauna. Additionally, mulched organic material incorporated into the soil (particularly the topsoil) will increase organic carbon levels over time, further stabilising the soil and landscape.

7.0 POTENTIAL IMPACTS AND MANAGEMENT

7.1 LAND SUITABILITY

The development of the Project will disturb land through the construction of infrastructure and operation of the mine. This disturbance will impact the land suitability of the Project throughout the life of the mine and after its closure. Pre-mining land suitability classes were outlined in Section 5.0 and are summarised below in Table 64.

Table 64 Summary of the Size and Suitability Classes for all SMUs

SMU	Land Suitability Class (Grazing)	Land Suitability Class (Cropping)	Total Area (ha)
Anderson	4	4	37.8
Barry	2	3	156.5
Charlevue	4	5	232.9
Cooinda	3	5	34.9
Ellesmere	3	5	14.6
Geoffrey	3	5	4,079
James	4	4	145.2
Kosh	2	5	927.6
Namoi	3	4	177.6
Nigel	4	5	286.4
Normanby	4	4	48.5
Wallace	3	5	32

Key: green shading suitable
red unsuitable

The majority of areas in the final landform will aim to restore a post-mining land use of grazing. The exceptions being water management features such as ponds and drains, which will be returned to a land use of native ecosystems or equivalent. This includes the final pit lake and high walls, that will be restored to achieve a fauna habitat land use. These areas are expected to be unsuitable for grazing and will achieve a reduced land suitability score of 5.

It should be noted that mining activities, including the stripping, stockpiling, handling, and compaction of soil, have the potential to impact its physical, chemical and biological properties. Therefore, the pre-mining land suitability for cattle grazing may be reduced for some rehabilitated landforms. Many of the potential impacts on soil can be mitigated through:

- Good topsoil management practices (See Section 6.0);
- The addition of fertilizers and soil ameliorants; and
- Timely seeding with suitable species.

Where the final landforms represent a relatively flat landscape (e.g. slopes less than 5%) it is envisaged that the post-mining land suitability for cattle grazing will generally reflect that of the pre-mining landscape.

Other areas, such as steeper outer slopes of spoil (e.g. slopes of greater than 10%) may be subject to erosion and as such may be less suited to cattle grazing than the pre-mining landscape. A reduced land suitability score is expected on these landforms.

Landform depressions that perennially hold surface water are expected on the rehabilitated spoil dump. These can act as dams for cattle grazing and can assist in trapping water within the surrounding growth medium. These areas typically do not support pasture species, with wetland flora usually established. As such, a reduction in land suitability for cattle grazing is also expected in these surface depressions.

7.2 EROSION

Disturbance of vegetation and the topsoil layer can lead to the mobilisation of soil through the process of erosion, particularly water erosion through heavy rainfall or overland flow. The risk of erosion at the Project will be increased by the following activities:

- Clearing of vegetation;
- Topsoil stripping and stockpiling;
- Construction of infrastructure; and
- Exposure of slopes.

Management recommendations to reduce the risk and impacts of erosion include:

- Limiting land clearing to the minimum amount of land required for safe operation of the Project;
- Diversion of overland flow/runoff around disturbed areas;
- Progressive rehabilitation of landforms and direct placement of topsoil to help preserve the seed bank and reduce erosion;
- Seeding of topsoil as soon as possible after placement onto rehabilitated areas, to ensure root masses assist in preventing erosion;
- Topsoil stockpiles should be placed away from drainage areas, roads, machinery, transport corridors, and stock grazing areas;
- Topsoil stockpiles should be seeded or covered with a water-shedding lining to prevent unnecessary erosion of soil; and
- The use of sediment control structures such as retention ponds, to minimise the release of water and suspended sediments into the receiving environment.

7.3 EROSION OF REHABILITED LANDFORMS

Erosion of rehabilitated landforms reduces the likelihood of revegetation success, and in extreme cases can compromise the structural integrity of the landform, making it unstable and unsafe. In addition, if not managed correctly, erosion can result in the release of suspended sediments and potential contaminants into the receiving environment.

SMUs within the Project have some dispersive characteristics, and will be potentially subject to erosion, particularly on artificial slopes. The rehabilitated landform design for the Project should consider implementing controls to manage surface runoff on final landform slopes. Such controls include:

- Limiting side slopes of spoil to a maximum slope of 1V:6H (vertical : horizontal) (approximately 16%) or less;
- Construction of contour banks on slopes at a recommended spacing of 80 m for slopes of 1V:6H (MCA 1998). Larger contour drains are generally more stable and longer lasting. It is recommended that drains/berms are a minimum of 5 m wide and a minimum of 500 mm in height. However, construction of larger contours is encouraged. Berms should be constructed of compacted material (IE Aust Erosion and Sediment Control Guidelines(Witheridge et al. 1996));
- Contour banks should convey water to engineered rock-lined spine drains on steep slopes. The size of the rock used should be approximately 300 to 450 mm in diameter. A competent basalt or alternative rock source is recommended. The use of geofabric in construction of rock lined spine drains is also recommended;
- To reduce the need for engineered drains, landform modelling should be centred around gentle concave slopes or terraced profiles. For some materials, designs such as these can significantly reduce runoff velocity and erosion by a magnitude of two or three times, however, the approach can be difficult to implement where space is a limiting factor;
- The incorporation of rock into the topsoil medium can also assist in reducing erodibility, as well as increasing infiltration (Alt et al. 2009); and
- Rehabilitated areas should be ripped to reduce compaction from heavy machinery, encourage infiltration of water and prevent erosion. If engineered waterways are included in the landform, areas should be ripped on a grade (e.g. 0.5%). Otherwise, areas should be ripped on the contour. Ripping depths will vary depending on the type of spoil material, depth of topsoil and equipment used for rehabilitation operations. Typical ripping depths would be 500 to1000 mm.

7.4 SOIL DEGRADATION

Stripping, stockpiling and handling of topsoil can potentially have a negative impact on the chemical and physical attributes of the soil. Specifically, the following impacts may occur as a result of mining activities:

- Exposure of saline or sodic subsoils during soil stripping;
- Loss of soil physical structure due to excavation and handling;
- Loss of the soil seedbank; and
- Impacts on soil fertility due to mixing with subsoils, or resulting from changes in chemistry when subsoils are exposed to oxygen.

Physiochemical changes to the soil may impact on the viability of the soil seed bank and reduce the likelihood of successful rehabilitation if not well managed. Management recommendations to reduce the risk of soil degradation and improve the chances of rehabilitation success include:

- Segregation of saline or sodic soils and clear demarcation of stockpiles to ensure appropriate use of the resource;

- Minimising the handling of topsoil;

- Ensuring that when required, stockpiles are generally less than 2 m high and contoured to encourage water to drain; and

- Carrying out routine testing of soil properties prior to use in rehabilitation. If required, fertilizers, soil ameliorants, and application of a seed mix is recommended to increase the likelihood of rehabilitation success.

Appendix B Soil Profile Data

Project Name: Dingo Soils

[Site Description]

Date:	20/06/2018		**Site:**	DP1	
Location:	Atkinson		**Coordinates:**	E 0731029	N 7377997
Landform Pattern:	Plain		**Micro Relief:**	-	
Landform Element:	Plain		**Rock Outcrops:**	-	
Morphological Type:	Flat		**S C Fragments:**	-	
Site Disturbance:	3		**Substrate:**	Sandstone/mudstone	
Erosion:	Stable		**Surface Condition:**	Firm	
Landform	Elevation:	160	**Permeability:**	1	
	Slope (%):	2	**Drainage:**	2	
	Relief:		**Run-off:**	2	

[Geoffrey]

[Soil Description]

Horizon	Depth (cm)	Boundary	Colour	Mottles	Texture	Coarse Fragments	Structure	Segregations	Consistency	Field pH	
A1	0-10	D	10YR6/3 (D) 10YR4/3 (W)	-	FLS	-	V	-	D2	5	6
A2E	10-60	A	10YR7/2 (D) 10YR5/3 (W)	-	FLS	-	G	-	D1	30	6
B2	60-90		10YR5/2	FO3	FSMC	-	M4LE	-	D5	60	6.5
										90	7.5

Vegetation: E. tesselaris, C. clarksoniana, E. crebra, A. rhodoxylon

Notes: Springwood/Luxoc? B2 grey matrix with orange mottles. Elevation? Refer to topo map.

Project Name: Dingo Soils

[Site Description]

Date:	21/06/2018		**Site:**	DP2	
Location:	Atkinson		**Coordinates:**	E 0729295	N 7378337

B2	55-70		5YR5/8	2FR1	LMC	12SM	MPO	-	D4	60	6.5

Vegetation: E. crebra (D), A. rhodoxylon, H. contortus

Notes: B2 – brown orange matrix

Project Name: Dingo Soils

[Site Description]

Date:	21/06/2018		**Site:**	DP4	
Location:	Atkinson		**Coordinates:**	E 0730098	N 7380449
Landform Pattern:	Rise		**Micro Relief:**	**Small cracks (shrink swell)**	
Landform Element:	Hill slope		**Rock Outcrops:**	**-**	
Morphological Type:	Upper slope		**S C Fragments:**	**-**	
Site Disturbance:	4		**Substrate:**	**Q. alluvium**	
Erosion:	Stable		**Surface Condition:**	**M**	
Landform	Elevation:	135	**Permeability:**	**3**	
	Slope (%):	1	**Drainage:**	**4**	
	Relief:		**Run-off:**	**2**	

[Wallace]

[Soil Description]

Horizon	Depth (cm)	Boundary	Colour	Mottles	Texture	Coarse Fragments	Structure	Segregations	Consistency	Field pH	
A	0-5	D	7.5YR2.5/2	-	MHC	-	W4LE	-	D5	3	6.5
B2	5-24	C	7.5YR2.5/2	-	HC	11SMS	M5SB	-	D5	15	6.5
C	24-50		7.5YR4/1	-	-			-	D6	35	6.5

Vegetation: Cleared, one grass species (A. latifolia)

Notes: Substrate not likely rock, but tertiary sediments. Slickensides in B2. Shrink swell clay forms small cracks across surface.

Project Name: Dingo Soils

[Geoffrey – shallow phase]

[Soil Description]

Horizon	Depth (cm)	Boundary	Colour	Mottles	Texture	Coarse Fragments	Structure	Segregations	Consistency	Field pH	
A1	0-11	D	7.5YR3/2	-	SL	-	V	-	D1	5	5.5
A2	11-19	C	10YR3/3	-	SL	-	W2AB	-	D2	15	5.5
B2	19-45	C	10YR5/2	M3DOC	SLC	-	W2LE	-	D3	30	5.5
B3	45-55		10YR5/3	M3DOC	SLC	32SM	V	-	D4	50	5.5

Vegetation: A. rhodoxylon and E. crebra

Notes: Soil increases down slope. Quartzite and redder soils up hill. Looks like shallow phase Geoffrey?

Project Name: Dingo Soils

[Site Description]

Date:	22/06/2018		**Site:**	DP10	
Location:	Atkinson		**Coordinates:**	E 0732219	N 7382129
Landform Pattern:	Plain		**Micro Relief:**	-	
Landform Element:	Plain		**Rock Outcrops:**	-

1.0 INTRODUCTION

AARC Environmental Solutions Pty Ltd (AARC) was commissioned by Magnetic South Pty Ltd (Magnetic South) to prepare an Environmental Offset Strategy for the Gemini Project (the Project). The Project is located approximately 110 km east of Emerald and 125 km west of Rockhampton in the Bowen Basin of Central Queensland, and within the Central Highlands Regional Council Local Government Area (LGA) (Figure 1).

The Project lies within Mining Lease Application (MLA) 700056, which falls within Exploration Permit Coal (EPC) 881. The Project is a greenfield, open-cut metallurgical coal mine, producing Pulverised Coal Injection (PCI) coal and coking coal for export for steel production. Existing local and regional infrastructure, facilities and services are proposed to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

The proponent is in the process of preparing an Environmental Authority (EA) under the *Environmental Protection Act 1994* (EP Act). This application was accepted on 23 October 2019 by the administering authority. This Offset Strategy has been developed in response to an Information Request (IR) received 31 January 2020. Prior to this, an *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) referral (2010/5775) was lodged in 2010 for the Project, which was declared 'Not a Controlled Action if undertaken in a Particular Manner' in July 2011.

An initial assessment of the terrestrial and aquatic ecological values was conducted within EPC 881 (herein referred to as the study area) by AARC in 2019. The *Terrestrial Ecology Assessment Report* and the *Aquatic Ecology Assessment Report* (AARC 2020a & 2020b) assessed the environmental values and potential impacts of the Project to ecological values including matters of state environmental significance (MSES). The findings of these studies have been used to inform this Environmental Offset Strategy; in particular:

- Vegetation mapping and community description;
- Likelihood of occurrence assessment for flora and fauna species of conservation significance;
- Habitat mapping for conservation significant species and communities;
- Detailed assessment of the ecological condition and value of waterways, wetlands and Groundwater Dependant Ecosystems (GDE);
- Impact assessments for MSES; and
- Offset requirements for impacted MSES.

1.1 PURPOSE

The purpose of this Environmental Offset Strategy is to outline the Project's environmental offset requirements under the applicable offset framework. The Environmental Offset Strategy includes:

- a summary of environmental offset requirements for the Project (Section 3.0); and
- proposed offset delivery mechanisms including staging (Section 4.0).

1.2 PROJECT DESCRIPTION

The Project involves the construction and operation of an open cut coal mine with a planned production rate of up to 1.9 million tonnes per annum (Mtpa) of ROM coal for export for steel production. The Project

term is anticipated to be 25 years from grant of the mining lease (ML); with this term including initial construction, mine operation and rehabilitation activities.

Mine construction activities are scheduled to commence in July 2021; subject to granting of the Project ML and EA. It is anticipated that it will take approximately six months to establish the necessary infrastructure to commence overburden removal and 18 months to commence coal production. A conceptual Project layout is provided in Figure 2, which represents the total area disturbed by mine operations only and does not equate to the disturbance footprint at any one point in time. The layout and mining sequence may vary from that shown in Figure 2 to account for localised geological features, detailed engineering design, mining economics and variations in market tonnages and quality requirements.

Open-cut mining areas will be developed and rehabilitated progressively. The total disturbance footprint for the Project is 1,953 ha which incorporates all mining and infrastructure components. the Project delivery has been split into two distinct stages based on the mine sequence. The total disturbance footprint for Stage 1 is approximately 1,267 ha, which includes Pit AB and associated infrastructure north west of Pit AB. Pit C and the haul road connecting Pit C and Pit AB will be developed in Stage 2, which is approximately 686 ha (refer Figure 2 and Figure 3).

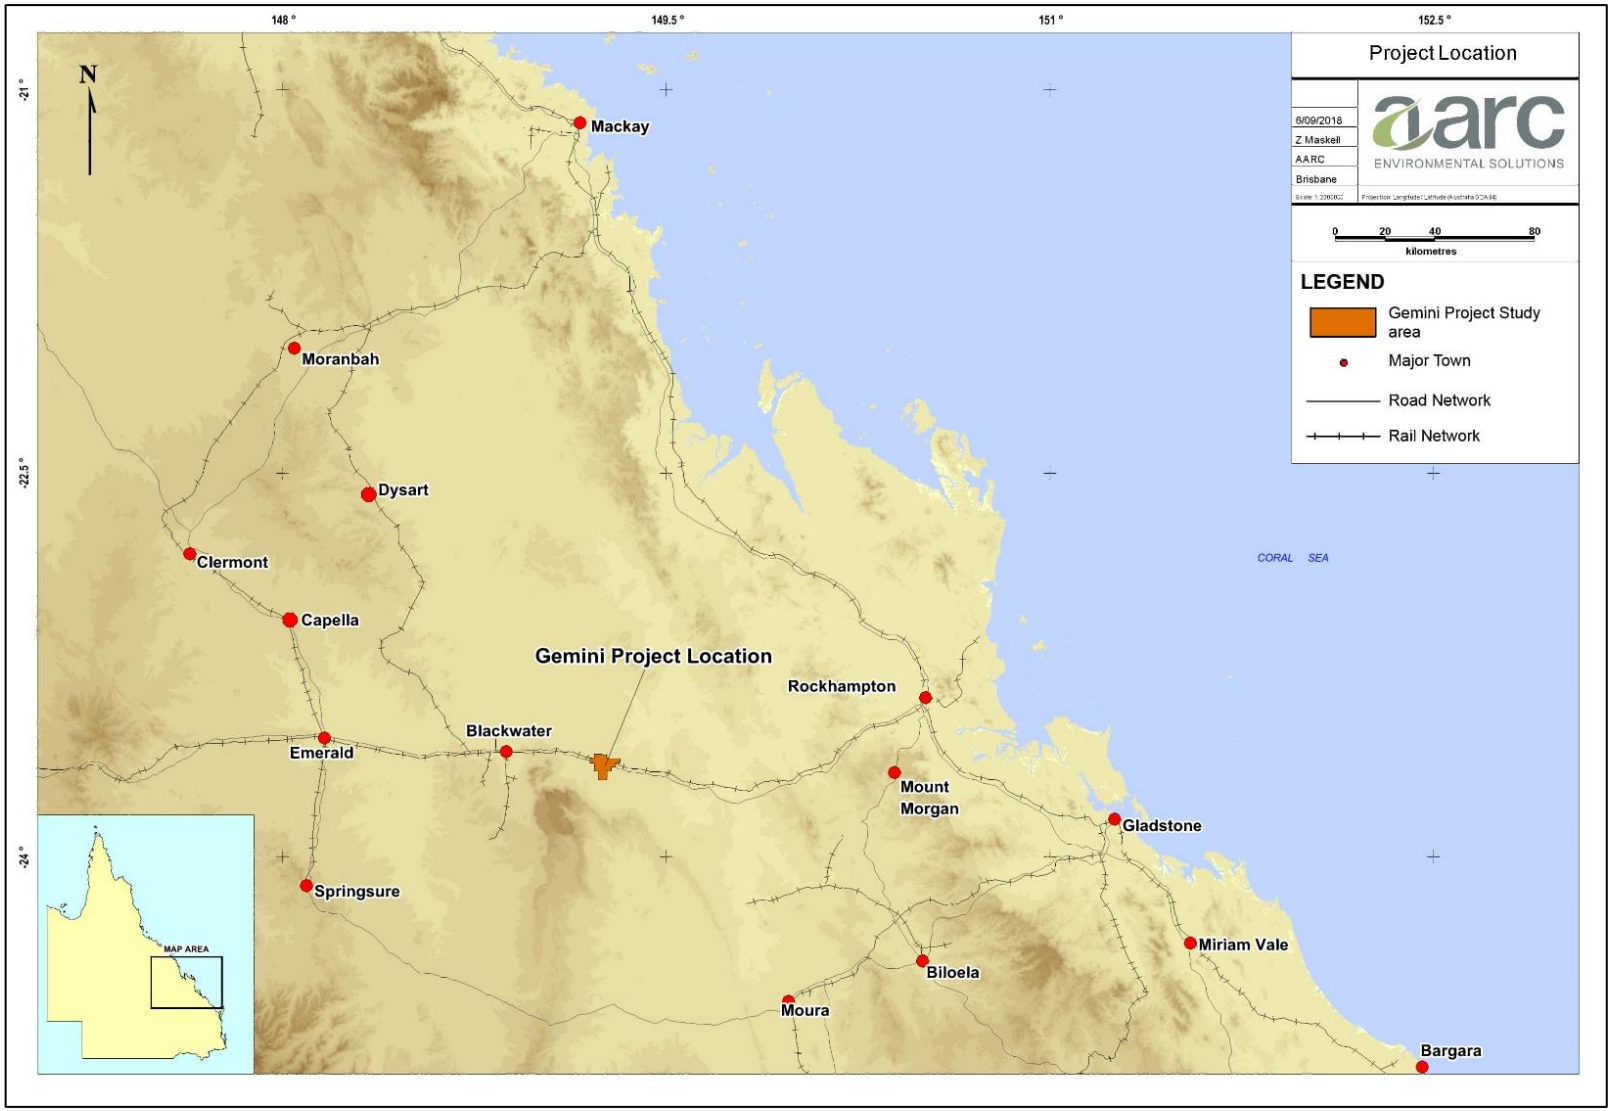

Figure 1: Project locality

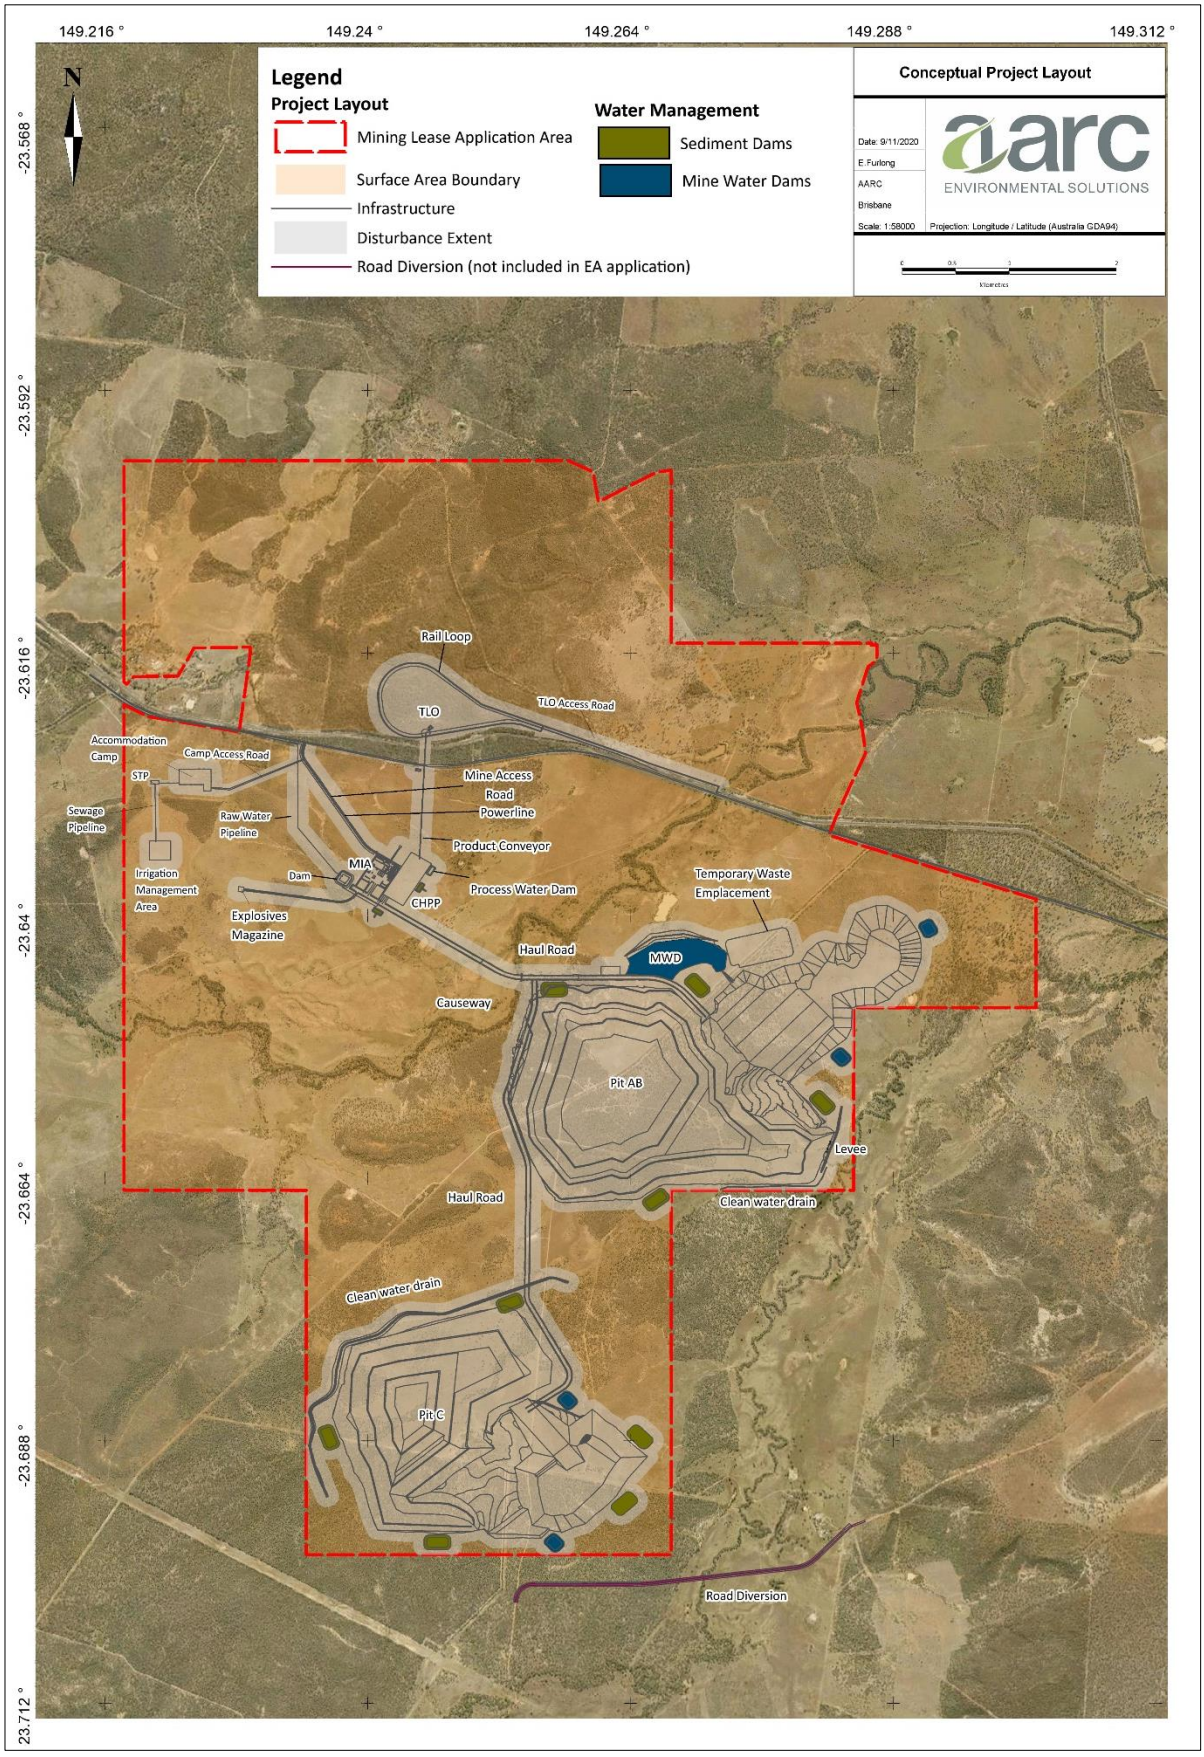

Figure 2: Project layout

2.0 LEGISLATION AND REGULATORY FRAMEWORK

Commonwealth, State and Local legislation policies and guidelines relevant to environmental offsets are discussed below.

2.1 ENVIRONMENTAL PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999

Under the *Commonwealth Environmental Protection and Biodiversity Conservation Act 1999* (EPBC Act), an action requires approval from the Federal Environment Minister if the action has, will have, or is likely to have a significant impact on a matters of national environmental significance (MNES). There are nine matters of national environmental significance listed under the act, which include:

- World heritage properties;
- National heritage places;
- Wetlands of international importance;
- The Great Barrier Reef Marine Park;
- Commonwealth marine areas;
- Listed threatened ecological communities;
- Listed threatened species;
- Listed threatened migratory species; and,
- A water resource, in relation to coal seam gas development and large coal mining development.

An EPBC Referral (2010/5775) was lodged in 2010 for the Gemini Project (the Project) previously known as the Dingo West Project by Dingo West Pty Ltd. The Project was declared 'Not a Controlled Action if undertaken in a Particular Manner' in July 2011.

The Particular Manner Decision conditions (EPBC 2010/5775) are as follows:

1. *To prevent downstream impacts to the Fitzroy river turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate pits in a manner that prevents surface water from entering the pit during a 1:1000 year flood event (as indicated in flood modelling).*

2. *To prevent downstream impacts to the Fitzroy river turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate dams in a manner that prevents surface water from entering or damaging the dams during a during a 1:1000 year flood event (as indicated in flood modelling).*

The Project requires no further assessment or provision of offsets under the EPBC Act.

2.2 QUEENSLAND ENVIRONMENTAL OFFSETS FRAMEWORK

Under Queensland law, offsets may be required for certain activities, where there is an unavoidable impact on significant environmental values. To counterbalance this loss, offsets, which can include improvement and protection of alternative sites and/or actions that improve environmental viability, can

provide a conservation outcome that is equivalent to the environmental value being lost at the impact site (DES 2020a).

The Queensland environmental offsets framework consists of:

- *Environmental Offsets Act 2014* (EO Act);
- *Environmental Offsets Regulation 2014* (EO Regulation);
- *Queensland Environmental Offsets Policy* (QEOP) (DES 2020a); and
- *QEOP Significant Residual Impact Guideline* (EHP 2014).

The offsets framework requires environmental offsets to be delivered where the Project (prescribed activity) is likely to result in a significant residual impact on a prescribed environmental matter. *The QEOP Significant Residual Impact Guideline* (EHP 2014) was used to determine if residual impacts on prescribed environmental matters were significant for the project (AARC 2020a).

2.2.1 Environmental Offsets Act 2014 and Environmental Offsets Regulation 2014

Significant impacts to MSES require environmental offsets under the EO Act. MSES are defined below and are outlined in Schedule 2 of the EO Regulation. They comprise:

- Regulated vegetation including:
  i. REs that are listed as 'Endangered' or 'Of Concern' (under the *Vegetation Management Act 1999* (VM Act));
  ii. REs that intersect areas shown as wetlands on the 'vegetation management wetlands map' (as certified under the VM Act);
  iii. REs located within the defined distance from the defining banks of a relevant watercourse or relevant drainage feature identified on the 'regulated vegetation management watercourse and drainage feature map' (as certified under the VM Act);
  iv. REs mapped as essential habitat on the 'essential habitat map' (as certified under the VM Act) for flora and fauna listed as 'endangered' or 'vulnerable' (under the *Nature Conservation Act 1992* (NC Act)); or
  v. A prescribed regional ecosystem is a matter of State environmental significance, for a prescribed activity mentioned in schedule 1, item 7(e) [1], if the ecosystem is an area of essential habitat on the essential habitat map for an animal that is near threatened wildlife or a plant that is near threatened wildlife;
- Remnant REs that contain an area of land required for ecosystem functioning (i.e. a connectivity area);
- Mapped wetlands and watercourses including:
  i. A wetland in a 'wetland protection area'; or of 'high ecological significance' as shown on the 'map of referable wetlands' (as defined under the *Environmental Protection Regulation 2019* (EP Regulation)); or

[1] Prescribed activity mentioned in schedule 1, item 7(e): development for which an environmental offset may be required under the State code 16 (Native vegetation clearing).

ii. A wetland or watercourse in 'high ecological value waters' (as defined under the *Environmental Protection (Water and Wetland Biodiversity) Policy* 2019);

- Designated precincts in a 'strategic environmental area' (under the *Regional Planning Interests Regulation 2014*);
- Protected wildlife habitat, which includes;
  i. High risk areas on the 'flora survey trigger map' that contain 'endangered' or 'vulnerable' plants (under the NC Act);
  ii. Areas (not on the 'flora survey trigger map') that contain 'endangered' or 'vulnerable' plants (under the NC Act);
  iii. Koala habitat area (as defined in the NC Act);
  iv. Habitat for 'endangered', 'vulnerable' and 'special least concern' animals (under the NC Act);
- Protected areas (under the NC Act) and highly protected zones of State marine parks (under the Marine Parks Act 2004);
- Fish habitat areas and waterways providing for fish passage (under the Fisheries Act 1994);
- Marine plants (under the Fisheries Act 1994); and
- Legally secured offset areas.

2.2.2 Queensland Environmental Offsets Policy

The QEOP is a statutory instrument that provides a single, streamlined framework for environmental offsets in Queensland. An offset may be delivered as a:

Proponent-driven offset: A proponent-driven offset may take the form of a traditional land-based offset; be undertaken through actions under a Direct Benefit Management Plan (DBMP); or a combination of both. For a proponent-driven offset, the offset delivery liability remains with the proponent and the offset must be delivered in accordance with an Offset Delivery Plan approved by the administering agency.

Financial settlement offset: For financial settlement offsets; the payment amount must be calculated in accordance with the methodology set out in in the QEOP. A web-based 'financial settlement offset calculator' is available on the Qld Government website that can assist in this process. The State is responsible for delivering a conservation outcome from the financial settlement offset payment.

A combination of a proponent-driven offset and financial settlement offset may be utilised.

2.3 MLES – CENTRAL HIGHLANDS REGIONAL COUNCIL

The project is located within the Central Highlands Regional Council LGA, which operates under the *Central Highlands Regional Council Planning Scheme 2016* (Central Highlands Regional Council 2016). As part of this Planning Scheme, matters of local environmental significance (MLES) are identified in overlay maps.

Searches of the *Central Highlands Regional Council Planning Scheme 2016* identified no MLES within the Project area.

3.0 PROJECT ENVIRONMENTAL OFFSET REQUIREMENTS

An ecological assessment comprising desktop assessments and field studies was undertaken to identify ecology values pertaining to the Project. The *Terrestrial Ecology Assessment Report* (AARC 2020a) provides details on the methods, results and impact assessments undertaken to determine if significant residual impacts to prescribed environmental matters are likely to occur as a result of the Project.

The Total Residual Impact Area has been calculated based on the remaining impact to prescribed environmental matters once all reasonable measures to avoid and minimise impacts to each matter was determined. Section 8.0 of the *Terrestrial Ecology Assessment Report* (AARC 2020a) outlines the mitigation and management strategies recommended to minimise and mitigate impacts to ecological values. Magnetic South has designed the project layout to aim to avoid areas of high ecological value, reducing impacts to prescribed environmental matters. Additional mitigation and management strategies are also recommended in the AARC (2020a) report.

3.1 PRESCRIBED MATTERS WITHIN THE STUDY AREA

Table 1 outlines the total offset requirements to be delivered under the QEOP (DES 2020a) as well as the requirements of staged offset strategy.

3.1.1 Endangered or Of Concern Regional Ecosystems

The study area consists of six vegetation communities. The remnant RE's associated with these vegetation communities include 11.5.2, 11.7.2, 11.3.25 and 11.3.2. *Eucalyptus populnea* (poplar box) woodland on alluvial plains (RE 11.3.2) is the only RE within the study area with a VM Act status Of Concern. Only small patches of this vegetation community occur within the study area, occupying 36.52 ha (0.5%) of the total area. Overall, 2.57 ha will be impacted due to Project activities that cannot be avoided or mitigated. Of this 2.57 ha, 1.83 ha will be impacted as part of Stage 1 and 0.74 ha will be impacted as part of Stage 2 (Figure 3).

3.1.2 Vegetation located the within a defined distance from the defining banks of a relevant watercourse

Several watercourses and waterways identified under the VM Act traverse the study area. The remnant vegetation located within the defined distance from the defining banks of identified VM Act watercourses, as defined in Appendix 3 of the QEOP, constitute a prescribed matter. Overall, 58.32 ha of this vegetation associated with the REs 11.5.2, 11.7.2, 11.3.25 and 11.3.2 will be impacted. Stage 1 impacts include 35.4 ha, whereas 22.39 ha will be impacted in Stage 2, due to Project activities that cannot be avoided or mitigated within these areas (Figure 3).

3.1.3 Connectivity areas

The Landscape Fragmentation and Connectivity Tool, used to determine whether a development significantly impacts Connectivity Areas as defined in Schedule 2 (DES 2018), was applied to the proposed extent of the disturbance area. The results found that significant impacts would occur to connectivity at both the local scale and to core remnant areas (Appendix B). It should be noted that the tool was run with the current regulated vegetation layer (DNRME 2020) instead of the field verified vegetation map due to technical limitations of the tool. This minor variation is highly unlikely to influence the results of analysis, being a significant impact on connectivity.

The total 710.72 ha of ground-truthed remnant vegetation within the proposed disturbance area has therefore been proposed to be offset, due to Project activities that cannot be avoided or mitigated. Specifically, 395.55 ha will require an offset in Stage 1 and 315.17 ha in Stage 2.

Table 1: MSES Offset Requirements

MSES	Regional Ecosystem	Residual Impact (ha)	Total Residual Impact Area (ha)	Residual Impact Stage 1 (ha)	Total Residual Impact Area Stage 1 (ha)	Residual Impact Stage 2 (ha)	Total Residual Impact Area Stage 2 (ha)	Habitat Description
Of Concern Regional Ecosystem	11.3.2	2.57	2.57	1.83	1.83	0.74	0.74	This vegetation community was decribed as *Eucalyptus populnea* (poplar box) woodland on alluvial plains. It was represented in several small to moderate patches within the study area and is subject to pressures from grazing and exotic species invasion.
REs located within the defined distance from the defining banks of a VM Act watercourse.	11.5.2	31.01	58.32	11.69	35.4	19.32	22.39	Several VM Act watercourses traverse the Study area. Impacts will occur to watercourse vegetation that is associated with RE 11.3.25, 11.5.2, 11.3.2 and 11.7.2.
	11.3.2	0.59		0.59		0		
	11.7.2	17.82		17.82		0		
	11.3.25	8.9		3.82		5.08		
Connectivity area	-	710.72	710.72	-	395.55	-	315.17	The Landscape Fragmentation and Connectivity Tool determined that there is significant impact to the connectivity of the remnant vegetation within the Project. Landscape Fragmentation and Connectivity Tool is based on current government mapping.
Total			**771.61**		**432.78**		**338.3**	

** The assessment of impact on connectivity using Landscape Fragmentation and Connectivity Tool is based on current government mapping; however, the total area to be offset has been proposed based on the field verified remnant vegetation within the impact area.*

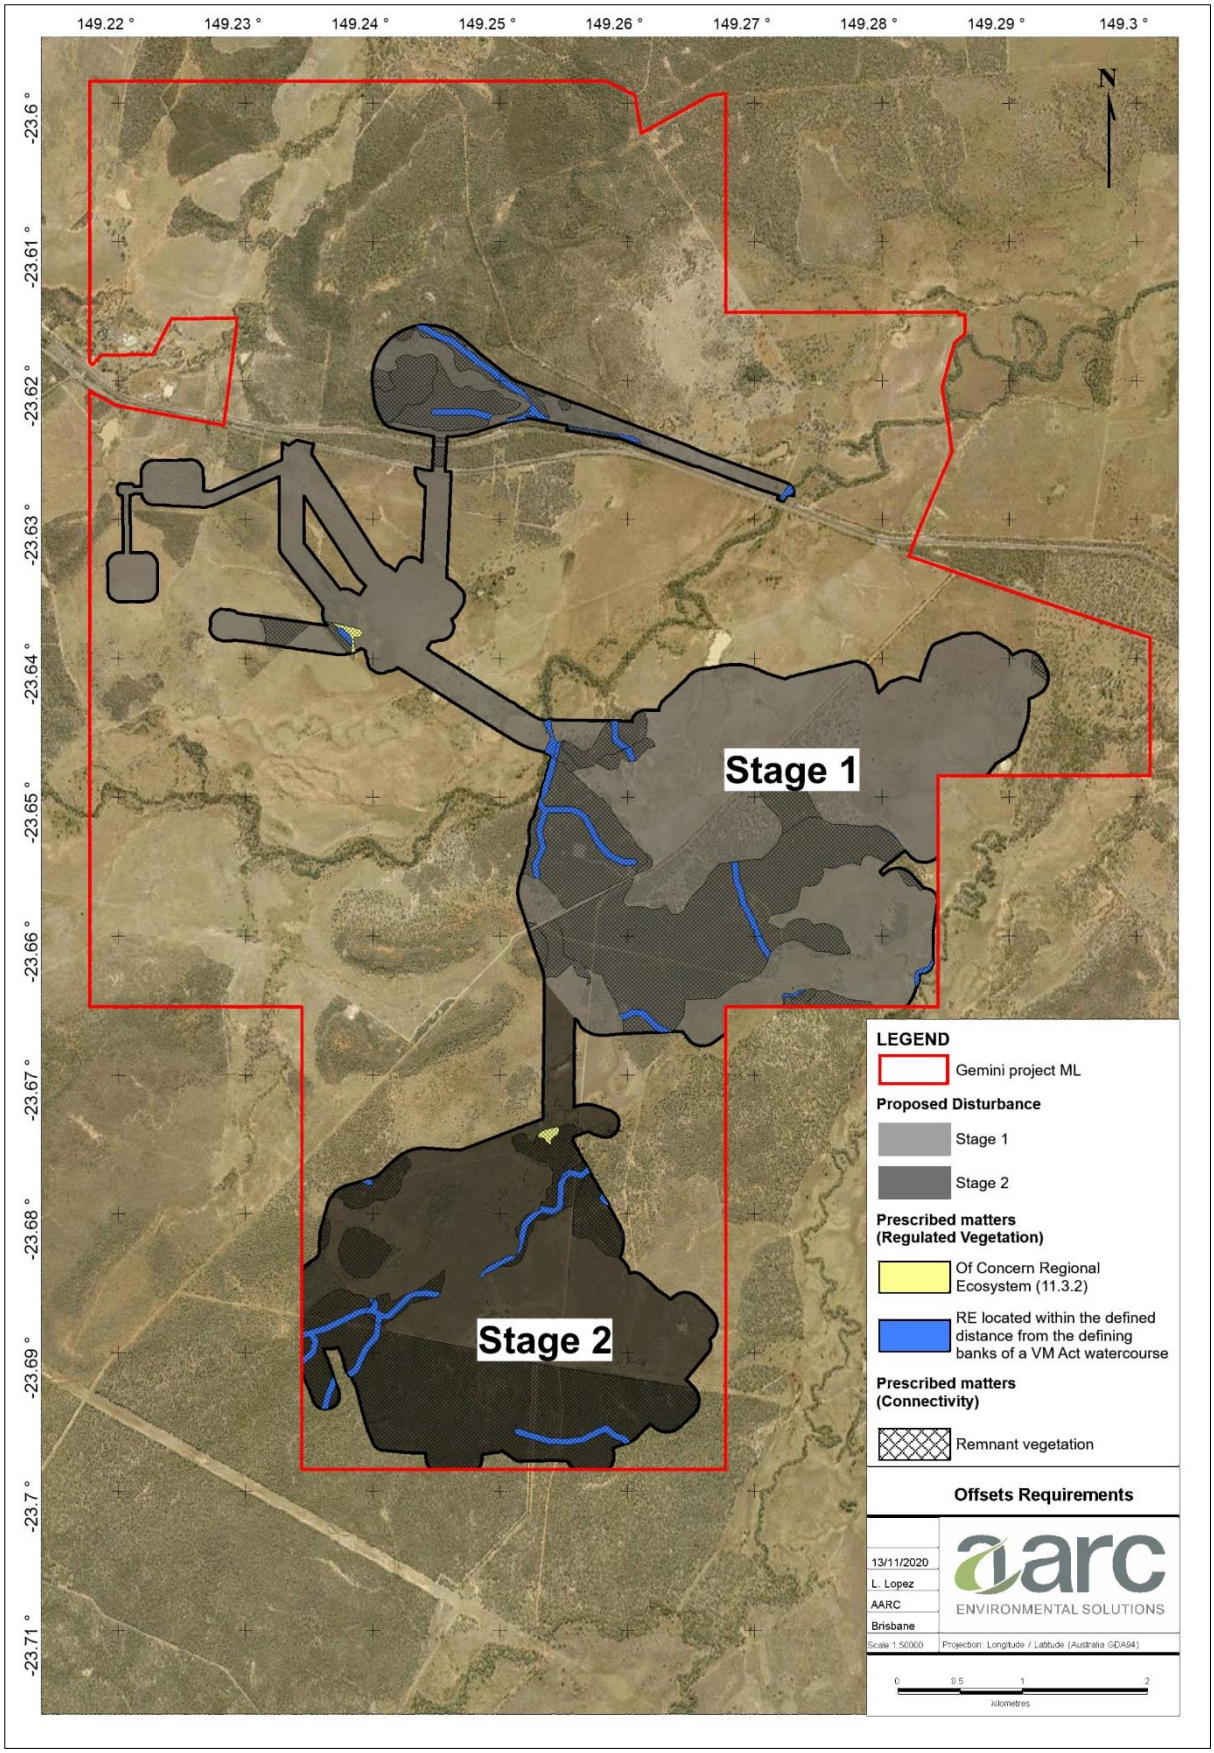

Figure 3: Distribution of prescribed environmental matters within the study area

4.0 OFFSET DELIVERY STRATEGY

The environmental offset requirements for the Project are proposed to compensate for the loss of connectivity, Regulated Vegetation (Of Concern REs), and remnant vegetation located within the defined distance from the defining banks of a VM Act watercourse, detailed in Section 3.1.2.

The Project will be developed progressively and as such, a staged offset delivery approach is proposed. This approach will enable offsets to be estimated accurately and delivered in a way that meets the obligations of the Project without over or underestimating the offset obligations. Staged offsets enable prescribed environmental matters to be accounted for as the project develops with time.

Figure 3 shows the study area and the approach to delivery of offsets.

The following sections outline the offset delivery options for the Project.

4.1 OFFSET DELIVERY ASSESSMENT

Under the QEOP there are three offset delivery options, which include:

- Proponent-driven offsets, taking the form of a land-based offset;
- Proponent-driven offsets, as part of a Direct Benefit Management Plan (DBMP) (can only be up to 10% of the offset delivery); and,
- Financial settlement offset.

A combination of offset delivery options is acceptable. However, the DBMP can only contribute up to 10% of the offset delivery.

Magnetic South is proposing to deliver a combination of Proponent-driven land-based offsets and financial settlement offsets. At this stage of Project development Magnetic South is yet to confirm exact proportions. This detail will be provided in the Offset Delivery Plan to be prepared following project approval before impact on the prescribed environmental matter occurs.

The offset delivery options described below are proposed.

4.1.1 Land-based offset

Magnetic South is likely to provide a portion of the offset delivery on suitable land they own in the vicinity of the Project or provided by a third-party offset provider.

4.1.1.1 Condition Assessment of land-based offsets

For land-based offsets, the suitability of the offset site relative to the impact site is measured by undertaking a habitat quality assessment. This assessment will be undertaken using the *Guide to Determining Terrestrial Habitat Quality* (DES 2020b) to measure a conservation outcome.

The *Guide to Determining Terrestrial Habitat Quality* (DES 2020b) outlines two processes that can be undertaken when determining habitat quality. The Rapid Assessment process can be used to approximate a habitat quality score without undertaking a Standard Assessment. This Rapid Assessment can only be used on the impact site, providing a habitat quality score of 7 out of 10. This score represents an average score of generic remnant RE's in Queensland derived from Queensland Herbarium experts.

The Standard Assessment process can also be used to determine habitat quality for impact sites and forms a requirement for offset supply sites. To determine the habitat quality score a more rigorous field evaluation is undertaken, including the measurement of ecological condition parameters from transects established within defined assessment units.

4.1.1.2 Calculation of offset supply

Once the habitat quality scores have been determined for the offset and impact sites these numbers are entered into the Land-based Offset Multiplier Calculator. This calculator uses the inputted information to determine the required size of an offset supply land for each value.

A multiplier is defined as "*a number used to calculate the size of the offset requirement given the significant residual impact area, for a given prescribed environmental matter*". The required offset area is calculated by multiplying the area of impact by the prescribed multiplier:

Offset Area = Area of Impact x Multiplier

The prescribed multiplier is set at a maximum of four (i.e. a maximum of four times the area of the residual impact), except for impacts to connectivity and waterways providing for fish passage, for which the prescribed multiplier is set to a maximum of one.

For the purposes of this Environmental Offsets Strategy, the maximum multiplier was assumed to calculate the maximum size of the offset supply. Estimated offset supply areas required for the Project are summarised in Table 2.

4.1.1.3 Offset delivery steps

The proponent will provide a notice of election including a proposed offset delivery plan, prior to impacts occurring.

Where land-based offsets are proposed, the next stage of offset delivery will include field ecology surveys of the potential offset supply sites. Surveys will aim to validate the suitability of habitats, assess ecological condition and collect information to support preparation of offset management plans. Final offset calculators will then be prepared post field validation to confirm the extent of offset supply land required.

An outline of potential offset supply areas for the Project has been described in Section 4.2, based on the land-based offset requirements mentioned below.

Table 2: Estimated offset supply requirement

MSES	Habitat Description	Regional Ecosystem	Total Residual Impact Area (ha)	Total Residual Impact Area Stage 1 (ha)	Total Residual Impact Area Stage 2 (ha)	QEOP Multiplier	Total Required Supply Area (ha)	Stage 1 Required Supply Area (ha)	Stage 2 Required Supply Area (ha)	QEOP Offset Supply Criteria
Of Concern Regional Ecosystem	This vegetation community was characterised by *Eucalyptus populnea* (poplar box) woodland on alluvial plains. It was represented in several small to moderate patches within the study area and is subject to pressures from grazing, exotic species invasion.	11.3.2	2.57	1.83	0.74	4	10.8	7.32	2.96	In relation to endangered and of concern regional ecosystems—the offset site must be: • Of the same broad vegetation group as the impacted Regional Ecosystem; • Of the same regional ecosystem status; and • Within the same bioregion
REs located within the defined distance from the defining banks of a VM Act watercourse.	Several VM Act watercourses traverse the Study area. Impacts will occur to watercourse vegetation that is associated with RE 11.3.25, 11.5.2, 11.3.2 and 11.7.2.	11.5.2	31.01	11.69	19.32	4	233.28	135.68	97.6	For vegetation intersecting a watercourse or drainage feature the offset site must be: • Of the same broad vegetation group as the impacted Regional Ecosystem; • Within the same bioregion; and • Associated with a watercourse or drainage feature
		11.3.2	0.59	0.59	0.00					
		11.7.2	17.82	17.82	0.00					
		11.3.25	8.9	3.82	5.08					
		Total	58.32	33.92	24.4					

Connectivity area	The Landscape Fragmentation and Connectivity Tool determined that there is significant impact to the connectivity of the remnant vegetation within the Project. Landscape Fragmentation and Connectivity Tool is based on current government mapping.	-	710.72	395.55	315.17	1	710.72	395.55	315.17	• Must be a non-remnant ecosystem; and • Must be in the same subregion; however, if the subregion is intact, the offset should be in the nearest fragmented subregion.
						Total	**954.8**	**538.55**	**415.73**	

4.1.2 Financial Settlement Offset

Magnetic South expect to deliver a portion of the offset supply requirement via financial settlement. This involves payment of an amount, calculated in accordance with the Financial Settlement Offset Calculation Methodology, outlined in Appendix 4 of the QEOP. The financial settlement calculation can be based off the *Queensland Government's Financial Settlement Offset Calculator* or the formula within Appendix 4 of the QEOP. It should be noted that both methods of calculation use the same components to determine the financial offset total.

The financial settlement calculation is based on the following formula:

Financial settlement = (total offset area x on-ground cost per ha) + landholder incentive payment + administrative cost

Each component within the above calculation uses different inputs and has its own specific formula, which is also outlined in Appendix 4 of the QEOP.

Calculation of the financial settlement for 100% of the offset requirement has been provided below and can be found in detail in Appendix B:

- In total $3,786,509.52 would be required to secure an offset of 954.8 ha for the entire study area;
- $2,192,600.70 would be required to secure an offset of 538.55 ha for Stage 1 only; and,
- $1,721,708.82 would be required to secure an offset of 415.73 ha for Stage 2 only.

Magnetic South will recalculate the financial offset contribution for the specific proportion of offset requirement determined. This will be defined in the Notice of Election and Offset Delivery Plan.

4.2 POTENTIAL OFFSET SUPPLY AREAS FOR THE PROJECT

Under the QEOP; to enhance the likelihood of the environmental offset being successful and achieving a conservation outcome, the offset should be in a strategic location that provides tangible benefits for the impacted prescribed environmental matter. This will be achieved through the following approach:

- Wherever possible offsets will be located within a Strategic Offset Investment Corridor (SOIC) closest to the impacted site; and
- In order of priority:
    - Offsets will be located within the same LGA; and/or
    - Offsets will be located within the same sub-region; and/or
    - Offsets will be located within the same bioregion.

4.2.1 Offset target areas

Figure 4 displays the study area in relation to the above supply location priorities. The Southern Brigalow Belt Bioregion has SOIC's defined, which occur in the same LGA and sub-bioregion as the Project. The area in Figure 5 represented by cross hatching shows the overlap of the Central Highlands Regional Council LGA, and the Woorabinda sub-bioregion (of the Southern Brigalow Belt Bioregion). This area (further accented by a pale pink background) represents the most strategic area for the Project's offset supply to be located, referred to as the Target Offset Supply Area.

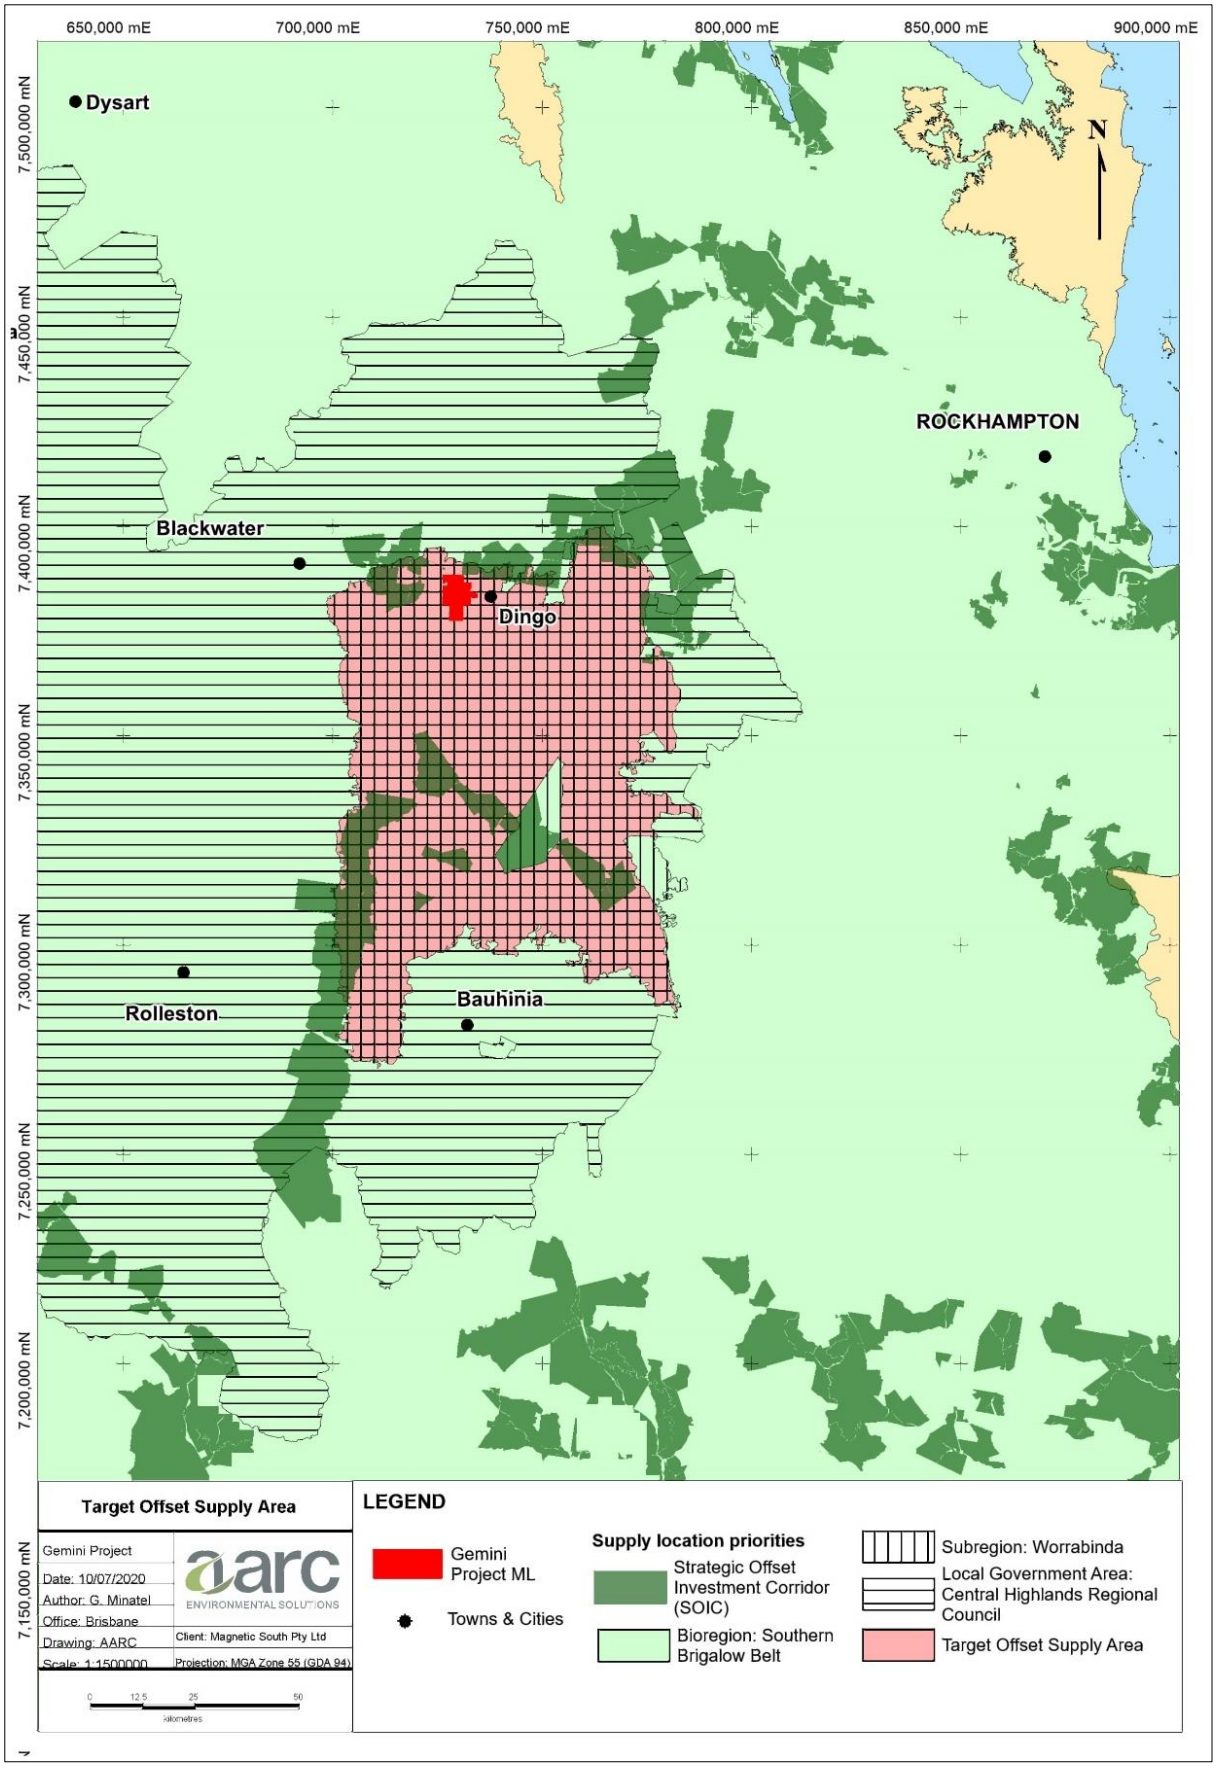

Figure 4: Target area for offset supply

Within the Target Offset Supply Area; pre-clear and remnant RE mapping was utilised to determine spatial availability of potential offset supply. Protected Areas, external Mining Leases, MSES legally secured offset areas and Category A regulated vegetation were removed from the potential offset supply areas, to give a more accurate estimation of the land that would be available for offsetting.

Table 3 outlines the potential supply area for each impacted matter, and the resulting targeted criteria for selection of potential offset supply. The available area for each impacted matter has been delineated into existing remnant vegetation, and non-remnant. Identification of suitable non-remnant sites was based on the *Vegetation management pre-clear regional ecosystem map - version 11.0* (DNRME 2019). The following calculations are based on the available area within the Target Offset Supply Area and within 35km from the study area.

Table 3: Potential offset supply area

Impacted Matter	Offset Supply Requirements	Total Supply Area Required (ha)	Stage 1 Required Supply Area (ha)	Stage 2 Required Supply Area (ha)	Supply Available: Non-remnant (ha)	Supply Available: Remnant (ha)
Of Concern Regional Ecosystem	• Of the same *broad vegetation group* as the impacted regional ecosystem; • Of the same regional ecosystem status; and • Within the same bioregion	10.8	7.32	2.96	14,137.01	2,780.61
REs located within the defined distance from the defining banks of a VM Act watercourse.	• Of the same broad vegetation group as the impacted regional ecosystem; • Within the same bioregion; and • Associated with a watercourse or drainage feature	233.28	135.68	97.6	4,454.30	2,652.00
Connectivity area	• A non-remnant ecosystem; and • In the same subregion; however, if the subregion is intact, the offset should be in the nearest fragmented subregion	710.72	395.55	315.17	157,710.89	-

Ideally, offset supply areas will be located close to the impact site. Figure 5 illustrates the potential offset supply within the Target Offset Supply Area and within 35 km of the Project. Subject to suitable land acquisition arrangements, it would be possible to satisfy 100% of required offset supply within these local areas.

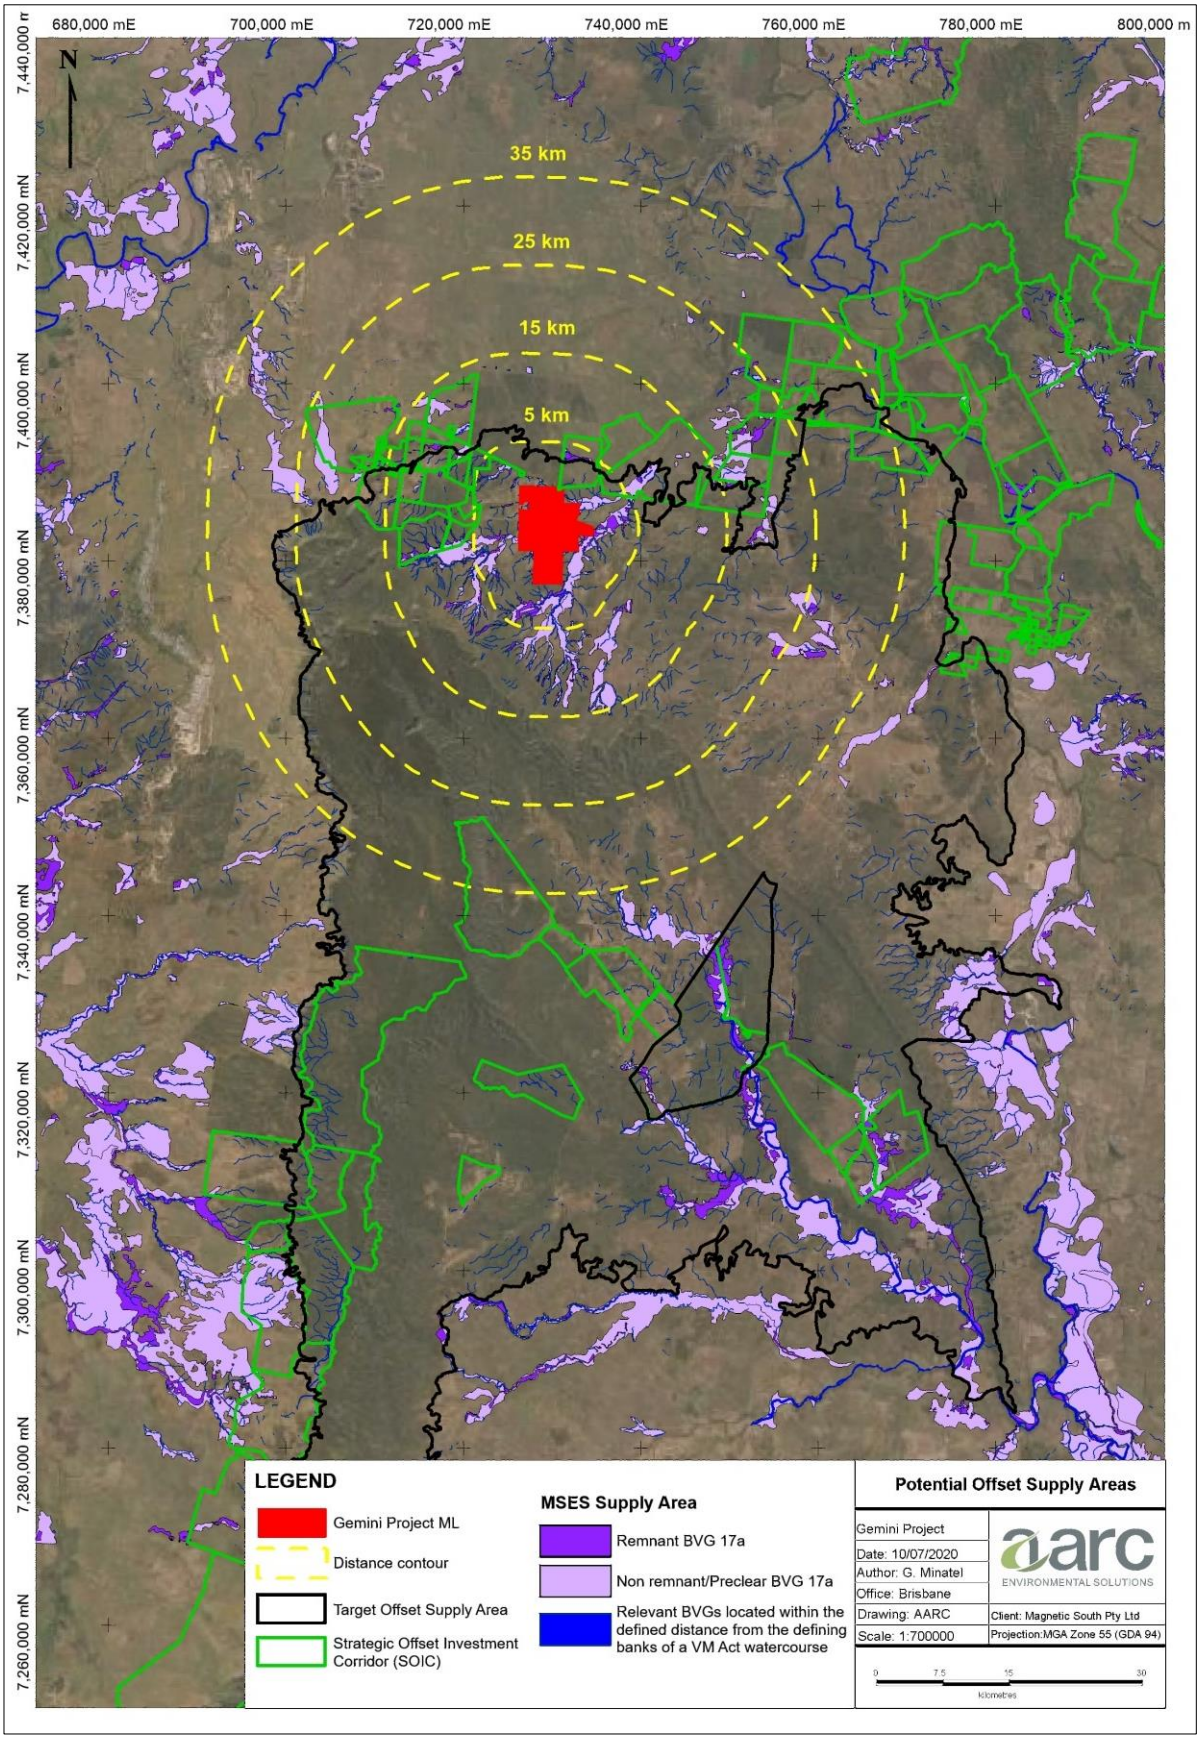

Figure 5: Potential offset supply areas within 35km

4.2.2 Offset supply on Magnetic South land

Magnetic South is the owner of land underlying the Project, along with some adjacent land parcels (Figure 6). Given the location of this land in relation to the proposed disturbance, this area is considered a suitable option for offset supply.

Although the final offset supply area will be subject to condition analysis, preliminary desktop assessment indicates the likely presence of sufficient offset supply land within Magnetic South properties to satisfy 100% of the offset requirement for the Project.

An impact area may have more than one prescribed environmental matter located on it. The Queensland Environmental Offsets Policy allows for the co-location of multiple prescribed environmental matters, except for species categorised into different functional groups.

Where possible, the offset requirements will be co-located (e.g. connectivity).

Table 4: Area of potential offset land within Magnetic South properties

Impacted Matter	Offset Supply Requirements	Total Supply Area Required (ha)	Stage 1 Required Supply Area (ha)	Stage 2 Required Supply Area (ha)	Supply Available: Non-remnant (ha)	Supply Available: Remnant (ha)
Of Concern Regional Ecosystem	• Of the same *broad vegetation group* as the impacted regional ecosystem; • Of the same regional ecosystem status; and • Within the same bioregion	10.8	7.32	2.96	1,744	426.99
REs located within the defined distance from the defining banks of a VM Act watercourse.	• Of the same broad vegetation group as the impacted regional ecosystem; • Within the same bioregion; and • Associated with a watercourse or drainage feature	233.28	135.68	97.6	355.13	355.2
Connectivity area	• A non-remnant ecosystem; and • In the same subregion; however, if the subregion is intact, the offset should be in the nearest fragmented subregion	710.72	395.55	315.17	4,763	-

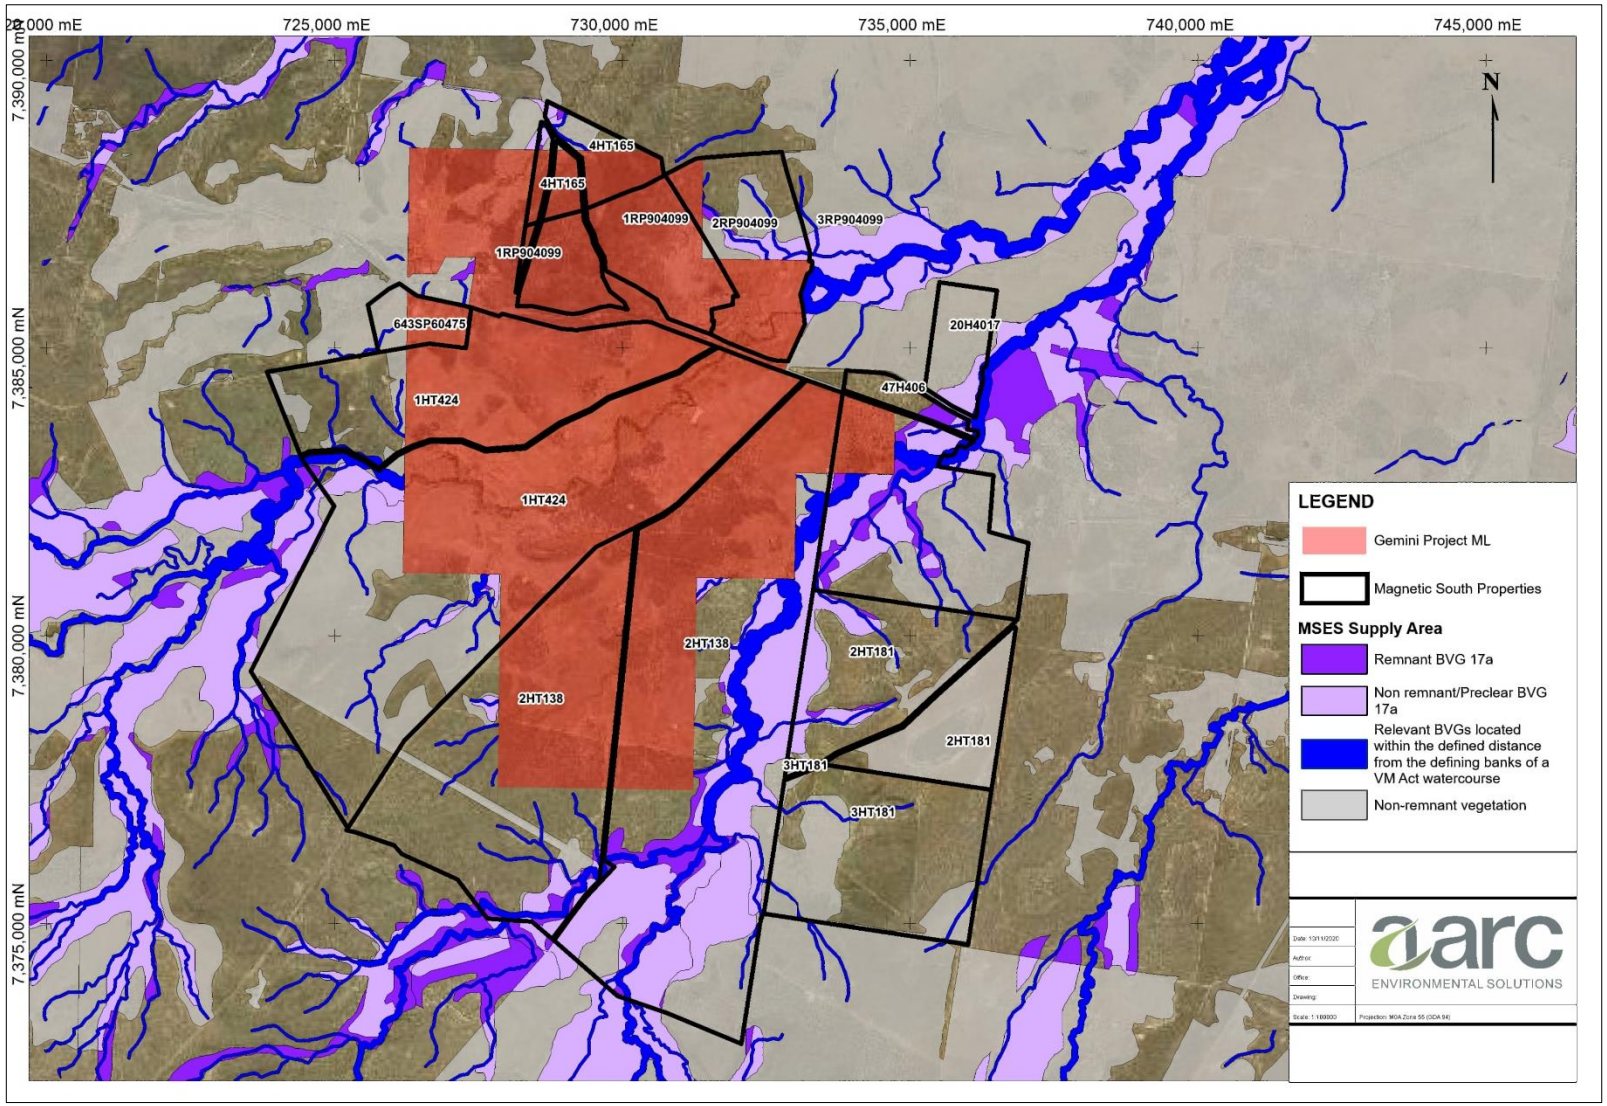

Figure 6: Potential offset supply areas within Magnetic South properties

5.0 CONCLUSION

Based on results of the significant residual impact assessment, impacts to three different MSES are proposed to be offset. Environmental offsets for the Project will include a combination of land-based offset supply and financial settlement. A two staged delivery approach is proposed.

A desktop assessment of offset supply areas was undertaken within properties owned by Magnetic South adjacent to the Project, as well as within a broader region (within 35 km of the Project). This analysis concluded that 100% of the offset requirement can likely be satisfied within the Magnetic South properties alone. However, substantial further supply opportunity exists in the surrounding landscape

Prior to project development, a condition assessment will be undertaken for both impacted land and offset supply land. A specific offset delivery plan will be prepared and submitted for approval prior to impacts occurring.

Analysing impact on Connectivity Areas

SIGNIFICANCE TEST ONE

The regional total area is 182159.98
The regional extent of core remnant is 85580.99
The regional extent of core remnant is 46.98 percent
This level of regional fragmentation sets a local impact threshold of: 10.0 percent

The table below lists the local impact thresholds for categories of regional core remnant extent:

REGIONAL CORE CATEGORY	LOCAL IMPACT THRESHOLD
< 10	2.0
10 - 30	5.0
30 - 50	10.0
50 - 70	20.0
70 - 90	30.0
>90	50.0

Area of core at the local scale (pre impact): 8941.33
Area of core at the local scale (post impact): 8264.93
Percent change of core at the local scale (post impact): 7.56 percent

SIGNIFICANCE TEST TWO

The number of core remnant areas occurring on the site: 10
The number of core remnant areas remaining on the site post impact: 7
(Only core polygons greater than or equal to 1 hectare are included)

RESULT

20:04:55 This analysis has determined a SIGNIFICANT impact on connectivity areas
(A significant reduction in core remnant at the local scale is False OR a change from core to non-core remnant at the site scale is True)

(Total area of RVM Cat B clearing is 783.38 hectares)

The significance table has been written to: ..\main_output\lfc_significance_assessment.csv
The local scale summary table has been written to: ..\main_output\lfc_local_scale_summary.csv
The site scale summary table has been written to: ..\main_output\lfc_site_scale_summary.csv
GIS layer files copied into folder \lyr_file within the project folder.
View layers in ArcMAP using..\W:\RACAD\AARC LFC TOOL - DINGO WEST\LFC OUTPUT\lyr_file\lyr_file\Connectivity Area Impact Assessment.lyr

Please scrutinise the output tables and spatial layers to confirm the desktop modelling of connectivity area impact

This analysis used an unedited copy of the Regulated Vegetation layer.

20:43:31 COMPLETED LANDSCAPE FRAGMENTATION AND CONNECTIVITY ANALYSIS

1.0 INTRODUCTION

AARC Environmental Solutions Pty Ltd (AARC) was commissioned by Magnetic South Pty Ltd (Magnetic South) to prepare a terrestrial ecology assessment for the Gemini Project, located approximately 110 km east of Emerald and 125 km west of Rockhampton in the Bowen Basin of Central Queensland (Figure 1). The Project is a proposed metallurgical open-cut coal mine and associated infrastructure, producing Pulverised Coal Injection (PCI) coal Coking Coal products for export for steel production.

An assessment of the terrestrial ecological values was conducted within Exploration Permit Coal (EPC) 881 (herein referred to as the study area). This assessment forms part of the supporting studies required for the Project's approval processes.

1.1 SCOPE OF STUDY

To assess the ecological values of terrestrial ecosystems within the study area, the following scope of works was undertaken:

- Database searches to identify species of conservation significance known from the region (provided in Appendix A). These species were targeted during the field survey component of the study;
- Field surveys employing standard methodologies such as the *Terrestrial Vertebrate Fauna Survey Guidelines of Queensland* (Eyre *et al.* 2018) and *Queensland Herbarium Methodology for Survey and Mapping of Regional Ecosystems and Vegetation Communities in Queensland Version 4.0* (Neldner *et al.* 2017) to identify terrestrial flora and fauna species inhabiting the study area, particularly species of conservation significance[1]; and
- Preparation of an assessment report describing the terrestrial ecological values identified on site, potential impacts of the Project, management strategies to minimise the impacts associated with the proposed mining activities and offset requirements.

1.2 PROJECT OVERVIEW

The main activities associated with the Project include:

- Exploration activities continuing in order to support mine planning;
- Development of a Mine Infrastructure Area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, explosives magazine and sewage, effluent and liquid waste storage;
- Construction and operation of a Coal Handling Preparation Plant (CHPP) and coal handling facilities adjacent to the MIA (including Run-of-Mine (ROM) coal and, product stockpiles and rejects bin/overflow [coarse and fine rejects]);

[1] 'Species of conservation significance' or 'threatened species' when referred to within this document are references to species listed as Near Threatened, Vulnerable or Endangered under the Queensland *Nature Conservation Wildlife Regulation 2006* or Vulnerable, Endangered, Critically Endangered or Migratory under the *Environmental Protection and Biodiversity Conservation Act 1999*.

- Construction and operation of a surface conveyor from the product stockpiles to a Train Load Out (TLO) facility and rail loop connecting to the Blackwater-Gladstone Branch Rail to transport product coal to coal terminals at Gladstone for export;
- Construction of access roads from the Capricorn Highway to the MIA, and to the TLO facility;
- Installation of a raw water supply pipeline to connect to the Blackwater Pipeline network;
- Construction of a 66 kilovolt (kV) transmission line and switching/substation to connect to the existing regional network;
- Other associated minor infrastructure, plant, equipment and activities;
- Development of mine areas (open cut pits) and out-of-pit waste rock emplacements;
- Drilling and blasting of competent waste material;
- Mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers);
- Mining up to 1.9 Million tonnes per annum (Mtpa) ROM Coal – average 1.8 Mtpa for a construction/production period of approximately 20 years;
- Progressive placement of waste rock in:
  - Emplacements, adjacent to and near the open cut voids;
  - Mine voids, behind the advancing open cut mining operations;
- Progressive rehabilitation of waste rock emplacement areas and mined voids;
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works). Material will be sourced from local quarries where required;
- Disposal of CHPP rejects (coarse and fine rejects) in out of pit spoil dumps, and in-pit behind the mining void;
- Progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access; and
- Development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, diversions and drains.

Existing local and regional infrastructure, facilities and services would be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

1.3 CURRENT LAND USE

The land within the study area is currently used for low intensity cattle grazing and resource exploration activities. The Capricorn Highway and a number of publicly gazetted roads including Charlevue, Cooinda, Red Hill, Normanby, and Ellesmere roads dissect the study area.

Located directly north of the study area is the Taunton National Park (Scientific), (Taunton Nation Park), a scientific reserve under the *Land Act 1994 (Queensland)*, with the aim of protecting a population of Bridled nail-tail wallabies. A small section of the Taunton National Park of around 2.5 hectares (ha) within the study area.

1.4 LOCAL WATERWAYS AND TOPOGRAPHY

The study area lies within the Fitzroy River Basin, which encompasses an area of 142,545 square kilometres (km^2) and contains the Comet, Connors, Dawson, Don, Nogoa and Mackenzie Rivers, which make up its six sub-catchment areas (BoM 2018; DES 2018a). The study area lies within the Mackenzie River sub-catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River catchment.

The major water body associated with the study area is Charlevue Creek, which traverses the study area in a north-easterly direction. This creek begins within the boundaries of Blackdown Tablelands National Park, flowing north-east before joining with Springton Creek and the Fitzroy River, eventually emptying into the Pacific Ocean approximately 46 km north of Gladstone. Stanley Creek and Springton Creek cross the study area in the north-west and south-east, respectively. These two creeks also eventually converge with the Mackenzie River. First and second order streams associated with Charlevue Creek and Springton Creek also occur in the study area. Figure 2 shows the extent and location of the waterways within the study area.

Springton Creek and Charlevue Creek are defined watercourses under the *Water Act 2000 (Queensland).* Springton Creek and Charlevue Creek within the study area are 5th order streams. Stanley Creek is considered a 2nd order stream.

Topography of the land varies from flat to undulating, with elevation within the study area ranging between 120 metres (m) and 150 m. The landscape is influenced by Charlevue Creek, which has a lower elevation than the surrounding landscape. The topography of the study area is representative of the surrounding region.

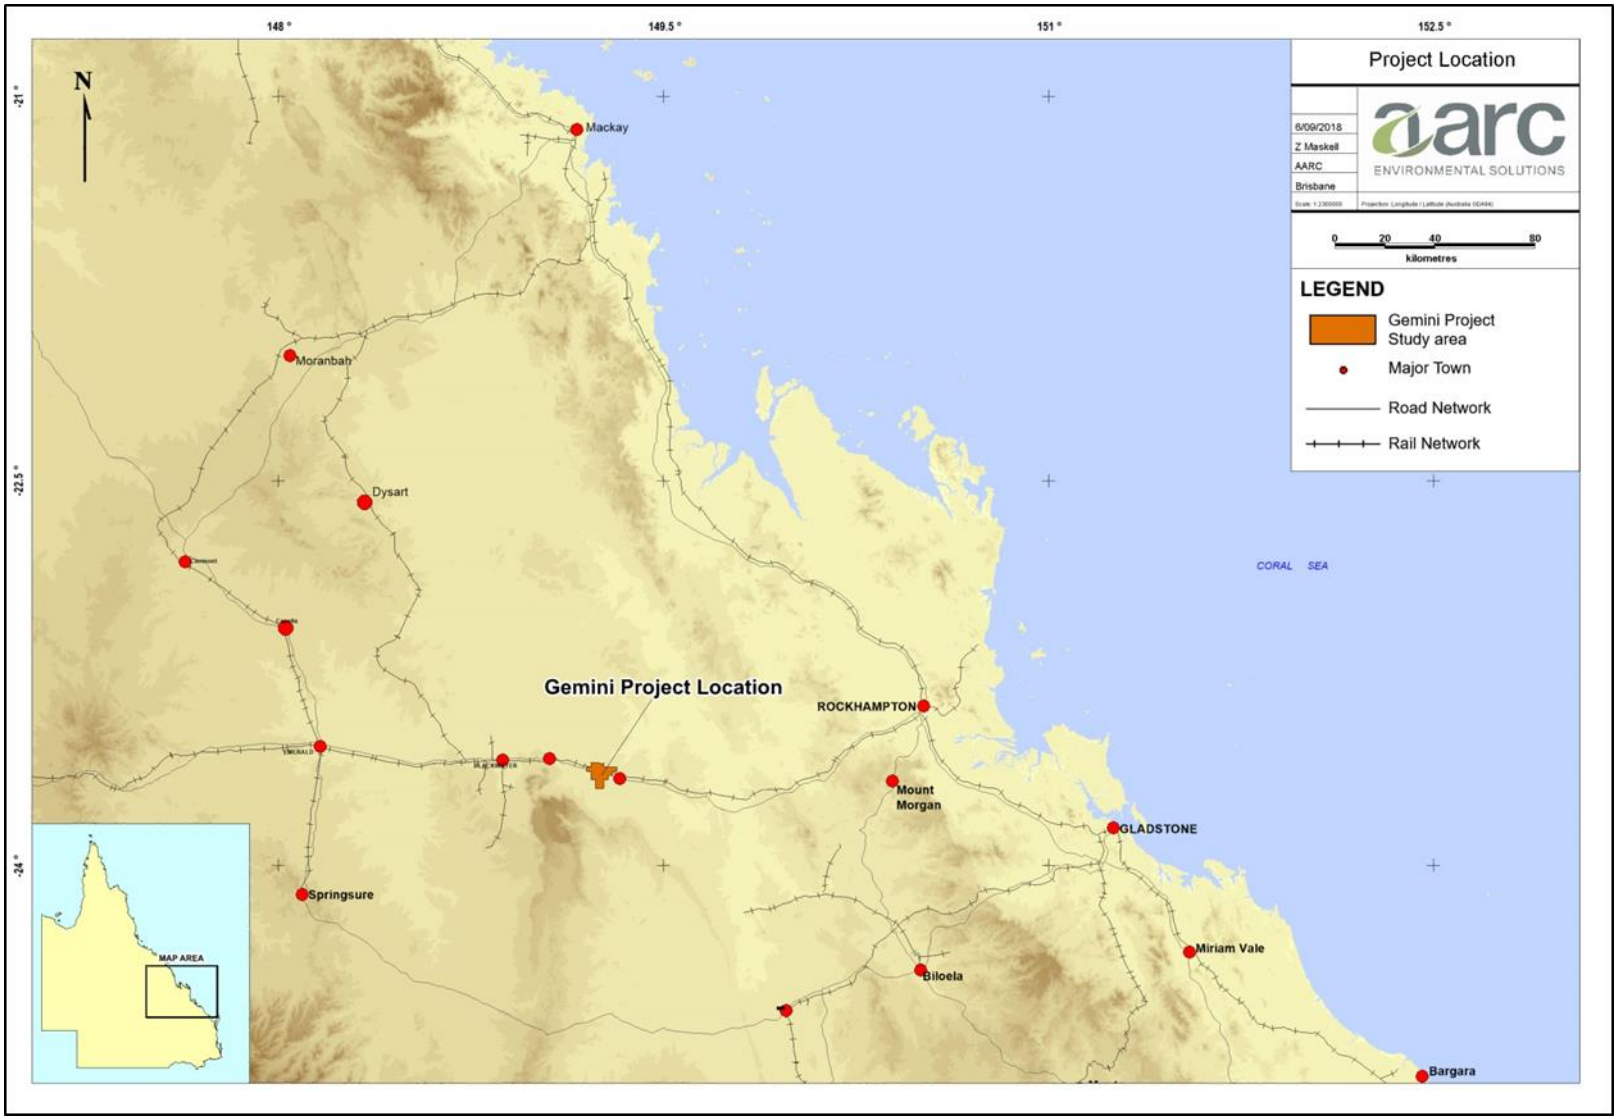

Figure 1 Project and Study Area Location

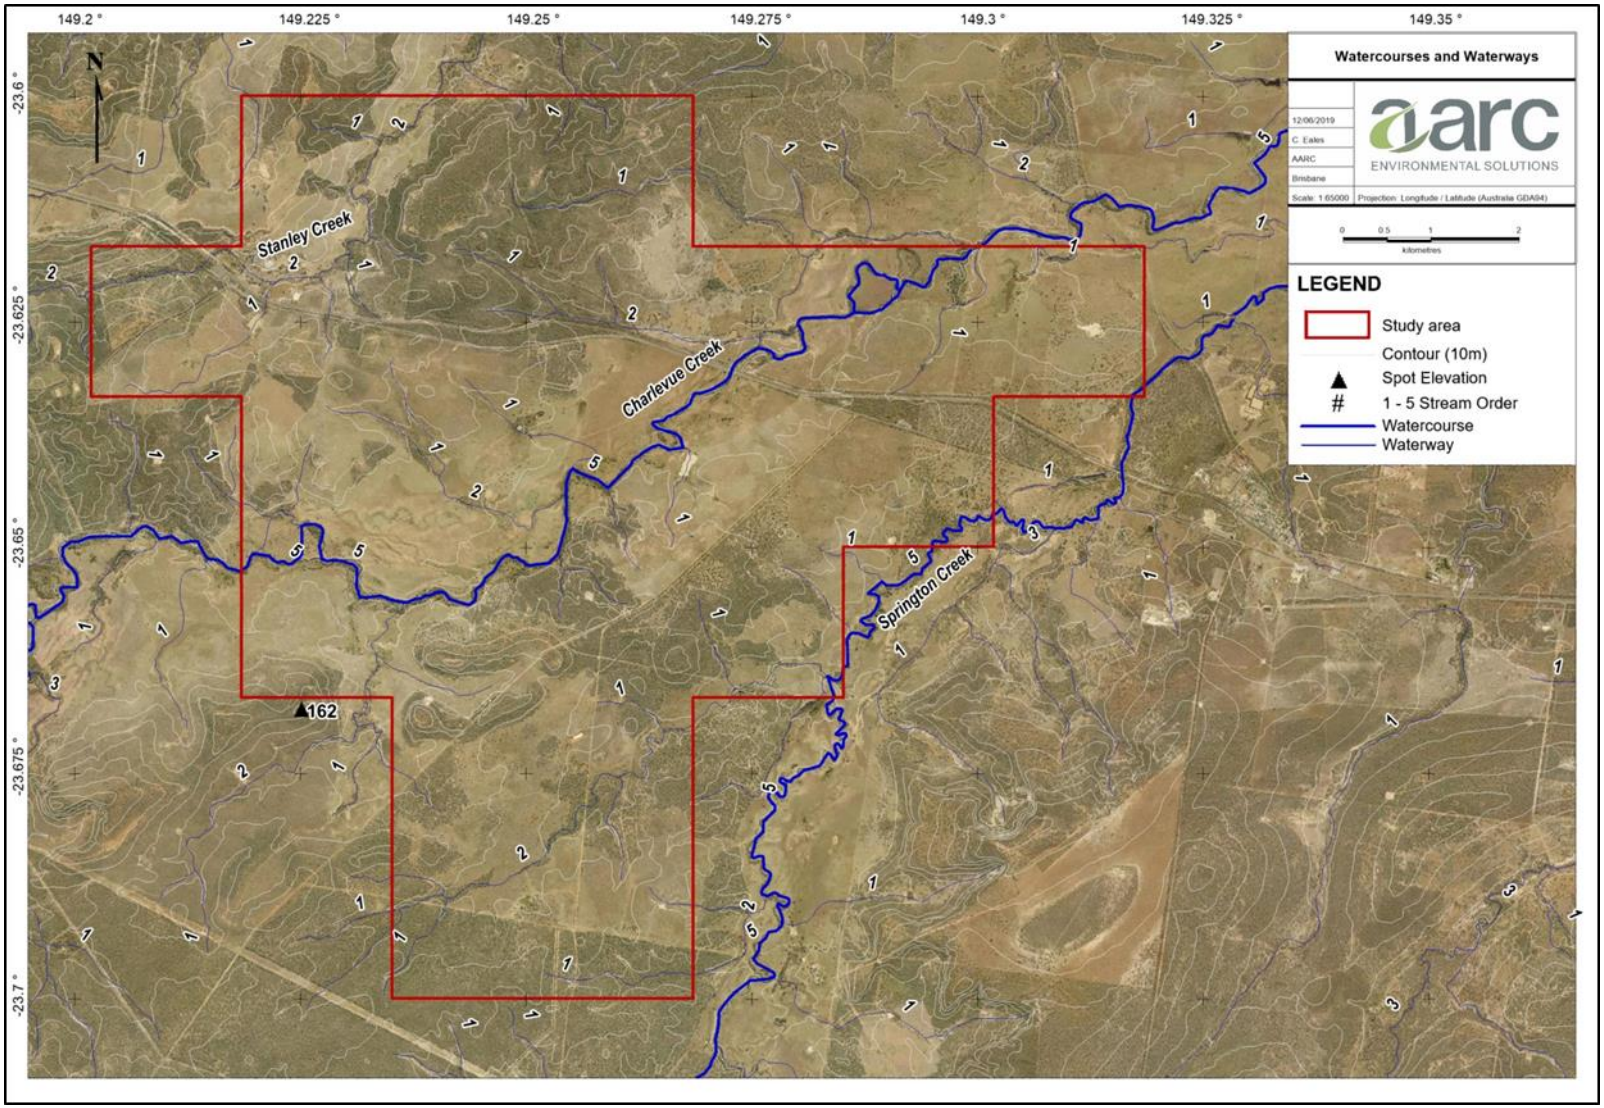

Figure 2 Waterways and topography associated with the Study Area

1.5 GEOLOGY

The geology of the region is dominated by its position within the Bowen Basin, one of Queensland's largest depositional regions, which formed through a period of rifting and subsidence lasting from the Early Permian - Mid-Triassic. The area is dominated by clastic sedimentary rocks of marine and lacustrine origin, including sandstones, conglomerates, mudstones, siltstones and coal (Geoscience Australia 2018).

The coastal and inland depositional environments which created these deposits allowed for the formation of extensive coal seams throughout the Bowen Basin, with the anoxic deposition of organic matter subsequently compacted and de-volatised through compression and increased temperatures (Brooks & Smith 1969).

Generally, coal seams found in the east-central part of the basin contain higher quality coking coal deposits, with rank falling below coking range farther south and west (Hutton 2009). The high-quality coal measures are of Permian age, buried less than 60 m from the surface (Mutton 2003).

1.6 REGIONAL CLIMATE

The regional climate is classified as semi-arid, characterised with warm dry summers and warm winters. Climate data for the study area has been sourced from Scientific Information for Land Owners (SILO) climate database (Queensland Government), which operates by interpolating data from the Commonwealth Bureau of Meteorology (BoM) into a single point data drill.

Figure 3 shows predicted average temperature and rainfall for the area from January 1999 to July 2019. The data indicates the annual mean rainfall for the region is highest between December and March with the maximum average occurring in December (111.5 millimetres (mm)).

The hottest months typically occur between October and March while the coolest months occur between May and September. The highest mean maximum temperature typically occurs in December (34.2 degrees Celsius (°C)) and the lowest mean minimum temperature in July (8.5°C). The mean annual maximum temperature for the region is predicted to be 29.8°C and the mean annual minimum temperature is predicted to be 16°C.

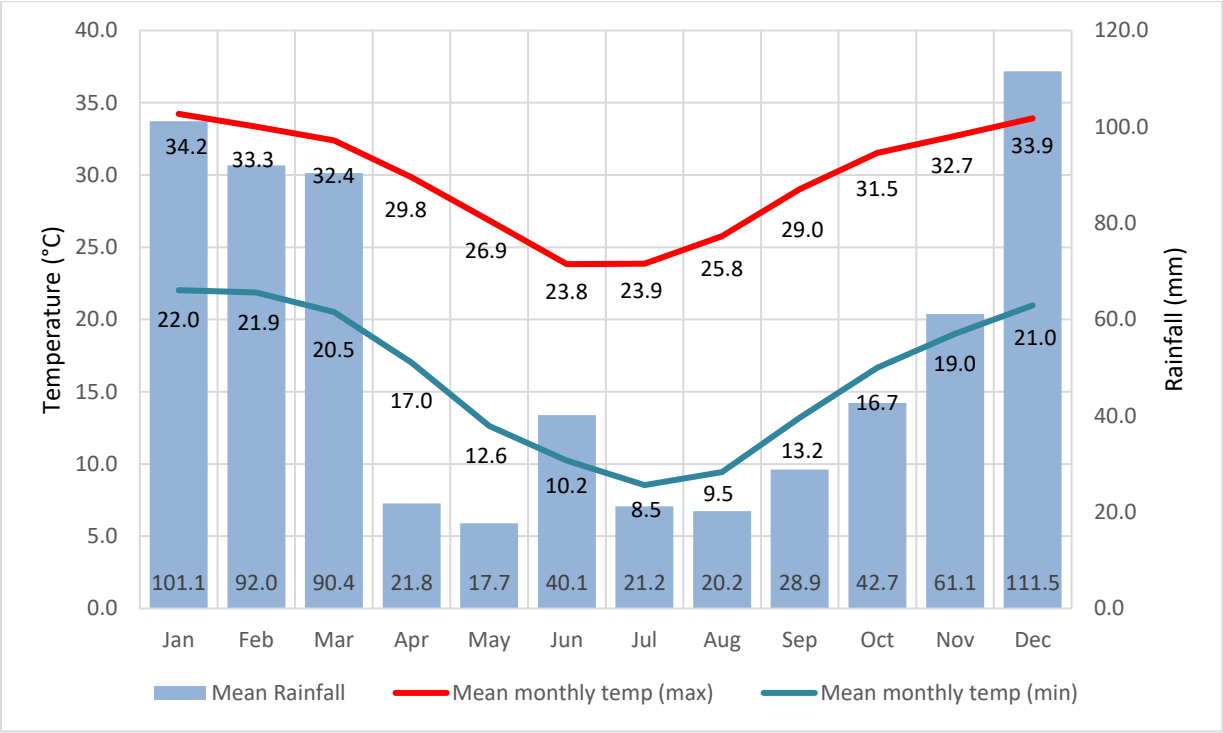

Figure 3 Mean temperature and rainfall data for the region (Source: SILO)

2.0 RELEVANT LEGISLATION AND POLICY

Commonwealth and State legislation and policies relevant to the assessment of terrestrial ecological values on the study area is discussed below.

2.1 ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999

Under the Commonwealth *Environmental Protection and Biodiversity Conservation Act 1999* (EPBC Act), an action requires approval from the Federal Environment Minister if the action has, will have, or is likely to have a significant impact on a Matter of National Environmental Significance (MNES).

An EPBC Referral (2010/5775) was lodged in 2010 for the Gemini Project previously known as the Dingo West Project by Dingo West Pty Ltd, which was declared 'Not a Controlled Action if undertaken in a Particular Manner' in July 2011.

The Particular Manner Decision conditions (EPBC 2010/5775) are as follows:

1. *To prevent downstream impacts to the Fitzroy River Turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate pits in a manner that prevents surface water from entering the pit during a 1:1000 year flood event (as indicated in flood modelling at Attachment A).*

2. *To prevent downstream impacts to the Fitzroy River Turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate dams in a manner that prevents surface water from entering or damaging the dams during a during a 1:1000 year flood event (as indicated in flood modelling at Attachment A).*

The Gemini Project complies with the Particular Manner Decision (EPBC 2010/5775). Furthermore, the level of impact to MNES have been assessed to be no greater than those described in the EPBC Referral (20105775).

The potential impact of the Project on the Fitzroy River Turtle is addressed in the Aquatic Ecology Assessment (AARC 2019).

2.2 NATURE CONSERVATION ACT 1992

The most relevant components of the Queensland *Nature Conservation Act 1992* (NC Act) to the Project, are the sections which pertain to Wildlife and Habitat Conservation. The classes of wildlife to which the NC Act applies includes protected wildlife, which is defined as Extinct wildlife; Endangered wildlife; Vulnerable wildlife; Near Threatened wildlife; and Least Concern wildlife.

'Threatening processes' are also relevant to wildlife and habitat conservation. The NC Act defines 'threatening processes' as any process that is capable of:

a) threatening the survival of any protected area, area of major interest, protected wildlife, community of native wildlife or native wildlife habitat; or

b) affecting the capacity of any protected area, area of major interest, protected wildlife, community of native wildlife or native wildlife habitat to sustain natural processes.

The NC Act is relevant to the Project for any protected flora or fauna species (as detailed in the NCWR) found in the study area.

2.2.1.1 Nature Conservation (Wildlife) Regulation 2006

Species listed under the above threatened species classes are published in the associated Nature Conservation (Wildlife) Regulation 2006 (NCWR). This report has considered the recent amendments made to listed threatened species in 2019.

2.2.1.2 Nature Conservation (Wildlife Management) Regulation 2006

The *Nature Conservation (Wildlife Management) Regulation 2006* provides for the management of wildlife, other than wildlife in a protected area.

This regulation also pertains to the clearing, growing, harvesting and trading of protected plants in Queensland. As per Section 282 of the Regulation, a protected plant clearing permit for protected plants (other than in a protected area) may be required for any vegetation clearing of an area containing EVNT species (DES 2019a).

2.3 BIOSECURITY ACT 2014

The Queensland *Biosecurity Act 2014* (Biosecurity Act) provides comprehensive biosecurity measures to safeguard our economy, agricultural and tourism industries, environment and way of life, from pests (e.g. wild dogs and weeds), diseases (e.g. foot-and-mouth disease), and contaminants (e.g. lead on grazing land).

Biosecurity matters are separated into three broad categories:

- A '**prohibited matter'** is a biosecurity matter that is not found in Queensland but would have a significant adverse impact on our health, way of life, and the economy or the environment if it entered the State. Prohibited matters must be reported to Biosecurity Queensland within 24 hours and all reasonable steps taken to minimise the risks of the prohibited matter and not make the situation worse.

- A '**restricted matter'** is a biosecurity matter found in Qld and has a significant impact on human health, social amenity, the economy or the environment. Restricted matters are further broken down into seven categories, with each category placing restrictions on the dealings with the biosecurity matter or actions required to be taken to minimise the spread and adverse impact of the biosecurity matter.

- An '**other matter'** is a biosecurity matter that is not a prohibited or restricted matter. Everyone is obligated to take all reasonable and practical steps to minimise the risks associated with other biosecurity matters under their control.

The Biosecurity Act is relevant to the Project in regard to the control and management of invasive plant and animal species.

2.4 VEGETATION MANAGEMENT ACT 1999

The *Vegetation Management Act 1999 (Qld)* (VM Act) is a part of a planning framework for the management of native vegetation across Qld. The *Vegetation Management Regulation 2012* (VMR) prescribes the status (otherwise known as the Vegetation Management Class (VM Class)) of each of the Regional Ecosystems (RE) identified within Qld.

The specific criteria used to assess the VM Class of RE are defined in Table 1. 'Remnant Vegetation' for an area of Queensland for which there is no RE map or remnant vegetation map, is any vegetation where the predominant canopy:

- covers more than 50% of the undisturbed predominant canopy;
- averages more than 70% of the vegetation's undisturbed height; and
- is composed of species characteristic of the vegetation's undisturbed dominant canopy.

Table 1 VM Class listing criteria for regional ecosystems

VM Class	Criteria
Endangered	• remnant vegetation is less than 10 % of its pre-clearing extent across the bioregion; or • 10–30% of its pre-clearing extent remains and the remnant vegetation is less than 10,000 ha.
Of Concern	• remnant vegetation is 10–30% of its pre-clearing extent across the bioregion; or • more than 30% of its pre-clearing extent remains and the remnant extent is less than 10,000 ha.
Least Concern	• remnant vegetation is over 30% of its pre-clearing extent across the bioregion, and the remnant area is greater than 10,000 ha.

2.5 BIODIVERSITY STATUS

The Department of Environment and Science (DES) Biodiversity Status is a classification assigned to REs and is used for a range of planning and management applications. These applications include the Biodiversity Planning Assessments and the determination of environmentally sensitive areas that are used for regulation of the mining industry through provisions in the *Environmental Protection Act 1994* (EP Act).

The biodiversity status is based on an assessment of the condition of remnant vegetation in addition to the criteria used to determine the class under the VM Act; including other threatening processes, such as reduction in biodiversity; weed invasion; grazing pressures; inappropriate fire management; fragmentation; and infrastructure development.

Table 2 Biodiversity Status additional listing criteria for regional ecosystems

Biodiversity Status	Criteria in addition to VM Class listing
Endangered	• less than 10% of its pre-clearing extent remains unaffected by severe degradation and/or biodiversity loss; or • 10–30% of its pre-clearing extent remains unaffected by severe degradation and/or biodiversity loss and the remnant vegetation is less than 10,000ha; or • it is a rare RE subject to a threatening process.
Of Concern	• 10–30% of its pre-clearing extent remains unaffected by moderate degradation and/or biodiversity loss.
No Concern at Present	• the degradation criteria listed above for 'endangered' or 'of concern' RE are not met.

2.6 QUEENSLAND ENVIRONMENTAL OFFSETS FRAMEWORK

The Queensland environmental offsets framework consists of the *Environmental Offsets Act 2014*, *Environmental Offsets Regulation 2014*, and the *Queensland Environmental Offsets Policy (*Version 1.6) (DES 2018b). The offsets framework requires environmental offsets to be delivered where an activity is likely to result in a significant residual impact on a prescribed environmental matter. The *Significant Residual Impact Guideline* (DES 2014a) is used to determine whether the residual impacts are significant.

Prescribed Environmental Matters include:

- Matters of National Environmental Significance (MNES);
- Matters of State Environmental Significance (MSES) (outlined below); and
- Matters of Local Environmental Significance (MLES).

MSES are defined in Schedule 2 of the *Environmental Offsets Regulation 2014*, and comprise:

- Regulated vegetation including:
    i. Endangered and Of Concern regional ecosystems;
    ii. Regional ecosystems (REs) that intersect areas shown as wetlands on the Vegetation Management Wetlands map;
    iii. REs located within a defined distance from the defining banks of a relevant watercourse or relevant drainage feature; or
    iv. REs mapped as essential habitat for endangered and vulnerable flora and fauna;
- Areas that provide connectivity and maintain ecosystem functioning;
- Mapped wetlands and watercourses including:
    i. Wetland protection areas, or areas of high ecological significance as shown on the Map of referable wetlands; or
    ii. High ecological value waters (as defined under the *Environmental Protection (Water) Policy 2009*);
- Designated precincts in a strategic environmental area under the *Regional Planning Interests Regulation 2014*;
- Protected wildlife habitat, which includes;
    i. High risk areas on the flora survey trigger map;
    ii. Areas that contain endangered or vulnerable plants;
    iii. Non-juvenile koala habitat trees in certain areas of south-east Queensland; or
    iv. Habitat for endangered, vulnerable and special least concern animals;
- Protected areas and highly protected zones of State marine parks;
- Fish habitat areas;
- Waterways providing for fish passage;
- Marine plants; and
- Legally secured offsets.

3.0 DESKTOP ASSESSMENT

Several desktop assessments were conducted to collate information on terrestrial ecological values identified in the region. These searches include previous surveys, community records and other sources. A review of databases facilitates the formulation of specific field survey techniques to target certain flora and fauna species known from the region.

All database searches were based on either the Lot/Plan, study area, or the central coordinate point (-23.6380 149.2514), depending on the database search undertaken. Database search results can be found in Appendix A. The following database searches were undertaken:

1. Environmental Reports Online (search based on EPC boundary);
    a. Biodiversity Planning Assessments;
    b. Matters of State Environmental Significance, including the regulated vegetation map;
    c. Regional Ecosystems;
2. Environmentally Sensitive Area (ESA) Mapping (search based on EPC boundary);
3. Regional Ecosystems Report (search based on EPC boundary);
4. Protected Plants Flora Survey Trigger Map (search based on central coordinate point);
5. EPBC Act Protected Matters Search Tool (PMST) (two searches based on central coordinate point with 10 km and 50 km buffers);
6. Wildlife Online Species List Request (two searches based on central coordinate point with 10 km and 50 km buffers);
    a. Rare and Threatened Species (two searches based on central coordinate point with 10 km and 50 km buffers);
    b. Introduced Species (search based on central coordinate point with 50 km buffer); and
7. Department of Environment and Science (DES) interactive Wetland*Maps* database and Map of Referable Wetlands;
8. Bureau of Meteorology (BoM) and Department of Natural Resources Mines and Energy (DNRME) mapping of Groundwater Dependent Ecosystems (GDEs); and
9. 'Back on Track' Species Prioritisation Framework Recovery Actions Database (RAD) for Queensland for the Fitzroy Natural Resource Management Region.

Additional resources that provide species records and related information such as the Atlas of Living Australia (ALA) and Queensland Museum were consulted where appropriate, such as to support determinations of the likelihood of individual species occurring (Appendix A).

The following sections address items of nature conservation relevant to the study area, that have been identified within the desktop assessment.

3.1 REGULATED VEGETATION

The Regulated Vegetation Management Map was consulted, and the following regulated vegetation categories have been identified within the Project:

- Category B: Remnant vegetation.
- Category C: High-value regrowth vegetation.
- Category R: Regrowth within 50 m of a watercourse or drainage feature located in Great Barrier Reef catchment areas.
- Category X: Non-remnant vegetation.

Figure 4 outlines the Endangered or Of Concern Regulated Vegetation identified as likely to occur within the study area.

3.1.1 Threatened Ecological Communities
