The *Conservation Advice (including listing advice) for the Poplar Box Grassy Woodland on Alluvial Plains* (TSSC n.d.) outlines five REs in Queensland that correspond fully or partly with the Poplar box TEC. Of these, RE 11.3.2 (*Eucalyptus populnea* woodland on alluvial plains) is mapped (desktop) as occurring within the study area. Consequently, the Poplar Box TEC has been added to the list of TECs potentially occurring within 50 km of the study area.

Each TEC, PMST type of presence and desktop assessment of likelihood of occurrence is outlined in Appendix B.

3.1.2 Regional Ecosystems

Current DES mapping identifies six remnant REs occurring within the study area (Table 3, Figure 5).

Table 3 Regional Ecosystems mapped within the study area

Regional Ecosystem	Description	VM Act Status	DES Biodiversity Status	EPBC Act
11.3.1	*Acacia harpophylla* and/or *Casuarina cristata* open forest on alluvial plains	Endangered	Endangered	Brigalow (*Acacia harpophylla* dominant and co-dominant)
11.3.2	*Eucalyptus populnea* woodland on alluvial plains	Of concern	Of concern	Poplar Box grassy woodland on alluvial plains Weeping Myall (*Acacia pendula)* Woodland
11.3.25	*Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines	Least concern	Of concern	
11.5.2	*Eucalyptus crebra, Corymbia spp.,* with *E. moluccana* woodland on lower slopes of Cainozoic sand plains and/or remnant surfaces	Least concern	No concern at present	
11.5.9b	*Eucalyptus crebra* and other *Eucalyptus spp.* and *Corymbia spp.* woodland on Cainozoic sand plains and/or remnant surfaces	Least concern	No concern at present	
11.7.2	*Acacia spp.* woodland on Cainozoic lateritic duricrust. Scarp retreat zone	Least concern	No concern at present

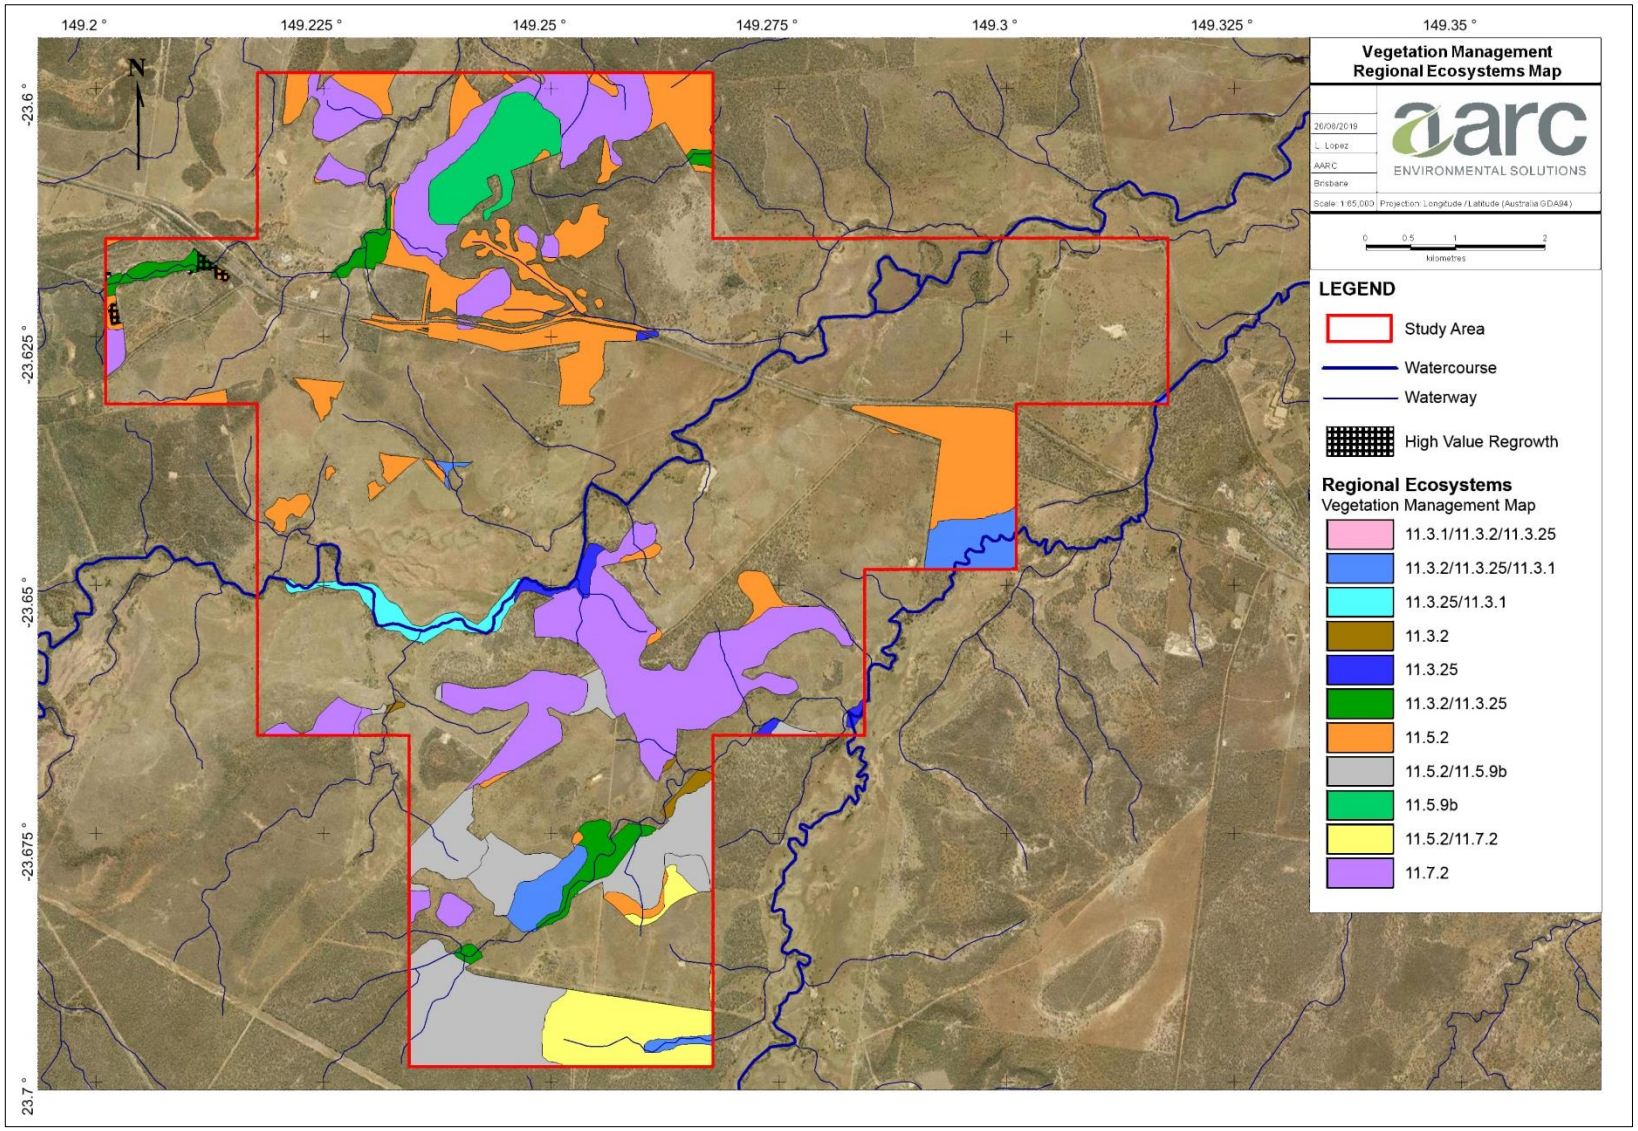

Figure 5 Regional Ecosystems Vegetation Management Map for the study area

3.2 SPECIES OF CONSERVATION SIGNIFICANCE

Species of conservation significance identified from the desktop assessment were assigned a likelihood of occurrence based on the criteria identified in Table 4. The assessment was based on the knowledge of ecologists, habitat suitability, previous surveys conducted near the study area and scientific literature.

Desktop assessments to determine the likelihood of each species identified during the database searches, with potential to occur on the study area, were undertaken prior to conducting the field surveys.

Targeted searches were undertaken in the field for species identified as either being likely to occur, or having potential to occur, within the study area, based on the desktop sources. The methodology was applied again after surveys to determine the likelihood of occurrence once additional site-based information became available.

Table 4 Criteria adopted for likelihood of occurrence determination

Likelihood of Occurrence	Criteria
Unlikely	• Species or species habitat may occur, is likely to occur or is known to occur from the broader search area (based on database searches); **but** ○ preferred habitat has not been identified within the study area; **and** there are no confirmed species records within 10 km of the study area; **or** ○ preferred habitat occurs within the study area, **but** there are no confirmed species records within 50 km of the study area.
Potential	• Species or species habitat may occur, is likely to occur or is known to occur from the broader search area (based on database searches); **and** ○ preferred habitat occurs within the study area; **but** there are no confirmed species records within 10 km of the study area; **however**, there are confirmed species records within 50 km of the study area; **or** • Species indicated as likely during desktop assessment, but field surveys revealed no evidence of occurrence in the study area.
Likely	• Preferred habitat occurs within the study area; **and** confirmed species records within 10 km of the study area; **however**, species not yet confirmed as occurring within the study area.
Known	• Confirmed species records within the study area (generally as a result of subsequent field survey).

3.2.1 Flora

3.2.1.1 State and Commonwealth Listed Flora Species

The PMST and the Wildlife Online Database identified 33 Endangered, Vulnerable or Near Threatened (EVNT) flora species with potential to occur within the 50 km buffer zone (Appendix A).

Each flora species, its protection status, habitat requirements, and assessment of likelihood of occurrence is provided in Appendix C.

Out of the 33 species identified by the desktop assessment six were considered to have the potential to occur within the study area and were targeted during the field survey. These six species and their conservation status under Commonwealth and State legislation are listed in Table 5.

3.2.1.2 Back on Track Flora Species Prioritisation

A RAD database search identified 35 Back on Track flora species ranked as either 'high' or 'critical' from the Fitzroy NRM Region. Of these 35 species, 30 are listed as EVNT under the NC Act and 16 are listed as EVNT under the EPBC Act. A list of these species and their relevant state and Commonwealth listings is presented in Table 6.

Table 6 Back on Track Priority Flora Species for the Fitzroy NRM Region

3.3 FAUNA

3.3.1 State and Commonwealth Listed Fauna Species

Database searches identified 29 EVNT fauna species with potential to occur within the 50 km of the study area (Appendix A).

A detailed assessment to determine the likelihood of EVNT species to occur on the study area was completed prior to conducting the field survey, for the purpose of determining targeted species and to guide field survey methodology. The detailed assessment was based on the knowledge of ecologists, habitat suitability and scientific literature. This assessment is provided in Appendix D.

The detailed assessment of likelihood of occurrence considered that 16 of the 29 species identified by the desktop assessment had the potential to occur within the study area and were targeted during the field survey. These 16 species and their conservation status under Commonwealth and State legislation are listed in Table 7.

Table 7 EVNT Fauna species with potential to occur within the study area

Scientific Name	Common Name	EPBC status	NC Act status

3.4 ENVIRONMENTALLY SENSITIVE AREAS

ESA mapping presents Category A, B, and C areas of conservation significance, including those under international agreements (e.g. Ramsar sites), fish habitat areas, declared catchment areas, Wild River nominated waterways and areas listed under the Directory of Important Wetlands. ESA mapping indicates that several ESAs occur within the study area (Appendix A).

A small section of (around 2.5 ha) of Taunton NP, falls within the study area, on the north west corner of the study area. This NP is identified as Category A ESA. Category B ESA, Endangered Regional Ecosystems is mapped as potentially occupying several parcels of land within the study area. These areas of Category B ESA represent the Endangered RE 11.3.1 (*Acacia harpophylla* and/or *Casuarina cristata* open forest on alluvial plains) as a mixed polygon, as mapped by the QLD Government in Figure 5.

3.5 WETLANDS

A review of the DES interactive Wetland*Maps* database and the Map of Referable Wetlands indicated three types of waterbodies are present within the study area. Riverine wetlands have been identified in association with the Charlevue Creek. Several small riverine, palustrine and lacustrine wetlands also mapped as potentially present within the study area (Figure 6). No wetlands of national or international importance have been recorded within the study area or surrounds. One High Ecological Significance (HES) wetland occurs approximately 4 km east of the study area (Figure 6).

The Aquatic Conservation Assessments defines the study area as having a sub-catchment conservation significance of medium, indicating that these wetlands have varied combinations of high and medium values amongst the assessment criteria.

3.5.1 Groundwater Dependant Ecosystem

Groundwater Dependant Ecosystems (GDEs) are ecosystems that are reliant on groundwater for their survival; they can be solely reliant on groundwater such as ecosystems relying on aquifers or may intermittently depend on groundwater, which would be the case of riparian vegetation, particularly on ephemeral river systems (IESC 2019). GDEs are grouped according to the 'Groundwater dependant ecosystem typology framework' which separates GDEs based on their type of groundwater reliance (DSITI 2015). The three GDE types include:

- surface expression GDEs, associated with springs, both permanent and non-permanent;
- terrestrial GDEs, reliant on the sub-surface presence of groundwater and their ability to draw upon this resource; and
- subterranean GDEs, wetland systems that occur below the surface of the ground and can include aquifer ecosystems and cave ecosystems.

The BoM has developed an interactive tool for assistance in the identification of GDEs, the National Atlas of GDEs (GDE Atlas) (BoM 2019a). GDE Atlas is a tool used for planning, management and development and incorporates a national dataset of GDEs throughout Australia. The GDE Atlas supplies information to support the identification of GDEs but does not provide a definitive map of GDEs. The BoM mapped both terrestrial and surface expression (aquatic) GDEs as having the potential to occur within the study area (Figure 7 and Figure 8). Within the study area high potential terrestrial GDEs were mapped in association with Charlevue Creek and Springton Creek and moderate with some of the smaller waterways.

The Department of Natural Resources, Mining and Energy (DNRME) also has developed mapping of potential GDEs throughout Queensland. No surface expression GDEs or Subterranean GDEs were mapped by DNRME as occurring or having the potential to occur within the study area. Within the study area there are several 'low-confidence' potential terrestrial GDE areas along Charlevue Creek, Springton Creek and Stanley Creek (Figure 9). According to Government RE mapping these are in association with RE 11.3.2, 11.3.25 and 11.3.1.

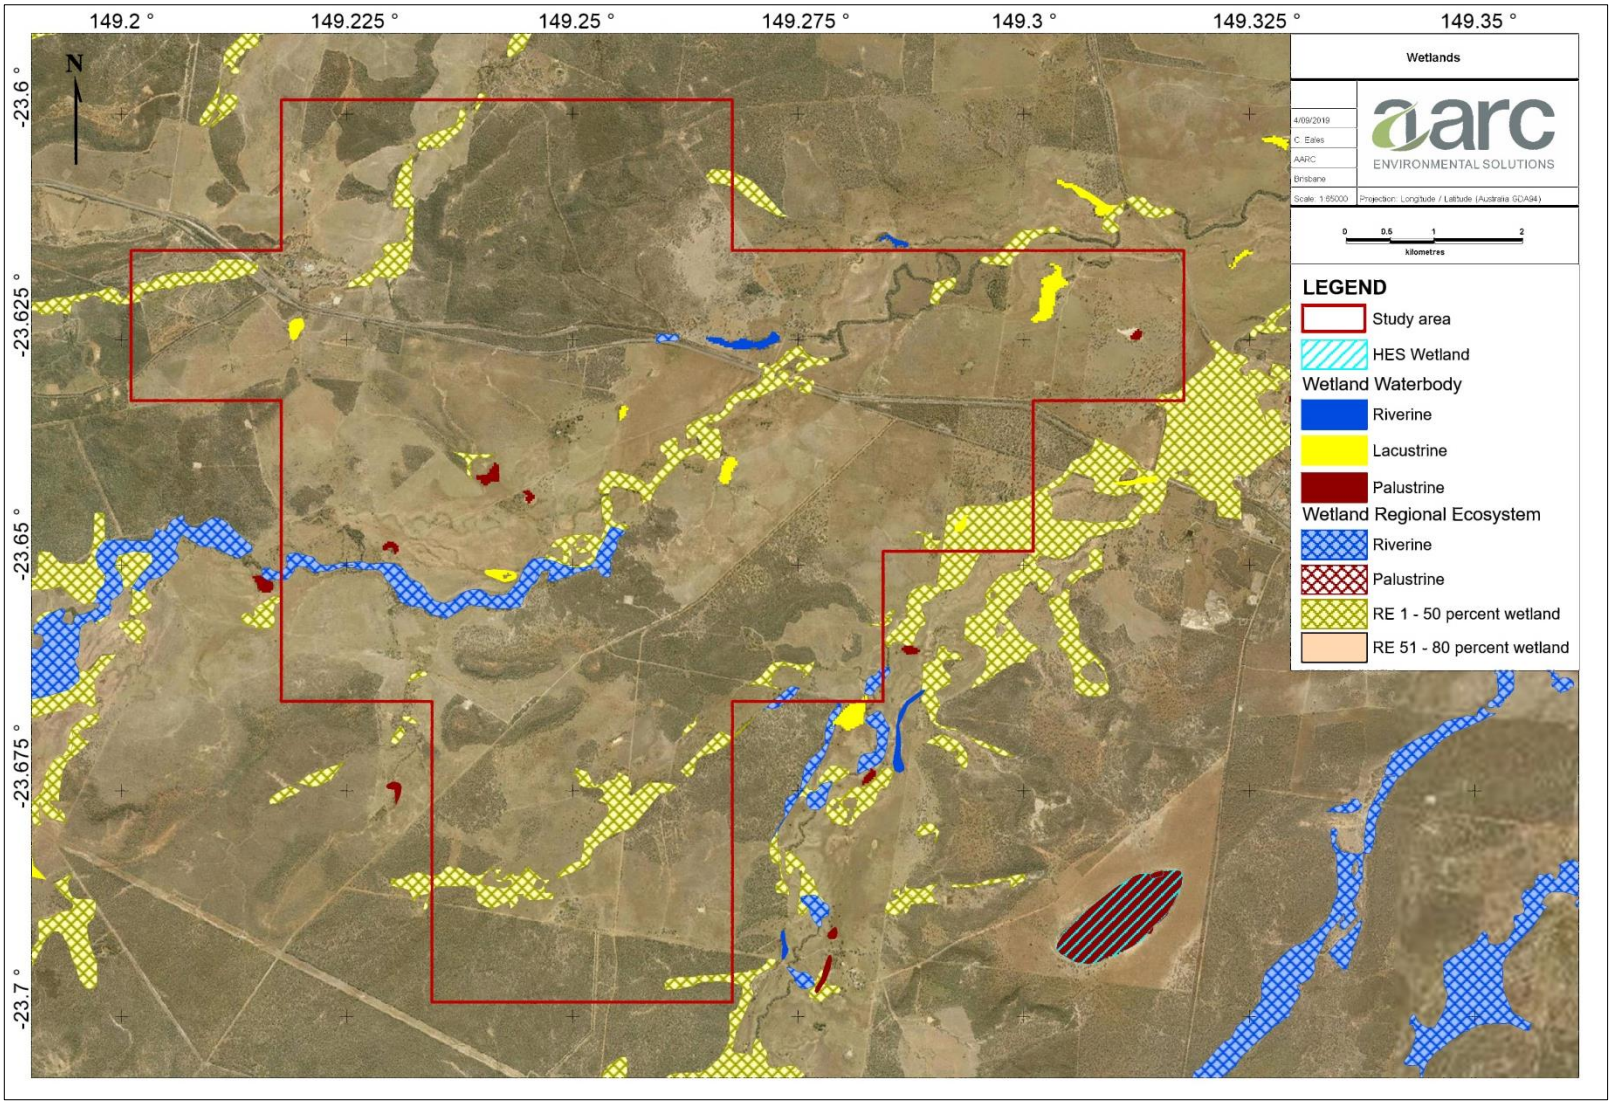

Figure 6 Wetland Habitats

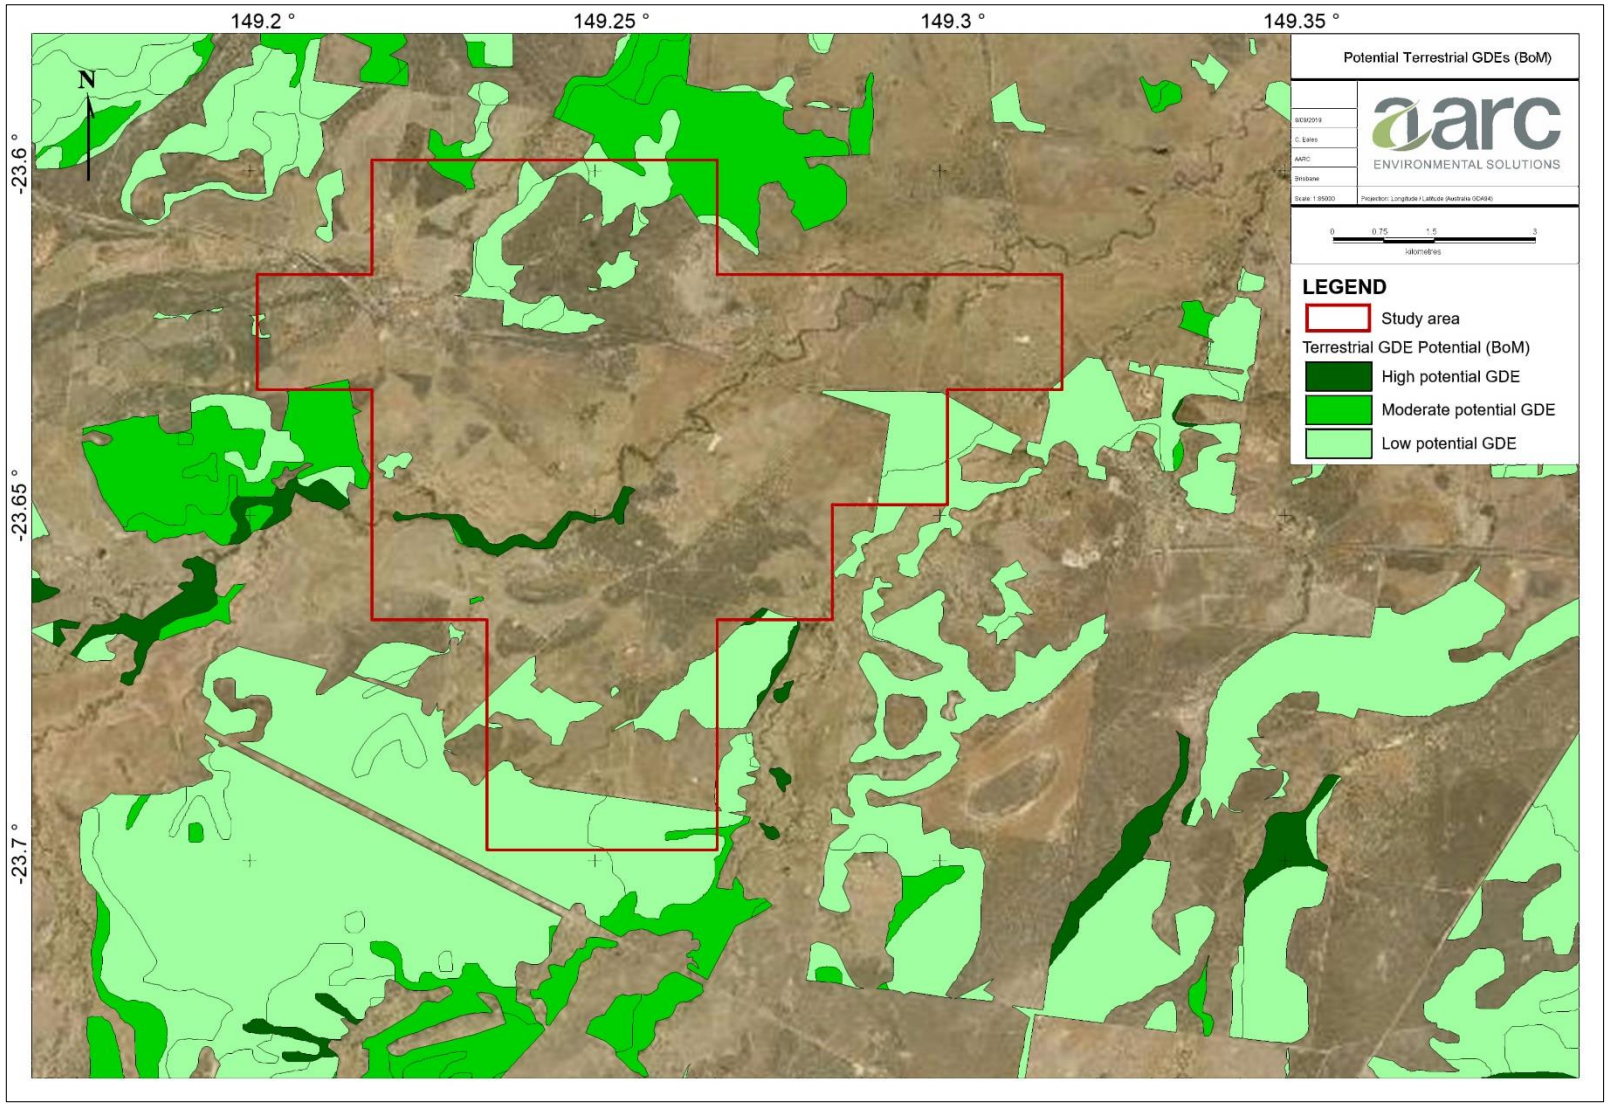

Figure 7 Potential Terrestrial GDEs (BoM)

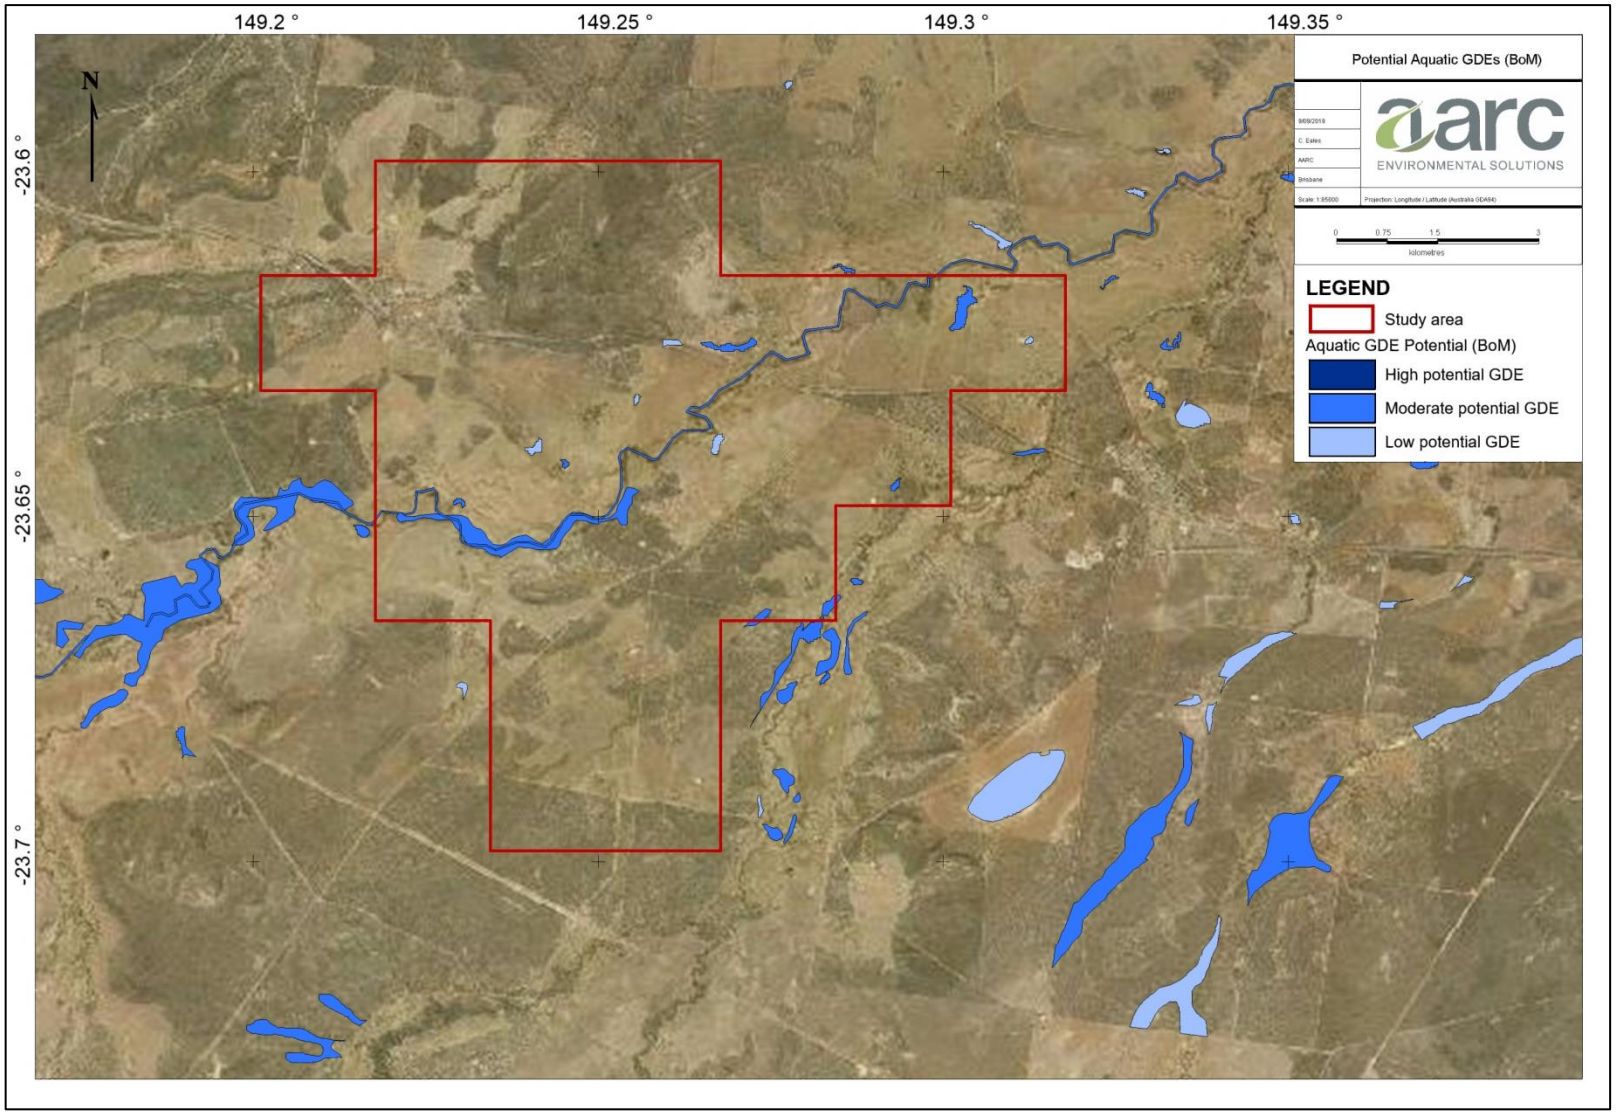

Figure 8 Potential Aquatic GDEs (BoM)

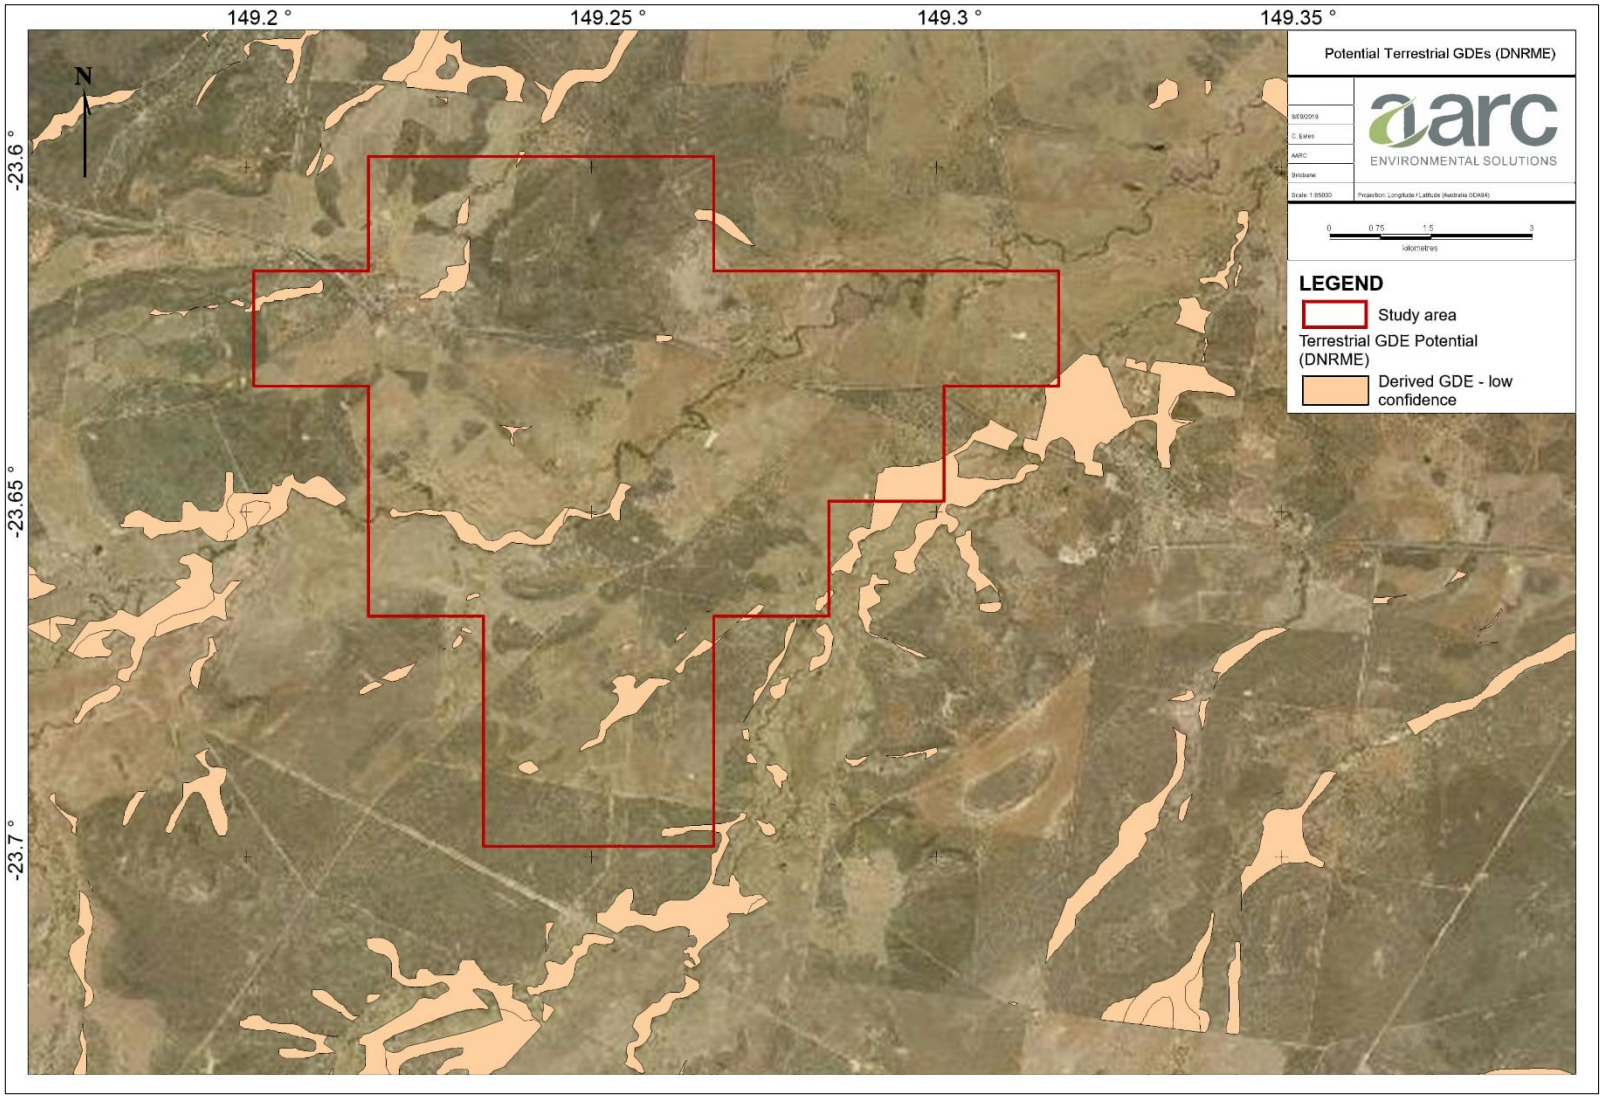

Figure 9 Potential Terrestrial GDEs (DNRME)

4.0 METHODOLOGY

4.1 BIOREGION

The study area is located within the Brigalow Belt bioregion. This bioregion occupies over a fifth of Queensland; from Townsville in the north to near the border of New South Wales in the south. The Brigalow Belt bioregion is characterised by Brigalow (*Acacia harpophylla*) woodland but presents other vegetation such as semi evergreen vine thickets, dry eucalypt woodlands and native Bluegrass (*Dichanthium* sp) grasslands. Due to the size of Brigalow Belt bioregion, it covers a broad climatic gradient as well as a diversity of soils and topography, the Brigalow Belt hosts a high diversity flora and fauna (Young et al 1999; McFarland et al. 1999 cited in DES 2018c).

As a result of agricultural and development activities, most of the relatively undisturbed areas is confined to the rugged parts of the landscape with less development value (DES 2018c), parks and reserve areas.

4.2 FIELD SURVEY GUIDELINES

Field surveys have been undertaken since 2017 covering a range of seasonal and climatic conditions. Over the study period several updates to existing survey guideline material occurred, as well as the introduction of entirely new material.

At the time of reporting the material that has guided methodology is as follows:

- *Site examination for threatened and endangered plant species* (Goff, Dawson & Rochow 1982);
- *Management of endangered plants* (Cropper 1993);
- *Survey guidelines for Australia's threatened bats* (DoEE 2010a);
- *Survey guidelines for Australia's threatened birds* (DoEE 2010b);
- *Survey guidelines for Australia's threatened mammals* (DoEE 2011a);
- *Survey guidelines for Australia's threatened reptiles* (DoEE 2011b);
- *Survey Standards: Greater Glider, Petauroides volans* (MacHunter, Brown, Loyn & Lumsden 2011);
- *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland (V3.0)* (Eyre *et al.* 2018);
- *Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland (V5.0)* (Neldner *et al.* 2019); and

4.3 SURVEY SEASONALITY

Survey timing was selected in accordance with the *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland V3.0* (Eyre *et al.* 2018). These guidelines recommend that fauna surveys within the Brigalow Belt bioregion should be conducted during spring to early summer (i.e. September to mid-November) and during autumn (i.e. March to mid-May).

The autumn survey should be undertaken after summer as the temperatures decrease but before the onset of cold winter nights. This coincides with another active period including dispersal and migration of many species (Eyre *et al.* 2018). The first and third ecological survey for the study area was undertaken during autumn, from the 4th - 12th May 2017 and from the 16th - 23rd February 2018.

The spring season timing provides ideal survey conditions as temperatures begin to rise and a peak in vertebrate activity is observed with the commencement of the breeding period for many species (Eyre *et al.* 2018). The second survey was undertaken during spring, from the 18th - 30th September 2017.

A fourth survey targeting Microchiroptera bat species and vegetation mapping took place from the 22nd - 29th March 2018, meeting the requirements for the *Survey Guidelines for Australia's Threatened Bats* (DoEE 2010a).

The final surveys to finalise the vegetation mapping took place on the 1st, 2nd and 19th August 2019.

Autumn 2017 Survey

Mild conditions were recorded on the study area during the May 2017 ecology survey according to data obtained with SILO and personal observations. Throughout the survey period, a total of 20.2 mm of rainfall was recorded within the region, however, within the study area the rain was only registered on the evening of the 9th and during the day on the 10th. Maximum daily temperatures were slightly lower than average for the study area's locality reaching only 28.5°C and dropping to 11°C at night.

Spring 2017 Survey

No rainfall was registered during the spring survey period. There was some fluctuation on the temperature throughout the fieldwork, with the highest temperature of 38.5°C recorded and a minimum temperature of 13°C in the region.

Autumn 2018 Surveys

Hot and wet conditions were recorded on the study area (SILO) during the autumn 2018 Ecology survey. Throughout the survey period, 61.5 mm of rainfall was recorded within the region, with most of the rainfall in the study area registered on the 20th February. Maximum daily temperatures reached 35.5°C, dropping to 19.5°C at night.

During the second autumn 2018 survey (consistent on targeted micro-bat and vegetation mapping survey) the conditions were mild, with 6.1 mm of rainfall registered in the region. Maximum temperatures of 34.5°C reached on the 28th of March and minimum temperatures reached 18°C.

Winter Surveys 2019

No rainfall was registered during the spring survey period. The field observations recorded as overcast the 1st of August and sunny and warm the 2nd and the 19th of August. The temperatures registered during the day in the region reached 29°C as maximum and 20°C as the minimum.

4.4 FLORA

The flora survey regime was designed to meet the following objectives:

1. Obtain a detailed floristic summary of the study area through the compilation of a flora species list;

2. Define distinct vegetation communities and compile detailed descriptions of the floristic assemblages in each community;

3. Detect and identify EVNT flora species and threatened ecological communities; and

4. Produce a comprehensive site vegetation map at a 1:10,000 scale.

Plants species were identified using several taxonomic keys, field guides and online reference material. For any plant species that could not be identified in the field, a sample was collected and sent to the Queensland Herbarium.

4.4.1 Vegetation Mapping and Community Description

Methods used to produce a vegetation map and define communities were in accordance with those described in *Methodology for surveying and mapping regional ecosystems and vegetation communities in Queensland* (V5.0) (Neldner *et al.* 2019). Version 1.0 of this document was first released by the Qld Herbarium in 1999, with further additions and refinement to the methodology documented in subsequent versions (2004, 2005, 2017, 2019). Field mapping and community description was undertaken in accordance with the version of this guideline that was current at the time of each flora survey.

All RE's are described in this consolidated report in accordance with the Qld RE Description Database (REDD) (DES 2019c). The use of the terms 'remnant' and 'non-remnant vegetation' are as per the definitions of the VM Act. Neldner *et al.* (2019) describes four levels of floristic sampling, two of which were utilised in the study area assessment and defined below.

Secondary Transects: were used for classification and detailed descriptions of regional ecosystems and vegetation communities. Each site consisted of a 50 m long transect specifically marked using a Global Positioning System (GPS) at the start and end points, each accompanied by a photograph taken with a viewpoint of the transect. Foliage projection cover was measured along the transect and calculated as a percentage. Percentage composition of each ground cover species was recorded in five 1 m x 1 m quadrats located at 10 m intervals along the transect line. Within the 50 m x 10 m plot, each species present was recorded including relative abundance within each stratum, height of each stratum, and stem density (for woody stems only). Species representative of the community but located outside of the plot were also recorded. Where a plant could not be positively identified to species level, a voucher specimen was collected for identification by the Qld Herbarium.

Quaternary Sites: are rapid vegetation assessments primarily used to verify regional ecosystem / vegetation community mapping. Each site consisted of a rapid assessment of the vegetation within an approximately 20 m by 20 m plot. Data collected included marking the GPS location, taking photographs, recording the dominant species in the characteristic stratum as well as stratum height. Soil and landform data was recorded to confirm land zone, as many REs can only be differentiated by the land zone they occur on, due to their floristic assemblage descriptions being virtually identical.

Flora was sampled in autumn, spring and winter season to best account for both annual and perennial species assemblages. Sampling was undertaken at a minimum density of 25 observations per 100 ha to complete mapping at the 1:10,000 scale. Subsequently, the flora sites were projected on a Geographical Information System (GIS), and used in conjunction with satellite images, aerial photographs, topographical and geological maps to effectively produce a ground verified vegetation map.

A total of 28 secondary transects and over 1000 quaternary sites were sampled across the study area. The locations of all the flora secondary transects and quaternary sites are shown in Figure 10.

4.4.2 Targeted Searches for Species of Conservation Significance

To gain an understanding of each EVNT species, preferred habitat and ecology, several resources were consulted to pre-determine habitat to be targeted during the field surveys. This included, but was not limited to:

- Commonwealth Listing Advice;
- Commonwealth Approved Conservation Advice;
- Species Profile and Threats Database (SPRAT); and
- WetlandInfo: Plants, Animals, Soils, Water and More Search Tool.

The predominant survey technique utilised for targeted species across the cumulative survey effort was the 'timed meander' technique (Cropper 1993; Goff 1982). This technique involved traversing suitable habitat in a random manner so as to maximise the coverage of habitat and the encounter rate of different species. For any EVNT plants observed the location recorded using a GPS. If there was any uncertainty in identification of a species, a representative voucher specimen was collected for identification by the Queensland Herbarium in accordance with the Herbarium procedures (DSITI 2016).

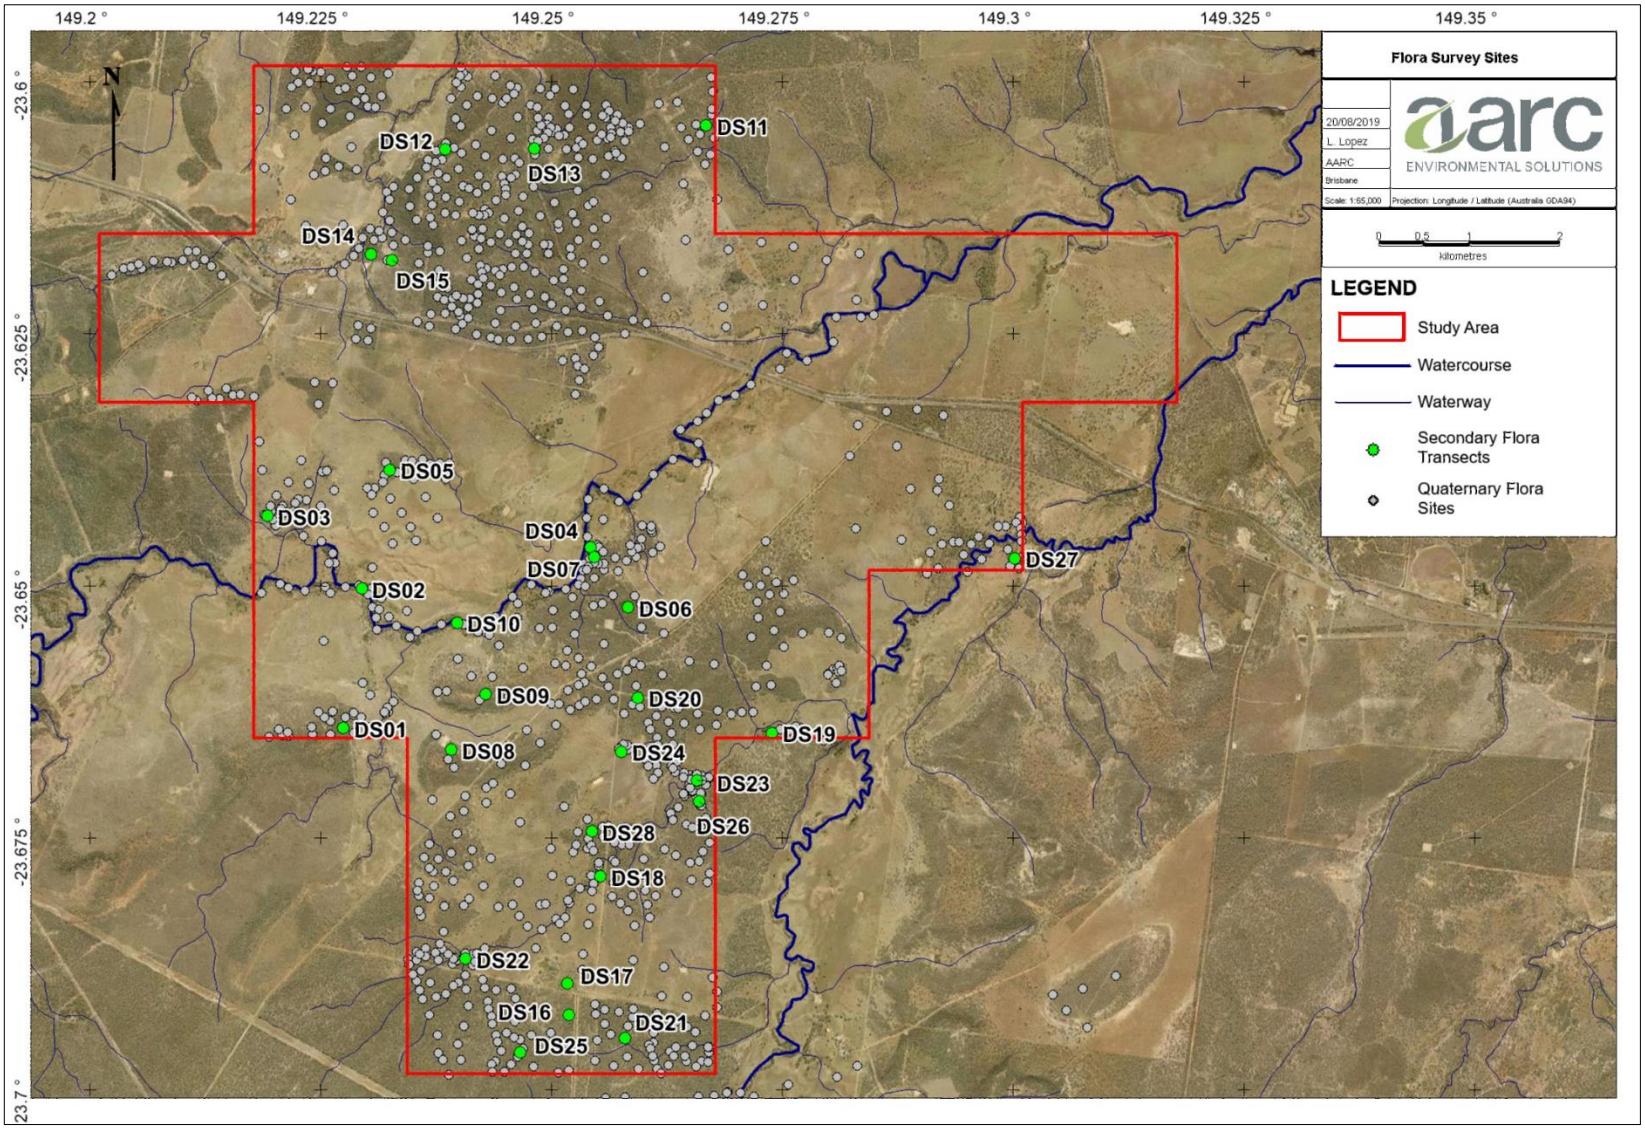

Figure 10 Gemini Project flora survey sites

4.5 FAUNA

4.5.1 Fauna Trapping Sites and Survey Locations

Site scoping was conducted prior to each survey by undertaking a desktop assessment to determine habitat types of the intended study area in accordance with survey objectives. Examination of satellite imagery, topographical features, broad vegetation group (BVG) guided the location of baseline fauna trapping efforts ensuring adequate distribution across, and representation of fauna habitat types. Preferred habitat of targeted species was identified in the same manner to locate targeted trapping and survey effort in suitable locations.

Vehicle-based reconnaissance was carried out, where possible, to assist in locating suitable survey sites, maximising the representative vegetation and fauna habitat survey coverage. This also aided in targeting habitats potentially occupied by species of conservation significance. Vegetation communities optimal for installing fauna sites were then surveyed on foot to allow further ecological familiarisation and comprehensive survey coverage.

The fauna survey methodology employed for the study area was based on the *Survey Guidelines for Australia's Threatened Bats* (DoEE 2010a) and the *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland V2.0* (Eyre *et al.* 2014) which was the current version at the time of all surveys. The survey was conducted in compliance with AARC's scientific purposes permit and animal ethics approval. All fauna trapping efforts were conducted over four consecutive nights (unless otherwise stated).

All fauna survey locations are illustrated in Figure 7 and Figure 8 and described in Table 7. The detection techniques employed at each site is defined in Appendix E, and for descriptions of each technique refer to Section 4.5.2. Total survey effort undertaken during each survey is detailed in Table 9, and total survey effort accumulated across all surveys is summarised in Table 10.

Sampling of vertebrate fauna was conducted primarily along transects established in each of the major fauna habitat types and at changes in vegetation community groups. During all surveys, observations of species outside the specific fauna study locations but within the survey area were noted as incidental observations.

Many fauna species, notably frogs and reptiles, do not have widely accepted common names. Scientific names for species often change with taxonomic revisions. For the purpose of this report, all nomenclature used will follow that used in the ALA database (ALA 2019).

4.5.2 Fauna Survey Sites

Fauna sampling was conducted amongst representative areas of the main habitat types on the study area site to maximise the potential for sampling all wildlife present:

- Habitat type 1: Woodlands dominated *Eucalyptus crebra* (Narrow-leaved red ironbark) frequently with *Corymbia spp.* or *Callitris spp.* on flat to undulating plains.
- Habitat type 2: Low woodlands to tall shrublands dominated by *Acacia* spp. on residuals. Species include *A. shirleyi* (Lancewood) and *A. rhodoxylon* (Rosewood).
- Habitat type 3: Open forests and woodlands dominated by *Eucalyptus tereticornis* (Blue gum) fringing drainage lines.
- Habitat type 4: Woodlands dominated by *Eucalyptus populnea* (Poplar box) on alluvium, sand plains and foot slopes of hills and ranges

A total of 15 full fauna survey sites, 8 harp trap sites and 3 mist nets were established across the study area during the ecology survey period.

Descriptions and photos of the survey sites are provided in Appendix E whereas all fauna survey locations indicating the habitat type where they were located and targeted micro-bat trapping sites are shown in Figure 11.

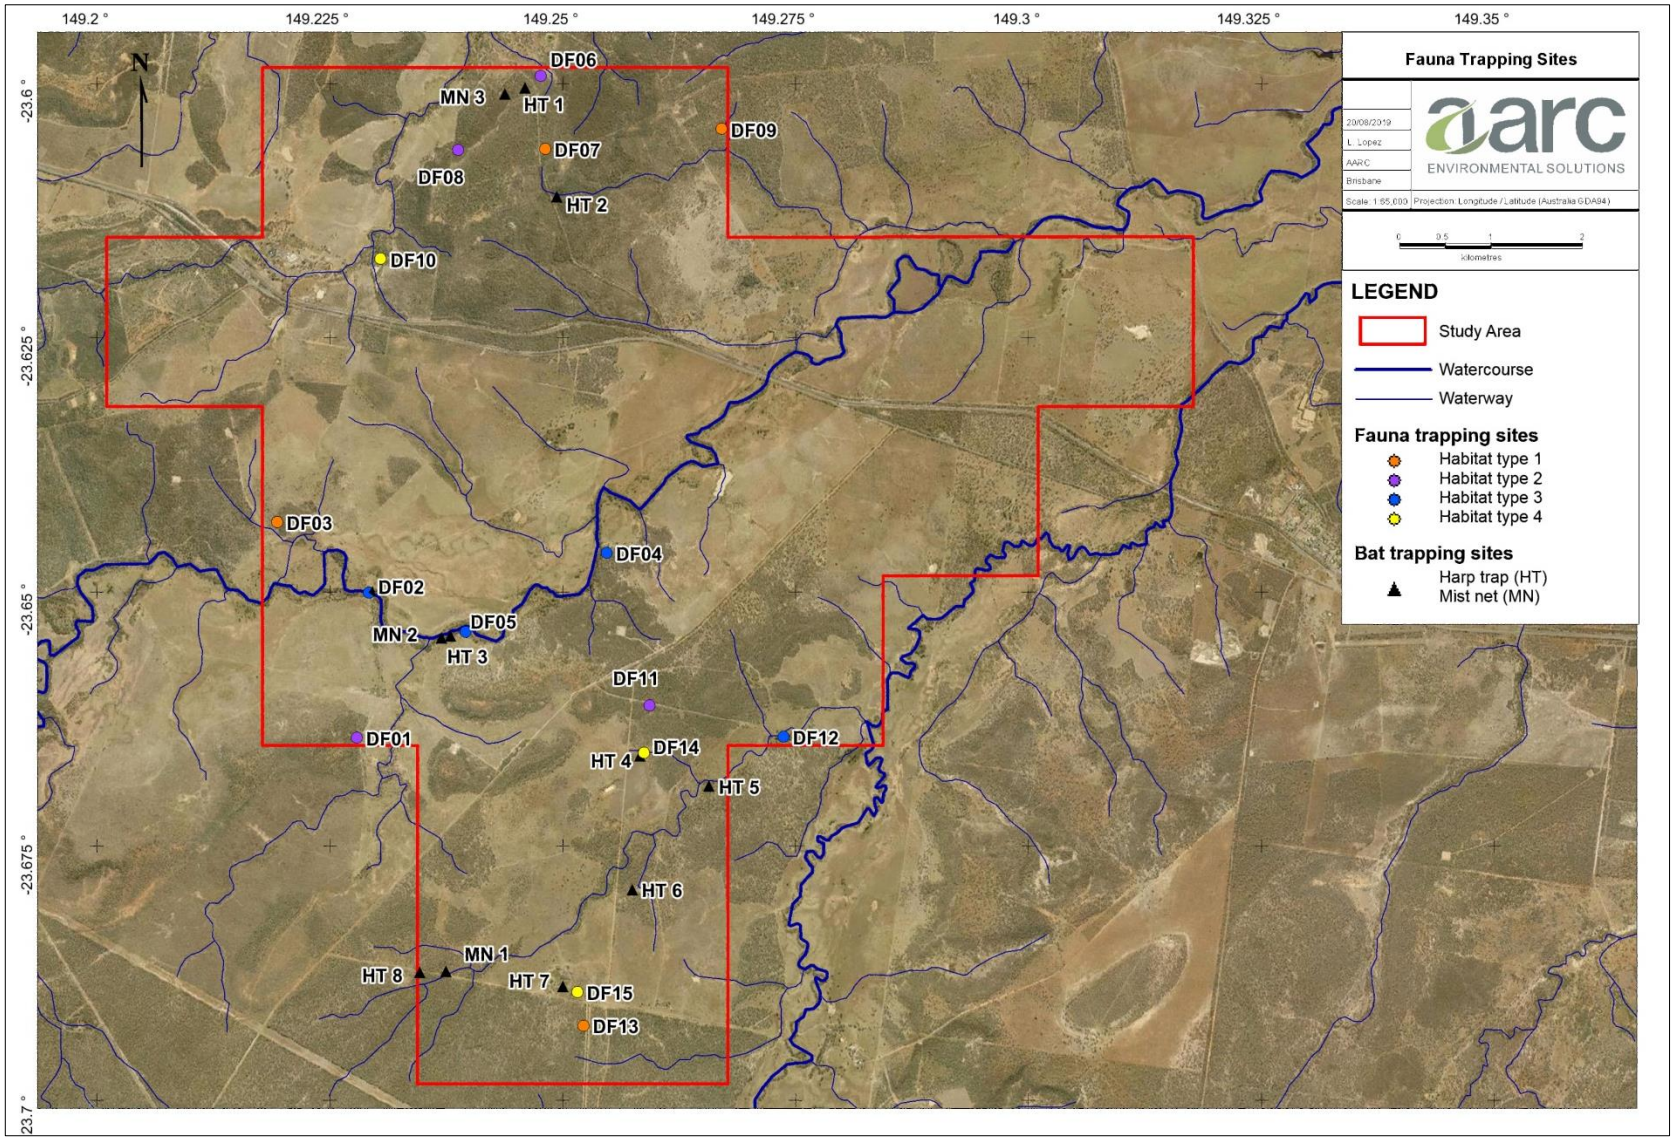

Figure 11 Gemini Project Fauna sites

4.5.3 Detection Techniques

A description of the techniques employed to survey the fauna occurring on the study area site (unless otherwise stated in the site description in Appendix E) is provided below:

Elliott trapping

Elliott traps are aluminium boxes with doors triggered by a floor treadle that are used to target small ground-dwelling mammals inhabiting the study area site. Traps were baited with a mixture of oats, peanut butter, and vanilla essence (referred to here-in as 'mammal bait'). At each site, two parallel lines each with 10 Elliott traps were placed at 10 m intervals. Alternatively, where fauna sites were established in linear riparian habitats, traps were positioned at 10 m intervals along a single central transect. Traps were strategically positioned under shrubs or beside logs to reduce exposure of trapped animals to the sun, wind and rain and maximise trap success.

Automated Camera Trapping

Automated camera trapping is a less invasive method of surveying medium and large-sized nocturnal terrestrial species. Cameras are usually attached to a tree in a position that offers an unobstructed view over a track or clearing. A bait tube constructed with PVC and filled with bait (on this occasion chicken necks), is pegged to the ground and positioned in clear view of the camera. Motion-sensing technology in the camera detect movement and trigger a photographic response. This is a highly effective survey method and is now widely used instead of cage trapping (Eyre *et al.* 2018). Automated cameras were deployed for four nights at all fauna survey locations during the survey period.

Pitfall Trapping

To target small ground-dwelling taxa (e.g. reptiles, mammals and amphibians), a pitfall trap line was established at all fauna sites. Each line consisted of a 30 centimetre (cm) tall drift fence running along the ground and crossing the middle of four 20 litre buckets buried flush with the soil surface. Each pitfall trapping line was constructed in a T-shape design with 45 m of drift fence and buckets placed at approximately 7.5 m intervals. The bottom edge of each drift fence was buried to guide target animals towards the buckets. A small amount of soil, vegetation litter, a damp sponge and a small plastic pipe were placed in the bottom of each bucket to provide shelter and moisture for captured wildlife.

Funnel Trapping

Funnel traps are elongated box-shaped traps made of wire and fine mesh. Six funnel traps were positioned at each fauna site in order to catch medium and large-sized terrestrial reptiles, snakes and some species of medium-sized skinks, dragons and geckos. Funnel traps were also set with a damp sponge and covered with hessian bags to provide shelter and moisture for captured wildlife. Where pitfall trapping lines were established at a fauna site, funnel traps were placed at the end of each drift fence. In the absence of a pitfall line, funnel traps were placed in suitable habitat along fallen timber or rocky outcrops throughout the fauna site (100 by 100 m plot).

Microbat Surveying

Micro-bats (Microchiropterans) form an extremely diverse group of wildlife and the identification of individual species requires the use of specialised survey methods due to the superficial similarity of many species, their small size, and largely inaudible calls.

The QLD Government *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland v3.0* recommended method for bat survey is the use of a bat recorder (i.e. ANABAT). These are automated

devices that record the echolocation calls of microbat species. The majority of microbat species in Australia can be identified from a species specific 'call signature'. However, there is a small selection of species that cannot be reliably identified to species level by call signature. The *Nyctophilus* genus has several species in Australia and cannot be identified further than the genus level. Corben's long-eared bat (*Nyctophilus corbeni*) is listed as Vulnerable under both the EPBC Act and the NC Act. The distribution of *Nyctophilus corbeni* overlies much of central Queensland, including the study area.

A Long-eared bat (*Nyctophilus* sp.) was detected via echolocation records on the study area during surveys but could not be identified to species level. Ecologists completed a targeted micro-bat survey in order to correctly identify the *Nyctophilus* species to adequately satisfy the *Survey Guidelines for Australia's Threatened Bats* (DoEE 2010a). This targeted micro-bat survey utilised Harp Traps and Mist Nets in addition to ANABAT recorder.

The use of the following methodology was conducted in accordance with the *Survey Guidelines for Australia's Threatened Bats* and the *Terrestrial Vertebrate Fauna Survey Guidelines for Queensland (Eyre et. al 2018).* These fauna survey methods were only adopted for the specialised Micro-bat 2018 autumn survey conducted by AARC ecologists.

ANABAT Recorders

In order to navigate and hunt at night micro-bats use high frequency echolocation calls, most of which are above the frequency range audible to humans (i.e. ultrasound). These echolocation calls provide an opportunity to unobtrusively survey and identify micro-bats through the use of a specialised ultrasonic recorders. During the survey event, bat call detection devices (i.e. Songmeter or ANABAT recorder) were strategically positioned to detect micro-bat calls at all fauna trapping sites. A bat call detector was left at each site for a minimum of 3 nights. This specialised micro-bat survey was utilised during all terrestrial surveys. A bat call detector was left at each site for 3 nights, and bat call analysis performed by Greg Ford of Balance Environmental (Appendix G).

Mist Net

Mist nets are more versatile than harp traps and can be used in a wider variety of habitat types and locations to capture bats, including open areas. The mist net consisted of fine monofilament net approximately 12 m wide by 5 m tall with a mesh size of 19 mm and was held in tension using rope rigging between two trees. The height of the net is divided into 'benches' or 'shelves', each with a loose pocket of netting that helps entangle the captured bats.

A single Mist Net was deployed at three locations over the second autumn survey. They were generally set several hours after sunset, these nets remained raised for a minimum of 1 hour at each survey site. The position of each Mist Net was marked using a handheld GPS. Photographs of each of these sites were taken with a digital camera and site data (such as vegetation type, weather conditions and habitat condition) was recorded.

Harp Trap

Harp trapping is employed for resolving the presence of species whose calls cannot be separated or identified using bat detectors, such as the *Nyctophilus* genus, and for collecting abundance and demographic information such as sex, age or breeding condition, which cannot be determined from call echolocation. Harp traps consisted of two or three banks of vertically strung nylon lines held in a rigid aluminium frame above a large calico holding bag and mounted on adjustable legs. Harp traps are most suited to restricted flyways in well vegetated areas, such as along creeks and tracks, preferably placed where fringing vegetation abuts the trap edges on both sides and above. Bats flying along a flyway are

typically unable to detect the lines and get caught between the banks of nylon line and slide down into the large, plastic-lined cloth holding bag, where the bats are unable to climb out.

A single two bank harp trap was deployed at eight sites. Traps were deployed for four nights per site. They were set up shortly before dusk each night and packed up either at dawn or in the early morning. Traps were checked several hours after dusk and again before dawn each night. The position of each trap was marked with a handheld GPS. Photographs of each trap site were taken with a digital camera and site data (such as vegetation type, weather conditions and habitat condition) was recorded.

Bird Surveying

Dedicated searches for birds was conducted visually and aurally during early mornings during peak avian activity. A dedicated search for diurnal birds was conducted visually and aurally at each fauna site. A minimum of one hour of bird surveying per fauna site was conducted in the early morning or late afternoon when bird activity was highest. In addition, opportunistic diurnal searches were also conducted on foot in areas considered likely to have high avian diversity (e.g. vegetated watercourses or dams), or likely to contain cryptic or threatened bird species.

Spotlighting

Spotlighting was carried out in the early evenings (before midnight) during all surveys to maximise encounter rate of nocturnal wildlife such as night birds and arboreal mammals primarily active at night. Two spotlighting techniques were employed:

1. Foot traverses: Dedicated spotlighting events were undertaken on foot at each fauna site. Searches were undertaken over two events where possible, one within the first hour following nightfall, and one after the first hour. Two ecologists randomly traversed the area with spotlights and binoculars, and wherever possible, bark crevices and tree hollows were examined. A slow walking speed (approximately 1 km per hour) was maintained across the length of the survey area to fully facilitate intensive listening and thorough visual searching.

2. Vehicle searches: During any driving on the study area after dark, spotlighting was conducted by the passenger/s from the slow-moving vehicle, to maximise study area coverage that cannot be achieved with foot traverses alone. Spotlights were used to scan trackside vegetation for arboreal and ground-dwelling wildlife.

Call Playback

Several nocturnal bird species are highly cryptic; occurring in naturally low population densities, are wide-ranging, and call infrequently. Detection rates are typically low without solicitation in the form of playback of pre-recorded calls to elicit a response (Kavanagh and Peake 1993; Debus 1995). Detectability of smaller nocturnal bird species such as the Southern Boobook *Ninox novaeseelandiae* and Australian owlet nightjar (*Aegotheles cristatus*), and the arboreal marsupial Yellow-bellied glider (*Petaurus australis*) also increase with playback of large owl calls. Smaller, cryptic arboreal species such as Squirrel glider (*P. norfolcensis*) and Sugar glider (*P. breviceps*) can also respond to owl call playback.

Call playback is undertaken prior to spotlighting foot traverses to minimise the chance of spooking species capable of leaving the area undetected. A series of species call would be selected depending on the surrounding habitat suitability, and each would be played for three minutes, followed by a two-minute listening period, with the cycle repeated three times for each species. Calls were played using a megaphone and loud enough so that the softest call could be heard 100-200 m away. Following the completion of all playback cycles, the area would then be spotlighted as described above.

Habitat Searching

To further enhance the likelihood of detecting small cryptic species, dedicated diurnal searches were conducted at each fauna site. This was spread over several events, two per site, during the survey period. Additional habitat searches were carried out during trap checks and while doing the flora surveys. Searches were typically undertaken during the late morning, allowing for reptile activity to increase with rising temperatures, but before the maximum heat of the day. Searching techniques involve the careful rolling of rocks and logs, rustling through leaf litter, and peeling back of exfoliating bark from standing trees. For targeted reptile species, dedicated searches were conducted opportunistically when preferred habitat was encountered (e.g. Gilgai formations or dense ground debris).

Evidence of wildlife was also searched for during these surveys' identification of tracks, scats and other signs of occupation (e.g. tree trunk scratches). For scats not identifiable in the field, they were collected and sent to a scat analysis expert (Barbara Triggs) for identification of the species responsible for the scat and/or where possible, the identification of prey species material present in predator scats.

Incidental Recordings

Throughout each survey period, ecologists were traversing the study area on foot and by vehicle every day for numerous hours whilst conducting routine survey activities (e.g. driving between sites, checking traps, vegetation surveys etc.). The ecologists remained alert and would record numerous wildlife species as observed or heard during the survey period. As with the habitat searches, this included signs or evidence of wildlife, and included constant vigilance for raptor nests. All areas of the study area have been visited by ecologists throughout the surveys.

4.5.4 Fauna Survey Effort

Survey effort undertaken during each survey event is detailed in Table 9 for each fauna sampling technique.

Table 9 Survey effort

Sampling Technique	Survey Effort				
	Autumn Survey 2017	Spring Survey 2017	Autumn Survey 2018	Micro-bat Survey 2018	Total Survey effort
Elliott Trapping	4 sites x 20 traps x 4 nights = 320 trap nights	6 sites x 20 traps x 4 nights = 480 trap nights	5 sites x 20 traps x 4 nights = 400 trap nights	-	1,200 TTN
Automated Camera Trapping	4 sites x 1 camera x 4 nights = 16 trap nights	6 sites x 1 camera x 4 nights = 24 trap nights	5 sites x 1 camera x 4 nights = 20 trap nights	-	60 TTN
Pitfall Trapping	4 sites x 4 pitfalls x 4 nights = 64 trap nights	6 sites x 4 pitfalls x 4 nights = 96 trap nights	5 sites x 4 pitfalls x 4 nights = 80 trap nights	-	240 TTN
Funnel Trapping	4 sites x 6 funnels x 4 nights = 96 trap nights	6 sites x 6 funnels x 4 nights = 144 trap nights	5 sites x 6 funnels x 4 nights = 120 trap nights	-	360 TTN
ANABAT	(3 sites x 1 bat detector x 3 nights) + (1 site x 1 bat detector x 2 nights) = 11 trap nights	(3 sites x 1 bat detector x 3 nights) + (1 site x 1 bat detector x 2 nights) + (1 site x 1 bat detector x 4 nights) = 15 trap nights	4 sites x 1 bat detector x 3 nights = 12 trap nights	-	38 TTN
Harp Trapping	-	-	2 sites x 1 harp x 4 nights = 8 trap nights	8 sites x 1 harp x 7 nights = 56 trap nights	64 TTN
Mist Netting	-	-	-	3 sites x 1 mist net = 3 trap nights	3 TTN
Call Playback (CPB) (30 minutes per session 2 sessions)	4 sites x 5 CPB x 2 nights = 40 CPB	6 sites x 4 CPB x 2 nights = 48 CPB	(4 sites x 4 CPB x 2 nights) + (1 site x 3 CPB x 1 night) + (1 site x 4 CPB x 1 night) = 39 CPB	-	127 CPB
Bird Surveying (60 minutes per session 2 sessions)	8 person hours at fauna sites 15 person hours of opportunistic bird surveying	12 person hours at fauna sites 20 person hours of opportunistic bird surveying	10 person hours at fauna sites 15 person hours of opportunistic bird surveying	-	80 TPH
Spotlighting (30 minutes per session 2 sessions)	4 person hours at fauna sites 4 person hours of opportunistic spot lighting	6 person hours at fauna sites 5 person hours of opportunistic spot lighting	5 person hours at fauna sites 5 person hours of opportunistic spot lighting	-	29 TPH
Habitat Searching (60 minutes per session 2 sessions)	8 person hours at fauna sites 12 person hours of opportunistic habitat searching	12 person hours at fauna sites 15 person hours of opportunistic habitat searching	10 person hours at fauna sites 10 person hours of opportunistic habitat searching	-	67 TPH

TTN: Total trap nights
TPH: Total person hours

5.0 FLORA RESULTS AND DISCUSSION

5.1 FLORA SURVEY RESULTS

A total of 207 flora species were identified in the study area. One flora species listed as Near Threatened under the NC Act but not listed under the EPBC Act, was observed on the Central East of the study area; *Cerbera dumicola*. A total of 33 introduced species were recorded on the study area, of which five are listed as weed species under the Queensland Biosecurity Act and/or classified by the Australian Government as a Weed of National Significance (WoNS). All four are listed as Restrictive Invasive plants for Queensland and only three of them are also classified as WoNS; Parthenium weed (*Parthenium hysterophorus*) and Velvety tree pear (*Opuntia tomentosa)*. A full flora list for the study area is provided in Appendix H. Weed species fact sheets for these species are attached in Appendix J.

Six vegetation communities classed as Remnant Vegetation as defined by the VM Act were identified on the study area during the field surveys. The vegetation communities have been mapped when possible as homogeneous polygons with the exception of some “mixed polygons” which consisted of two or more vegetation communities that were mapped together due to the impracticability in clearly delineating each RE.

Associations within the communities reflect different vegetation structures and compositions, which occur on different geophysical locations. Table 10 outlines the RE characteristic of each vegetation community, where applicable, as well as a short description of the vegetation present. A description is provided in Sections 5.1.1 to 5.1.7 whilst Figure 12 shows the distribution of vegetation communities on the study area.

Analysis of the vegetation communities recorded within the study area confirm that none meet the condition thresholds to constitute a TEC, listed as threatened at the national level (see Section 5.3.1).

Table 10 Vegetation Community Overview

Vegetation Community	Regional Ecosystem	Community Description
VC 1	11.5.2	Narrow-leaved ironbark and Clarkson’s bloodwood woodland with a sparse shrub layer on sand plains.
VC 2	11.7.2	Lancewood (*Acacia shirleyi*) and/or Rosewood (*Acacia rhodoxylon)* woodland on lateritic duricrust.
VC 3	11.3.25	Blue gum (*Eucalyptus tereticornis)* with *Bauhinia* spp. and *Casuarina cunninghamiana* fringing woodland on drainage features.
VC 4	11.3.2	Poplar box (*Eucalyptus populnea)* woodland on alluvial plains.
VC 5	11.5.2/11.3.25	Mixed polygon where the dominant vegetation community was VC 1 (*Eucalyptus crebra* and *Corymbia clarksoniana* woodland) but along ephemeral creeks and with an important presence of Blue gums.
VC 6	11.3.25/11.3.2/11.5.2	Mixed polygon as a result of combination of VC 3 with elements of VC 4 and some elements of VC 1 due to edge effect.
Non-Remnant	NA	Non-remnant vegetation

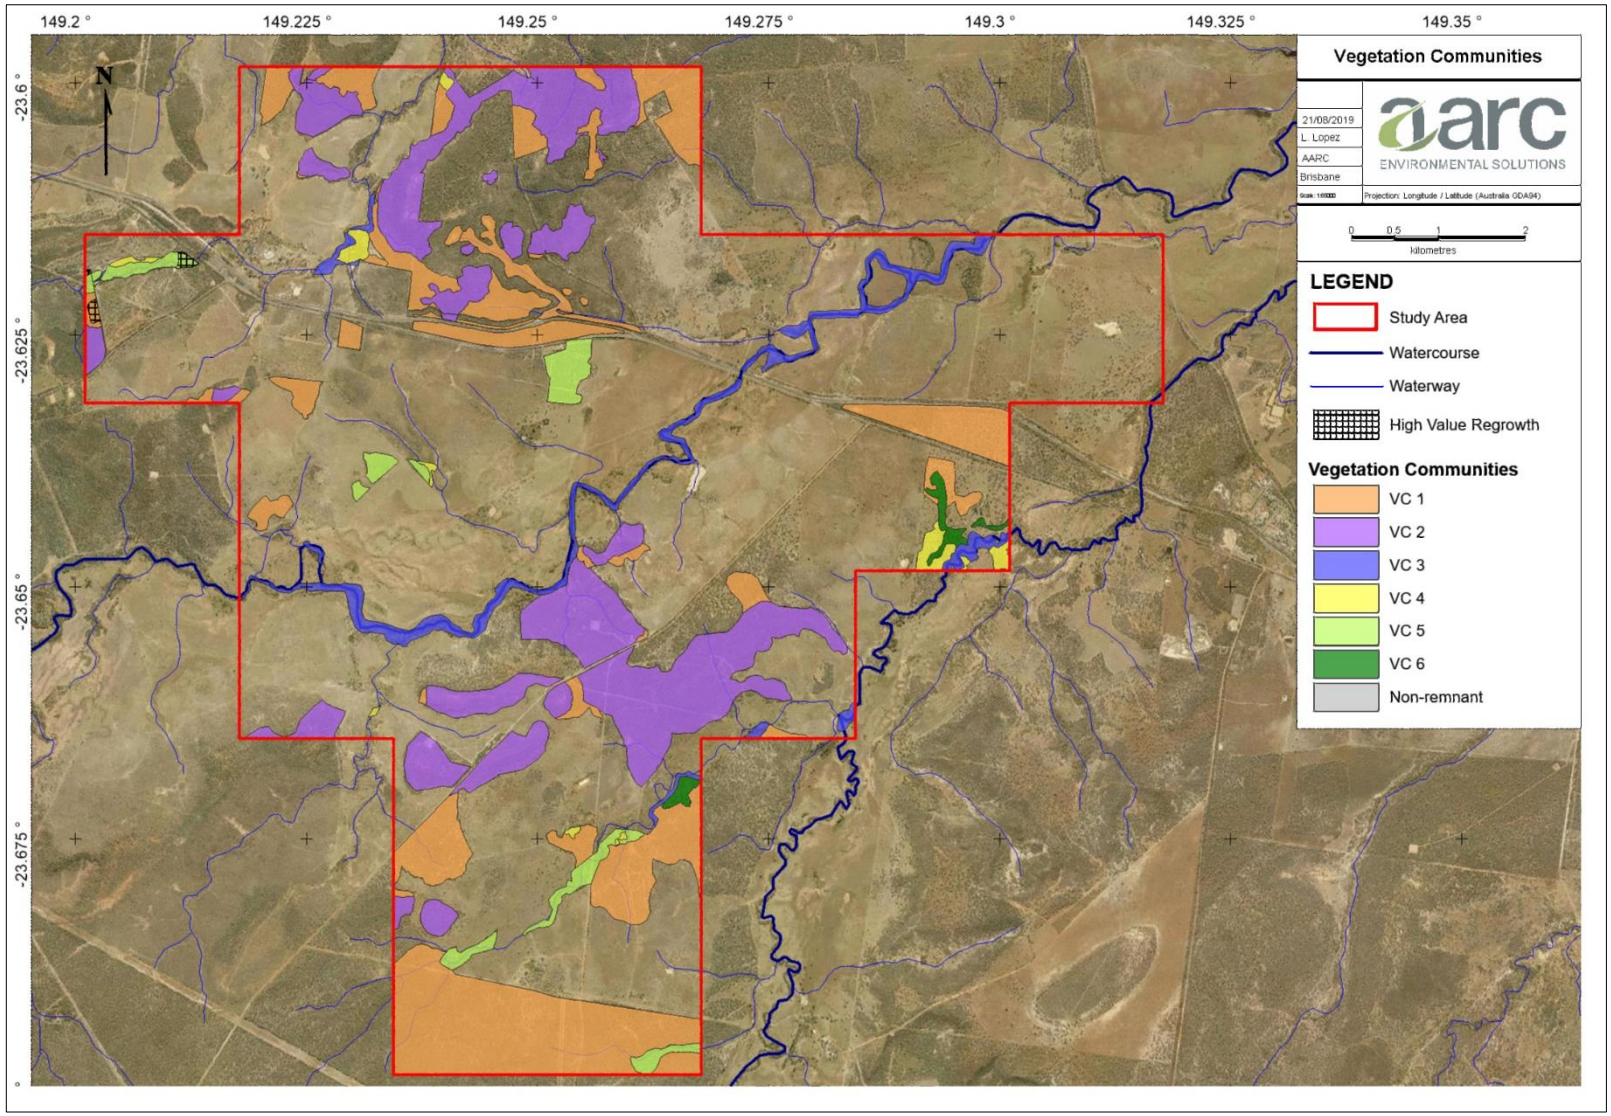

Figure 12 Vegetation Communities within the study area

5.1.1 VC 1: Narrow-leaved ironbark and Clarkson's bloodwood woodland with a sparse shrub layer on sand plains

VC 1 consists of Narrow-leaved ironbark (*Eucalyptus crebra)* and Clarkson's bloodwood (*Corymbia clarksoniana)* woodland with a sparse shrub layer on sand plains and is consistent with RE 11.5.2. *Allocasuarina luehmannii* is dominant in some sandy patches throughout the study area.

VC 1 is the most abundant vegetation community, covering a total of 872.23 ha (12.02%) of the study area. Table 11 provides a summary of community structure and corresponding conservation status.

Table 11 Vegetation Community 1 Profile

Associated Regional Ecosystem	11.5.2: *Eucalyptus crebra*, *Corymbia* spp., with *E. moluccana* woodland on lower slopes of Cainozoic sand plains and/or remnant surfaces
Extent within Project	872.23 ha
Remnant Status	Remnant and 2.71 ha mapped as High Value Regrowth
EPBC Act	Not listed
VM Act Status	Least Concern
Biodiversity Status	No concern at present
Tree Layer	*Eucalyptus crebra* and *Corymbia clarksonia* (12 - 14 m) and occasionally *Allocasuarina luehmannii* dominant on the tree layer. *Alphitonia excelsa* and *Petalostigma pubescens* are dominant in a smaller tree layer.
Shrub Layer	The 0.5 m to 2 m tall shrub layer is normally dominated by *Erythroxylum australe, Petalostigma pubescens, Psydrax johnsonii* and *Carissa spinarum.*
Ground Layer	The ground layer is typically dominated by *Cleistochloa sp. (*Duaringa K.B.Adison 42*)*, *Eragrostis lacunaria, Aristida calycina, Aristida caput-medusae*, and sometimes exotics such as *Melinis repens* and *Urochloa mosambicensis.*
Structure Category	Sparse
Biosecurity Act and/or WoNS Weed Species	*Opuntia tomentosa*
Crown Cover (%)	Average of 60% canopy cover
Ground Cover (%)	On average, bare ground comprised 29% of the total area, whilst organic litter comprised 60%

Photo Plate 1 Ironbark and Bloodwood woodland on sand plains

Conservation Value

No species of conservation significance were recorded in this vegetation community.

The following exotic species were recorded in VC 1 during the ecology surveys: Velvety tree pear (*Opuntia tomentosa),* Red natal grass (*Melinis repens*), Paddy's lucerne (*Sida rhombifolia*) and Green panic (*Megathyrsus maximum*). Velvety Tree Pear is classified as a WoNS.

Vegetation Condition and Habitat Value

RE 11.5.2 is listed as Least Concern under the VM Act and the DES's Biodiversity Status. The extent of this community in reserve areas is low (DES 2019c).

VC 1 presents patches of regrowth vegetation thorough the study area. Areas that have been subjected to past disturbance such as fire, dieback and selective logging now hold coloniser species. Patches of *Acacia cretata* and *Acacia rhodoxylon* young trees of about 1.5-2m dominate the shrub layer across the study area (Photo Plate 2).

Photo Plate 2 VC 1 regrowth patch with *Acacia spp.*

5.1.2 VC 2: Lancewood (*Acacia shirleyi)* and/or Rosewood (*Acacia rodoxylon)* woodland on lateritic duricrust

VC 2 consists of *Acacia* monospecific woodland on lateritic soil, mainly Lancewood (*Acacia shirleyi*) and Rosewood (*Acacia rhodoxylon).* It occurs around rocky areas in the North of the study area but also on flat lateritic areas in the centre and south, covering approximately 734.23 ha (10.12%) of the study area. This community occurs on lateralised mesa slopes, breakaways, scree slopes and remnant colluvium. A summary of VC 2 is presented below in Table 12.

Table 12 Vegetation Community 2 Profile

Associated Regional Ecosystem	11.7.2*: Acacia spp.* woodland on Cainozoic lateritic duricrust. Scarp retreat zone.
Extent within the study area	734.23 ha
Remnant Status	Remnant
EPBC Act	Not listed
VM Act Status	Least Concern
Biodiversity Status	Of Concern
Tree Layer	*Eucalyptus crebra* as occasional emergent tree with *Acacia shirleyi* or *Acacia rhodoxylum* monospecific dominant in the tree layer.
Shrub Layer	Very sparse shrub layer with dominance of *Acacia rhodoxylum, Erythroxylum australe, Alstonia constricta, Psydrax forsteri* and *Carissa spinarum.*
Ground Layer	The ground layer is typically dominated by *Entolasia stricta* (D)*, Calyptochloa gracilima* (D)*, Aristida caput-medusae* (D) *and Paspalidium caespitosum* (D)*.*
Structure Category	Sparse
Biosecurity Act and/or WoNS Weed Species	None
Crown Cover (%)	Average of 70% canopy cover
Ground Cover (%)	On average, bare ground comprised 15.5% of the total area, whilst organic litter comprised 65%

D – Dominant

Photo Plate 3 Lancewood woodland within the study area

Conservation Value

Cerbera dumicola, listed as NT under the NC Act was recorded in two locations within the study area, both of them associated with VC 2. Section 5.3 below discusses this listed species in further detail.

The following exotic species were recorded in VC 2 during the ecology surveys: Sabi grass (*Urochloa mosambicensis*), *Sida cordifolia,* Red natal (*Melinis repens), Malvastrum americanum* and Shrubby stylo *(Stylosanthes scabra)*.

Vegetation Condition and Habitat Value

RE 11.7.2 is listed as Least Concern under the VM Act and the DES's Biodiversity Status. The extent of this community in reserve areas is low (DES 2019c).

VC 2 presents different degrees of disturbance thorough the study area. As per VC 1, areas that have been subjected to past fire, dieback and selective logging. Rosewood has been targeted for logging due to its high value as fence post. Lancewood, on the other hand, has been left relatively undisturbed due to its value stabilising the soil in an area highly susceptible to erosion. *Acacia rhodoxylon* young and thin trees of about 1.5-2m can be found in patches across the study area.

5.1.3 VC 3: Blue gum (*Eucalyptus tereticornis)* with *Bauhinia* spp. and *Casuarina cunninghamiana* fringing woodland on drainage features

This community is located along Charlevue Creek and other ephemeral creeks within the study area. It covers approximately 143.74 ha, close to 2% of the study area, and occurs on alluvial plains. Table 13 provides a detailed description of VC 3. Occasional small patches of *Corymbia tessellaris* or *Eucalyptus populnea* were present on adjacent alluvial floodplains.

Table 13 Vegetation Community 3 Profile

Associated Regional Ecosystem	11.3.25: *Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines.
Extent within Project	143.74 ha
EPBC Act	Not listed
VM Act Status	Least Concern
Biodiversity Status	Of Concern
Tree Layer	*Eucalyptus tereticornis* dominant species with occasional *Eucalyptus crebra, Eucalyptus populnea, Corymbia tessellaris and Corymbia clarksoniana.* In a lower tree layer, the dominant species are *Bauhinia carronii* and *Cassia brewsterii* and occasionally *Melaleuca nervosa* would be the dominant species.
Shrub Layer	The 0.5 m to 2 m tall shrub layer is normally dominated by *Carissa spinarum, Terminalia oblongata, Melaleuca nervosa* and *Alphitonia constricta.*
Ground Layer	The ground layer is typically dominated by *Dichantium sericeum* (D)*, Megathyrsus maximus* (D)*, Cenchrus ciliaris* (D)*, Urochloa mosambicensis* (D) and *Bothriochloa ewartiana* (D)*.*
Structure Category	Mid-dense

Biosecurity Act and/or WoNS Weed Species	*Cryptostegia grandiflora*, *Parthenium hysteropus* and *Opuntia tomentosa*
Crown Cover (%)	Average of 58% canopy cover
Ground Cover (%)	On average, bare ground comprised 8.5% of the total area, whilst organic litter comprised 53%

D – Dominant

Photo Plate 4 Blue gum (*Eucalyptus tereticornis)* woodland along the Charlevue Creek

Conservation Value

No species of conservation significance were recorded within VC 3.

The weed species Rubber vine (*Cryptostegia grandiflora*), Parthenium weed (*Parthenium hysteropus*) and Velvety tree pear (*Opuntia tomentosa)* were recorded in this community, along the Charlevue Creek.

Introduced species Buffel grass *(Cenchrus ciliaris),* Green panic *(Megathyrsus maximus*), Sabi grass *(Urochloa mosambicensis) Sida cordifolia, Malvastrum americanum* and *Bidens pilosa* were recorded in VC 3. Buffel grass and Green panic were occasionally recorded as the dominant species in the ground layer.

Vegetation Condition and Habitat Value

RE 11.3.25 is listed as Least Concern under the VM Act and Of Concern under DES's Biodiversity Status. The extent of this RE in reserves is low (DES 2019c).

Often associated with regional ecosystems 11.3.2 and 11.3.4, elements of which such as *Corymbia tessellaris* and *Eucalyptus populnea* may occur on adjacent alluvial plains. In highly cleared areas, in particular north of the Capricorn Highway, a narrow fringe of riparian vegetation is often the only surviving woody vegetation and it is not mapped as remnant in the Government vegetation map. This RE is impacted by grazing pressure and edge effects, where the dominant ground layer is dominated by the exotic pasture species that grow in the grazing area.

The presence of large, remnant, hollow-bearing trees such as *Eucalyptus tereticornis* provides important denning and breeding habitat for a variety of arboreal mammals and birds.

5.1.4 VC 4: Poplar box *(Eucalyptus populnea)* woodland on alluvial plains

This community is located in small patches within the study area. It covers approximately 36.52 ha (0.5%) of the study area on alluvial soils. Table 14 provides a summary of conservation status and vegetative structure for VC 4.

Table 14 Vegetation Community 4 Profile

Associated Regional Ecosystem	11.3.2: *Eucalyptus populnea* woodland on alluvial plains.
Extent within Project	36.52 ha
EPBC Act	Analysis of this vegetation (Section 5.3.1) confirms that VC4 does not meet the condition thresholds to constitute a TEC.
VM Act Status	Of Concern
Biodiversity Status	Of Concern
Tree Layer	Tree layer dominated by *Eucalyptus populnea* (in some occasions *E. melanophloia*) (12-14m), with occasional *Corymbia dallachiana, C. clarksoniana* and *C. tessellaris.*
Shrub Layer	Very spare shrub layer dominated by *Atalaya hemiglauca, Archidendropsis basaltica, Flindersia dissosperma, Carissa spinarum* (dominant in the lower shub layer) and occasionally *Alphitonia excelsa.*
Ground Layer	The ground layer is typically dominated by *Bothriochloa ewartiana, Aristida calycina, Aristida perniciosa* (D)*, Eragrostis sororia, Eragrostis lacunaria, Cynodon dactylon, Urochloa mosambicensis* (D)*, Heteropogon contortus* (D) and *Themeda triandra,*
Structure Category	Sparse
Biosecurity Act and/or WoNS Weed Species	*Harrisia martini* and *Vachellia farnesiana*
Crown Cover (%)	Average of 53% canopy cover
Ground Cover (%)	On average, bare ground comprised 12.5% of the total area, whilst organic litter comprised 34%

D - Dominant

Photo Plate 5 Poplar box *(Eucalyptus populnea)* woodland on alluvial plains

Conservation Value

No species of conservation significance were recorded within VC 4.

The exotic species Sabi grass (*Urochloa mosambicensis*), *Sida cordifolia*, Shrubby stylo (*Stylosanthes scabra*), Red natal (*Melinis repens*), *Malvastrum americanum*, *Bidens pilosa,* Mimosa bush (*Vachellia farnesiana*) and Harrisia cactus (*Harrisia martinii*) were recorded in VC 4.

VC4 is most consistent with RE 11.3.2, which is an associated RE of the Poplar box grassland on alluvial plains and Weeping myall woodland TEC. None of these TECs were identified within the study area. A summary of the survey effort to determine the presence of both TECs is detailed in Section 5.3.1.

Vegetation Condition and Habitat Value

RE 11.3.2 is classified as Of Concern under the VM Act and Of Concern at present under DES's Biodiversity Status. The extent of this RE in reserves is low.

VC 4 was only present in small patches within the study area, some of them too small to map. This community presented evidence of edge effect with exotic pasture species such as *Urochloa mosambicensis* occasionally dominating the ground layer. Regrowth of VC 4 was recorded in the south of the study area and along Cooinda road, in the middle of the study area. Recruitment of Poplar box was observed across the study area, with sections within VC 4 of very young and thin trunks.

5.1.5 VC 5: Mixed polygon: Ironbark, Bloodwood and Blue gum woodland along ephemeral creeks

VC 5 is limited to small patches within the study area and consist on a combination of VC 1 with elements of VC 3 (Blue gums, 20% of the vegetation community) due to the presence of ephemeral drainage features in the vicinity of VC 1. *Melaleuca nervosa* is occasionally present as dominant species on the tree and shrub layers. It covers approximately 96.71 ha (1.33%) of the study area.

VC 5 is illustrated in Photo Plate 6.

Conservation Value

No species of conservation significance were recorded within VC 5. The same exotic pasture species recorded in VC 1 where observed in the ground layer of this community throughout the study area.

Vegetation Condition and Habitat Value

This community was only present in three patches within the study area, where it was not possible to separate the vegetation into two defined communities. There is evidence of edge effect, where exotic pasture species are present in the groundcover. Regrowth of VC 5 was similar to the regrowth of VC 1, with the same pioneer *Acacia* spp. as described before. Both RE's, 11.5.2 and 11.3.25 are classified as Least Concern under the VM Act but while RE 11.5.2 is classified as Least Concern under the DES's Biodiversity Status, RE 11.3.25 is classified as Of Concern. The extent of these REs in reserves is low (DES 2019c).

Photo Plate 6 VC 5 – RE 11.5.2/11.3.25

5.1.6 VC 6: Mixed polygon: Blue gum, Poplar box and Ironbark woodland along ephemeral creeks

VC 6 is located in small patches within the study area and consist on a combination of VC 3 (Blue gums) along several small ephemeral drainage channels, with elements of VC 4 (Poplar box), present in the alluvial plains between the channels and VC 1 (Ironbark) due to edge effect. VC 6 covers a total of 21.83 ha (0.3%) of the study area.

VC 5 is illustrated in Photo Plate 7.

Conservation Value

No species of conservation significance occurred within VC 6.

Habitat Value

VC 6 was only present in two patches within the study area, where it was not possible to separate the vegetation into three defined communities. As per VC 5, there is evidence of edge effect, with exotic pasture species present in the groundcover and occasionally dominant. The RE classification for the three REs present is as follows: 11.3.25 is listed as Least Concern under the VM Act and Of Concern under DES's Biodiversity Status; 11.3.2 is listed as Of Concern under the VM Act and the DES's Biodiversity Status; and 11.5.2 is listed as Least Concern under the VM Act and the DES's Biodiversity Status. The extent of these RE in reserves is low (DES 2019c).

Photo Plate 7 VC 6 – RE 11.3.25/11.3.2/11.5.2

5.1.7 Non-remnant and Regrowth Vegetation

Non-remnant regrowth vegetation is present in areas that have been disturbed by human activities, such as logging and preparation for grazing through the entire study area. There are numerous patches of regrowth vegetation, including areas that are mapped as remnant in the Vegetation Management Regional Ecosystem Map but have been assessed as non-remnant as a result of the field surveys.

This vegetation is not classed as remnant vegetation, therefore is not defined by an RE.

There is one large patch of vegetation north of the study area mapped as remnant which vegetation consists on *Acacia* spp regrowth. According to local knowledge (farmers) around six years ago there was a fire that affected the north part of the EPC, the area north of the Capricorn Highway. As a result of that fire, there is regrowth across all the vegetation communities, especially VC 1 and VC 4. A large patch of woodland originally mapped as 11.5.9b is now categorised as non-remnant vegetation. This particular area presents only an extremely sparse tree layer (*Eucalyptus crebra* and *Corymbia clarksoniana*) and a dense shrub layer of pioneer *Acacia* spp. mainly *Acacia cretata.*

Photo Plate 8 Non-remnant *Acacia* spp regrowth

The areas of the study area not mapped in Figure 12 are mainly pasture land with more or less evidence of regrowth, or dead vegetation. This regrowth corresponds with early stages of V4, V1 or V2. Regrowth of *Acacia cretata* is especially abundant within several vegetation communities, such V1, but also in pasture area. Evidence of burning and ring barking has been recorded thorough these pasture areas.

The ground layer of the non-remnant vegetation is dominated by exotic pasture grasses such as Buffel grass (*Cenchrus ciliaris*), Indian bluegrass (*Bothriochloa pertusa*), Sabi grass (*Urochlora mosambicensis*) and Red natal grass (*Melinis repens).*

5.2 WEEDS OF MANAGEMENT CONCERN

A total of 33 introduced species were identified onsite. The exotic pasture grasses dominate the ground layer of the study area, particularly in cleared areas. A range of other exotic grasses and forbs are also

present across the study area in low to moderate abundance. A complete list of the flora species, indicating their native or introduced status can be found in Appendix H.

Three of these introduced species are classed as WoNS; Parthenium weed (*Parthenium hysterophorus*), Rubber vine (*Cryptostegia grandiflora)* and Velvety tree pear (*Opuntia tomentosa*). Introduced plant species are classified by the Commonwealth Government as WoNS if they present a serious threat to industry, water supply, human health/safety, plant communities and/or cultural values.

The above mentioned three species, together with Harrisia cactus *(Harrisia martini)* are similarly classed as Restricted Invasive Species under the Biosecurity Act (DAF 2018).

Vachellia farnesiana, also found in the study area, is not a prohibited or restricted invasive plant under the Biosecurity Act. However, by law, everyone has a general biosecurity obligation (GBO) to take reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control (DAF 2016).

Weed species of management concern found in the study area are listed in Table 15. All species present are known to occur commonly throughout the broader region.

Table 15 Weed species of management concern identified on the study area

Scientific name	Common name	WoNS Status	*Biosecurity Act 2014* Category 3
Harrisia martinii	Harrisia cactus	-	x
Cryptostegia grandiflora	Rubber vine	Yes	x
Opuntia tomentosa	Velvety tree pear	Yes	x
Parthenium hysterophorus	Parthenium	Yes	x
Bryophyllum sp	Mother of millions	-	x
*Vachellia farnesiana**	Mimosa bush	-	-

Note: * Considered a noxious weed of management concern.
Category 3: A person must not distribute the invasive plant either by sale or gift, release it into the environment.

Photo Plate 9 *Cryptostegia grandiflora* identified on the study area

5.3 FLORA OF CONSERVATION SIGNIFICANCE

5.3.1 Threatened Ecological Communities not identified on the study area

Brigalow (*Acacia harpophylla dominant and co-dominant)*

The Brigalow (*Acacia harpophylla* dominant and co-dominant) TEC comprises patches of vegetation in which *Acacia harpophylla* is one of the most abundant tree species. The tree layer may be dominated by *Acacia harpophylla* or have a co-dominant presence with other species such as Belah (*Casuarina cristata*) and other species of Acacia or Eucalyptus. Within Queensland, the Brigalow TEC is consistent with 16 RE described by the Queensland Herbarium, including RE 11.3.1, originally mapped within the study area.

A patch must meet the following condition thresholds to be considered the Brigalow TEC:

- The patch is 0.5 ha or more in size; and
- Exotic perennial plants comprise less than 50% of the total vegetation cover of the patch, as assessed over a minimum sample area of 0.5 ha (100 m by 50 m), that is representative of the patch.

Despite being mapped as present along the Charlevue and Springton Creeks in association with RE 11.3.1, Brigalow (*Acacia harpophylla)* was only recorded within the study area as a few individual stands. Two trees were recorded along the Charlevue Creek and a small patch with six trees was recorded on the bank of Springton Creek, close to the eastern boundary of the study area.

The sparse Brigalow individuals do not form a clear vegetation community, not reaching dominance in the canopy nor the minimum size of 0.5 ha specified as condition thresholds to qualify as Brigalow TEC.

Weeping myall *(Acacia pendula)* Woodland

Weeping myall woodlands often occur as monotypic stands generally 4 – 12 m high in which Weeping myall trees are the sole or dominant overstorey species. Other canopy species such as Western rosewood (*Alectryon oleifolius* subsp. elongatus), Poplar box (*Eucalyptus populnea*), or Black box (*Eucalyptus largiflorens*) may occur in association with this community.

Within Queensland, this community is known to occur in association with two REs including RE 11.3.2 (*Eucalyptus populnea* woodland on alluvial plains) and 11.3.28 (*Eucalyptus coolabah* +/- *Casuarina cristata* open woodland on alluvial plains). Of the extent of these REs throughout Queensland, it is estimated that only 5% supports the Weeping myall woodlands community. Most patches of the TEC are less than 1 or 2 ha in area.

This TEC has been previously described as potentially occurring on the study area based on the mapping of Poplar box woodlands on alluvial plains (11.3.2), has been ground-truthed as non-remnant based on the negligible canopy cover. However, due to the cycles of senescence that affect the dominant species Weeping myall, the criteria used to assess a vegetation community includes canopy cover as sparse as 5% and dominated by living, dead or defoliated Weeping myall trees (DEWHA 2009). As a result, additional survey effort was employed in this area, to identify any dead and/or defoliated trees. This area was dominated by *Acacia cretata* regrowth, confirming the absence of Weeping myall woodland TEC on the study area.

Poplar box Grassy Woodland on Alluvial Plains

Assessments of the RE 11.3.2 present within the study area (VC 4) have concluded that the TEC Poplar box Grassy Woodland is not present within the study area.

To be listed as TEC, the Poplar box in alluvial plains is to meet certain thresholds, such as size and vegetation condition. The following thresholds have been sourced from the *Draft Conservation Advice (including listing advice) for the Poplar Box Grassy Woodland on Alluvial Plains* (TSSC n. d.):

Class A Highest Quality

- **Category A1:** Patch equal or larger than 1 ha: The patch has little or no perennial weeds and a diverse native understorey. 90% or more of the perennial vegetation cover is native species **and** with 30 or more native plant species in the ground layer per ha.

- **Category A2:** Patch equal or larger than 5 ha. A large patch with low perennial weeds and diverse native understorey. 70% or more of the perennial vegetation cover is ground layer is native **and** with 30 or more native plant species in the ground layer per ha.

- **Category A3:** Patch equal or larger than 5 ha. A large patch with high quality habitat features. 10 trees per ha that either are large (30 cm or more in diameter at breast height) and/or have developed hollows **and** smaller trees, saplings or seedlings suggesting of periodic recruitment **and** with 20 or more native plant species in the ground layer per ha.

Class B Moderate Quality

- A large patch with moderate quality native understorey. 50% of perennial vegetation cover in ground layer is native **and** 20 or more native plant species per ha in the ground layer **or** 10 trees per ha that either are large (30 cm or more in diameter at breast height) and/or have developed hollows

VC 4 does not meet the threshold to constitute a TEC due to the size of the patches and poor condition of the community with a high presence of exotic pastures, occasionally dominant. Some trees recorded from the largest patch of VC 4 within the study area were larger than 30cm in diameter at breast height, however, some sections of the same patch presented younger and smaller specimens, not meeting the average of 10 or more per ha.

5.3.2 Flora Species of Conservation Significance Identified on the Study Area

Targeted searches across the study area detected the presence of one flora species of conservation significance in several of the seasonal surveys, *Cerbera dumicola* (Photo Plate 10). This species is listed as NT under the NC Act.

Cerbera dumicola is a shrub or small tree growing to 4 m high (DES 2018b). The species occurs across a range of habitats in central and southern Queensland. This species is associated with a range of vegetation communities such as sandstone hills in open *Eucalyptus umbra* subsp. *carnea*; woodlands of *Acacia shirleyi* with *Corymbia dolichocarpa*; acidic soils in mine rehabilitation area; woodland of *A. catenulata* and *A. shirleyi* with *E. thozetiana* on a slope of sand/clay soil; semi-deciduous notophyll-microphyll vine forest of *Brachychiton australis*, *Gyrocarpus americanus*, *Flindersia australis*, *Pleiogynium timorense*, *Drypetes deplanchei* and *Sterculia quadrifida* on rhyolite hillslopes; open-woodland of *E. melanophloia* with occasional *Acacia shirleyi*, *E. populnea* and *E. brownii*; semi-evergreen vine thicket with *Corymbia citriodora* and *Corymbia aureola emergents*; woodland of *A. rhodoxylon* on brown, sandy loam; and in *Corymbia tessellaris* - *Acacia aneura* open woodland (DES 2018b).

Cerbera dumicola has been severely impacted by land clearing with extensive fragmentation of its original habitat. While it can be very common at some of its known localities, many of the remnant populations comprise few individuals. It is likely to be more widespread than is currently known as these eucalypt dominated woodlands are poorly surveyed in southern Queensland. Threatening processes include:

- Land clearing for agriculture, which has undoubtedly been the main reason in the past for reductions in the area of occupancy, number of populations, number of individuals. Many populations are in areas mapped as 'non-remnant vegetation', hence are still able to be cleared; and

- Land clearing for mining. Several populations have been recorded from mining leases in the central highlands coalfields and are presumed lost (DES 2018b).

Cerbera dumicola has been identified during the vegetation surveys in two very localised rocky areas associated with vegetation community VC 2 and VC 1 (on an ecotone with VC 2) (Figure 14). This species was not identified elsewhere in the study area, within similar habitat types, during targeted searches.

The species is regionally abundant, having been recorded outside of the study area on multiple occasions (AVH 2019).

It is not expected that the proposed Project will impact on the known *Cerbera dumicola* individuals due to their location. The species has been recorded at the boundary of the study area and adjacent to areas of existing disturbance. Suitable habitat is extensive throughout the local area including immediately east of the study area.

Photo Plate 10 ***Cerbera dumicola*** **at the study area**

5.3.3 Flora Species of Conservation Significance Not Identified on the Study Area

Table 16 below discusses EVNT species that are known from the broader region and have been identified from desktop searches but were not observed on site during surveys.

The assessment of potential for presence and impact on each species is based on the knowledge of ecologists, information obtained from field surveys on the study area, previous surveys conducted on or near the study area and scientific literature. This assessment revealed that of the four species previously assessed with potential to occur within the study area, three were considered unlikely to occur within the study area.

Table 16 Flora Species of Conservation Significance not identified on the study area

Scientific Name Common Name	Status		Likelihood of Occurrence Post Survey
	EPBC Act	NC Act	
Bertya opponens	V	C	Potential The study area contained suitable habitat. However, there are no records of the species within 50 km of the study area and the species was not identified during the field survey. It is therefore considered unlikely the Project will impact on this species.
Bertya pedicellata	-	NT	Potential The study area contained suitable habitat. However, the species was not identified during the field survey, it is considered unlikely the Project will impact on this species.
Solanum adenophorum	-	V	Unlikely The study area did not contain suitable habitat for this species in the form of cracking clay soils and Brigalow woodland. The species was not detected during the field survey, indicating potential for Project impact to be low.
Solanum dissectum	E	E	Unlikely The study area did not contain suitable habitat for this species in the form of cracking clay soils and Brigalow woodland. The species was not detected during the field survey, indicating potential for Project impact to be low.
Solanum elachophyllum	-	E	Unlikely The study area did not contain suitable habitat for this species in the form of cracking clay soils. Further, the species was not detected during the field survey, indicating potential for Project impact to be low.

EPBC – *Environment Protection and Biodiversity Conservation Act 1999*
NC Act – *Nature Conservation Act 1992*
CE – Critically Endangered
NT – Near Threatened
V – Vulnerable
E – Endangered
C – Least Concern

5.4 WETLANDS

Field surveys concluded that all the potential lacustrine and palustrine wetlands within the study area (Figure 6) are either not present or have been identified as artificial (farm) dams. The only wetlands confirmed within the study area in accordance to the DES interactive Wetland*Maps* database are riverine wetlands and have been mapped as VC 3, VC 5 and VC 6.

Outside the study area, there is a large palustrine wetland (approximately 82 ha in area) located about 4 km to the east of the boundary. This wetland, identified as HES, is not connected to the study area through any waterbodies or watercourses and does not occur on the same drainage system that flow through the study area. This wetland has been identified as Category X vegetation under the Regulated Vegetation The pre-clearing Government RE mapping (Appendix A) of this wetland identified it as RE 11.3.27. RE 11.3.27 is described as freshwater wetland; with variable vegetation compositions including; open water with or without aquatic species and fringing sedge lands and eucalypt woodlands (DES 2019c). Current Government mapping and field inspections of the mapped wetlands identify the

vegetation as non-remnant. No water was observed during the site inspection (Photo Plate 11). Assessment of potential impact to this wetland as an MSES have been addressed in Section 9.1.3.

Field surveys concluded that all the potential lacustrine and palustrine wetlands identified within the study area from desktop searches (Figure 6) are either not present or have been identified as artificial (farm) dams. The only natural wetlands within the study area are riverine wetlands associated with riparian and vegetation along Charlevue Creek and have been mapped as VC 3, VC 5 and VC 6 (Figure 12).

Outside the study area, there is a large palustrine wetland (approximately 82 ha in area) located about 4 km to the east of the boundary. This wetland, identified as High Ecological Significance (HES) under the *Environmental Protection (Water and Wetland Biodiversity) Policy* 2019, is not connected to the study area through any waterbodies or watercourses. Current Government mapping and field inspections of the mapped wetlands identified the vegetation as non-remnant. Field assessment identified the presence of lfora species known to inhabit wetland environements. No water was observed during the site inspection.

Photo Plate 11 *Melaleuca spp.* dominated HES wetland

5.4.1 Groundwater Dependent Ecosystems

The above-mentioned wetlands have the potential to be partially dependent on groundwater (BoM 2019). Within the study area high potential terrestrial Groundwater Dependent Ecosystems (GDEs) and moderate potential aquatic GDEs were identified by database searches in association with Charlevue Creek and Springton Creek. Moderate potential terrestrial GDEs were also mapped in association with some of the smaller waterways.

The groundwater within the study area has been assessed and the bores located in close proximity of Charlevue Creek show a below surface depth of groundwater of 8.77 meters below ground level (mbgl)

while Springton Creek has a below surface depth of groundwater of 11.19 mbgl. The bores within the study area along the associated tributaries have a groundwater depth of over 16 mbgl. Based on the known rooting depth of dominant tree species, the assessment concluded thatThe potential GDEs within the study area are in only riverine ecosystems located in close proximity to Charlevue Creek and Springton Creek have potential dependency on groundwater.

Wetland habitats identified within the study area are mapped in Figure 13.

The HES wetland located 4 km to the east of the study area is also potentially groundwater dependant; however, it is noted that this wetlands isare ephemeral and does not hold water throughout the year.

Assessment of the GDEs has been addressed in Section 7.1.5 of this report.

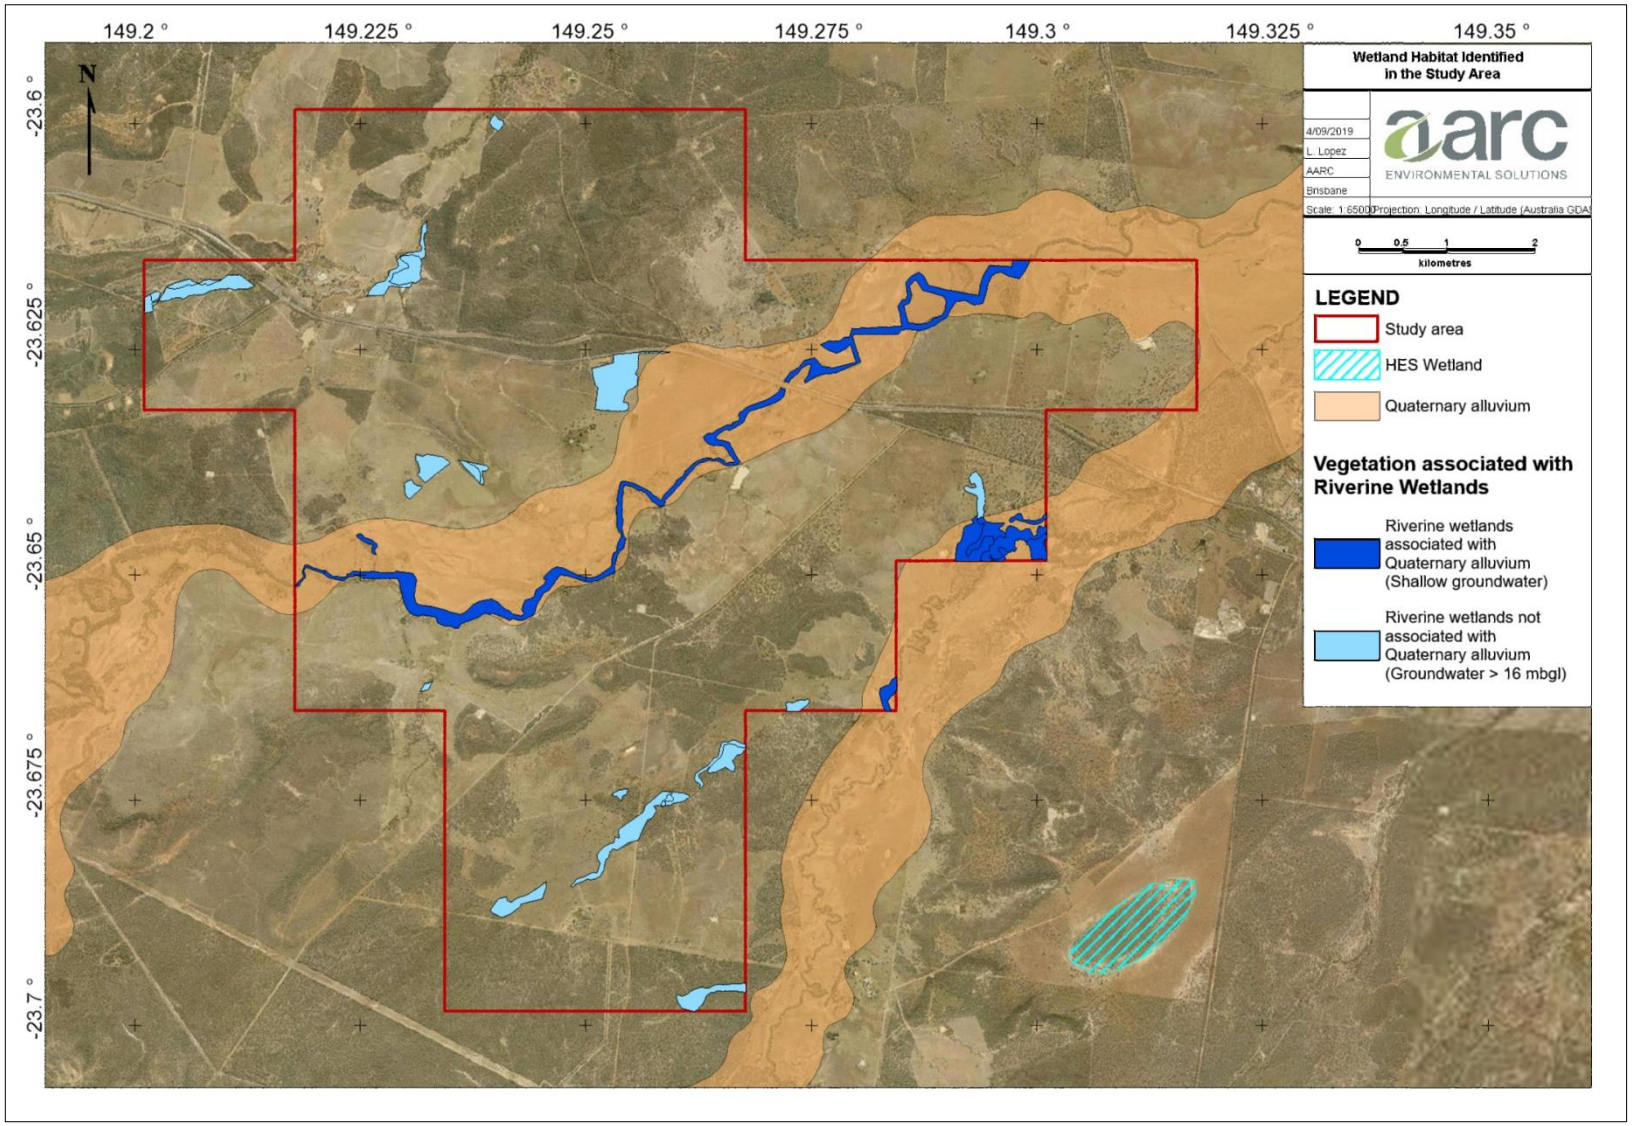

Figure 13 Wetland Habitats Identified in the Study Area

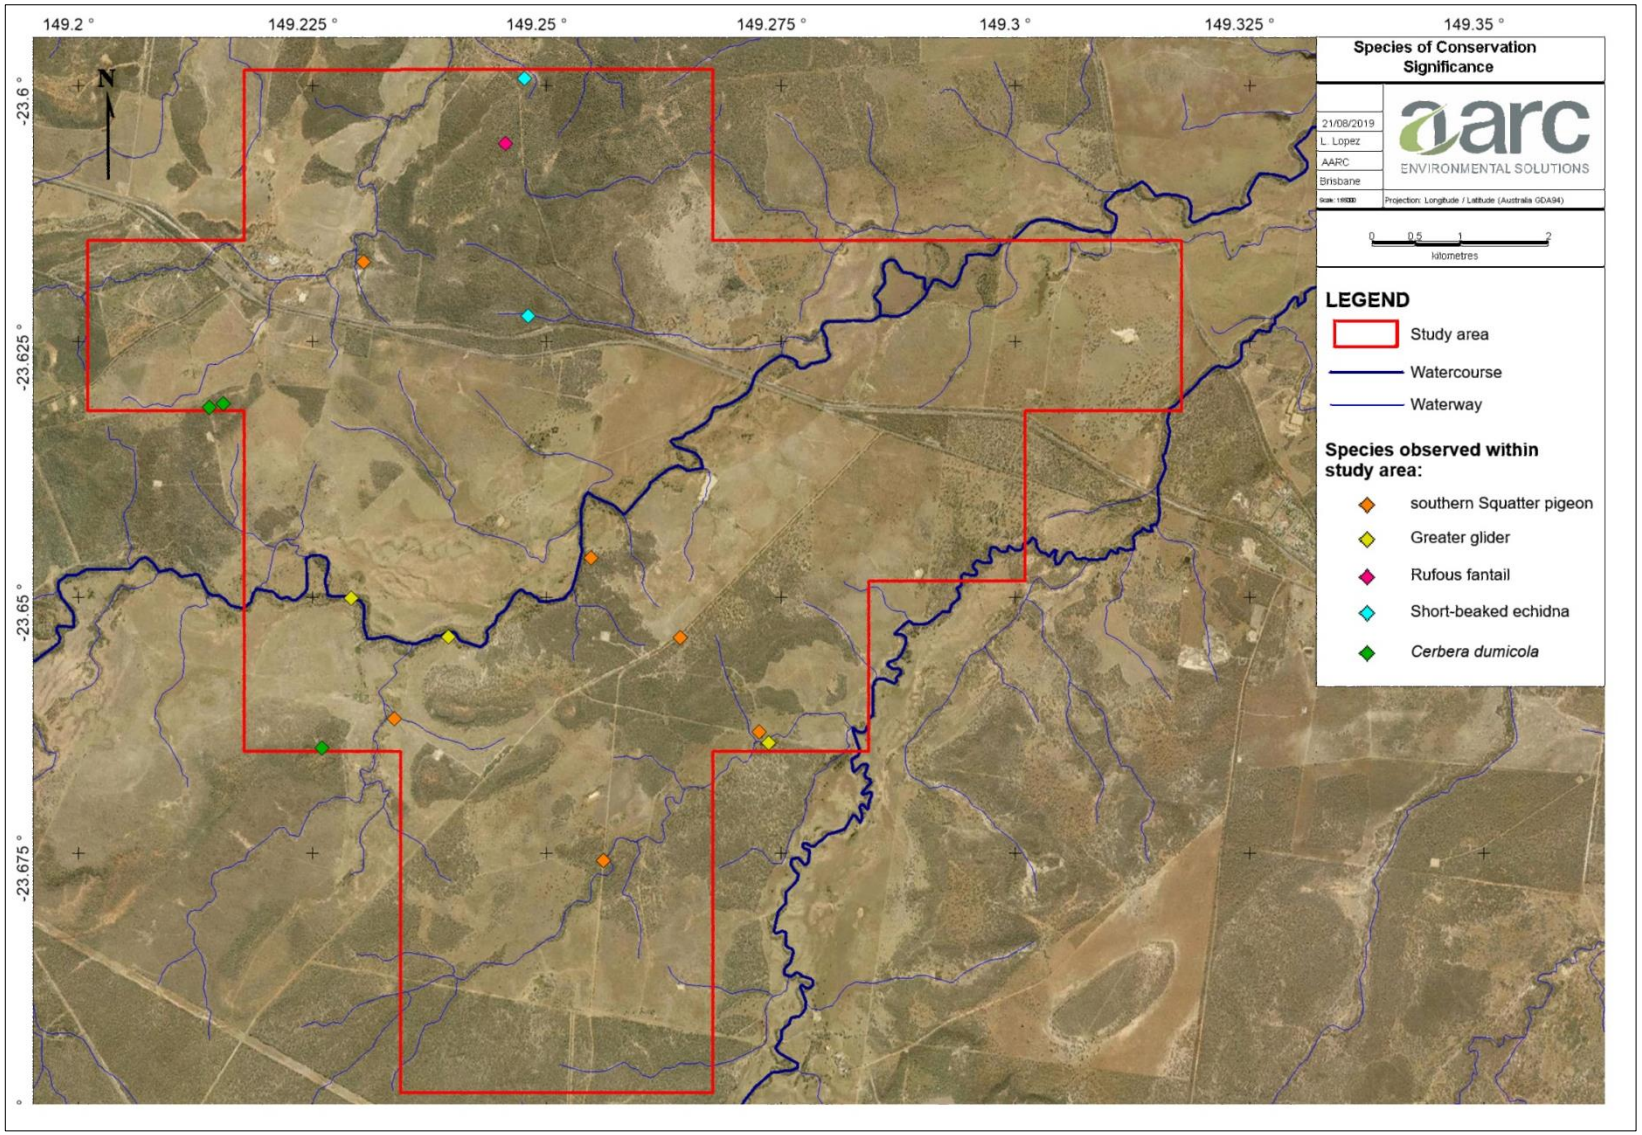

Figure 14 Species of Conservation Significance observed within the study area

6.0 FAUNA RESULTS AND DISCUSSION

6.1 FAUNA SURVEY RESULTS

A total of 145 vertebrate species were positively identified on the study area during the surveys, comprising 8 amphibians, 83 birds, 33 mammals and 21 reptiles. Six of these species are introduced. One migratory and marine species and one marine species were recorded during the survey. Two threatened fauna species were observed on site. A complete list of the fauna species recorded on the study area is included in Appendix I.

During the conduction of the aquatic ecology assessment (AARC 2019), a number of vertebrate fauna species were recorded in the study area. These are detailed in the aquatic ecology assessment. One species recorded by the aquatic ecology survey was not recorded by the terrestrial ecology survey, namely the Keelback snake (*Tropidonophis mairii*), which was identified along Charlevue Creek.

6.1.1 Amphibians

Habitat Values

The species recorded within the study area are well adapted to the habitats identified, with permanent water sources and areas subject to seasonal inundation. These species employ periods of dormancy to contend with drier, less favourable conditions. Habitat variation and suitability increase in response to increased rainfall during the wet season (November - March) providing viable breeding opportunities.

The amphibian species identified are all common species and impacts from the Project are likely to be localised with minimal effects to broader populations.

Observed Species

A total of 8 amphibian species were recorded during the surveys, comprising seven native species and the introduced Cane toad (*Rhinella marina*). The Cane toad is listed as an invasive biosecurity matter under the revised version of the Biosecurity Actand are a major pest species that compete for food with native species.

The native species recorded on site were Ornate burrowing frog (*Platypectrum ornatum*), Common green tree frog (*Litoria caerulea*) Photo Plate 12, Naked tree frog (*Litoria rubella*), Broad-palmed frog (*Litoria latopalmata*), Bumpy rocket frog (*Litoria inermis*), Salmon-striped frog (*Limnodynastes salmini*) and Spotted grass frog (*Limnodynastes tasmaniensis*).

Photo Plate 12 Common green tree frog (*Litoria caerulea*) observed at DF02

Amphibians of Conservation Significance

No amphibian species of conservation significance were observed on the study area during field surveys. However, the Tusked frog (*Adelotus brevis*) has been identified as potentially occurring within the study area due to the proximity of its known range and the presence of suitable habitat (such as dams).

6.1.2 Reptiles

Habitat Values

The study area provided a variety of habitat types such as vegetated drainage features, woodlands to open forests and rocky areas to promote reptile diversity. This included several microhabitats such as tree hollows, fallen timber, dense leaf litter, soil cracks and rock crevices which provide shelter from extreme climates, protection from aerial predators and as habitat for hunting and foraging for food.

Observed Species

A total of 21 reptile species were recorded within the study area during the field surveys, all of which are listed in Appendix I.

The suite of reptiles occurring on the study area included seven species of skink and one species of legless lizard. These species include the Eastern striped skink (*Ctenotus robustus*), Elegant snake-eyed skink (*Cryptoblepharus pulcher*), Shaded litter rainbow-skink (*Carlia munda*), South-eastern morethia skink (*Morethia boulengeri)*, Fire-tailed skink (*Morethia taeniopleura*), the Orange-flanked Rainbow skink (*Carlia rubigo*) and Burton's legless lizard (*Lialis burtonis).*

Five gecko species were identified on the study area, including the Eastern stone gecko (*Diplodactylus vittatus*), Dubious dtella *(Gehyra dubia),* Bynoe's Gecko *(Heteronotia binoei),* Box-patterned gecko *(Lucasium steindachneri)* (Photo Plate 13) and the Prickly knob-tailed gecko (*Nephrurus asper*).

Photo Plate 13 *Box-patterned gecko (Lucasium steindachneri)* observed at DF09

Field surveys also detected the presence of three dragon species, Bearded dragon (*Pogona barbata*), Tommy roundhead (*Diporophora australia*) and Freckled monitor (*Varanus tristis orientalis*).

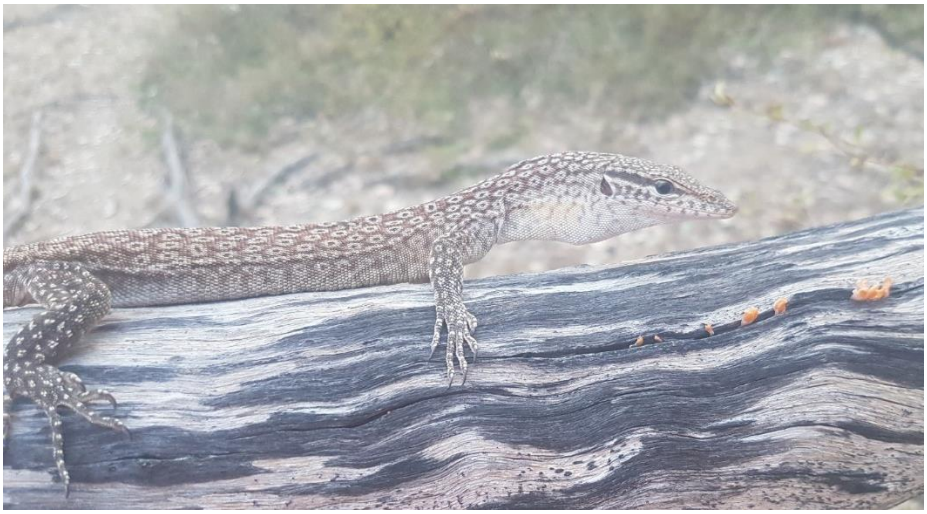

Photo Plate 14 Freckled monitor (*Varanus tristis orientalis*) observed at DF10

Six snake species namely the Black headed python (*Aspidites melanocephalus*), Eastern brown snake (*Pseudonaja textilis*), Pale-headed snake (*Hoplocephalus bitorquatus*) (Photo Plate 15), Carpentaria snake (*Cryptophis boschmai*), Yellow-faced whip snake (*Demansia psammophis)* and Orange-naped snake (*Furina ornata*) were recorded within the study area.

Photo Plate 15 Pale-headed snake (*Hoplocephalus bitorquatus*) observed at DF01

Reptile Species of Conservation Significance

No reptiles of conservation significance were observed on the study area during the survey period. Database searches identified seven reptile species of conservation significance within the region. The habitat requirements and likelihood of each conservation significance species occurring on the study area are described in Appendix D.

6.1.3 Birds

Habitat Values

Avian assemblages are generally determined by factors such as food sources (e.g. fruit, nectar, seeds, and insects), as well as a mosaic of habitat structures such as grasses, thick understorey, mid-storey and canopy vegetation (i.e. vertical habitat complexity). Generally, the more food sources available and the more complex the structure of the vegetation, the more diverse the avifauna will be.

Food sources across the study area comprised seeds, fruit, nectar, insects and vertebrate prey items (or carrion). The diversity of forage resources available in the surveyed habitats suggests that the Project can support a variety of native avian species.

Observed Species

A total of 83 bird species were observed on the study area. Most species observed were common species representative of the dry woodland habitat dominating the study area, however, two species of conservation significance were identified in the study area during the survey period. These species are discussed in more detail in Section 6.3. A full list of bird species observed on the study area is presented in Appendix I.

A variety of granivorous birds were found to be present including the Sulphur-crested cockatoo (*Cacatua galerita*), Crested pigeon (*Ocyphaps lophotes lophotes*), Peaceful dove (*Geopelia striata placida*), southern squatter pigeon (*Geophaps scripta scripta*), Bar-shouldered dove (*Geopelia humeralis*), and Double-barred finch (*Taeniopygia bichenovii*).

The study area was found to support a number of honeyeaters including the White-throated honeyeater (*Melithreptus albogularis*), Brown honeyeater (*Lichmera indistincta ocularis*), Blue-faced honeyeater (*Entomyzon cyanotis*) and Noisy friarbird (*Philemon corniculatus*).

The suite of insectivorous birds recorded on site included the Grey fantail (*Rhipidura albiscapa*), Magpie-lark (*Grallina cyanoleuca*), Black-faced cuckoo-shrike (*Coracina novaehollandiae*), Grey-crowned babbler (*Pomatostomus temporalis*) and Striated pardalote (*Pardalotus striatus*).

A large diversity of omnivorous and carnivorous species was detected on the study area, including the Apostlebird (*Struthidea cinerea*), Pheasant coucal (*Centropus phasianinus*), Grey butcherbird (*Cracticus torquatus*), Australian magpie (*Cracticus tibicen*), Australian raven (*Corvus coronoides*), Laughing kookaburra (*Dacelo novaeguineae*) and Emu (*Dromaius novaehollandiae*).

Several nocturnal bird species including the Tawny Frogmouth (*Podargus strigoides*), Barn owl (*Tyto alba*) and Southern boobook (*Ninox boobook*) were observed during field surveys. Five raptor species, including Whistling kite (*Haliastur sphenurus*) and Brown falcon (*Falco berigora*) (Photo Plate 16) were also recorded on the study area.

Photo Plate 16 Brown falcon (*Falco berigora*) observed on the study area

Aquatic bird species such as the Brolga (*Grus rubicunda*) were also recorded during field surveys.

Birds of Conservation Significance

Threatened Species

The southern subspecies of the Squatter pigeon (*Geophaps scripta scripta*) was recorded in several locations (Figure 14) on the study area at the time of the surveys (Photo Plate 17).

The southern Squatter pigeon occurs along the inland slopes of the Great Dividing Range with a distribution from the Burdekin-Lynd divide in central Queensland, west to Charleville and Longreach, east to the coastline between Proserpine and Gladstone, and south to scattered sites throughout south-eastern Queensland (Cooper *et al.* 2004).

Suitable habitat for the southern Squatter Pigeon exists in open grassy woodland throughout the study area. Within this suitable habitat, fifteen birds were observed during the ecological survey period, the majority of them observed during the spring survey in September 2017. The species is regionally abundant, having been observed outside of the study area on multiple occasions, with AARC ecologists observing the species multiple times on local roads and elsewhere while traversing the local area. No breeding activity was observed within the study area.

It is unlikely that the proposed Project will have a significant impact on the local population of the southern Squatter Pigeon; either the local population or the population in its entirety due to:

- the abundance of more suitable habitat outside of the study area in connected woodland; and
- the local abundance of the southern Squatter pigeon.

A *Significant Residual Impact Assessment* (DEHP 2014a) for the southern Squatter pigeon can be found in Section 9.1.2 of this report.

Photo Plate 17 Squatter Pigeon (*Geophaps scripta scripta*) observed at the study area

Marine and Migratory Species

The EPBC Act lists bird species that are classified as migratory and/or marine. Two migratory and/or marine birds were identified on the study area (Figure 14), comprising of the Rufous fantail (*Rhipidura rufifrons*) which is a migratory and marine species and the Rainbow bee-eater (*Merops ornatus*) which is a marine species.

The Rufous fantail (also listed as Special Least Concern under the NC Act) is found in northern and eastern coastal Australia, being more common in the north. It is also found in New Guinea, the Solomon Islands, Sulawesi and Guam. The Rufous fantail is found in rainforest, dense wet forests, swamp woodlands and mangroves, preferring deep shade, and is often seen close to the ground. During migration, it may be found in more open habitats or urban areas. The Rufous fantail is a common and secure species (Blakers *et al.* 1984).

The Rainbow bee-eater inhabits all of mainland Queensland, as well as Indonesia, New Guinea and the Solomon Islands. This species is widespread and breeds throughout most of its range, with the exception of southern birds, which move north to breed.

None of the marine species which utilise the study area are at the extent of their known range and the local populations do not constitute an 'ecologically significant proportion' of the total population of the species. While these marine species do inhabit the site, the surrounding region provides suitable habitat that can be utilised and impacts from the study area are unlikely to significantly impact the habitat or distribution of this species in the region. Due to the ephemeral nature of the waterways identified onsite it is unlikely that the Project provides year-round habitat for these species.

6.1.4 Mammals

Habitat Values

Mammal morphology varies widely from small rodents to larger kangaroos to bats. The ecology of each of these groups is equally variable and they are assessed separately in the following sections.

Small Mammals

Habitats suitable for small mammals include areas that provide a plentiful food source and suitable shelter sites. The highest density of small mammal species is usually associated with reliable rainfall which is reflected in a reliable source of food and dense ground vegetation, particularly shrubs and grasses.

The diversity of small mammals is often limited by the lack of a predictable food supply and open ground vegetation. Consequently, small mammal populations can fluctuate dramatically in response to rainfall which increases seed production and insect abundance. During less favourable periods, small mammal populations can be very low.

The study area provides a variety of habitat types suitable for small ground-dwelling mammals, including vegetated woodlands, open forests and watercourses, found in vegetation communities VC 1, VC 2 and VC 3. The majority of the study area is comprised of non-remnant vegetation which is mostly utilized as grazing pasture. This community reduces the availability of shelter.

Medium and Large Mammals

Factors affecting the occurrence of medium and large sized mammals are varied. Important factors can include land-clearing, feral animal predation and grazing pressures. Regardless of the clearing that has occurred on the Project, larger macropods have been much less affected than some other mammals. Larger macropods are considered generalists, likely to thrive and flourish in response to areas of grasslands and open vegetation, as they are less vulnerable to small predators such as foxes and cats. They are also highly opportunistic breeders, especially in the presence of permanent water sources such as the dams found onsite.

Most of the study area habitats include pastural land and large areas of low open woodlands. These habitats are likely to support most medium mammals occurring in the region. In particular, the riparian habitats along waterways and watercourses are likely to provide important corridor values for this mammal group.

Larger mammals such as kangaroos have been much less affected by predation than other mammals and by land clearing activities. In fact, many species have flourished in response to increased areas of grassland and open vegetation caused by land clearing activities.

Arboreal Mammals

The majority of arboreal mammals that occur in Australia utilise tree hollows for nesting and shelter (Menkhorst and Knight 2011). A shortage of nest hollows is likely to limit arboreal mammal populations where the density of hollow bearing trees is less than two to eight trees per ha (Smith and Lindenmayer 1988).

Hollow-bearing trees on the study area generally occur along creek-lines or in adjoining vegetation communities. Away from the waterway corridors, hollow-bearing trees are few and are separated by vast open areas that would be difficult for arboreal mammals to cross without venturing onto the ground. Due to the previously cleared and disturbed nature of the study area, arboreal mammal habitat is largely restricted to the waterway corridors of the study area.

Bats

The density and diversity of Australian bat species is determined primarily by the availability of suitable nesting and roosting sites. Roosting sites can include locations such as thick foliage, loose exfoliating bark, rock caves or cavities, tree hollows or even fabricated structures such as old buildings and culverts (Churchill 2008).

Consequently, areas with a large number of hollow-bearing trees that occur within remnant vegetation are of high value to many bat species. As bats have a small body size, these hollows can be much smaller in size than required by some arboreal mammals. Possible roosting sites observed on the study area included tree hollows and exfoliating bark, particularly in VC 1, VC 2 and VC 3.

Potential roosting habitat including rocky areas and drainage areas on the study area were surveyed with an ANABAT echolocation call recorder. Riparian zones with large hollow bearing trees located adjacent to the study area were also surveyed.

Observed Species

In total, 33 mammal species were recorded in the study area, comprising 28 native species and five introduced species, all listed in Appendix I. All introduced species recorded are discussed in Section 6.2.

The suite of native mammal species recorded as having a presence on the study area included the Red-necked wallaby (*Macropus rufogriseus*), Short-beaked echidna (*Tachyglossus aculeatus*), Common brushtail possum (*Trichosurus vulpecula*), Water rat (*Hydromys chrysogaster*), Swamp wallaby (*Wallabia bicolor*), Greater glider (*Petauroides volans volans*), Rufous bettong (*Aepyprymnus rufescens*) (Photo Plate 18), Wallaroo (*Macropus robustus*), Eastern grey kangaroo (*Macropus giganteus*), Black-striped wallaby (*Notamacropus dorsalis*) and Delicate mouse (*Pseudomys delicatulus*).

Photo Plate 18 Rufous bettong (*Aepyprymnus rufescens*) observed in the study area

A total of 17 bat species were positively identified on the study area, none of which are listed under the EPBC Act. Those bat species positively identified on the study area included the Gould's wattled bat (*Chalinolobus gouldii*), Little pied bat (*Chalinolobus picatus*), Hoary wattled bat (*Chalinolobus nigrogriseus*), Northern free-tailed bat (*Chaerephon jobensis*), Eastern bentwing bat (*Miniopterus schreibersii oceanensis*), Inland forest bat (*Vespadelus baverstocki*), Rides free-tailed bat (*Ozimops ridei*), Inland free-tailed bat (*Ozimops petersi*), Northern free-tailed bat (*Ozimops lumsdenae*), Western broad-nosed bat (*Scotorepens balstoni*), Little broad-nosed bat (*Scotorepens greyii*), White-striped Free-tailed bat (*Austronomus australis*), Troughton's Sheath-tailed bat (*Taphozous troughtoni*), Lesser long-eared bat (*Nyctophilus geoffroyi*) and Yellow-bellied sheathtail bat (*Saccolaimus flaviventris*).

A Long-eared bat (Nyctophilus sp.) was also detected through the use of ANABAT recorders on the study area; but could not be identified to species level. The Nyctophilus genus has several species in Australia and cannot be identified further then the genus level through ANABATs and a positive identification requires active trapping. The region is known to form part of the distribution of the Vulnerable *Nyctophilus corbeni* (EPBC Act, NC Act). In response to this, ecologists conducted a targeted micro-bat survey in line with the *Survey Guidelines for Australia's Threatened Bats* (DoEE 2010a). The targeted micro-bat survey utilised Harp Traps and Mist Nets. The targeted micro-bat survey did not identify the Vulnerable species *Nyctophilus corbeni* within the study area but trapped the Lesser long-eared bat (*Nyctophilus geoffroyi*). It is highly likely that the *Nyctophilus* sp. call registered in the ANABAT belonged to the Least Concern *Nyctophilus geoffroyi.*

Several other species of bats not listed as threatened, could not be reliably identified from call analysis due to either poor data quality and/or similarities in call characteristics between species known to occur in the region. Unconfirmed species records include species that could not be distinguished between a group of two to three species. The bat call analysis results are detailed in Appendix G.

Mammals of Conservation Significance

The Short-beaked echidna (*Tachyglossus aculeatus*) (Photo Plate 19) was recorded in the study area across several sites (Figure 14). This species is not an EVNT species but is listed under the NC Act as Special Least Concern and is not listed under the EPBC Act.

The Short-beaked echidna is found in a variety of habitat types including open forests, grasslands and heavily vegetated woodlands. It's distribution spans across Australia, including Tasmania and is considered a habitat generalist. This species presence relies on the abundance of ants which are its only food source (Van Dyck *et al.* 2013). Due to the generality and wide distribution of this species, it is not expected that mining activity will have an impact of this species.

A *Significant Residual Impact Assessment* (DEHP 2014a) for the Short-beaked echidna can be found in Section 9.1.2 of this report.

Photo Plate 19 Short-beaked Echidna (*Tachyglossus aculeatus*) observed at the study area

The Greater glider (*Petauroides volans*) (Photo Plate 20), was detected during the field survey of the study area (Figure 14). The Greater glider is listed under the EPBC Act 1999 as a "Vulnerable" species (DoEE, 2018).

The Greater glider is restricted to eastern Australia, occurring from the Windsor Tableland in north Queensland through to central Victoria, with an elevational range from sea level to 1200 m above sea level. The broad extent of occurrence is unlikely to have changed appreciably since European settlement, however the area of occupancy has decreased substantially, mostly due to land clearing (TSSC 2016a).

The Greater glider is an arboreal nocturnal marsupial, largely restricted to eucalypt forests and woodlands. It is primarily folivorous, with a diet mostly comprising eucalypt leaves, and occasionally flowers. Preferred habitat consists of taller, montane, moist eucalypt forests with relatively old trees and abundant hollows. It also favours forests with a diversity of eucalypt species, due to seasonal variation in its preferred tree species (TSSC 2016a).

Critical microhabitat is an abundance of large hollows of large, old trees for daily denning shelters and breeding purposes. The species is absent from cleared areas and has little ability to disperse between fragments across cleared areas, with habitat connectivity critical to species survival (TSSC 2016a).

Major threats include habitat loss from clearing, high intensity fires, and logging and woodland thinning practices (TSSC 2016a).

Some of the study area has been subject to vegetation clearing to allow cattle grazing. Consequently, only small areas of suitable habitat remain on the site. Generally, habitat of the Great glider is confined to the Eucalypt riparian woodlands such as along the Charlevue Creek. This woodland suits the Greater glider's preferred habitat of tall open woodland with a sparse shrub layer. Vegetation community mapping identified this suitable habitat as VC 3.

Habitat values of the study area are limited by the large areas of non-remnant vegetation and the impacts of grazing. Considering the extent and connection to surrounding good quality habitat and the minimal disturbance caused by the Project to Charlevue Creek, impacts on a local population of Greater glider is unlikely to be significant.

A *Significant Residual Impact Assessment* (DEHP 2014a) for the Greater glider can be found in Section 9.1.2 of this report.

Photo Plate 20 Greater glider (*Petauroides volans*) observed at the study area

6.2 PEST SPECIES

Field surveys positively identified six introduced and/or pest fauna species as having a presence within the study area. Introduced species were recorded through detection of scats, tracks or other traces (e.g. skulls), sensor camera detection and/or direct observation. The suite of introduced species includes the Cane toad (*Rhinella marina*), Wild dog/Dingo (*Canis familiaris/Canis lupus dingo*), Feral cat (*Felis catus*), Rabbit (*Oryctolagus cuniculus*), House mouse (*Mus musculus*) and Feral pig (*Sus scrofa*).

All the non-native fauna species reported from the study area, with the exception of the Cane toad and the House mouse are listed as restricted species under the Biosecurity Act 2014 (DAF 2019) as shown in Table 17.

Table 17 Introduced species identified on the study area

Scientific name	Common name	*Biosecurity Act 2014*			
		Category 3	Category 4	Category 5	Category 6
Canis familiaris or Canis lupus dingo	Wild dog/Dingo	x	x	x	x
Oryctolagus cuniculus	Rabbit	x	x	x	x
Felis catus	Feral cat	x	x	-	x
Sus scrofa	Feral pig	x	x	-	x

Category 3: the invasive animal must not be distributed either by sale or gift or released into the environment.
Category 4: the invasive animal must not be moved.
Category 5: the invasive animal must not be kept.
Category 6: the invasive animal must not be fed.

Photo Plate 21 Feral cat (*Felis catus*) recorded on the camera trap at DF05

The Cane toad and the House mouse are not a prohibited or restricted invasive animal under the Biosecurity Act 2014; however, everyone has a general biosecurity obligation (GBO) to take reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control (DAF 2016b). Cane Toads are recognised as an invasive species, as they present a serious threat to native wildlife. The Cane Toad consumes a wide variety of native animals including frogs, small reptiles, mammals and birds and cause the death of native predators that consume their toxins.

6.3 FAUNA SPECIES OF CONSERVATION SIGNIFICANCE

6.3.1 Fauna Species of Conservation Significance Identified on the Study Area

Field surveys across the study area detected the presence of five fauna species of conservation significance:

- The southern Squatter pigeon (*Geophaps scripta scripta*) and Greater glider (*Petauroides volans*), both species are listed as Vulnerable under the EPBC Act and the NC Act;

- The short beaked Short-beaked echidna (*Tachyglossus aculeatus*) This species is not an EVNT species but is listed under the NC Act as Special Least Concern; and

- The Rufous fantail (*Rhipidura rufifrons*) listed as migratory and marine species, was identified on the study area.

A description of the four species is included in Sections 6.1.3 and 6.1.4, respectively.

6.3.2 Fauna Species of Conservation Significance Not Identified on the Study Area

Table 18 discusses EVNT and Migratory species that are known from the broader region and have been identified from desktop searches already identified as likely or potential to occur within the study area but were not observed on site during surveys.

The assessment of potential for presence and impact on each species is based on the knowledge of ecologists, information obtained from field surveys on the study area, previous surveys conducted on or near the study area and scientific literature. This assessment indicated that only 11 of the 19 species were considered as possible to occur on the Project.

The distribution of the marine and migratory species identified from desktop searches is widespread in eastern Australia (Simpson and Day, 2010). The study area is not at the limit of these species' range, nor are these species considered to be declining within the region. Therefore, it is unlikely that the study area will have a significant impact on the regional populations of these species.

Table 18 Fauna Species of Conservation Significance not identified on the study area

Species Name **Common Name**	**EVNT Listing**		**Likelihood of Occurrence Post Survey**
	EPBC Act	**NC Act**	
Amphibians			
Adelotus brevis Tusked frog	NL	V	Potential The study area occurs within the vicinity of the known range of the Tusked frog and suitable habitat is available year-round due to the presence of dams. Despite not being found during targeted field surveys (Aquatic survey, AARC 2019), it is a potential that the study area can support a population of Tusked frogs.
Reptiles			
Delma torquata Adorned delma	V	V	Potential Suboptimal habitat is present within the study area. However, field surveys revealed no evidence of this species occurring within the study area site.
Strophurus taenicauda *Golden-tailed gecko*	NL	NT	Potential Suitable habitat is present within the study area. However, field surveys revealed no evidence of this species occurring within the study area site.
Birds			
Calidris acuminate Sharp-tailed Sandpiper	Ma, Mi	SL	Potential There is the potential for this species to utilise the study area due to the presence of suitable habitat within the study area's boundary.

Species Name **Common Name**	**EVNT Listing**		**Likelihood of Occurrence Post Survey**
	EPBC Act	**NC Act**	
Calyptorhynchus lathami erebus Glossy black-cockatoo (northern)	-	V	Potential Suitable habitat occurs in the broader region and within the study area. This species is highly reliant on fodder species (*Allocasuarina* and *Casuarina* species). Within the study areas the species *Allocasuarina luehmannii* (Bull oak) was identified as present dominant in small patches. As such it is potential that the study area provides suitable habitat or food sources for this species.
Erythrotriorchis radiatus Red goshawk	V	E	Potential There is the potential for this species to utilise the study area due to the presence of suitable habitat within the study area's boundary. Additional suitable habitat is found throughout the surrounding region.
Hirundapus caudacutus White-throated needletail	Ma, Mi	SL	Potential There is the potential for this species to utilise the study area due to the presence of suitable habitat within the study area's boundary.
Grantiella picta Painted honeyeater	E	V	Unlikely This species is highly reliant on the presence of mistletoes in the canopy strata, no mistletoes were recorded during the terrestrial or aquatic field surveys. The study area is unlikely to provide suitable habitat for this species.
Lathamus discolour Swift Parrot	CE	E	Unlikely Limited suitable habitat occurs for this species was recorded along the watercourses within the study area. The study area occurs at the most upper limit of this species distribution.

Species Name **Common Name**	**EVNT Listing**		**Likelihood of Occurrence Post Survey**
	EPBC Act	**NC Act**	
Monarcha melanopsis Black-faced Monarch	Ma, Mi	SL	Potential There is the potential for this species to utilise the study area due to the presence of suitable habitat within the study area's boundary.
Motacilla flava Yellow wagtail	Ma, Mi	SL	Potential There is the potential for this species to utilise the study area due to the presence of suitable habitat within the study area's boundary.
Myiagra cyanoleuca Satin flycatcher	Ma, Mi	SL	Potential There is the potential for this species to utilise the study area due to the presence of suitable habitat within the study area's boundary.
Ninox strenua Powerful owl	-	V	Unlikely While there are hollow bearing trees along the watercourses within the study area, these hollows are generally small in nature and are unlikely to be of value to Powerful owls for nesting/shelter. Limited remnant vegetation has been mapped within the study area due to extensive clearing.
Pedionomus torquatus Plains wanderer	CE	V	Unlikely No native grasslands occur within the study areas boundary. This species is often absent from areas that are too dense or sparse. All open areas are heavily grazed and dominated by introduced pasture species.

Species Name Common Name	EVNT Listing		Likelihood of Occurrence Post Survey
	EPBC Act	NC Act	
Poephila cincta cincta Black-throated finch (white-rumped subspecies)	E	E	Unlikely No suitable habitat for this species occurs within the study area. Additionally, this species is not known from the area and was not detected during ecological surveys on site.
Turmix melanogaster Black-breasted button-quail	V	V	Unlikely No suitable habitat for this species was recorded within the study areas boundary.
Mammals			
Chalinolobus dwyeri *Large-eared pied bat*	V	V	Unlikely No sandstone gorges were recorded within the study area, the study area has also undergone extensive clearing limiting the extent of suitable habitat.
Onychogalea fraenata Bridle nailtail wallaby	E	E	Potential No preferred habitat such as Brigalow woodland and only small disconnected patches of Poplar box woodland have been identified in the study area. However, the only native population of this species is located directly north of the study area. This species could potentially utilise the habitat in the study area for foraging.
Phascolarctos cinereus Koala	V	V	Unlikely Suitable habitat is present within the study area. However, the amount of suitable habitat is limited on the study area and displays limited connectivity to the other known habitat preferences for the species. Field surveys revealed no evidence of this species occurring within the study area.

EPBC – *Environment Protection and Biodiversity Conservation Act 1999*
NC Act – *Nature Conservation Act 1992*
CE – Critically Endangered
V – Vulnerable
E – Endangered
C – Least Concern
SL – Special Least Concern
Mi - Migratory

7.0 POTENTIAL IMPACTS

Potential impacts of the Project (Figure 15) on terrestrial ecology values are described below. Mitigation measures and management strategies for the potential impacts are described in Section 8.0.

7.1 TERRESTRIAL FLORA

7.1.1 Vegetation Communities

The Project will include vegetation clearance and land disturbance during the construction and operation of the mine. The extent of land disturbance would be approximately 1961 ha, of which, approximately 720 ha of remnant vegetation clearing is required over the life of the Project.

Other potential impacts to vegetation communities include:

- Removal of habitat for terrestrial flora and fauna.
- Further habitat fragmentation and loss of connectivity. It is noted that existing vegetation clearing due to agricultural land use has already limited connectivity within this community;
- Potential for reduced condition of neighbouring vegetation communities due to the introduction of weeds or the release of contaminants associated with mine operations.

7.1.2 Flora Species of Conservation Significance and Habitat

Cerbera dumicola has been identified during the vegetation surveys in two very localised rocky areas associated with vegetation community VC 2 and VC 1 (Figure 14). This species was not identified elsewhere in the study area, within similar habitat types, during targeted searches.

The proposed mining activity proposes no impacts to populations of *Cerbera dumicola*. The nearest land disturbance is located 1.3 km to the east.

7.1.3 Weed Species

Project development has the potential to create or enhance conditions for invasive weed species, that may spread and out-compete native and pasture species. Weed species may be introduced via the spread of seed on persons, vehicles and equipment. Weed species may quickly colonise disturbed areas if left untreated.

The introduction of weed species can reduce native species abundance and diversity through competition. Ultimately this can lead to the reduced condition of vegetation and native fauna habitat.

7.1.4 Wetlands

The Project has potential to impact on wetlands via

- Direct clearing;
- Changes in hydrology;
- Erosion and sedimentation; and
- Contaminant release.

7.1.5 Groundwater Dependant Ecosystems

Where wetlands exhibit a degree of dependence on groundwater for survival, drawdown from the mine can result in a reduced ecosystem condition, changes to vegetation composition or die back.

A groundwater assessment was undertaken by JBT Consulting (2019) in the study. Data obtained in this study, such as water quality, groundwater level and groundwater drawdown estimation were used in the assessment of the GDEs and the associated impact of drawdown.

Potential Impacts to GDEs within the study area

The potential GDEs within the study area are riverine type wetlands including riparian vegetation on watercourses and floodplains. The dominant species of this vegetation is Blue gum (*Eucalyptus tereticornis*), with *Bauhinia* spp., River oak (*Casuarina cunninghamiana*), Paperbark tea-tree (*Melaleuca* spp.) and Poplar box (*Eucalyptus populnea)* as associated species. Published research has identified the rooting depth of the Blue gum as 10 m (Boland *et al* 2006).

Groundwater modelling estimated that the Project has the potential to cause a maximum drawdown of 5 m (steady-state post-mining drawdown) at some locations below the Charlevue and Springton Creeks (JBT 2019). The groundwater adjacent to Charlevue Creek has been recorded at a depth of 8.8 mbgl with an Electrical Conductivity (EC) range from 15,200 µS/cm to 16,600 µS/cm, whilst Springton Creek registered a depth of 11.2 mbgl with a recorded EC of 5,948 µS/cm (from a single bore) (JBT 2019).

Considering Blue gum and River oak have moderate salinity tolerance of 4,000 to 8,000 µS/cm (DA 2002), it is concluded that the groundwater within the Charlevue Creek alluvium is too saline to be useable by the vegetation along the Charlevue Creek.

The salinity recorded adjacent to Springton Creek alluvium is within the tolerance level of the dominant species (DA 2002). However, it is also noted that the depth to groundwater in that area (11.19 mbgl) is potentially beyond the depth that is accessible by vegetation.

Charlevue and Springton Creeks are highly ephemeral watercourses subject to occasional flow events that replenish the alluvial aquifers. As a result, fluctuations in the groundwater level throughout the year are likely within these riverine ecosystems. Based on the existing condition of the riverine vegetation communities within the study area, it is highly likely that this vegetation has a very low reliance on groundwater aquifers for survival, if any at all. Rather the riverine communities represent facultative GDEs, capable of surviving on soil moisture present in unsaturated shallow soil layers.

It is therefore concluded that there is a very low risk that groundwater drawdown would result in a significant impact to these riverine communities.

Potential impacts to the HES wetland outside the study area

The groundwater assessment (Appendix E) included an assessment of the potential GDE / wetland located to the south east of study area. The groundwater study predicted a 2m drawdown within the community, post mining.

The potential GDE is located on an elevated ridgeline; the feature is located within a shallow depression on the ridgeline that is surrounded to the south, west and east by elevation contours at 170 m Australian height datum (AHD), with the central of the depression falling below 165 mAHD. The feature is well above the natural ground surface within the MLA, which ranges from 125 to 135 mAHD, with the elevation of the Springton Creek floodplain dropping below 120 mAHD.

The potential GDE is therefore located within a shallow depression on the ridgeline that is likely to be internally draining under average rainfall conditions and that only discharges to the northeast under high rainfall conditions. It is interpreted that, under average rainfall conditions and at the tail end of high rainfall conditions, surface runoff within the relatively small catchment that reports to this area will pond in the area of the shallow depression and provide localised recharge to an underlying groundwater lens that is likely to be disconnected from the regional groundwater system.

Registered bores indicate the depth to water for bores constructed within Tertiary sediments and Permian coal measures ranges from 26.25 to 32.37 mbgl in this area. This equates to a groundwater elevation of 108-110 mAHD for bores in topographically elevated areas. The water level in the site monitoring bores, which were assessed to be representative of the regional groundwater level, are therefore considerably lower than the elevation of the base of the potential GDE, which is at an elevation approximately 165 mAHD.

Based on the observations discussed above, it is concluded that:

- The potential GDE is located on an elevated ridgeline, but within a shallow depression that is likely to drain internally under average rainfall conditions but drains to the northeast under high rainfall conditions;
- The drainage of surface runoff to the shallow depression is likely to result in localised recharge to a perched lens of groundwater that is disconnected from the regional groundwater system;
- It is probable that this perched groundwater lens provides water to vegetation within the depression during the dry season, but that the groundwater lens is an extremely localised system that relies on replenishment by seasonal rainfall rather than being maintained by the regional groundwater system.

It is noted the EC of site groundwater monitoring bores, which are interpreted to be within the regional groundwater system, is high (15,000 µS/cm to 29,000 µS/cm – refer Section 4.3). However, it is also noted that the EC of the registered bores to the north of the potential GDE is very low, with bore 111570 recording an EC of 240 µS/cm and bore 161093 recording an EC of 710 µS/cm. This provide further evidence that the groundwater system in this area is perched above the regional groundwater system, with the flowline from the area of the potential GDE (where recharge is interpreted to occur) to the area where these bores are located being very short.

It is concluded that the potential GDE is maintained by localised runoff and shallow recharge and that a reduction in the regional groundwater level of approximately 2 m, at a vertical distance of approximately 50 to 60 m below the base of the potential GDE, has a very low risk of impacting groundwater levels beneath the potential GDE.

7.2 TERRESTRIAL FAUNA

7.2.1 Fauna Species of Conservation Significance and Habitat

Field surveys across the study area detected the presence of three fauna species of conservation significance; the southern Squatter pigeon (*Geophaps scripta scripta*), the Greater glider (*Petauroides volans*) and the Short-beaked echidna (*Tachyglossus aculeatus*).

Potential impacts of the Project to threatened fauna species include:

- Direct clearing of habitat within the Project defined impact areas;

- Further habitat fragmentation and loss of connectivity, particularly along Charlevue Creek which provides partial connectivity to larger downstream riparian communities. It is noted that existing vegetation clearing due to agricultural land use has already limited connectivity within this community;

- Potential for fauna mortality through interactions with vehicles on roads and/or heavy machinery used for land clearing;

- Potential for habitat degradation through increased risk of release of contaminants or sediments into receiving environments within and downstream of the Project; and

- Potential for increased invasive flora and fauna.

Southern Squatter Pigeon (*Geophaps scripta scripta*)

Suitable habitat for the southern Squatter Pigeon exists in open grassy woodland throughout the study area. Within this suitable habitat, fifteen birds were observed during the ecological survey period, the majority were observed during the spring survey in September 2017. The species is regionally abundant, having been observed outside of the study area on multiple occasions, with ecologists observing the species multiple times on local roads and elsewhere while traversing the local area. No breeding activity was observed within the study area.

It is unlikely that the proposed Project will have a significant impact on the southern Squatter Pigeon; either the local population or the population in its entirety due to:

- The species being highly mobile;

- The abundance of equivalent and more suitable habitat outside of the study area in adjacent areas;

- The observed high local abundance of the southern Squatter pigeon within and surrounding the study area; and

- The likely suitable habitat to be provided by rehabilitated land, post mining.

Greater glider (*Petauroides volans*)

The Greater glider preferred habitat consists of taller, montane, moist eucalypt forests with relatively old trees and abundant hollows. It also favours forests with a diversity of eucalypt species, due to seasonal variation in its preferred tree species (TSSC 2016a). Critical microhabitat is an abundance of large hollows of large, old trees for daily denning shelters and breeding purposes. The species is absent from cleared areas and has little ability to disperse between fragments across cleared areas, with habitat connectivity critical to species survival (TSSC 2016a).

Habitat of the Great glider within the study area is confined to the Eucalypt riparian woodlands such as along the Charlevue Creek. This woodland suits the Greater glider's preferred habitat of tall open woodland containing hollows with a sparse shrub layer.

It is unlikely that the proposed Project will have a significant impact on the Greater glider; either the local population or the population in its entirety due to:

- No significant impact proposed to habitat within the study area, specifically Charlevue Creek. Proposed disturbance within this habitat is limited to the development of a small culvert crossing;

- The observed abundance of Greater Gliders within the study area and within the broader Central Queensland region; and
- The abundance of equivalent and more suitable habitat outside of the study area in adjacent areas.

Short-beaked echidna (*Tachyglossus aculeatus)*

The Short-beaked echidna is found in a variety of habitat types including open forests, grasslands and heavily vegetated woodlands. Suitable habitat for the species exists across the study area.

It is unlikely that the proposed Project will have a significant impact on the Short-beaked echidna (*Tachyglossus aculeatus)*; either the local population or the population in its entirety due to:

- The known abundance and wide-ranging distribution of the species;
- The presence of ample equivalent or better suited habitat surrounding the Project;
- The relatively small extent of impact proposed by the Project; and
- The likely suitable habitat to be provided by rehabilitated land, post mining.

7.2.2 Migratory Fauna Species

The Rufous fantail (*Rhipidura rufifrons*), a listed migratory bird species under the EPBC Act, was identified within the study area. The Rufous fantail is generally found in rainforest, dense wet forests, swamp woodlands and mangroves, preferring deep shade, and is often seen close to the ground. During migration, it may be found in more open habitats, such as those within the study area.

It is unlikely that the proposed Project will have a significant impact on the Rufous fantail (*Rhipidura rufifrons*); either the local population or the population in its entirety due to:

- The Rufous fantail is a common and secure species (Blakers *et al.* 1984);
- The study area does not contain the preferred habitat type for the species;
- The species is highly mobile and likely only passing through the Project site on its migratory path;
- No known breeding sites or nesting habitat was identified on the study area; and
- Ample equivalent or higher quality habitat exists surrounding the study area.

7.2.3 Pest Species

Pest species compete with and prey on native fauna. Construction and operation of the Project increases the risk of pest species on the study area through:

- Generation of food and other waste that may attract pests; and
- Creation of artificial ponding areas providing habitat for pest species such as cane toads.

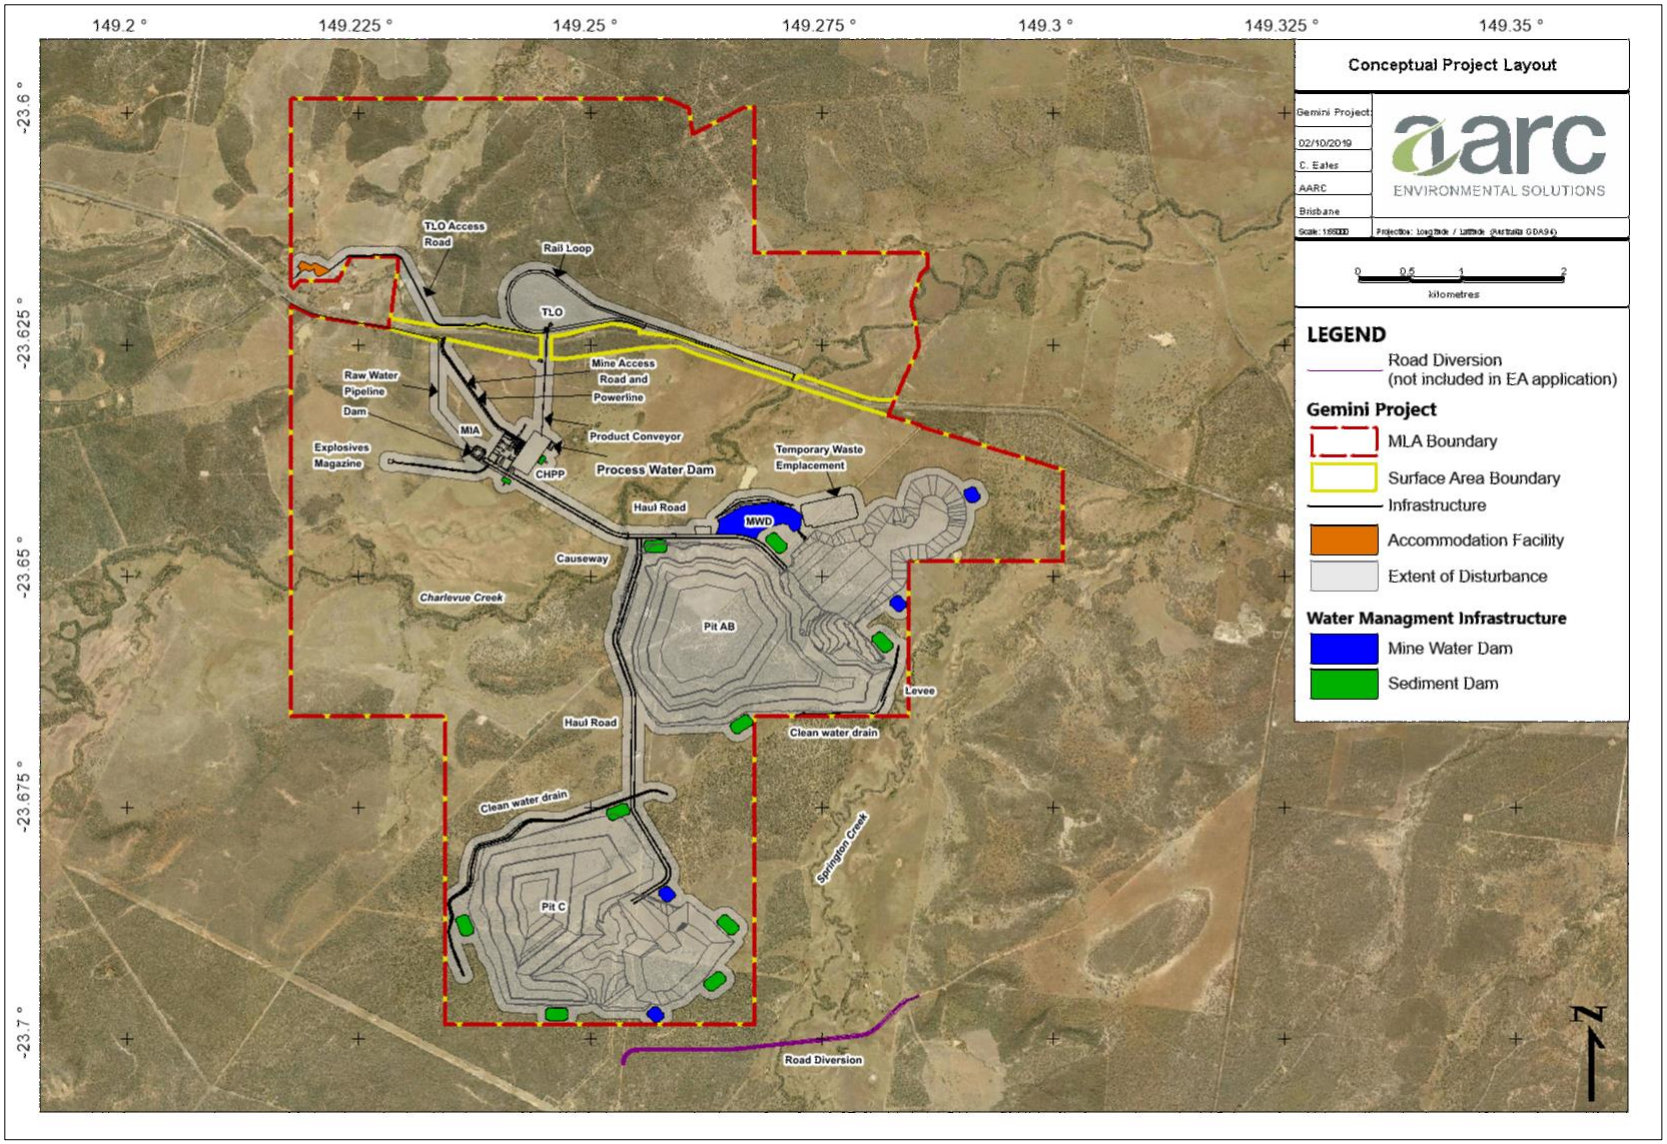

Figure 15 Conceptual Project Layout

8.0 MITIGATION AND MANAGEMENT STRATEGIES

8.1.1 Terrestrial Flora

8.1.1.1 Vegetation Communities

To minimise and mitigate impacts to vegetation communities on the Project area the following management strategies will be implemented:

- Clearing of land and vegetation will be limited to areas defined in the Project approval and required for safe operation.
    - An internal Permit to Disturb system will be implemented to minimise the chances of unauthorised clearing;
    - Areas to be cleared will be clearly defined and demarked to equipment operators;
- Inductions and training materials provided to employees will identify the environmental values of the site as well as the company procedures for managing impacts within its authority;
- Rehabilitation will be undertaken progressively and will aim to return the land to the pre-mining land use where possible;
- Where impact to Matters of State Environmental Significance cannot be avoided and are authorised by the Project approval, environmental offsets will be provided.

8.1.1.2 Flora Species of Conservation Significance

Suitable habitat for the *Cerbera dumicola* exists to the west of the Project, within the MLA. The proposed mine construction and development will not impact on the populations.

- An internal Permit to Disturb system will be implemented to minimise the chances of unauthorised clearing and impacts to the populations within the MLA;
- Inductions and training materials provided to employees will identify the environmental values of the site as well as the company procedures for managing impacts within its authority; and
- Existing populations will be monitored for abundance, distribution and health over the mine life.

8.1.1.3 Weed Species

To control the abundance and spread of weed species the following management strategies will be implemented:

- A pest and weed management plan will be prepared and implemented prior to construction;
- As required, weeds within the MLA will be controlled using herbicides and other recommended methods;
- Inductions and training materials provided to employees will assist the identification of common weeds and will include procedures for reporting; and
- Access to vehicle wash down facilities will be provided for vehicles at risk of spreading weeds.

8.1.1.4 Wetlands / GDEs

Wetlands / GDEs include Riverine vegetation on the MLA, particularly riparian vegetation associated with Charlevue and Springton Creeks. In addition, a HES wetland is located to the south east of the Project. To manage potential impacts on wetlands, the following will be undertaken:

- Sediment and erosion control structures will be installed and maintained near all at risk areas to prevent sediment release to wetlands;
- A Receiving Environment Monitoring Program (REMP) will be implemented and will include monitoring of water, sediments, riparian / riverine vegetation health and biological indicators in aquatic environments;
- The release of Mine Affected Water, will be in accordance with the quality controls provided by the model mining conditions; and
- Groundwater bores adjacent to Charlevue Creek (DW7076W) and Springton Creek (DW7292W1), will be fitted with dataloggers. This data will allow the assessment of the range of water levels within the alluvium and the response of groundwater levels within the alluvium to rainfall recharge, stream flow events and mining activities.

8.1.2 Terrestrial Fauna

8.1.2.1 Fauna Species of Conservation Significance

Fauna species of conservation significance associated with the Project site include; the southern Squatter pigeon (*Geophaps scripta scripta*), the Greater glider (*Petauroides volans*), the Short-beaked echidna (*Tachyglossus aculeatus*) and the Rufous fantail (*Rhipidura rufifrons*) (Migratory). To ensure no significant impact to these species, the following strategies will be implemented:

- An internal Permit to Disturb system will be implemented to minimise the chances of unauthorised clearing and impacts to the threatened fauna within the MLA;
- Inductions and training materials provided to employees will identify the environmental values of the site as well as the company procedures for managing impacts within its authority;
- Vehicles speeds will be limited within the MLA, to minimise the risk of collision;
- Vegetation clearing will be done in a staged manner, allowing time for fauna to escape the area; and
- Pre-clearing inspections will be undertaken by qualified staff to minimise the risk of fauna mortality.

8.1.2.2 Pest Species

To prevent the introduction of pest species and to control their spread, the following management strategies will be implemented for the Project:

- A pest and weed management plan will be prepared and implemented prior to construction;
- Rubbish and food scraps will be managed so as not to encourage pest species;

- Inductions and training materials provided to employees will assist the identification of common pests and will include procedures for reporting; and

- Control of feral cats and other animals will be undertaken within the MLA.

9.0 PROJECT ENVIRONMENTAL OFFSETS

The offsets framework requires environmental offsets to be delivered where an activity is likely to result in a significant residual impact on a prescribed environmental matter. The *QEOP Significant Residual Impact Guideline* (DES 2014b) is used to determine whether residual impacts are considered to be significant.

Prescribed environmental matters (MSES) are listed in Schedule 2 of the Environmental Offsets Regulation. The following prescribed matters were mapped or identified within the Project area by the terrestrial ecology surveys:

- Regulated vegetation including:
    - Regional Ecosystems (REs) that are listed as Endangered or Of Concern (under the *Vegetation Management Act 1999* (VM Act));
    - REs located within the defined distance from the defining banks of a relevant watercourse or relevant drainage feature identified on the Regulated Vegetation Management Watercourse and Drainage Feature Map (as certified under the VM Act);
    - REs mapped as essential habitat on the Essential Habitat Map (as certified under the VM Act) for flora and fauna listed as Endangered and Vulnerable (under the *Nature Conservation Act 1992* (NC Act)); or
    - With specific application to the prescribed activity of 'native vegetation clearing' a RE mapped as essential habitat on the Essential Habitat Map (as certified under the VM Act) for flora and fauna listed as Near Threatened (under the NC Act);
- Remnant REs that contain an area of land required for ecosystem functioning (a connectivity area);
- Protected wildlife habitat, which includes;
    - Habitat for Endangered, Vulnerable and Special Least Concern animals (under the NC Act);

9.1 ASSESSMENT OF PRESCRIBED MATTERS IDENTIFIED IN THE STUDY AREA

9.1.1 Regulated Vegetation

The ground verified vegetation map identified the following regulated vegetation categories, under the VM Act:

- REs that are listed as Of Concern (under the VM Act);
- REs that are located within the prescribed distance from the defining banks of a relevant VM Act watercourse; and

The *QEOP Significant Residual Impact Guideline* (DES 2014a) covers vegetation clearing in excess of thresholds of between 0.5 ha and 5 ha, depending on the structural category of the vegetation. All regulated vegetation proposed to be cleared for the Project is in excess of the larger 5 ha threshold, and no further breakdown is defined (Table 19).

Figure 16 illustrates the distribution of vegetation in relation to proposed disturbance areas, whilst Figure 17 summarises the regulated vegetation present within the proposed disturbance.

Table 19 Summary of regulated vegetation within the proposed disturbance

RE	VM Act Status	Proposed Disturbance (ha)	Significant Residual Impact
RE 11.3.2	OC	7.53	Yes
REs located within the defined distance from the defining banks of a VM Act watercourse	-	59.79	Yes

Notes: * within complete study area

The Project is likely to result in a significant residual impact to MSES, through the clearing of regulated vegetation above the significant residual impact thresholds.

9.1.2 Conservation Significant Species, Protected Wildlife Habitat and Essential Habitat

The *Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a) outlines the criteria for identifying when an impact on prescribed environmental matters (MSES) may be significant. The significant impact criteria provide a trigger for consideration of offsets (DEHP 2014a).

As stated in the *Environmental Offsets Regulation 2014* an area of habitat (e.g. foraging, roosting, nesting or breeding habitat) for an animal that is endangered, vulnerable or a special least concern is considered Protected Wildlife Habitat under the *Environmental Offsets Regulation 2014* (DEHP 2014a).

As previously discussed, three listed EVNT species under the NC Act were present within the study area, Greater glider, southern Squatter pigeon and the plant species *Cerbera dumicola.* Essential habitat for all three species has been mapped by the DES in accordance to the VM Act (Figure 18).

An assessment following the Significant residual impact criteria for vulnerable wildlife habitat (including essential habitat) has been conducted for the Greater glider and the southern Squatter pigeon. Similarly, an assessment for the special least concern animal wildlife habitat has been conducted for the Short-beaked echidna, also identified within the study area.

The *Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a) does not include specific criteria for assessing impacts to Near Threatened wildlife. An assessment of the significant residual impact for *Cerbera dumicola* has been carried out in accordance with the criteria for Vulnerable wildlife, as described in Section 5.1 of the guideline.

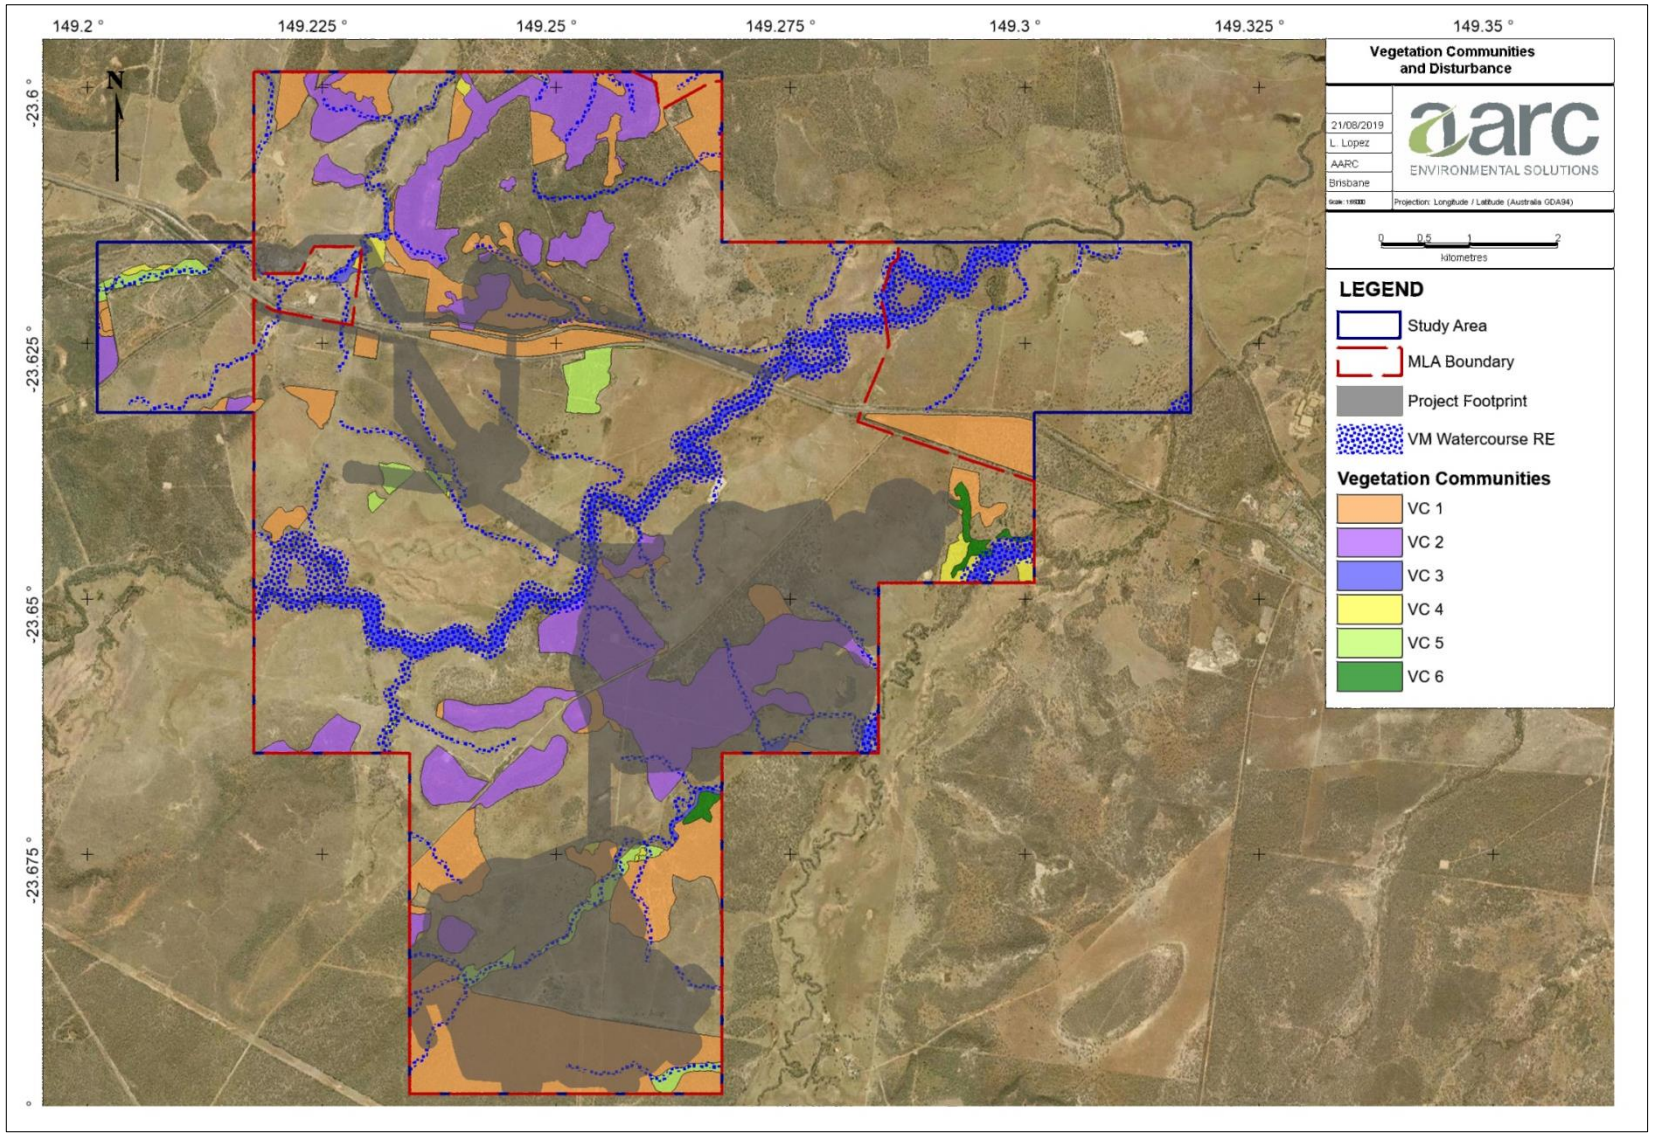

Figure 16 Vegetation Communities and Disturbance

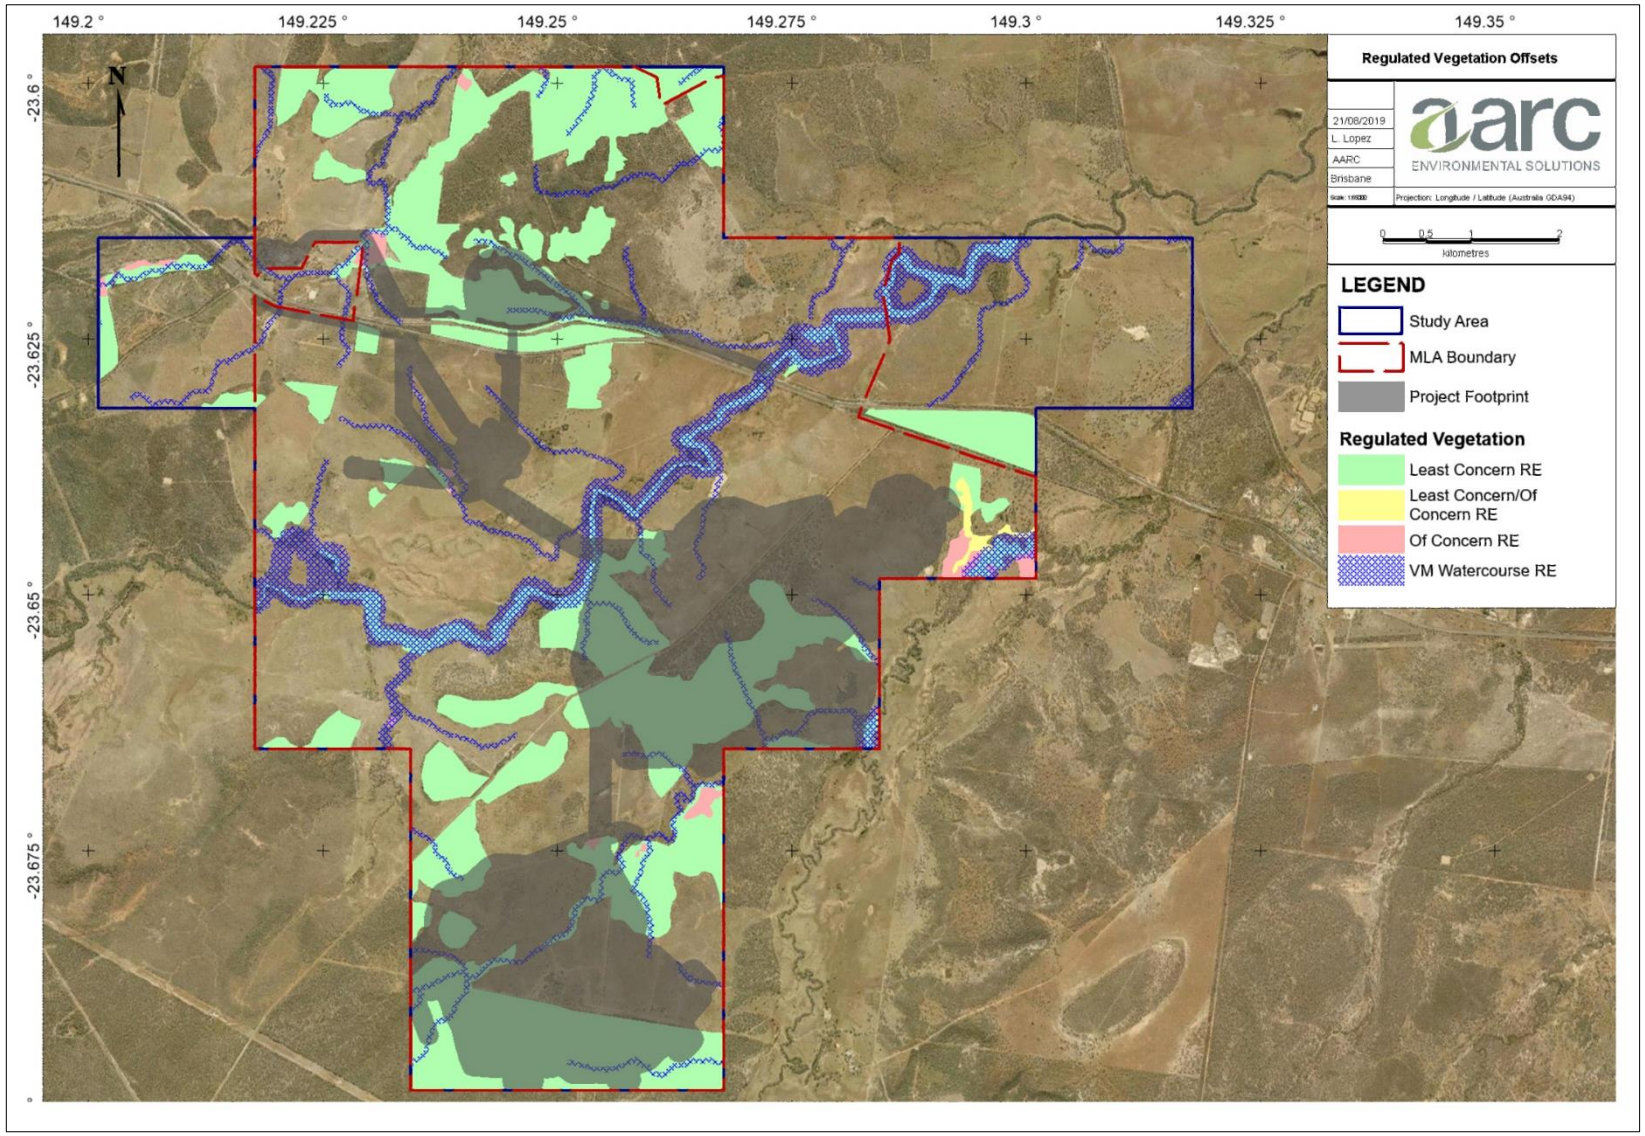

Figure 17 Regulated Vegetation Offsets Requirements

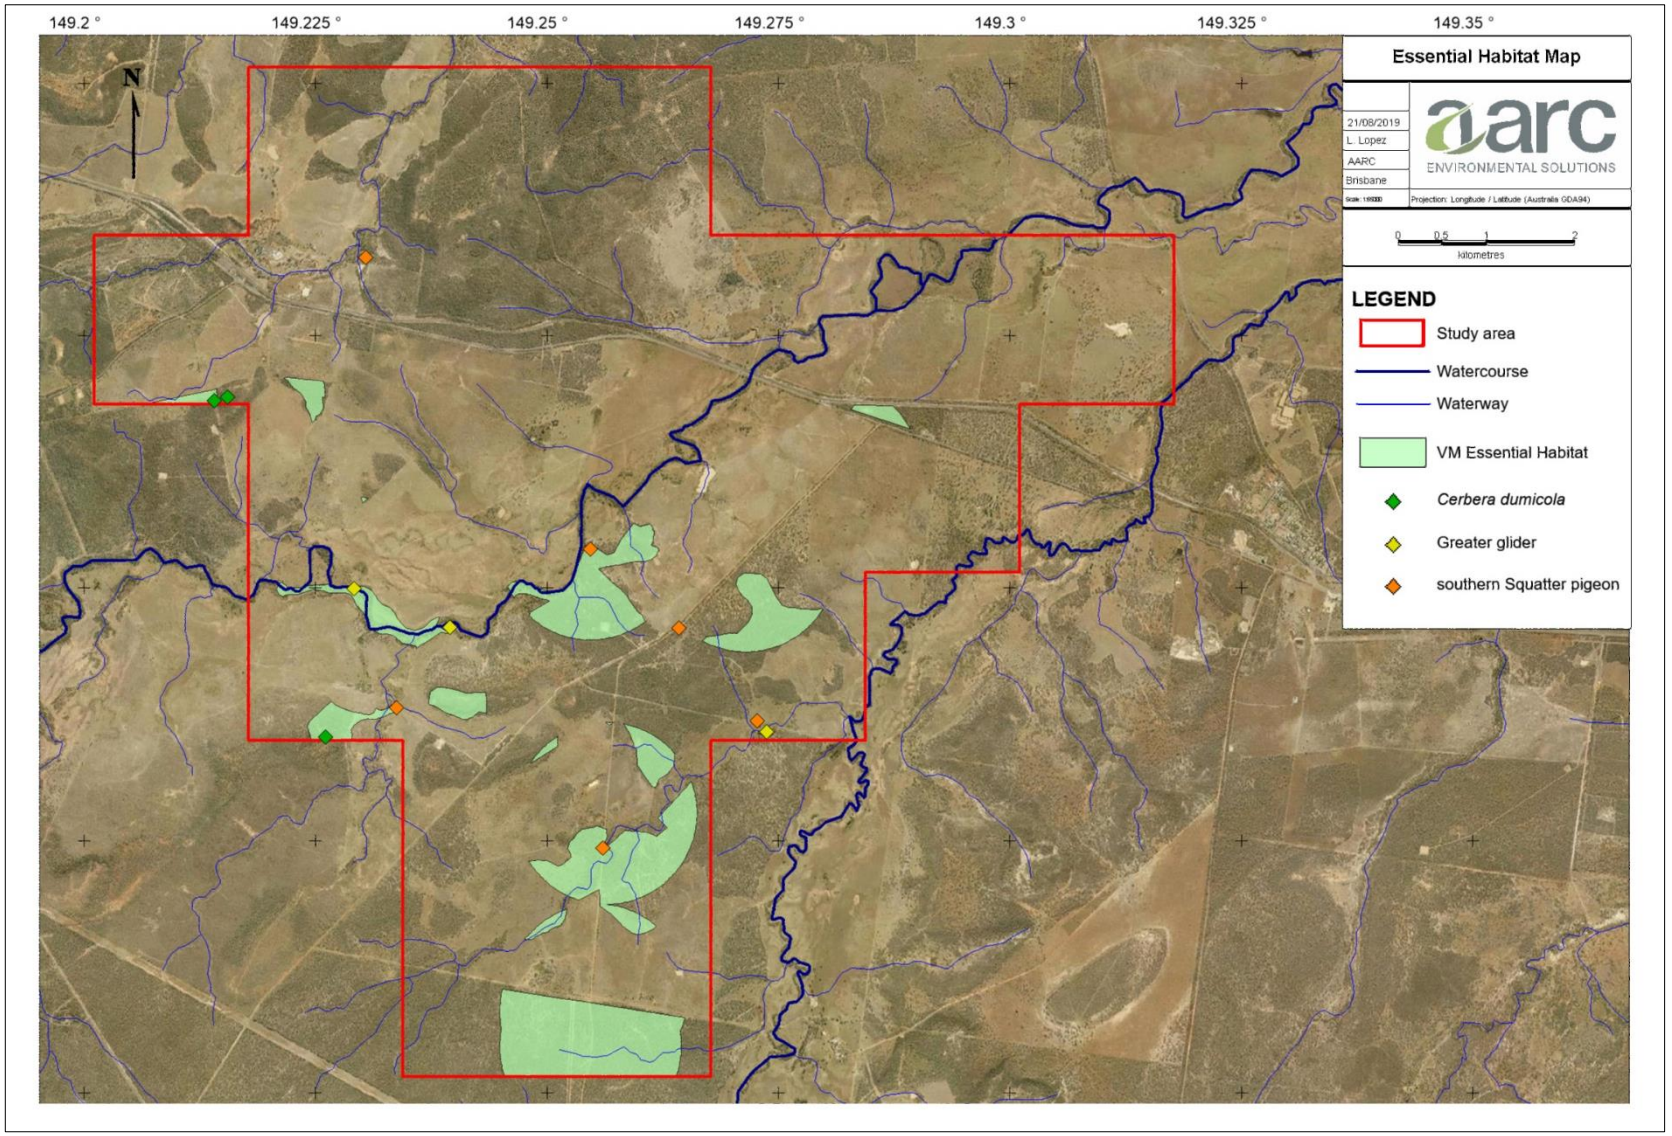

Figure 18 Essential Habitat (VM Act)

Significant Residual Impact Assessment on Vulnerable Species Under the NC Act

When assessed against the significant residual impact criteria, the Project is considered unlikely to result in any significant impact on the southern Squatter pigeon. An assessment of the potential impact of the Project on the southern Squatter pigeon using significant residual impact criteria is presented in Table 20.

When assessed against the significant impact guidelines (Table 21), the Project is considered unlikely to result in a significant impact on the Greater glider. The Project will not fragment available habitat to the extent of fragmenting the Greater glider population. There is considerable alternative habitat available in the surrounding region, and dispersal opportunities will not be impacted as habitat corridors will be retained.

Table 20 MSES Impact Assessment of the Project on the southern Squatter pigeon

Significant Impact Criteria	Impact Assessment
Will the action lead to a long-term decrease in the size of a local population of a species?	No, the Project would not fragment potential habitat for this species to the extent that it would decrease the size of local population of the species.
Will the action reduce the extent of occurrence of the species?	No, the species is highly mobile and individuals in the same area would have access to more suitable habitat through connecting open grasslands. The Project would not fragment potential habitat for this species to the extent that it would reduce the extent of occurrence of the species.
Will the action fragment an existing population?	No, this species is highly mobile and individuals in the same area would have access to more suitable habitat through connecting open grasslands. The Project includes measures to prevent significant impacts on this species. This Project will not result in the fragmentation of an existing population into two or more populations.
Will the action result in genetically distinct populations forming as a result of habitat isolation adversely?	No, the Project would not result in habitat isolation for the southern Squatter pigeon to the extent that this species will form genetically distinct populations.
Will the action disrupt ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species?	No, this species is mobile, and the surrounding habitat provides suitable sites for breading, feeding, nesting, migration or resting activities. Given the minimal disturbance to suitable habitat for this species and the interconnectedness of habitats, the Project would not disrupt ecologically significant locations for this species.
Will the action result in invasive species that are harmful to the species becoming established in the species habitat?	No, while the southern Squatter pigeon is vulnerable to predation from introduced pest species; pest management strategies will be implemented to minimise the risk of introduced pest species predating on this species.
Will the action introduce disease that may cause the population to decline, or interfere with the recovery of the species?	No diseases are known for the species that could be caused by mining activities and cause the species' population to decline, nor would actions associated with mining activities interfere substantially with the recovery of the species.

Table 21 MSES Impact Assessment of the Project on the Greater glider

Significant Impact Criteria	Impact Assessment
Will the action lead to a long-term decrease in the size of a local population of a species?	No, the Project would not fragment potential habitat for this species to the extent that it would decrease the size of local population of the species.
Will the action reduce the extent of occurrence of the species?	No, the Project would not fragment potential habitat for this species to the extent that it would reduce the extent of occurrence of the species.
Will the action fragment an existing population?	No, the clearance of suitable habitat will impact individuals of a local population. This Project will not result in the fragmentation of an existing population into two or more populations.
Will the action result in genetically distinct populations forming as a result of habitat isolation adversely?	No, the Project would not result in habitat isolation for the Greater glider to the extent that this species will form genetically distinct populations.
Will the action disrupt ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species?	No, this species is mobile, and the surrounding habitat provides suitable sites for breading, feeding, nesting, migration or resting activities. *E. tereticornis* (Blue gum) provides hollows and offers optimal habitat for Greater gliders. Given the minimal disturbance to suitable habitat for this species and the interconnectedness of habitats, the Project would not disrupt ecologically significant locations for this species.
Will the action result in invasive species that are harmful to the species becoming established in the species habitat?	No, while the Greater glider is vulnerable to predation from introduced pest species; pest management strategies will be implemented to minimise the risk of introduced pest species predating on this species.
Will the action introduce disease that may cause the population to decline, or interfere with the recovery of the species?	No diseases are known for the species that could be caused by mining activities and cause the species' population to decline, nor would actions associated with mining activities interfere substantially with the recovery of the species.

Significant Residual Impact Assessment for Near Threatened Species Under the NC Act

When assessed against the significant residual impact criteria, the Project is considered unlikely to result in any significant impact on *Cerbera dumicola*. An assessment of the potential impact of the Project on *Cerbera dumicola* using significant residual impact criteria is presented in Table 22.

Table 22 MSES Impact Assessment of the Project on the *Cerbera dumicola*

Significant Impact Criteria	Impact Assessment
Will the action lead to a long-term decrease in the size of a local population of a species?	No, *Cerbera dumicola* was not recorded within the proposed disturbance area following targeted surveys, nor is this area regarded as most suitable habitat for this species.

Significant Impact Criteria	Impact Assessment
Will the action reduce the extent of occurrence of the species?	No, the species was not recorded within the proposed disturbance area following targeted surveys, nor is this area regarded as most suitable habitat for this species.
Will the action fragment an existing population?	No, the proposed disturbance area is already moderately disturbed due to grazing. Suitable habitat for the species exists within the surrounding woodland.
Will the action result in genetically distinct populations forming as a result of habitat isolation adversely?	No, the proposed disturbance area will cover land where no *Cerbera dumicola* was not recorded.
Will the action disrupt ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species?	No, *Cerbera dumicola* is capable of producing suckers (plant growth that develops from the rootstock of a plant).
Will the action result in invasive species that are harmful to the species becoming established in the species habitat?	No, invasive species management strategies will be implemented to minimise the risk that introduced species pose for the native wildlife.
Will the action introduce disease that may cause the population to decline, or interfere with the recovery of the species?	No diseases are known for the species that could be caused by mining activities and cause the species' population to decline, nor would actions associated with mining activities interfere substantially with the recovery of the species.

Significant Residual Impact Assessment for Special Least Concern (non-migratory) Species Under the NC Act

When assessed against the significant residual impact criteria, the Project is considered unlikely to result in any significant impact on the Short-beaked echidna. An assessment of the potential impact of the Project on the Short-beaked echidna using significant residual impact criteria is presented in Table 23.

Table 23 MSES Impact Assessment of the Project on the Short-beaked echidna

Significant Impact Criteria	Impact Assessment
Will the action lead to a long-term decrease in the size of a local population of a species?	No, the Project would not fragment potential habitat for this species to the extent that it would decrease the size of local population of the species.
Will the action reduce the extent of occurrence of the species?	No, the species can be found in a variety of habitat types including open forests, grasslands and heavily vegetated woodlands. It's distribution spans across Australia, including Tasmania and is classified as a habitat generalist (Van Dyck *et al.* 2013). Suitable alternative habitat occurs throughout the broader region and immediately surrounding the study area.
Will the action fragment an existing population?	No, this Project will not result in the fragmentation of an existing population into two or more populations.
Will the action result in genetically distinct populations forming as a result of habitat isolation adversely?	No, the Project would not result in habitat isolation for the species to the extent that this species will form genetically distinct populations.

Significant Impact Criteria	Impact Assessment
Will the action disrupt ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species?	No, the surveys did not identify any unique habitat or significant breeding populations on the study area. This species presence relies on the abundance of ants which are its only food source.

9.1.3 HES Wetland

One HES wetland was identified to occur approximately 4 km east of the study area (Section 5.4). The *Queensland Environmental Offsets Policy: Significant Residual Impact Guideline* (DEHP 2014) is designed to assist in determining whether or not the impacts of a project will or is likely to have a significant residual impact on a MSES.

When assessed against the MSES significant residual impact guidelines, the Project is considered unlikely to result in a significant residual impact on the HES wetland to the east of the study area.

Table 24 MSES Wetland Significant Residual Impact Assessment

Significant Residual Impact Criteria	Ecological Assessment
Will the action result in areas of the wetland being destroyed or artificially modified?	No, the Project will not result in the wetland being destroyed or artificially modified. The HES wetland is located approximately 3.6 km east of the Project.
Will the action result in a measurable change in water quality of the wetland, for example a change in the level of the physical and/or chemical characteristics to a level that exceeds the water quality guidelines for the waters?	No, the Project will not result in a measurable change in water quality of the wetland. The wetland is not connected to the surface waters of the Project and does not have the potential to be affected by controlled water releases from the Project.
Will the action impact on the habitat or lifecycle of native species, including invertebrate fauna and fish species, dependant upon the wetland being seriously affected?	No, the Project will not impact the habitat or lifecycle of native species dependent upon the wetland given there would not be any impacts to the wetland habitat as a result of the Project.
Will the action result in a substantial and measurable change in the hydrological regime or recharge zones of the wetland? For example a substantial change to the volume, timing, duration and frequency of ground and surface water flows to and within the wetland?	No, the Project will not result in a substantial and measurable change in the hydrological regime of this wetland. Potential groundwater drawdown is not likely to affect this site since the wetland groundwater system is very localised and it perched above the regional groundwater system (JBT 2019).
Will the action result in an invasive species that is harmful to the environmental values of the wetland being established (or an existing invasive species being spread) in the wetland?	No, while the wetland is vulnerable to impacts from invasive species; pest and weed management strategies will be implemented to minimise the risk of introduced pest species (such as feral pigs, *Sus scrofa*) and invasive weed species (such as parthenium (*Parthenium hysterophorus)* impacting upon the HES wetland.

9.2 OFFSETS REQUIREMENTS

The prescribed matters identified within the Project area and potentially impacted by the proposed disturbance are summarised in Table 25 to determine the Project's MSES offset requirements.

Table 25 Summary of Assessment of Prescribed Matters

MSES	Total Impact Area (ha)	Impact Assessment	Offset Requirement
Of Concern RE11.3.2	7.53	Clearing is non-linear and exceeds the clearing threshold.	Offsetting Required
REs located within the defined distance from the defining banks of a VM Act watercourse	59.79	Clearing of watercourse vegetation is required. The clearing widths and areas exceed significant impact guidelines. REs supporting watercourse vegetation includes RE 11.3.25, 11.5.2, 11.3.2 and 11.7.2	Offsetting Required
Essential habitat	197.23	Greater glider: Significant impact assessment for the greater glider was completed under *MSES: Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a). It was found there would be no significant impact to the species and its habitat (Section 9.1.2).	Not Required
	303.88	southern Squatter pigeon: Significant impact assessment for the southern Squatter pigeon was completed under *MSES: Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a). It was found there would be no significant impact to the species and its habitat (Section 9.1.2).	Not Required
	106.65	Clearing of the regional ecosystem 11.7.2 mapped in the essential habitat map for the *Cerbera dumicola* is required.	Not Required
Connectivity area*	720.74	The Landscape Fragmentation and Connectivity Tool* was applied to the proposed extent of disturbance area. The results found that significant impact would occur to connectivity at both local scale and to core remnant areas.	Offsetting Required
Wildlife Habitat for Vulnerable species	13.35	Greater glider: 13.35 ha of suitable habitat is proposed to be cleared, which is 7.9% of the suitable habitat available within the study area. The Project will not fragment the habitat or local population, there is considerable habitat available in the surrounding region, and dispersal opportunity will not be impacted; by retaining corridors. Significant impact assessment for the greater glider was completed under *MSES: Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a). It was found there would be no significant impact to the species and its habitat (Section 9.1.2).	Not Required

MSES	Total Impact Area (ha)	Impact Assessment	Offset Requirement
	720.74	southern Squatter pigeon: Significant impact assessment for the southern Squatter pigeon was completed under *MSES: Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a). It was found there would be no significant impact to the species and its habitat (Section 9.1.2).	Not Required
Wildlife Habitat for Special Least Concern species.	720.74	Short-beaked echidna: Significant impact assessment for the Short-beaked echidna was completed under *MSES: Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (DEHP 2014a). It was found there would be no significant impact to the species and its habitat (Section 9.1.2).	Not Required

* Landscape Fragmentation and Connectivity Tool is based on current government mapping.

A summary of MSES environmental offset requirements to be delivered under the QEOP is provided in Table 26, including the total extent of impact area to be offset.

Table 26 MSES Offset Requirements

MSES	Area to be Impacted (ha)	Habitat Description
RE 11.3.2 *Eucalyptus populnea* (Poplar box) woodland on alluvial plains	7.53	This vegetation community was characterised by *Eucalyptus populnea* (Poplar box) woodland on alluvial plains. It was represented in several small to moderate patches within the study area and is subject to pressures from grazing, exotic species invasion.
REs located within the defined distance from the defining banks of a VM Act watercourse.	59.79	A number of VM Act watercourses traverse the Project area. Impacts will occur to watercourse vegetation that is associated with RE 11.3.25, 11.5.2, 11.3.2 and 11.7.2
RE mapped as essential habitat on the Essential Habitat Map (as certified under the VM Act) for flora and fauna listed as Near Threatened (under the NC Act)	106.65	Clearing of RE 11.7.2 within the mapped essential habitat map for the *Cerbera dumicola* will require an offset.
Connectivity area*	720.74	The Landscape Fragmentation and Connectivity Tool determined that there is significant impact to the connectivity of the remnant vegetation within the Project.

* Landscape Fragmentation and Connectivity Tool is based on current government mapping.

Distribution of MSES requiring offsets in association with the footprint of Gemini Project is illustrated in Figure 17.

It is recommended that Magnetic South deliver the offset requirements agreed in the EA prior to disturbance of the area. Offsets may be delivered as a financial settlement, proponent-driven offset (i.e. a land-based offset or Direct Benefit Management Plan) or a combination of proponent-driven offset and financial settlement offset.

Area of Interest: epc: 881

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or Area of Interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "Central co-ordinates" option, the resulting assessment area encompasses an area extending from 2km radius from the point of interest.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 1994). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no values have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Please direct queries about these reports to: biodiversity.planning@ehp.qld.gov.au

Summary Information

Tables 1 to 8 provide an overview of the AOI with respect to selected topographic and environmental values.

Table 1: Area of interest details

Area of Interest	EPC881
Size (ha)	7219.6
Local Government(s)	CENTRAL HIGHLANDS REGIONAL
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda
Catchment(s)	Fitzroy

The following table identifies available Biodiversity Planning Assessments (BPAs) and Aquatic Conservation Assessments (ACAs) with respect to the AOI.

Table 2: Available Biodiversity Planning and Aquatic Conservation Assessments

Assessment Type	Assessment Area and Version
Biodiversity Planning Assessment(s)	Brigalow Belt v1.3
Aquatic Conservation Assessment(s) (riverine)	Great Barrier Reef Catchment v1.1
Aquatic Conservation Assessment(s) (non-riverine)	Great Barrier Reef Catchment v1.3

Table 3: Remnant regional ecosystems within the AOI as per the Qld Herbarium's 'biodiversity status'

Biodiversity Status	Area (Ha)	% of AOI
Endangered	6.4	0.1%
Of Concern	237.3	3.3%
No concern at present	1842.0	25.5%

The following table identifies the extent and proportion of the user specified area of interest (AOI) which is mapped as being of "State", "Regional" or "Local" significance via application of the Queensland Department of Environment and Heritage Protection's *Biodiversity Assessment and Mapping Methodology* (BAMM).

Table 4: Summary table, biodiversity significance

Biodiversity significance	Area (Ha)	% of AOI
State Habitat for EVNT taxa	0.0	0.0%
State	759.7	10.5%
Regional	167.0	2.3%
Local or Other Values	1232.6	17.1%

Table 5: Non-riverine wetlands intersecting the AOI

Non-riverine wetland types intersecting the area of interest	#
Number of Palustrine wetlands	4
Number of Lacustrine wetlands	2
Total number of non-riverine wetlands	6

NB. The figures presented in the table above are derived from the relevant non-riverine Aquatic Conservation Assessment(s). Later releases of wetland mapping produced via the Queensland Wetland Mapping Program may provide more recent information in regards to wetland extent.

Table 6: Named waterways intersecting the AOI

Name	Permanency
CHARLEVUE CREEK	Non-perennial
SPRINGTON CREEK	Non-perennial
STANLEY CREEK	Non-perennial

Refer to **Map 1** for general locality information.

The following two tables identify the extent and proportion of the user specified AOI which is mapped as being of "Very High", "High", "Medium", "Low", or "Very Low" aquatic conservation value for riverine and non-riverine wetlands via application of the Queensland Department of Environment and Heritage Protection's *Aquatic Biodiversity Assessment and Mapping Method* (AquaBAMM).

Table 7: Summary table, aquatic conservation significance (riverine)

Aquatic conservation significance (riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0%
High	0.0	0.0%
Medium	7219.6	100.0%
Low	0.0	0.0%
Very Low	0.0	0.0%

Table 8: Summary table, aquatic conservation significance (non-riverine)

Aquatic conservation significance (non-riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0%
High	0.0	0.0%
Medium	10.9	0.2%
Low	0.0	0.0%
Very Low	0.0	0.0%

Biodiversity Planning Assessments

Introduction

The department of Environment and Heritage Protection (EHP) attributes biodiversity significance on a bioregional scale through a Biodiversity Planning Assessment (BPA). A BPA involves the integration of ecological criteria using the *Biodiversity assessment and Mapping Methodology* (BAMM) and is developed in two stages: 1) **diagnostic criteria**, and 2) **expert panel criteria**. The diagnostic criteria are based on existing data which is reliable and uniformly available across a bioregion, while the expert panel criteria allows for the refinement of the mapped information from the diagnostic output by incorporating local knowledge and expert opinion.

The BAMM methodology has application for identifying areas with various levels of significance solely for biodiversity reasons. These include threatened ecosystems or taxa, large tracts of habitat in good condition, ecosystem diversity, landscape context and connection, and buffers to wetlands or other types of habitat important for the maintenance of biodiversity or ecological processes. While natural resource values such as dryland salinity, soil erosion potential or land capability are not dealt with explicitly, they are included to some extent within the biodiversity status of regional ecosystems recognised by the EHP.

Biodiversity Planning Assessments (BPAs) assign three levels of overall biodiversity significance.

- **State significance** - areas assessed as being significant for biodiversity at the bioregional or state scales. They also include areas assessed by other studies/processes as being significant at national or international scales. In addition, areas flagged as being of State significance due to the presence of endangered, vulnerable and/or near threatened taxa, are identified as "State Habitat for EVNT taxa".
- **Regional significance** - areas assessed as being significant for biodiversity at the subregional scale. These areas have lower significance for biodiversity than areas assessed as being of State significance.
- **Local significance and/or other values** - areas assessed as not being significant for biodiversity at state or regional scales. Local values are of significance at the local government scale.

For further information on released BPAs and a copy of the underlying methodology, go to:

http://www.qld.gov.au/environment/plants-animals/biodiversity/planning/

The GIS results can be downloaded from the Queensland Spatial Catalogue at:

http://qspatial.information.qld.gov.au/geoportal/

The following table identifies the extent and proportion of the user specified AOI which is mapped as being of "State", "Regional" or "Local" significance via application of the BAMM.

Table 9: Summary table, biodiversity significance

Biodiversity significance	Area (Ha)	% of AOI
State Habitat for EVNT taxa	0.0	0.0%
State	759.7	10.5%
Regional	167.0	2.3%
Local or Other Values	1232.6	17.1%

Refer to **Map 2** for further information.

Diagnostic Criteria

Diagnostic criteria are based on existing data which is reliable and uniformly available across a bioregion. These criteria are diagnostic in that they are used to filter the available data and provide a "first-cut" or initial determination of biodiversity significance. This initial assessment is then combined through a second group of other essential criteria.

A description of the individual diagnostic criteria is provided in the following sections.

Criteria A. Habitat for EVNT taxa: Classifies areas according to their significance based on the presence of endangered, vulnerable and/or rare (EVNT) taxa. EVNT taxa are those scheduled under the *Nature Conservation Act 1992* and/or the *Environment Protection and Biodiversity Conservation Act 1999*. It excludes highly mobile fauna taxa which are instead

considered in Criterion H and brings together information on EVNT taxa using buffering of recorded sites or habitat suitability models (HSM) where available.

Criteria B. Ecosystem value: Classifies on the basis of biodiversity status of regional ecosystems, their extent in protected areas (presence of poorly conserved regional ecosystems), the presence of significant wetlands and intertidal zones; and areas of national importance such as World Heritage areas and Ramsar sites. Ecosystem value is applied at a bioregional (**B1**) and regional (**B2**) scale.

Criteria C. Tract size: Measures the relative size of tracts of vegetation in the landscape. The size of any tract is a major indicator of ecological significance, and is also strongly correlated with the long-term viability of biodiversity values. Larger tracts are less susceptible to ecological edge effects and are more likely to sustain viable populations of native flora and fauna than smaller tracts.

Criteria D. Relative size of regional ecosystems: Classifies the relative size of each regional ecosystem unit within its bioregion (**D1**) and its subregion (**D2**). Remnant units are compared with all other occurrences with the same regional ecosystem. Large examples of a regional ecosystem are more significant than smaller examples of the same regional ecosystem because they are more representative of the biodiversity values particular to the regional ecosystem, are more resilient to the effects of disturbance, and constitute a significant proportion of the total area of the regional ecosystem.

Criteria F. Ecosystem diversity: Is an indicator of the number of regional ecosystems occurring within an area. An area with high ecosystem diversity will have many regional ecosystems and ecotones relative to other areas within the bioregion.

Criteria G. Context and connection: Represents the extent to which a remnant unit incorporates, borders or buffers areas such as significant wetlands, endangered ecosystems; and the degree to which it is connected to other vegetation.

A summary of the biodiversity status based upon the diagnostic criteria is provided in the following table.

Table 10: Summary of biodiversity significance based upon diagnostic criteria with respect to the AOI

Biodiversity significance	Description	Area (Ha)	% of AOI
Regional	Remnant contains at least one Of Concern RE (B1)	274.7	3.8
Local or Other Values	Refer to diagnostic data for additional information	1884.7	26.1

Assessment of diagnostic criteria with respect to the AOI

The following table reflects an assessment of the individual diagnostic criteria noted above in regards to the AOI.

Table 11: Assessment of individual diagnostic criteria with respect to the AOI

Diagnostic Criteria	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
A: Habitat for EVNT Taxa					427.6	5.9	1731.7	24.0
B1: Ecosystem Value (Bioregion)			274.6	3.8	1884.7	26.1		
B2: Ecosystem Value (Subregion)					2159.3	29.9		
C: Tract Size			1868.8	25.9	194.1	2.7	96.4	1.3
D1: Relative RE Size (Bioregion)							2159.3	29.9
D2: Relative RE Size (Subregion)							2159.3	29.9
F: Ecosystem Diversity	32.2	0.4	795.7	11.0	1206.0	16.7	125.4	1.7
G: Context and Connection	225.3	3.1	576.7	8.0	1294.0	17.9	63.3	0.9

Other Essential Criteria

Other essential criteria (also known as expert panel criteria) are based on non-uniform information sources and which may rely more upon expert opinion than on quantitative data. These criteria are used to provide a "second-cut" determination of biodiversity significance, which is then combined with the diagnostic criteria for an overall assessment of relative biodiversity significance. A summary of the biodiversity status based upon the other essential criteria is provided in the following table.

Table 12: Summary of biodiversity significance based upon other essential criteria with respect to the AOI

Biodiversity significance	Description	Area (Ha)	% of AOI
State	Remnant contains Special Biodiversity Values (view Expert Panel data for further information) (I)	239.1	3.3
State	Remnant contains Special Biodiversity Values (view Expert Panel data for further information) (I) Remnant forms part of a bioregional corridor (J)	369.1	5.1
State	Remnant forms part of a bioregional corridor (J)	151.3	2.1
Regional	Remnant forms part of a bioregional corridor (J)	1.0	0.0

A description of each of the other essential criteria and associated assessment in regards to the AOI is provided in the following sections.

Criteria H. Essential and general habitat for priority taxa: Priority taxa are those which are at risk or of management concern, taxa of scientific interest as relictual (ancient or primitive), endemic taxa or locally significant populations (such as a flying fox camp or heronry), highly specialised taxa whose habitat requirements are complex and distributions are not well correlated with any particular regional ecosystem, taxa important for maintaining genetic diversity (such as complex spatial patterns of genetic variation, geographic range limits, highly disjunct populations), taxa critical for management or monitoring of biodiversity (functionally important or ecological indicators), or economic and culturally important taxa.

This criterion can be used to identify essential and general habitat for EVNT and other priority taxa additional to that derived under Diagnostic Criterion A. Information sources include expert and local knowledge, technical reports and papers, and modelled maps of essential and general habitat.

Criteria I. Special biodiversity values: areas with special biodiversity values are important because they contain multiple taxa in a unique ecological and often highly biodiverse environment. Areas with special biodiversity values can include the following:

- Ia - centres of endemism - areas where concentrations of taxa are endemic to a bioregion or subregion are found.
- Ib - wildlife refugia (Morton *et al*. 1995), for example, islands, mound springs, caves, wetlands, gorges, mountain ranges and topographic isolates, ecological refuges, refuges from exotic animals, and refuges from clearing. The latter may include large areas that are not suitable for clearing because of land suitability/capability.
- Ic - areas with concentrations of disjunct populations.
- Id - areas with concentrations of taxa at the limits of their geographic ranges.
- Ie - areas with high species richness.
- If - areas with concentrations of relictual populations (ancient and primitive taxa).
- Ig - areas containing REs with distinct variation in species composition associated with geomorphology and other environmental variables.
- Ih - an artificial waterbody or managed/manipulated wetland considered by the panel/s to be of ecological significance.
- Ii - areas with a high density of hollow-bearing trees that provide habitat for animals.
- Ij - breeding or roosting sites used by a significant number of individuals.
- Ik - climate change refuge.

The following table identifies the value and extent area of the Other Essential Criteria H and I within the AOI.

Table 13: Relative importance of expert panel criteria (H and I) used to access overall biodiversity significance with respect to the AOI

Expert Panel	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
H: Core Habitat Priority Taxa	520.5	7.2						

Expert Panel	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
Ia: Centres of Endemism								
Ib: Wildlife Refugia	608.4	8.4						
Ic: Disjunct Populations								
Id: Limits of Geographic Ranges								
Ie: High Species Richness								
If: Relictual Populations								
Ig: Variation in Species Composition								
Ih: Artificial Wetland								
Ii: Hollow Bearing Trees								
Ij: Breeding or Roosting Site								
Ik: Climate Refugia								

NB. Whilst biodiversity values associated with Criteria I may be present within the site (refer to tables 12 and 15), for the New England Tableland and Central Queensland Coast BPAs, area and % area figures associated with Criteria Ia through to Ij cannot be listed in the table above (due to slight variations in data formats between BPAs).

Criteria J. Corridors: areas identified under this criterion qualify either because they are existing vegetated corridors important for contiguity, or cleared areas that could serve this purpose if revegetated. Some examples of corridors include riparian habitats, transport corridors and "stepping stones".

Bioregional and subregional conservation corridors have been identified in the more developed bioregions of Queensland through the BPAs, using an intensive process involving expert panels. Map 3 displays the location of corridors as identified under the Statewide Corridor network. The Statewide Corridor network incorporates BPA derived corridors and for bioregions where no BPA has been assessed yet, corridors derived under other planning processes. *Note: as a result of updating and developing a statewide network, the alignment of corridors may differ slightly in some instances when compared to those used in individual BPAs.*

The functions of these corridors are:

- **Terrestrial** Bioregional corridors, in conjunction with large tracts of remnant vegetation, maintain ecological and evolutionary processes at a landscape scale, by:

  • Maintaining long term evolutionary/genetic processes that allow the natural change in distributions of species and connectivity between populations of species over long periods of time;

  • Maintaining landscape/ecosystems processes associated with geological, altitudinal and climatic gradients, to allow for ecological responses to climate change;

  • Maintaining large scale seasonal/migratory species processes and movement of fauna;

  • Maximising connectivity between large tracts/patches of remnant vegetation;

  • Identifying key areas for rehabilitation and offsets; and

- **Riparian** Bioregional Corridors also maintain and encourage connectivity of riparian and associated ecosystems.

The location of the corridors is determined by the following principles:

- Terrestrial
    - Complement riparian landscape corridors (i.e. minimise overlap and maximise connectivity);
    - Follow major watershed/catchment and/or coastal boundaries;
    - Incorporate major altitudinal/geological/climatic gradients;
    - Include and maximise connectivity between large tracts/patches of remnant vegetation;
    - Include and maximise connectivity between remnant vegetation in good condition; and

- Riparian
    - Located on the major river or creek systems within the bioregion in question.

The total extent of remnant vegetation triggered as being of "State", "Regional" or "Local" significance due to the presence of an overlying BPA derived terrestrial or riparian corridor within the AOI, is provided in the following table. For further information on how remnant vegetation is triggered due to the presence of an overlying BPA derived corridor, refer to the relevant landscape BPA expert panel report(s).

Table 14: Extent of triggered remnant vegetation due to the presence of BPA derived corridors with respect to the AOI

Biodiversity Significance	Area (Ha)	% of AOI
State	520.5	7.2%
Regional	1.0	0.0%
Local or Other Values	0.0	0.0%

NB: area figures associated with the extent of corridor triggered remnant vegetation are only available for those bioregions where a BPA has been undertaken.

Refer to **Map 3** for further information.

Threatening process/condition (Criteria K) - areas identified by experts under this criterion may be used to amend (upgrade or downgrade) biodiversity significance arising from the "first-cut" analysis. The condition of remnant vegetation is affected by threatening processes such as weeds, ferals, grazing and burning regime, selective timber harvesting/removal, salinity, soil erosion, and climate change.

Assessment of Criteria K with respect to the AOI is not currently included in the "Biodiversity and Conservation Values" report, as it has not been applied to the majority of Queensland due to data/information limitations and availability.

Special Area Decisions

Expert panel derived "Special Area Decisions" are used to assign values to Other Essential Criteria. The specific decisions which relate to the AOI in question are listed in the table below.

Table 15: Expert panel decisions for assigning levels of biodiversity significance with respect to the AOI

Decision Number	Description	Panel Recommended Significance	Criteria Values
brbn_l_17	Terrestrial corridors	State Regional	J (Terrestrial Corridor): STATE J (Terrestrial Corridor): REGIONAL
brbn_l_62	Taunton Scientific Reserve and remnants around it, especially riparian vegetation	State	J (wildlife corridor): STATE H (core habitat for priority taxa): VERY HIGH

Decision Number	Description	Panel Recommended Significance	Criteria Values
brbn_l_69	Core areas in fragmented subregions: Dawson River Downs Callide Creek Downs Isaac - Comet Downs Upper Belyando Floodout	State	Ib (wildlife refugia): VERY HIGH
brbs_l_17	Terrestrial Bioregional Corridors	State or Regional	J (Terrestrial Corridor): STATE or J (Terrestrial Corridor): REGIONAL

Expert panel decision descriptions:

brbn_l_17

The corridors along the Great Dividing Range Corridor and the eastern ranges, which span large distances, are mapped by including remnant vegetation within a 5 kilometre buffer either side of a centre line. Some of the other more significant corridors that cross bioregions are also mapped in this way. Where corridors are shorter and more numerous the corridors are mapped by including remnant vegetation within a 2.5 kilometre buffer either side of a centre line.

More information for this decision exists in the BRB BPA North Landscape Report.

brbn_l_62

Taunton National Park (Scientific) is essential habitat for the conservation of the endangered Bridled nail-tail wallaby. The surrounding landscape is extensively cleared, however, Bridled nail-tail wallabies have been recorded in remnant vegetation surrounding the park. Dispersal of wallabies to suitable habitat relies on retaining connectivity from the park, particularly along the following creeks: Five Mile, Duckworth, Walton, Iguana, Stanley, Charlevue, Spectacle, Lagoon and Wild Horse.

Regrowth and remnant vegetation along creek lines in the vicinity of Taunton should be considered essential habitat.

brbn_l_69

Tracts are patches of continuous remnant vegetation. The size of any tract is a major indicator of ecological significance, and is also strongly correlated with the long-term viability of biodiversity values. The northern Brigalow Belt has some very large tracts of vegetation. Based on the Tract Size analysis (Criterion C), the following core areas are identified for the northern Brigalow Belt. They are the fragmented subregions:

More information for this decision exists in the BRB BPA North Landscape Report.

brbs_l_17

Maintaining connectivity across a landscape, either through corridors or "stepping-stones" of remnant vegetation, is important for the long-term conservation of biodiversity.

The corridors along the Great Dividing Range and the eastern ranges, which span large distances, are mapped by including remnant vegetation within a 5 kilometre buffer either side of a centre line. Some of the other more significant corridors that cross bioregions are also mapped in this way. Remnant ecosystem polygons which had 30% or more of its total area within the 5km buffered zone were included within the corridor and assigned a J Rating. The significance of this J Rating was based on the significance given to that corridor by the Expert Panel. Where corridors are shorter and more numerous (i.e. between the ranges and the coastline) the corridors are mapped by including remnant vegetation within a 2.5 kilometre buffer either side of a centre line.

More information for this decision exists in the BRB BPA South Landscape Report.

Aquatic Conservation Assessments

Introduction

The Aquatic Biodiversity Assessment and Mapping Method or AquaBAMM (Clayton *et al.* 2006), was developed to assess conservation values of wetlands in queensland, and may also have application in broader geographical contexts. It is a comprehensive method that uses available data, including data resulting from expert opinion, to identify relative wetland conservation/ecological values within a specified study area (usually a catchment). The product of applying this method is an Aquatic Conservation Assessment (ACA) for the study area.

An ACA using AquaBAMM is non-social, non-economic and identifies the conservation/ecological values of wetlands at a user-defined scale. It provides a robust and objective conservation assessment using criteria, indicators and measures that are founded upon a large body of national and international literature. The criteria, each of which may have variable numbers of indicators and measures, are naturalness (aquatic), naturalness (catchment), diversity and richness, threatened species and ecosystems, priority species and ecosystems, special features, connectivity and representativeness. An ACA using AquaBAMM is a powerful decision support tool that is easily updated and simply interrogated through a geographic information system (GIS).

Where they have been conducted, ACAs can provide a source of baseline wetland conservation/ecological information to support natural resource management and planning processes. They are useful as an independent product or as an important foundation upon which a variety of additional environmental and socio-economic elements can be added and considered (i.e. an early input to broader 'triple-bottom-line' decision-making processes). An ACA can have application in:

- determining priorities for protection, regulation or rehabilitation of wetlands and other aquatic ecosystems
- on-ground investment in wetlands and other aquatic ecosystems
- contributing to impact assessment of large-scale development (e.g. dams)
- water resource and strategic regional planning prcesses

For a detailed explanation of the methodology please refer to the summary and expert panel reports relevant to the ACA utilised in this assessment. These reports can be accessed at Wetland*Info*:

http://wetlandinfo.ehp.qld.gov.au/wetlands/assessment/assessment-methods/aca

The GIS results can be downloaded from the Queensland Spatial Catalogue at:

http://qspatial.information.qld.gov.au/geoportal/

Explanation of Criteria

Under the AquaBAMM, eight criteria are assessed to derive an overall conservation value. Similar to the Biodiversity Assessment and Mapping Methodology, the criteria may be primarily diagnostic (quantitative) or primarily expert opinion (qualitative) in nature. The following sections provide a brief description of each of the 8 criteria.

Criteria 1. Naturalness - Aquatic: This attribute reflects the extent to which a wetland's (riverine, non-riverine, estuarine) aquatic state of naturalness is affected through relevant influencing indicators which include: presence of exotic flora and fauna; presence of aquatic communities; degree of habitat modification and degree of hydrological modification.

Criteria 2. Naturalness - Catchment: The naturalness of the terrestrial systems of a catchment can have an influence on many wetland characteristics including: natural ecological processes e.g. nutrient cycling, riparian vegetation, water chemistry, and flow. The indicators utilised to assess this criterion include: presence of exotic flora and/or fauna; riparian, catchment and flow modification.

Criteria 3. Naturalness - Diversity and Richness: This criterion is common to many ecological assessment methods and can include both physical and biological features. It includes such indicators as species richness, riparian ecosystem richness and geomorphological diversity.

Criteria 4. Threatened Species and Ecosystems: This criterion evaluates ecological rarity characteristics of a wetland. This includes both species rarity and rarity of communities / assemblages. The communities and assemblages are best represented by regional ecosystems. Species rarity is determined by NCA and EPBC status with Endangered, Vulnerable or Near-threatened species being included in the evaluation. Ecosystem rarity is determined by regional ecosystem biodiversity status i.e. Endangered, Of Concern, or Not of Concern.

Criteria 5. Priority Species and Ecosystems: Priority flora and fauna species lists are expert panel derived. These are aquatic, semi-aquatic and riparian species which exhibit at least 1 particular trait in order to be eligible for consideration. For flora species the traits included:

- It forms significant macrophyte beds (in shallow or deep water).
- It is an important food source.
- It is important/critical habitat.
- It is implicated in spawning or reproduction for other fauna and/or flora species.
- It is at its distributional limit or is a disjunct population.
- It provides stream bank or bed stabilisation or has soil binding properties.
- It is a small population and subject to threatening processes.

Fauna species are included if they meet at least one of the following traits:

- It is endemic to the study area (>75 per cent of its distribution is in the study area/catchment).
- It has experienced, or is suspected of experiencing, a serious population decline.
- It has experienced a significant reduction in its distribution and has a naturally restricted distribution in the study area/catchment.
- It is currently a small population and threatened by loss of habitat.
- It is a significant disjunct population.
- It is a migratory species (other than birds).
- A significant proportion of the breeding population (>one per cent for waterbirds, >75 per cent other species) occurs in the waterbody (see Ramsar criterion 6 for waterbirds).
- Limit of species range.

See the individual expert panel reports for the priority species traits specific to an ACA.

Criteria 6. Special Features: Special features are areas identified by flora, fauna and ecology expert panels which exhibit characteristics beyond those identified in other criteria and which the expert panels consider to be of the highest ecological importance. Special feature traits can relate to, but are not solely restricted to geomorphic features, unique ecological processes, presence of unique or distinct habitat, presence of unique or special hydrological regimes e.g. spring-fed streams. Special features are rated on a 1 - 4 scale (4 being the highest).

Criteria 7. Connectivity: This criterion is based on the concept that appropriately connected aquatic ecosystems are healthy and resilient, with maximum potential biodiversity and delivery of ecosystem services.

Criteria 8. Representativeness: This criterion applies primarily to non-riverine assessments, evaluates the rarity and uniqueness of a wetland type in relation to specific geographic areas. Rarity is determined by the degree of wetland protection within "protected Areas" estate or within an area subject to the *Fisheries Act 1994*, *Coastal Protection and Management Act 1995*, or *Marine Parks Act 2004*. Wetland uniqueness evaluates the relative abundance and size of a wetland or wetland management group within geographic areas such as catchment and subcatchment.

Riverine Wetlands

Riverine wetlands are all wetlands and deepwater habitats within a channel. The channels are naturally or artificially created, periodically or continuously contain moving water, or connecting two bodies of standing water. AquaBAMM, when applied to riverine wetlands uses a discrete spatial unit termed subsections. A subsection can be considered as an area which encompasses discrete homogeneous stream sections in terms of their natural attributes (i.e. physical, chemical, biological and utilitarian values) and natural resources. Thus in an ACA, an aquatic conservation significance score is calculated for each subsection and applies to all streams within a subsection, rather than individual streams as such.

Please note, the area figures provided in Tables 16 and 17, are derived using the extent of riverine subsections within the AOI. Refer to **Map 5** for further information. A summary of the conservation significance of riverine wetlands within the AOI is provided in the following table.

Table 16: Overall level/s of riverine aquatic conservation significance

Aquatic conservation significance (riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0%
High	0.0	0.0%

Aquatic conservation significance (riverine wetlands)	Area (Ha)	% of AOI
Medium	7219.6	100.0%
Low	0.0	0.0%
Very Low	0.0	0.0%

The individual aquatic conservation criteria ratings for riverine wetlands within the AOI are listed below.

Table 17: Level/s of riverine aquatic conservation significance based on selected criteria

Criteria	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
1. Naturalness aquatic					1273.2	17.6	5946.3	82.4
2. Naturalness catchment	2.5		7217.0	100.0				
3. Diversity and richness	1273.2	17.6	2074.2	28.7	3872.1	53.6

6. Special features								
7. Connectivity			5946.3	82.4	1273.2	17.6		

The table below lists and describes the relevant expert panel decisions used to assign conservation significance values to riverine wetlands within the AOI.

Table 18: Expert panel decisions for assigning overall levels of riverine aquatic conservation significance

(No Records)

4 is the highest rating/value

Expert panel decision descriptions:

(No Records)

Non-riverine Wetlands

Non-riverine wetlands include both lacustrine and palustrine wetlands, however, do not currently incorporate estuarine, marine or subterranean wetland types. A summary of the conservation significance of non-riverine wetlands within the AOI is provided in the following table. Refer to **Map 6** for further information.

Table 19: Overall level/s of non-riverine aquatic conservation significance

Aquatic conservation significance (non-riverine wetlands)	Area (Ha)	% of AOI
Very High	0.0	0.0%
High	0.0	0.0%
Medium	10.9	0.2%
Low	0.0	0.0%
Very Low	0.0	0.0%

The following table provides an assessment of non-riverine wetlands within the AOI and associated aquatic conservation criteria values.

Table 20: Level/s of non-riverine aquatic conservation significance based on selected criteria

Criteria	Very High Rating - Area (Ha)	Very High Rating - % of AOI	High Rating - Area (Ha)	High Rating - % of AOI	Medium Rating - Area (Ha)	Medium Rating - % of AOI	Low Rating - Area (Ha)	Low Rating - % of AOI
1. Naturalness aquatic	4.7	0.1			6.2	0.1		
2. Naturalness catchment					10.9	0.2		
3. Diversity and richness			6.9	0.1	3.7	0.1	0.3	
4. Threatened species and ecosystems	2.5		4.4	0.1				
5. Priority species and ecosystems			10.9	0.2				
6. Special features								
7. Connectivity								
8. Representative-ness					6.9	0.1		

The table below lists and describes the relevant expert panel decisions used to assign conservation significance values to non-riverine wetlands within the AOI.

Table 21: Expert panel decisions for assigning overall levels of non-riverine aquatic conservation significance.

Decision number	Special feature	Catchment	Criteria/Indicator/Measure	Conservation rating (1-4)
ma_nr_fl_02	Regional ecosystems 8.3.4 11.3.27	Mackenzie	5.2.1	3

4 is the highest rating/value

Expert panel decision descriptions:

ma_nr_fl_02

These regional ecosystems contain significant habitat values that are under threat from threatening processes such as physical alteration/ destruction and invasion by **hymenachne**.

Note: This priority ecosystem decision applies to the following catchments: Calliope, Comet, Dawson, Fitzroy, Isaac, Mackenzie, Misc Other Islands, Nogoa, O'Connell, Pioneer, Plane, Proserpine, Shoalwater, Styx and Waterpark.

Threatened and Priority Species

Introduction

This chapter contains a list of threatened and priority flora and/or fauna species that have been recorded on, or within 4km of the Assessment Area.

The information presented in this chapter with respect to species presence is derived from compiled databases developed primarily for the purpose of BPAs and ACAs. Data is collated from a number of sources and is updated periodically.

It is important to note that the list of species provided in this report, may differ when compared to other reports generated from other sources such as the State government's WildNet, Herbrecs or the federal government's EPBC database for a number of reasons.

Records for threatened and priority species are filtered and checked based on a number of rules including:

- Taxonomic nomenclature - current scientific names and status,
- Location - cross-check co-ordinates with location description,
- Taxon by location - requires good knowledge of the taxon and history of the record,
- Duplicate records - identify and remove,
- Expert panels - check records and provide new records,
- Flora cultivated records excluded,
- Use precise records less than or equal to 2000m,
- Use recent records greater than or equal to 1975 animals, greater than or equal to 1950 plants.

Threatened Species

Threatened species are those species classified as "Endangered" or "Vulnerable" under the *Environment Protection and Biodiversity Conservation Act 1999* or "Endangered", "Vulnerable" or "Near threatened" under the *Nature Conservation Act 1992*.

The following threatened species have been recorded on, or within approximately 4km of the AOI.

Table 22: Threatened species recorded on, or within 4km of the AOI

Species	Common name	NCA status	EPBC status	Back on Track rank	Migratory species*	Wetland species**	Identified flora/fauna
Geophaps scripta scripta	squatter pigeon (southern subspecies)	V	V	Medium			FA
Dichanthium setosum		C	V	Low			FL
Onychogalea fraenata	bridled nailtail wallaby	E	E	Critical			FA
Solanum elachophyllum		E		Medium			FL

NB. Please note that the threatened species listed in this section are based upon the most recently compiled DEHP internal state-wide threatened species dataset. This dataset may contain additional records that were not originally available for inclusion in the relevant individual BPAs and ACAs.

**JAMBA - Japan-Australia Migratory Bird Agreement; CAMBA - China-Australia Migratory Bird Agreement; ROKAMBA - Republic of Korea-Australia Migratory Bird Agreement; CMS - Convention on the Conservation of Migratory Species*.

***Y - wetland indicator species*.

BPA Priority Species

A list of BPA priority species that have been recorded on, or within approximately 4km of the AOI is contained in the following table.

Table 23: Priority species recorded on, or within 4km of the AOI

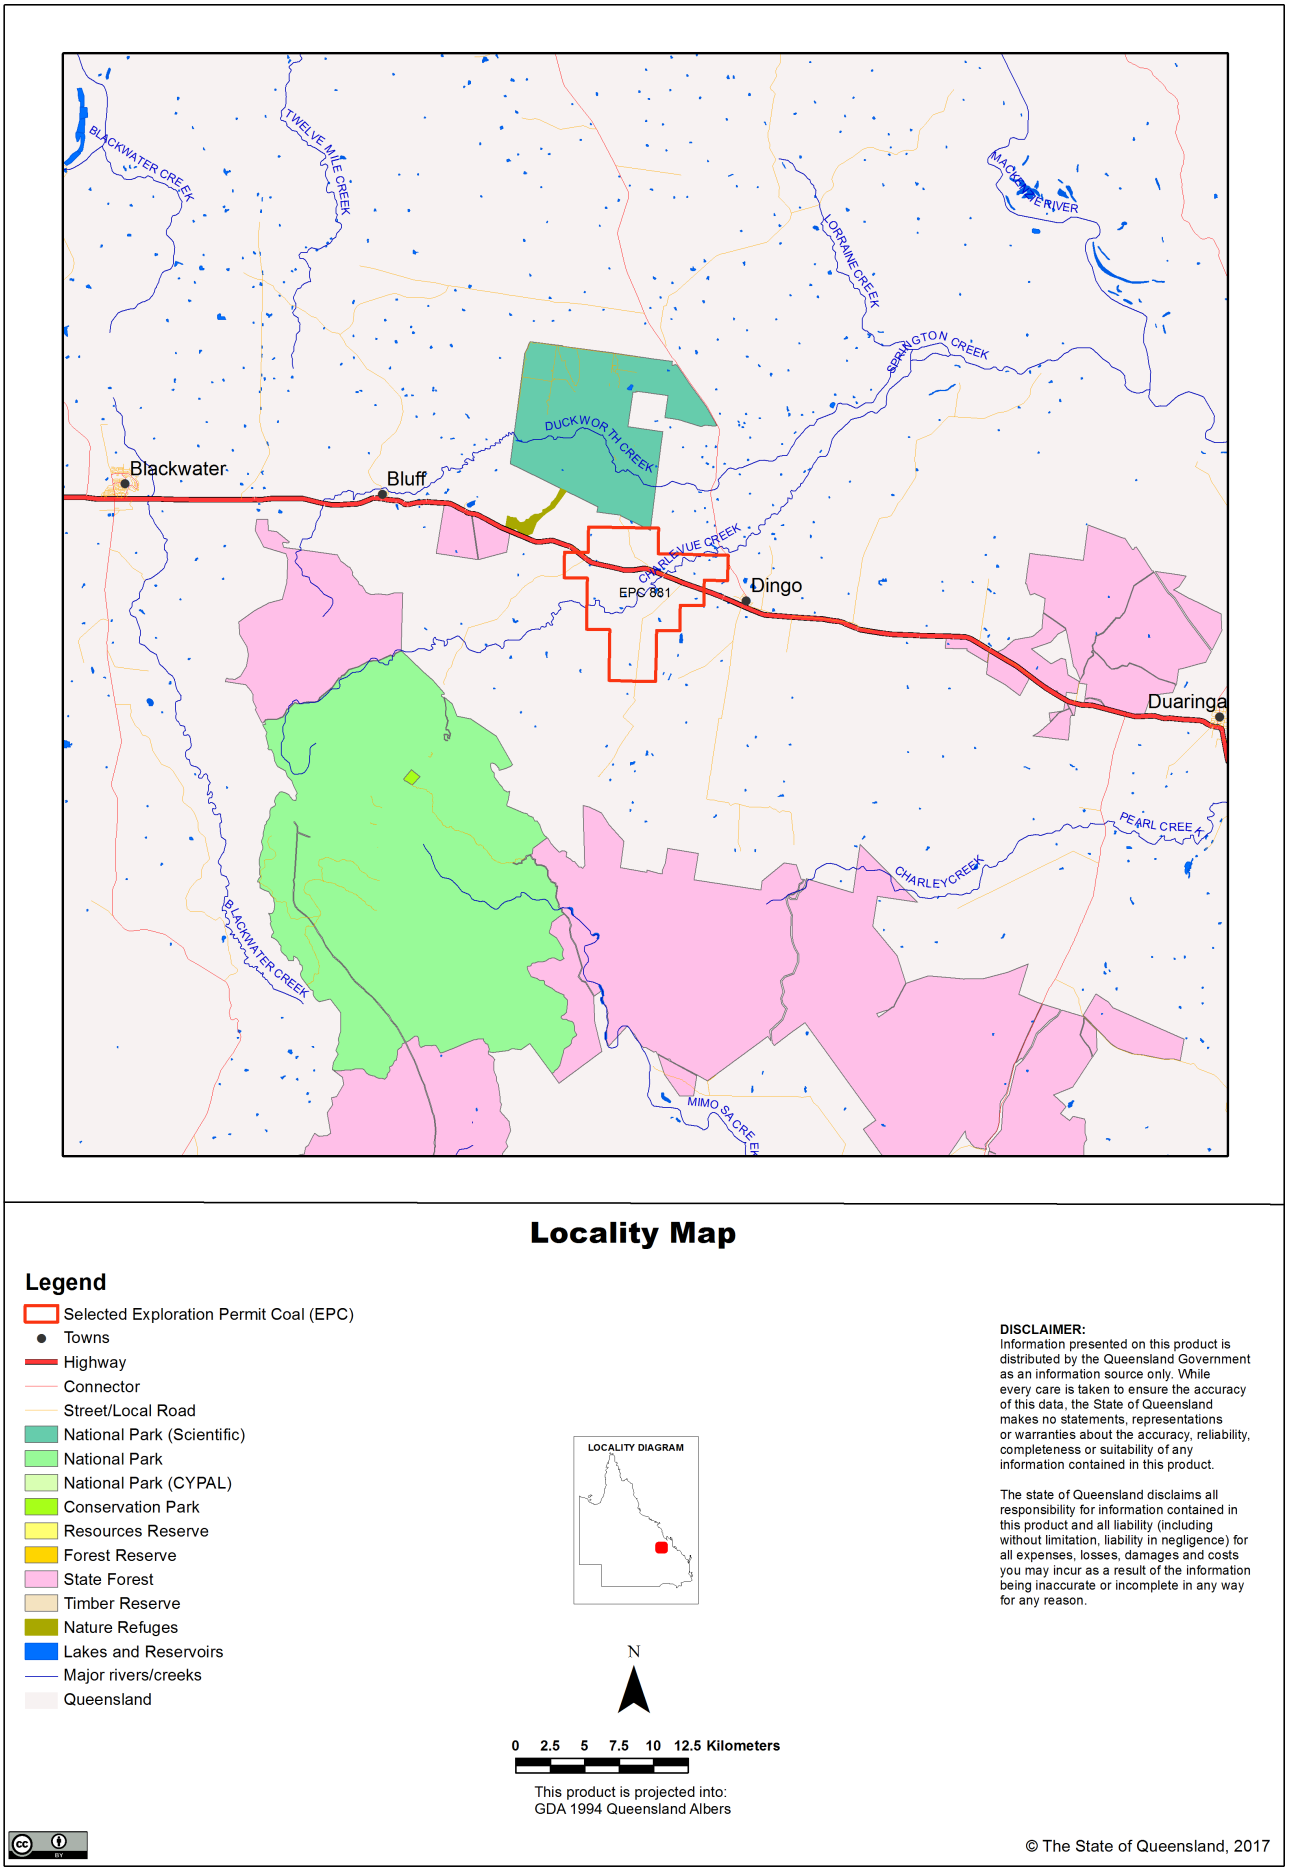
(no results)

NB. Please note that the list of priority species is based on those species identified in the BPAs, however records for these species may be more recent than the originals used. furthermore, the BPA priority species databases are updated from time to time. At each update, the taxonomic details for all species are amended as necessary to reflect current taxonomic name and/or status changes.

ACA Priority Species

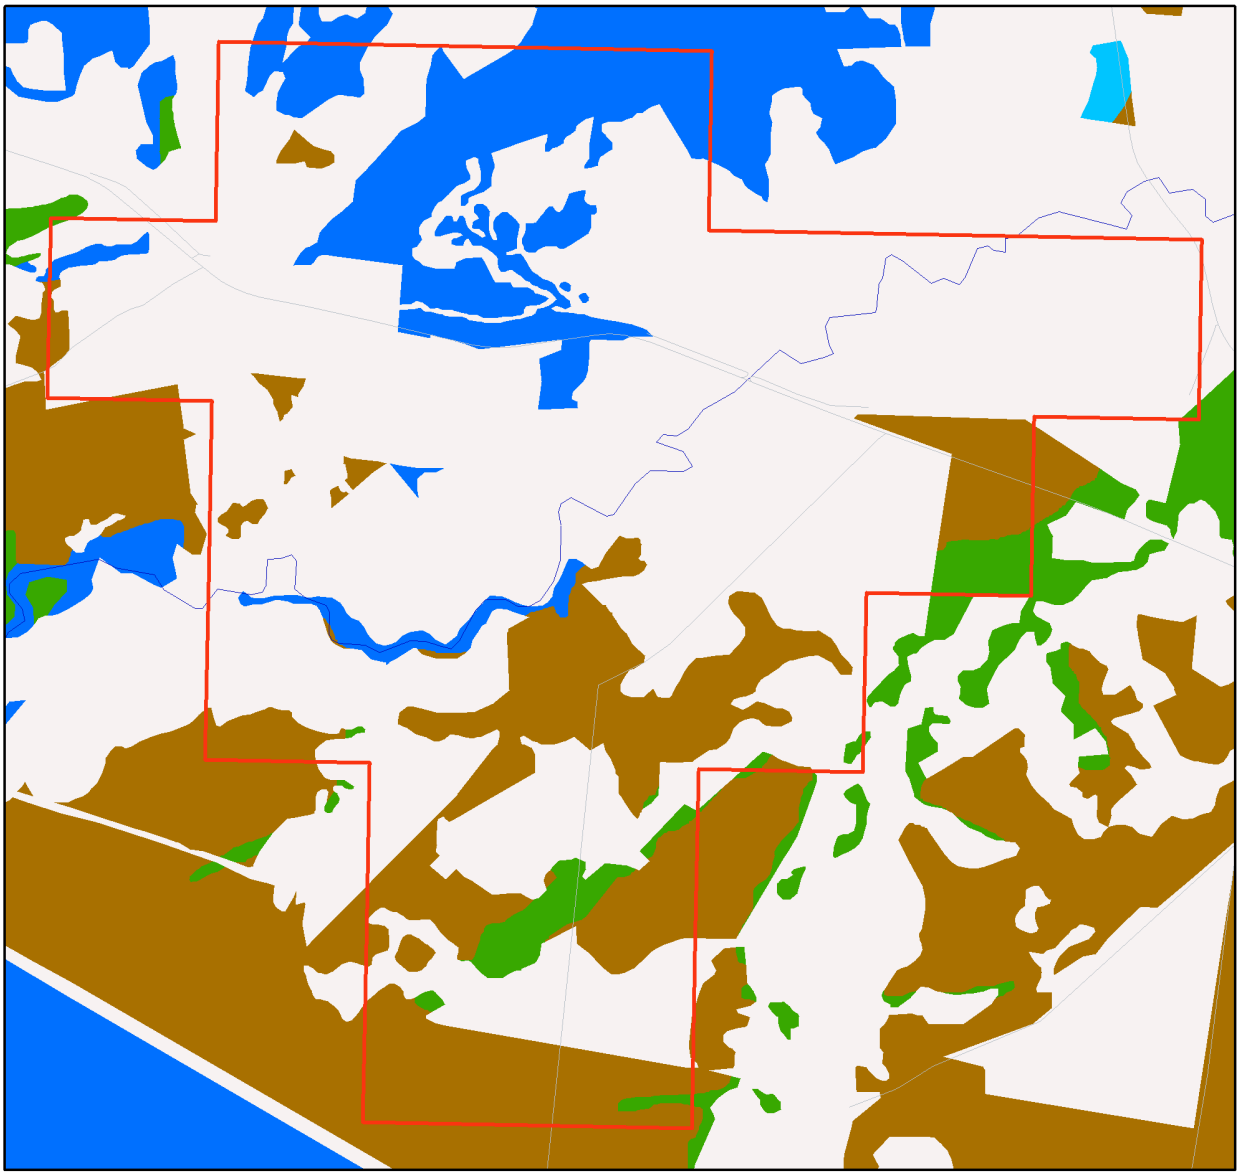
A list of ACA priority species used in riverine and non-riverine ACAs that have been recorded on, or within approximately 4km of the AOI are contained in the following tables.

Table 24: Priority species recorded on, or within 4 km of the AOI - riverine



Species	Common name	Back on Track rank	Identified flora/fauna
Eucalyptus tereticornis			FL
Lomandra longifolia			FL
Eucalyptus camaldulensis			FL

Table 25: Priority species recorded on, or within 4 km of the AOI - non-riverine



Species	Common name	Back on Track rank	Identified flora/fauna
Eucalyptus tereticornis			FL

NB. Please note that the priority species records used in the above two tables are comprised of those adopted for the released individual ACAs. The ACA riverine and non-riverine priority species databases are updated from time to time to reflect new release of ACAs. At each update, the taxonomic details for all ACAs records are amended as necessary to reflect current taxonomic name and/or status changes.

Matters of State Environmental Significance

Area of Interest: epc: 881

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or area of interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "Central co-ordinates" option, the resulting assessment area encompasses an area extending for a 2km radius from the point of interest.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 1994). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no values have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Please direct queries about these reports to: Planning.Support@ehp.qld.gov.au

Disclaimer

Whilst every care is taken to ensure the accuracy of the information provided in this report, the Queensland Government makes no representations or warranties about its accuracy, reliability, completeness, or suitability, for any particular purpose and disclaims all responsibility and all liability (including without limitation, liability in negligence) for all expenses, losses, damages (including indirect or consequential damage) and costs which the user may incur as a consequence of the information being inaccurate or incomplete in any way and for any reason.

Assessment Area Details

The following table provides an overview of the area of interest (AOI) with respect to selected topographic and environmental values.

Table 1: Summary table, AOI details

Area of Interest	EPC881
Size (ha)	7219.6
Local Government(s)	CENTRAL HIGHLANDS REGIONAL
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda
Catchment(s)	Fitzroy

Refer to **Map 1** for locality information.

Matters of State Environmental Significance (MSES)

MSES Categories

Queensland's State Planning Policy (SPP) includes a biodiversity State interest that states:

'The sustainable, long-term conservation of biodiversity is supported. Significant impacts on matters of national or state environmental significance are avoided, or where this cannot be reasonably achieved; impacts are minimised and residual impacts offset.'

The MSES mapping product is a guide to assist planning and development assessment decision-making. Its primary purpose is to support implementation of the SPP biodiversity policy. While it supports the SPP, the mapping does not replace the regulatory mapping or environmental values specifically called up under other laws or regulations. Similarly, the SPP biodiversity policy does not override or replace specific requirements of other Acts or regulations.

The SPP defines matters of state environmental significance as:

- Protected areas (including all classes of protected area except coordinated conservation areas) under the *Nature Conservation Act 1992*;

- Marine parks and land within a 'marine national park', 'conservation park', 'scientific research', 'preservation' or 'buffer' zone under the *Marine Parks Act 2004*;

- Areas within declared fish habitat areas that are management A areas or management B areas under the Fisheries Regulation 2008;

- Threatened wildlife under the *Nature Conservation Act 1992* and special least concern animals under the Nature Conservation (Wildlife) Regulation 2006;

- Regulated vegetation under the *Vegetation Management Act 1999* that is:

  • Category B areas on the regulated vegetation management map, that are 'endangered' or 'of concern' regional ecosystems;

  • Category C areas on the regulated vegetation management map that are 'endangered' or 'of concern' regional ecosystems;

  • Category R areas on the regulated vegetation management map;

  • Regional ecosystems that intersect with watercourses identified on the vegetation management watercourse and drainage feature map;

  • Regional ecosystems that intersect with wetlands identified on the vegetation management wetlands map;

- Strategic Environmental Areas under the *Regional Planning Interests Act 2014*;

- Wetlands in a wetland protection area of wetlands of high ecological significance shown on the Map of Referable Wetlands under the Environmental Protection Regulation 2008;

- Wetlands and watercourses in high ecological value waters defined in the Environmental Protection (Water) Policy 2009, schedule 2;

- Legally secured offset areas.

Refer to **Appendix 1** for a description of MSES categories.

MSES Values Present

The MSES values that are present in the area of interest are summarised in the table below:

Table 2: Summary of MSES present within the AOI

MSES Criteria 1 - STATE CONSERVATION AREAS	3.7 ha	0.1%
1.1 Protected Areas	3.7 ha	0.1%
1.2 Marine Parks	0.0 ha	0.0%
1.3 Fish Habitat Areas	0.0 ha	0.0%
MSES Criteria 2 - WETLANDS AND WATERWAYS - area features	0.0 ha	0.0%
MSES Criteria 2 - WETLANDS AND WATERWAYS - linear features	0.0 km	Not applicable
2.1 High Ecological Significance wetlands on the map of Referable Wetlands	0.0 ha	0.0%
2.2 High Ecological Value (HEV) wetlands	0.0 ha	0.0%
2.2 High Ecological Value (HEV) waterways **	0.0 km	Not applicable
2.3 Strategic Environmental Areas (SEA)	0.0 ha	0.0%
MSES Criteria 3 - SPECIES	0.0 ha	0.0%
3.1 Threatened species and Iconic species	0.0 ha	0.0%
MSES Criteria 4 - REGULATED VEGETATION - area features	252.2 ha	3.5%
MSES Criteria 4 - REGULATED VEGETATION - linear features	81.4 km	Not applicable
4.1 Vegetation Management Regional Ecosystems and Remnant Map *	252.2 ha	3.5%
4.2 Vegetation Management Wetland Map *	0.0 ha	0.0%
4.3 Vegetation Management Watercourse Map **	81.4 km	Not applicable
MSES Criteria 5 - OFFSET AREAS	0.0 ha	0.0%
5.1 Legally secured offset areas	0.0 ha	0.0%
Total MSES (criteria 1.1, 1.2, 1.3, 2.1, part of 2.2, 2.3, 3.1, 4.1, 4.2 and 5.1) calculated for area features only	255.9 ha	3.5%

Please note that the area and percent area figures in the table above will not necessarily add up to the "Total MSES" figures due to overlapping values.

**The total extent area of regulated vegetation (Criteria 4.1) may be overestimated due to the presence of dominant and/or subdominant non-regulated regional ecosystems in mixed patches of vegetation, i.e. the total area of mixed vegetated patches is included irrespective of whether the patch consists only partly of endangered, of concern or wetland regional ecosystems.*

***The total linear extent of watercourses may be overestimated in some instances, as both banks (rather than the centreline) of waterbodies and larger watercourses where present are mapped by the State, increasing the extent of linear features*.

Appendices

Appendix 1 - Matters of State Environmental Significance (MSES) Criteria

Feature Name	Description
1.1 Protected Areas (NCA)	Protected areas under the *Nature Conservation Act 1992*, except coordinated conservation areas.
1.2 Marine Parks (MPA)	The following State marine parks zones under the *Marine Parks Act 2004*: - Marine National Park zone; - Marine Conservation Park zone; - Scientific Research zone; - Preservation zone; - Buffer zone.
1.3 Fish Habitat Areas (FA)	The following areas under the *Fisheries Act 1994* including: All fish habitat areas.
2.1 'High Ecological Significance' wetlands on the Map of Referable Wetlands	All natural wetlands that are 'High Ecological Significance' (HES) on the Map of Referable Wetlands. Exclude: any amendments to the Map of Referable Wetlands.
2.2 High Ecological Value (HEV) wetlands and waterways (EP Act)	Natural wetlands and waterways that occur in HEV (maintain) freshwater and estuarine areas under the Environmental Protection (Water) Policy.
2.3 Strategic Environmental Areas (RPI Act)	Designated precinct areas under the *Regional Planning Interests Act 2014*.
3.1 Threatened species and Iconic species (NCA)	Habitat for: Threatened wildlife under *Nature Conservation Act 1992* including: 'Endangered' and 'Vulnerable' species. Special least concern animals under the *Nature Conservation Act 1992* including: Koala (outside SEQ); Echidna and Platypus.
4.1 Vegetation Management Regional Ecosystem and Remnant Map (VMA)	Include VMA 'Endangered' and 'Of Concern' remnant (Category A and B) and high value regrowth (Category C) REs and Category R (GBR regrowth watercourse) areas from the Regulated Vegetation Management Map.
4.2 Vegetation Management Wetland Map (VMA)	Wetlands that are lakes and swamps shown on the Vegetation Management Wetlands Map.
4.3 Vegetation Management Watercourse and Drainage Feature Map (VMA)	Watercourses shown on the Vegetation Management Watercourse and Drainage Feature Map.
5.1 Legally secured offset areas (VMA, EP Act, SPA, TIA, EA)	Offset areas legally secured under a covenant, conservation agreement or development approval condition.

The Queensland Government's "Method for mapping - matters of state environmental significance for use in land use planning and development assessment" can be downloaded from:

http://www.ehp.qld.gov.au/land/natural-resource/method-mapping-mses.html.

Appendix 2 - Source Data

The datasets listed below are available on request from:

http://qldspatial.information.qld.gov.au/catalogue/custom/index.page

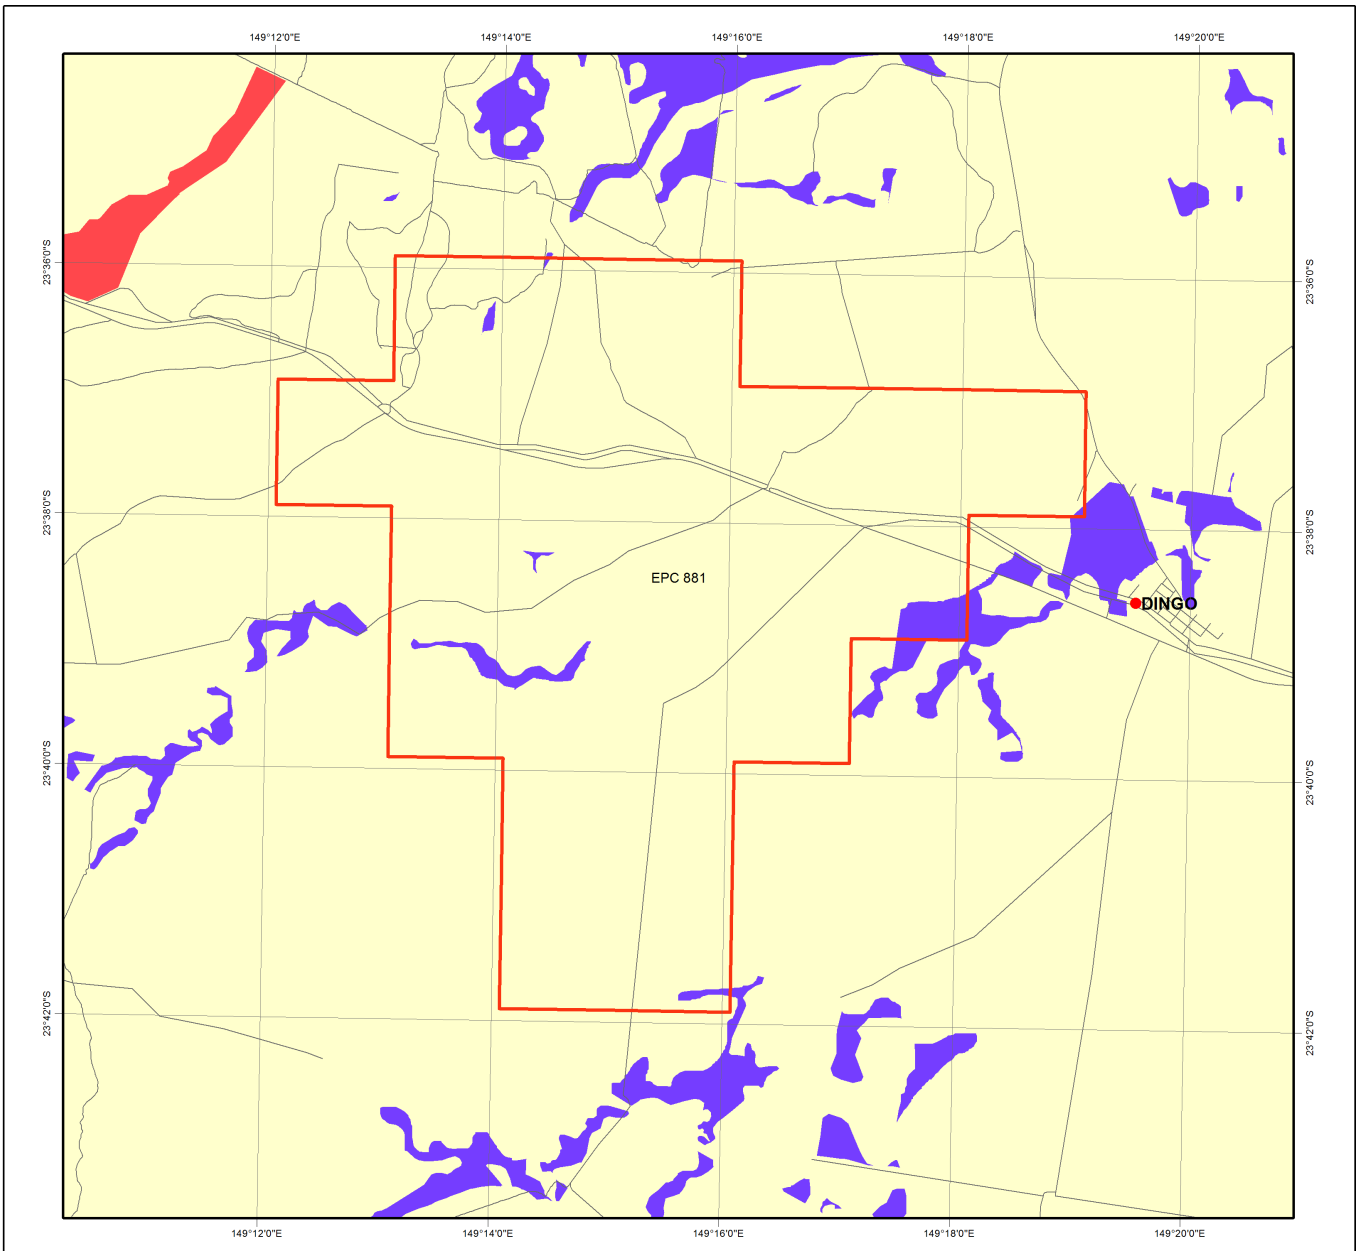
- Matters of State environmental significance
- Matters of State environmental significance drainage lines
- Boundaries of the Great Barrier Reef Marine Park

Note: MSES mapping is a regional-scale representation of the definition for MSES under the State Planning Policy (SPP). The compiled MSES mapping product is a guide to assist planning and development assessment decision-making. Its primary purpose is to support implementation of the SPP biodiversity policy. While it supports the SPP, the mapping does not replace the regulatory mapping or environmental values specifically called up under other laws or regulations. Similarly, the SPP biodiversity policy does not override or replace specific requirements of other Acts or regulations.

MSES mapping is not based on new or unique data. The primary mapping product draws data from a number of underlying environment databases and geo-referenced information sources. MSES mapping is a versioned product that is updated generally on a twice-yearly basis to incorporate the changes to underlying data sources. Several components of MSES mapping made for the current version may differ from the current underlying data sources. To ensure accuracy, or proper representation of MSES values, it is strongly recommended that users refer to the underlying data sources and review the current definition of MSES in the State Planning Policy, before applying the MSES mapping.

Underlying data sources used to develop individual releases of complied MSES mapping include, but are not limited to:

- Regulated vegetation including:
  - Regulated Regional Ecosystems and Regrowth
  - Regulated Essential habitat
  - Regulated Wetlands
  - Regulated Watercourses and Drainage
  - Former Regrowth



- Queensland Wetland Mapping (v3)
- Essential Habitat Mapping
- Protected Areas
- Marine Parks
- Fish Habitat Areas
- Strategic Environmental Areas
- The Map of Referable Wetlands:
  - Wetland Protection Areas (HES wetlands in the GBR)
  - Wetland Management Areas (contains other HES wetlands)

Datasets reflective of the above matters can be downloaded via the Queensland Spatial Catalogue:

http://qldspatial.information.qld.gov.au/catalogue/custom/index.page

Information presented on this product is distributed by the Queensland Government as an information source only. While every care is taken to ensure the accuracy of this data, The State of Queensland makes no statements, representations or warranties about the accuracy, reliability, completeness or suitability of any information contained in this product.

The State of Queensland disclaims all responsibility for information contained in this product and all liability (including without limitation, liability in negligence) for all expenses, losses, damages and costs you may incur as a result of the information being inaccurate or ncomplete in any way for any reason.

External contributors (non-government parties) of the data for this product are: Great Barrier Reef Marine Park Authority

Regional ecosystem mapping (remnant biodiversity status) may incorporate amendments, resulting from property level assessments, to the release version of the mapping available on QSpatial.

NOTE TO USER: Themes presented in this map are indicative only. Field survey may be required to verify the 'true' spatial extent and value. Not all environmentally sensitive areas are presented in this map. A user should refer to the particular circumstances relevant to their situation to assess the 'completeness' of themes provided.

The user should note that some boundaries and indicated values are ambient and may change over time (e.g. regional ecosystem boundaries and conservation status, watercourse mapping etc).

The user should be aware that due to multiple overlapping themes/ layers present, some themes/layers may be obscured by others. Ordering in the Legend does not accurately reflect the order by which themes/layers are displayed.

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or area of interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "Central co-ordinates" option, the resulting assessment area encompasses an area extending for a 2km radius from the input coordinates.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 1994). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no matters of interest have been identified within the site.

The information presented in this report should be considered as a guide only and field survey may be required to validate values on the ground.

Important Note to User

Information presented in this report is based upon the Queensland Herbarium's Regional Ecosystem framework. The Biodiversity Status has been used to depict the extent of "Endangered", "Of Concern" and "No Concern at Present" regional ecosystems in all cases, rather than the status used for the purposes of the *Vegetation Management Act 1999* (VMA). Mapping and figures presented in this document reflect the Queensland Herbarium's Remnant and Pre-clearing Regional Ecosystem Datasets, and not the certified mapping used for the purpose of the VMA.

For matters relevant to vegetation management under the VMA, please refer to the Department of Natural Resources and Mines website

https://www.dnrm.qld.gov.au/

Please direct queries about these reports to: Queensland.Herbarium@dsitia.qld.gov.au

Disclaimer

Whilst every care is taken to ensure the accuracy of the information provided in this report, the Queensland Government makes no representations or warranties about its accuracy, reliability, completeness, or suitability, for any particular purpose and disclaims all responsibility and all liability (including without limitation, liability in negligence) for all expenses, losses, damages (including indirect or consequential damage) and costs which the user may incur as a consequence of the information being inaccurate or incomplete in any way and for any reason.

Summary Information

The following table provides an overview of the AOI with respect to selected topographic and environmental themes. Refer to **Map 1** for locality information.

Table 1: Area of interest details

Area of Interest	EPC881
Size (ha)	7219.6
Local Government(s)	CENTRAL HIGHLANDS REGIONAL
Bioregion(s)	Brigalow Belt
Subregion(s)	Woorabinda
Catchment(s)	Fitzroy

The table below summarizes the extent of remnant vegetation classed as "Endangered", "Of concern" and "No concern at present" classified by Biodiversity Status within the area of interest (AOI).

Table 2: Summary table, biodiversity status of regional ecosystems within the AOI

Biodiversity Status	Area (Ha)	% of AOI
Endangered	6.4	0.1
Of concern	237.5	3.3
No concern at present	1842.1	25.5
Total remnant vegetation	2086.0	28.9

Refer to **Map 2** for further information.

Regional Ecosystems

1. Introduction

Regional ecosystems are vegetation communities in a bioregion that are consistently associated with a particular combination of geology, landform and soil. Descriptions of Queensland's Regional ecosystems are available online from the Regional Ecosystem Description Database (REDD). Descriptions are compiled from a broad range of information sources including vegetation, land system and geology survey and mapping and detailed vegetation site data. The regional ecosystem is regularly reviewed as new information becomes available. A number of vegetation communities may form a single regional ecosystem and are usually distinguished by differences in dominant species, frequently in the shrub or ground layers and are denoted by a letter following the regional ecosystem code (e.g. a, b, c).

The Queensland Herbarium has developed a methodology for mapping regional ecosystems across Queensland. As new information is obtained, the descriptions and status of regional ecosystems is updated. Regional ecosystems and broad vegetation groups descriptions in the format of Sattler and Williams (1999) are maintained in the Regional Ecosystem Description Database (REDD). Vegetation communities and regional ecosystems are amalgamated into the higher level classification of broad vegetation groups (BVGs).

This report provides information on the type, status, and extent of vegetation communities, regional ecosystems and broad vegetation groups present within a user specified area of interest. Please note, for the purpose of this report, the Biodiversity Status is used. This report has not been developed for application of matters relevant to the *Vegetation Management Act 1999* (VMA). Additionally, information generated in this report has been derived from the Queensland Herbarium's Regional Ecosystem Mapping, and not mapping certified for the purposes of the VMA. If your interest/matter relates to regional ecosystems and the VMA, users should refer to the Department of Natural Resources and Mines website.

https://www.dnrm.qld.gov.au/

With respect to the Queensland Biodiversity Status,

"Endangered" regional ecosystems are described as those where:

- remnant vegetation is less than 10 per cent of its pre-clearing extent across the bioregion; or 10-30% of its pre-clearing extent remains and the remnant vegetation is less than 10,000 hectares, or
- less than 10 per cent of its pre-clearing extent remains unaffected by severe degradation and/or biodiversity loss*, or
- 10-30 per cent of its pre-clearing extent remains unaffected by severe degradation and/or biodiversity loss and the remnant vegetation is less than 10,000 hectares; or
- it is a rare** regional ecosystem subject to a threatening process.***

"Of concern" regional ecosystems are described as those where:

- the degradation criteria listed above for 'Endangered' regional ecosystems are not met and,
- remnant vegetation is 10-30 per cent of its pre-clearing extent across the bioregion; or more than 20 per cent of its pre-clearing extent remains and the remnant extent is less than 10,000 hectares, or
- 10-30 percent of its pre-clearing extent remains unaffected by moderate degradation and/or biodiversity loss.****

and "No concern at present" regional ecosystems are described as those where:

- remnant vegetation is over 30 per cent of its pre-clearing extent across the bioregion, and the remnant area is greater than 10,000 hectares, and
- the degradation criteria listed above for 'Endangered' or 'Of concern' regional ecosystems are not met.

**Severe degradation and/or biodiversity loss is defined as: floristic and/or faunal diversity is greatly reduced but unlikely to recover within the next 50 years even with the removal of threatening processes; or soil surface is severely degraded, for example, by loss of A horizon, surface expression of salinity; surface compaction, loss of organic matter or sheet erosion.*

***Rare regional ecosystem: pre-clearing extent (1000 ha); or patch size (100 ha and of limited total extent across its range).*

****Threatening processes are those that are reducing or will reduce the biodiversity and ecological integrity of a regional ecosystem. For example, clearing, weed invasion, fragmentation, inappropriate fire regime or grazing pressure, or infrastructure development.*

*****Moderate degradation and/or biodiversity loss is defined as: floristic and/or faunal diversity is greatly reduced but unlikely to recover within the next 20 years even with the removal of threatening processes; or soil surface is moderately degraded.*

2. Remnant Regional Ecosystems

The following table identifies the remnant regional ecosystems and vegetation communities mapped within the AOI, the associated short description, Biodiversity Status using the Queensland Herbarium's framework and the extent area present within the selected AOI. Please note, where heterogeneous vegetated patches (mixed patches of remnant vegetation mapped as containing multiple regional ecosystems) occur within the AOI, they have been split and listed as individual regional ecosystems (or vegetation communities where present) for the purposes of the table below. In such instances, associated area figures have been generated based upon the estimated proportion of each regional ecosystem (or vegetation community) predicted to be present within the larger mixed patch.

Table 3: Remnant regional ecosystems, description and status within the AOI

Regional Ecosystem	Short Description	BD Status	Area (Ha)	% of AOI
11.3.1	Acacia harpophylla and/or Casuarina cristata open forest on alluvial plains	Endangered	6.4	0.1
11.3.2	Eucalyptus populnea woodland on alluvial plains	Of concern	125.3	1.7
11.3.25	Eucalyptus tereticornis or E. camaldulensis woodland fringing drainage lines	Of concern	112.1	1.6
11.5.2	Eucalyptus crebra, Corymbia spp., with E. moluccana woodland on lower slopes of Cainozoic sand plains and/or remnant surfaces	No concern at present	1004.5	13.9
11.5.9b	Eucalyptus crebra and other Eucalyptus spp. and Corymbia spp. woodland on Cainozoic sand plains and/or remnant surfaces	No concern at present	142.9	2.0
11.7.2	Acacia spp. woodland on Cainozoic lateritic duricrust. Scarp retreat zone	No concern at present	694.7	9.6
non-rem	None	None	5133.6	71.1

Refer to **Map 2** for further information. **Map 3** also provides a visual estimate of the distribution of regional ecosystems present before European settlement.

Table 4 provides further information in regards to the remnant regional ecosystems present within the site with respect to the extent of remnant vegetation remaining within the bioregion, the 1:1,000,000 broad vegetation group (BVG) classification, whether the regional ecosystem is identified as a wetland, and extent of representation in Queensland's Protected Area Estate. For a description of the vegetation communities within the AOI and classified according to the 1:1,000,000 BVG, refer to **Table 6**.

Table 4: Remnant regional ecosystems within the AOI, additional information

Regional Ecosystem	Remnant Extent	BVG (1 Million)	Wetland	Representation in protected estate
11.3.1	In 2013, remnant extent was > 10,000 ha and 10-30% of the pre-clearing area remained	25a	None	Low
11.3.2	In 2013, remnant extent was > 10,000 ha and 10-30% of the pre-clearing area remained	17a	Contains palustrine wetland (e.g. in swales).	Low

Regional Ecosystem	Remnant Extent	BVG (1 Million)	Wetland	Representation in protected estate
11.3.25	In 2013, remnant extent was > 10,000 ha and >30% of the pre-clearing area remained	16a	Riverine wetland or fringing riverine wetland.	Low
11.5.2	In 2013, remnant extent was > 10,000 ha and >30% of the pre-clearing area remained	18b	None	Low
11.5.9b	In 2013, remnant extent was > 10,000 ha and >30% of the pre-clearing area remained	18b	None	Low
11.7.2	In 2013, remnant extent was > 10,000 ha and >30% of the pre-clearing area remained	24a	None	Low
non-rem	None	None	None	None

Representation in Protected Area Estate: High greater than 10% of pre-clearing extent is represented; Medium 4 - 10% is represented; Low less than 4% is represented, No representation.

Map 6 displays the distribution of mapped wetland systems within the area of interest.

The following table lists known special values associated with a regional ecosystem type.

Table 5: Remnant regional ecosystems within the AOI, special values

Regional Ecosystem	Special Values
11.3.1	Habitat for threatened fauna species including painted honeyeater, Grantiella picta particularly in subregion 35 (Oliver et al. 2003).
11.3.2	Habitat for threatened flora species Homopholis belsonii.
11.3.25	Habitat for threatened flora species including Eucalyptus raveretiana. Shown to be associated with a high fauna species richness in the Taroom area (Venz et al. 2002). Within parts of the Fitzroy catchment, this RE is known habitat for the threatened freshwater turtle Rheodytes leukops. Known to be important habitat for other riparian freshwater turtle species.
11.5.2	None
11.5.9b	None
11.7.2	Habitat for threatened flora species including Acacia wardellii.
non-rem	None

3. Remnant Regional Ecosystems by Broad Vegetation Group

BVGs are a higher-level grouping of vegetation communities. Queensland encompasses a wide variety of landscapes across temperate, wet and dry tropics and semi-arid climatic zones. BVGs provide an overview of vegetation communities across the state or a bioregion and allow comparison with other states. There are three levels of BVGs which reflect the approximate scale at which they are designed to be used: the 1:5,000,000 (national), 1:2,000,000 (state) and 1:1,000,000 (regional).

A comprehensive description of BVGs is available at:

https://publications.qld.gov.au/dataset/vegetation-qld/resource/921fa786-e6d5-4a8a-9b0c-e532d2ce3f32

The following table provides a description of the 1:1,000,000 BVGs present and their associated extent within the AOI.

Table 6: Broad vegetation groups (1 million) within the AOI

BVG (1 Million)	Description	Area (Ha)	% of AOI
None	None	5133.6	71.1
16a	Open forest and woodlands dominated by Eucalyptus camaldulensis (river red gum) (or E. tereticornis (blue gum)) and/or E. coolabah (coolabah) (or E. microtheca (coolabah)) fringing drainage lines. Associated species may include Melaleuca spp., Corymbia tessellaris (carbeen), Angophora spp., Casuarina cunninghamiana (riveroak). Does not include alluvial areas dominated by herb and grasslands or alluvial plains that are not flooded. (land zone 3) (MGD, BRB, GUP, CHC, MUL, DEU, EIU, NWH, SEQ, [NET, WET]) (All bioregions except CYP and CQC)	112.1	1.6
17a	Woodlands dominated by Eucalyptus populnea (poplar box) (or E. brownii (Reid River box)) on alluvium, sand plains and footslopes of hills and ranges. (land zones 3, 5, 10, 9, 4, 11, 12, [8]) (BRB, MUL, DEU, MUL, EIU)	125.3	1.7
18b	Woodlands dominated Eucalyptus crebra (sens. lat.) (narrow-leaved red ironbark) frequently with Corymbia spp. or Callitris spp. on flat to undulating plains. (land zones 5, 3) (BRB, DEU, EIU, GUP, CYP)	1147.4	15.9
24a	Low woodlands to tall shrublands dominated by Acacia spp. on residuals. Species include A. shirleyi (lancewood), A. catenulata (bendee), A. microsperma (bowyakka), A. clivicola, A. sibirica, A. rhodoxylon (rosewood) and A. leptostachya (Townsville wattle). (land zones 7, 10, 5, 12, 11, [9, 3]) (MUL, CHC, BRB, GUP, EIU, MGD, DEU, NWH, [CYP])	694.7	9.6
25a	Open forests to woodlands dominated by Acacia harpophylla (brigalow) sometimes with Casuarina cristata (belah) on heavy clay soils. Includes areas co-dominated with A. cambagei (gidgee) and/or emergent eucalypts (land zones 4, 9, 3, 11, 7, 12, [5, 8]) (BRB, MUL, MGD, DEU, [SEQ])	6.4	0.1

Refer to **Map 4** for further information. **Map 5** also provides a representation of the distribution of vegetation communities as per the 1:5,000,000 BVG believed to be present prior to European settlement.

4. Technical and BioCondition Benchmark Descriptions

Technical descriptions provide a detailed description of the full range in structure and floristic composition of regional ecosystems (e.g. 11.3.1) and their component vegetation communities (e.g. 11.3.1a, 11.3.1b). See:

http://www.qld.gov.au/environment/plants-animals/plants/ecosystems/technical-descriptions/

The descriptions are compiled using site survey data from the Queensland Herbarium's CORVEG database. Distribution maps, representative images (if available) and the pre-clearing and remnant area (hectares) of each vegetation community derived from the regional ecosystem mapping (spatial) data are included. The technical descriptions should be used in conjunction with the fields from the regional ecosystem description database (REDD) for a full description of the regional ecosystem.

Quantitative site data from relatively undisturbed sites are extracted from CORVEG and summarized to provide information specific to each vegetation community.

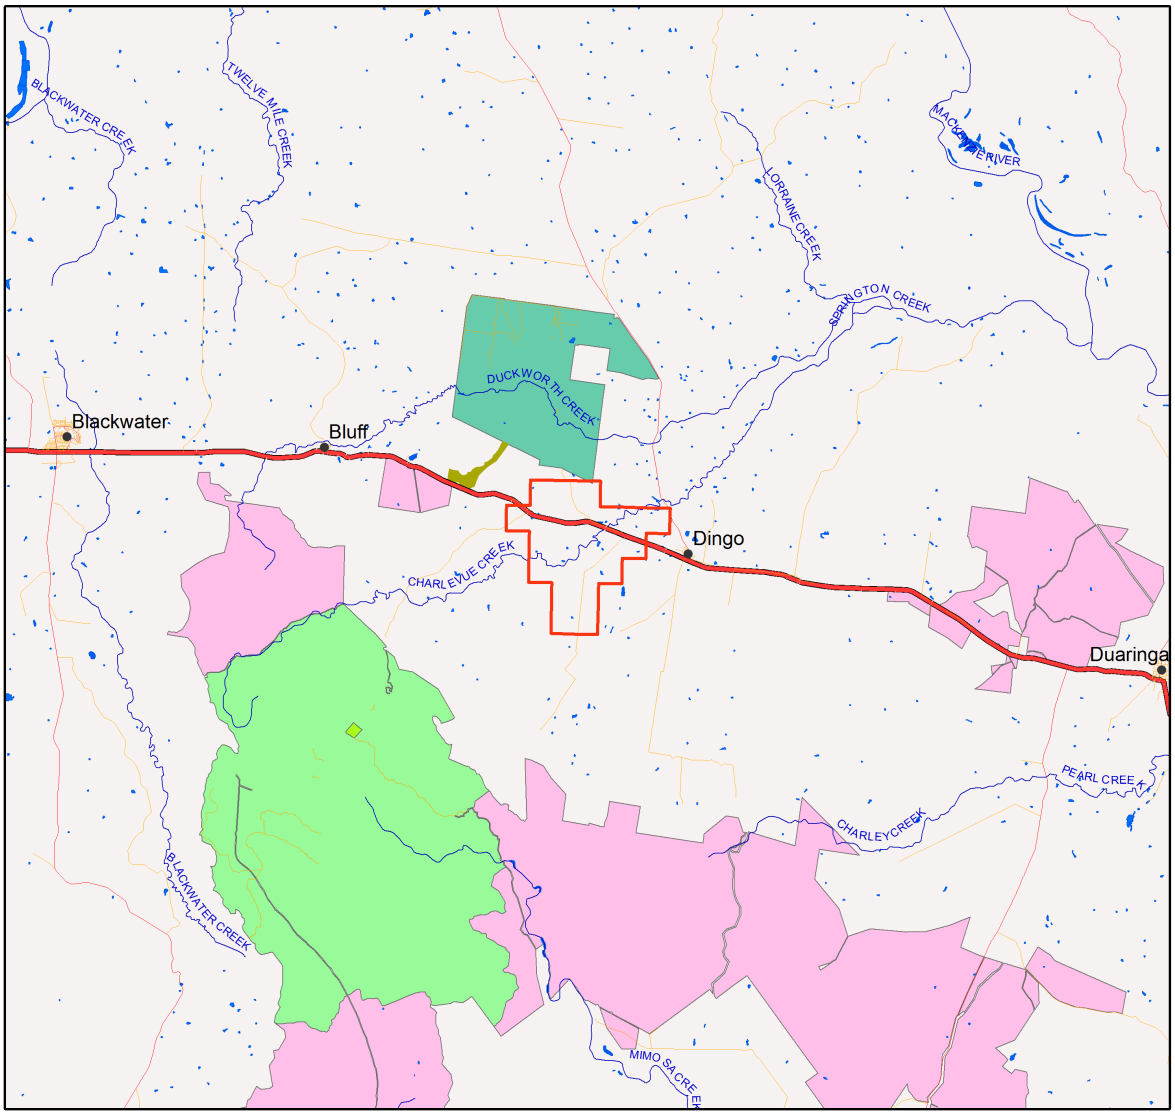
Technical descriptions include the attributes: tree canopy height and cover and native plant species composition of the predominant layer, which are used to assess the remnant status of vegetation under the *Vegetation Management Act 1999*.

However, as technical descriptions reflect the full range in structure and floristic composition across the climatic, natural disturbance and geographic range of the regional ecosystem, local reference sites should be used where possible (Neldner et al. 2012 (PDF)* section 3.3.1 of:

http://www.qld.gov.au/environment/assets/documents/plants-animals/herbarium/herbarium-mapping-methodology.pdf

The technical descriptions are subject to review and are updated as additional data becomes available.

When conducting a BioCondition assessment, these technical descriptions should be used in conjunction with BioCondition benchmarks for the specific regional ecosystem, or component vegetation community.



http://www.qld.gov.au/environment/plants-animals/biodiversity/benchmarks/

Benchmarks are subject to review based on additional data and expert opinion. Benchmarks are based on a combination of quantitative and qualitative information and should be used as a guide only. Benchmarks are specific to one regional ecosystem vegetation community, however, the natural variability in structure and floristic composition under a range of climatic and natural disturbance regimes has been considered throughout the geographic extent of the regional ecosystem. Local reference sites should be used for this spatial and temporal (seasonal and annual) variability.

Table 7: List of remnant regional ecosystems within the AOI for which technical and biocondition benchmark descriptions are available

Regional ecosystems mapped as within the AOI	Technical Descriptions	Biocondition Benchmarks
11.3.1	Not currently available	Available
11.3.2	Not currently available	Available
11.3.25	Not currently available	Available
11.5.2	Not currently available	Not currently available
11.5.9b	Not currently available	Not currently available
11.7.2	Not currently available	Not currently available
non-rem	Not currently available	Not currently available

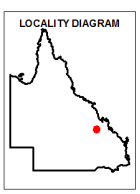
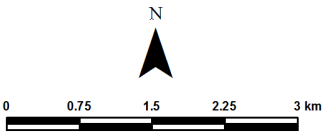


Map 2 - Remnant regional ecosystems



Remnant 2015 Regional Ecosystems

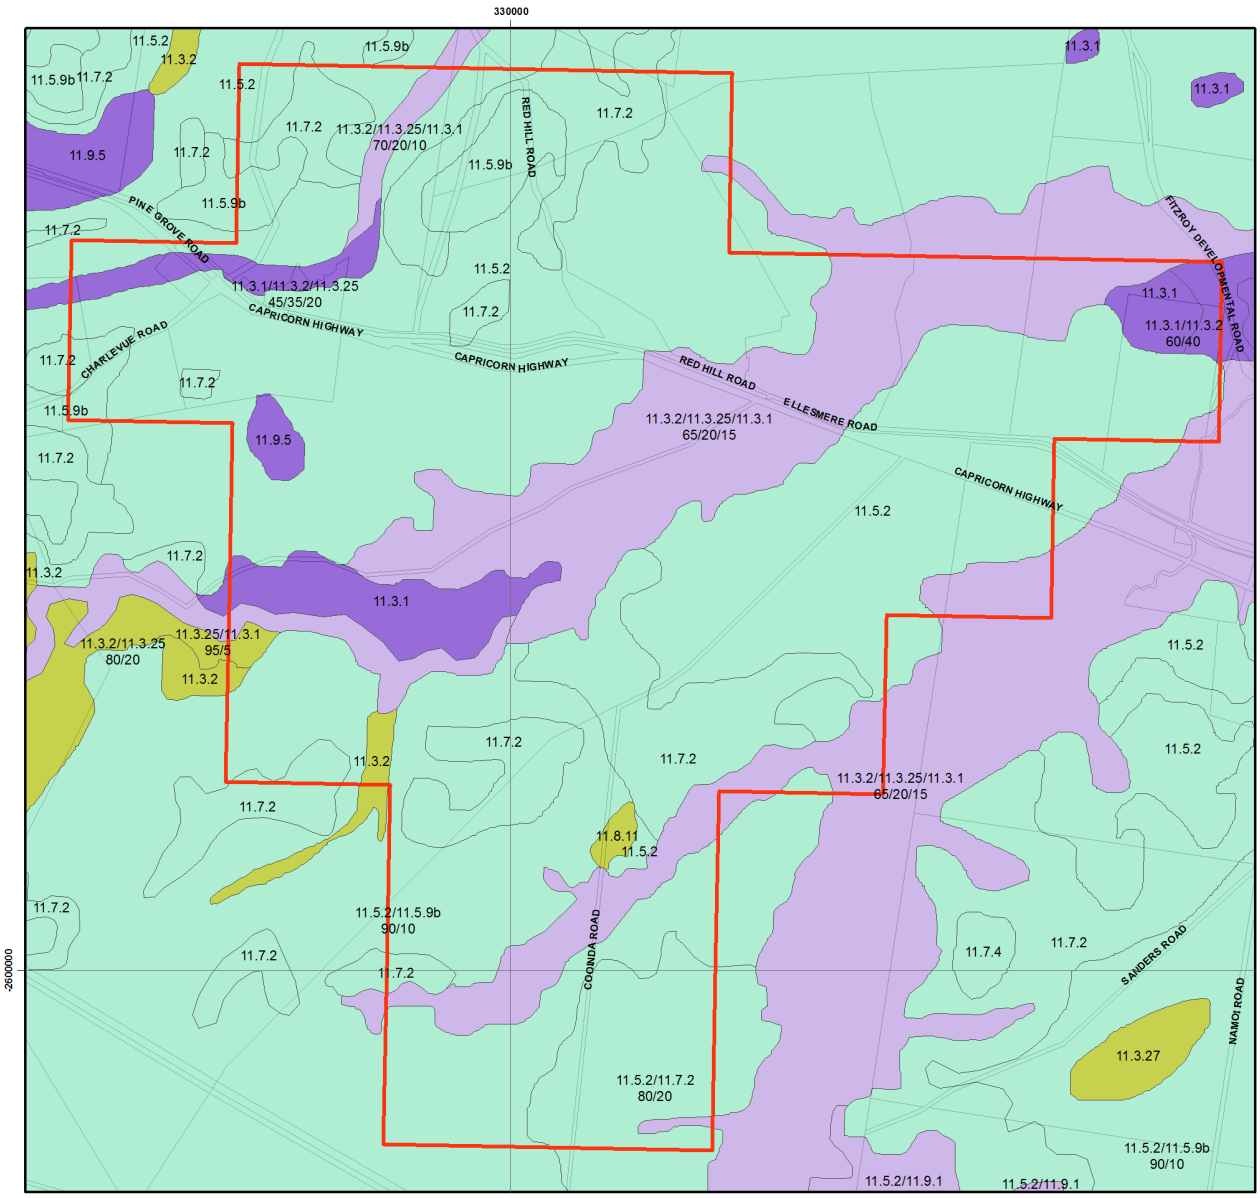
Biodiversity Status

- Selected Exploration Permit Coal (EPC)
- Endangered - Dominant vegetation
- Endangered - Sub-dominant
- Of Concern - Dominant
- Of Concern - Sub-dominant
- No concern at present
- Non-remnant vegetation, cultivated or built environment
- Plantation
- Water
- Cadastral Boundaries

This product is projected into GDA 1994 Queensland Albers

Regional ecosystem mapping over the majority of Queensland is produced at a scale of 1:100,000. At this scale, the minimum remnant polygon area is 5 hectares or minimum remnant width of 75 metres. Regional ecosystem linework reproduced at a scale greater than 1:100,000, except in designated areas, should be used as a guide only. The precision of polygon boundaries or positional accuracy of linework is 100 metres.

Regional ecosystems are defined as vegetation communities in a bioregion that are consistently associated with a particular combination of geology, landform and soil. The polygons are labelled by regional ecosystem (RE); where more than one RE occurs, the percentage of each is labelled. The label consists of 3 components: bioregion, land zone, and vegetation community – the dominant canopy species. e.g.: RE 12.3.3. Descriptions of REs are found online. Use the search term "Regional Ecosystem Framework".



Regional ecosystem mapping at 1:100,000 map scale is derived from the following sources: 1:80,000 B&W 1960's aerial photography, Landsat TM imagery, geology, soils, land systems data, field survey and historical records.

Remnant woody vegetation is defined as vegetation that has not been cleared or vegetation that has been cleared but where the dominant canopy has >70% of the height and >50% of the cover relative to the undisturbed height and cover of that stratum and is dominated by species characteristic of the vegetation's undisturbed canopy.

Non-remnant vegetation includes regrowth and disturbed native vegetation.

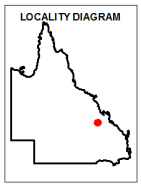

Map 4 - Remnant regional ecosystems by BVG (5M)

Remnant 2015 Regional Ecosystems coloured by Broad Vegetation Groups

Broad Vegetation Groups
BVG5M Description (BVG1M codes)

- Selected Exploration Permit Coal (EPC)
- 1. Rainforests and scrubs (1-7b)
- 2. Wet eucalypt open forests (8-8b)
- 3. Eucalypt woodlands to open forests (mainly eastern Qld) (9-15b)
- 4. Eucalypt open forests to woodlands on floodplains (16-16d)
- 5. Eucalypt dry woodlands on inland depositional plains (17-18d)
- 6. Eucalypt low open woodlands usually with spinifex understorey (19-19d)
- 7. Callitris woodland - open forests (20a)
- 8. Melaleuca open woodlands on depositional plains (21-22c)
- 9. Acacia aneura (mulga) dominated open forests, woodlands and shrublands (23-23b)
- 10. Other acacia dominated open forests, woodlands and shrublands (24-26a)
- 11. Mixed species woodlands, open woodland - (inland bioregions) includes wooded downs (27-27c)
- 12. Other coastal communities or heaths (28-29b)
- 13. Tussock grasslands, forblands (30-32b)
- 14. Hummock grasslands (33-33b)
- 15. Wetlands (swamps and lakes) (34-34g)
- 16. Mangroves and saltmarshes (35-35b)
- Non-remnant vegetation, cultivated or built environment
- Water
- Cadastral Boundaries

Accuracy information: The positional accuracy of wetland data mapped at a scale of 1:100,000 is +/-100m with a minimum polygon size of 5ha or 75m wide for linear features, except for areas along the east coa st which are mapped at the 1:50,000 scale with a positional accuracy of +/-50m, with a minimum polygon size of 1ha or 35m wide for linear features. Wetlands smaller than 1ha are not delineated on the wetland data. Consideration of the effects of mapped scale is necessary when interpret ing data at a larger scale, e.g. 1:25,000. For property assessment, digital linework should be used as a guide only. The extent of wetlands depicted on this map is based on rectified 2013 Landsat ETM+ imagery supplied by Statewide Landcover and Trees Study (SLATS), Department of Science, Information Technology and Innovation (DSITI). The extent of water bodies is based on the maximum extent of inundation derived from available Landsat imagery up to and including the 2013 imagery.

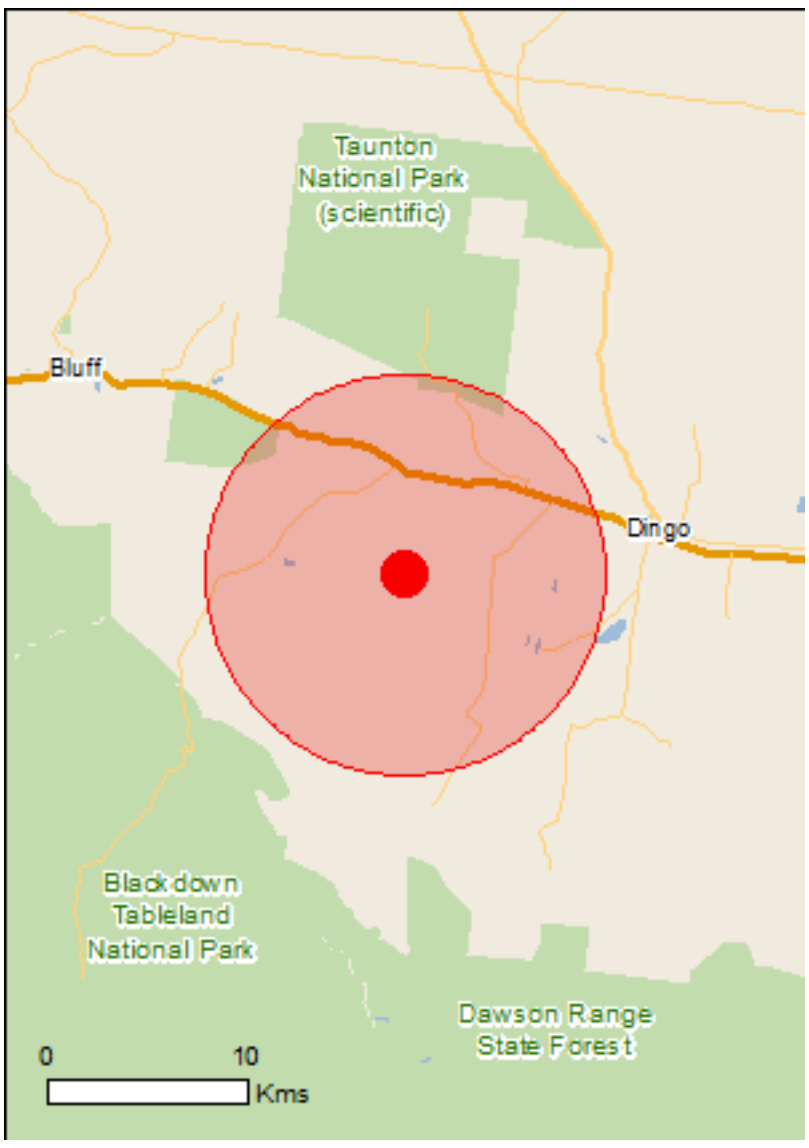
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.



Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 03/06/19 10:44:27

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	3
Listed Threatened Species:	25
Listed Migratory Species:	12

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	18
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	2
Regional Forest Agreements:	None
Invasive Species:	21
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Brigalow (Acacia harpophylla dominant and co-dominant)	Endangered	Community known to occur within area
Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	Endangered	Community may occur within area
Weeping Myall Woodlands	Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Geophaps scripta scripta Squatter Pigeon (southern) [64440]	Vulnerable	Species or species habitat known to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Neochmia ruficauda ruficauda Star Finch (eastern), Star Finch (southern) [26027]	Endangered	Species or species habitat likely to occur within area
Poephila cincta cincta Southern Black-throated Finch [64447]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species habitat may occur within area
Fish		
Maccullochella peelii Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Mammals		

Name	Status	Type of Presence
Chalinolobus dwyeri Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat may occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Nyctophilus corbeni Corben's Long-eared Bat, South-eastern Long-eared Bat [83395]	Vulnerable	Species or species habitat may occur within area
Onychogalea fraenata Bridled Nail-tail Wallaby, Bridled Nailtail Wallaby [239]	Endangered	Species or species habitat known to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat likely to occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT) Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat likely to occur within area
Plants		
Cadellia pentastylis Ooline [9828]	Vulnerable	Species or species habitat likely to occur within area
Dichanthium setosum bluegrass [14159]	Vulnerable	Species or species habitat likely to occur within area
Logania diffusa [24159]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat likely to occur within area
Denisonia maculata Ornamental Snake [1193]	Vulnerable	Species or species habitat may occur within area
Egernia rugosa Yakka Skink [1420]	Vulnerable	Species or species habitat may occur within area
Elseya albagula Southern Snapping Turtle, White-throated Snapping Turtle [81648]	Critically Endangered	Species or species habitat likely to occur within area
Furina dunmalli Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Rheodytes leukops Fitzroy River Turtle, Fitzroy Tortoise, Fitzroy Turtle, White-eyed River Diver [1761]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		

Name	Threatened	Type of Presence
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Cuculus optatus		
Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area
Monarcha melanopsis		
Black-faced Monarch [609]		Species or species habitat likely to occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca		
Satin Flycatcher [612]		Species or species habitat may occur within area
Rhipidura rufifrons		
Rufous Fantail [592]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Gallinago hardwickii		
Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Extra Information

State and Territory Reserves [Resource Information]

Name	State
Taunton	QLD
Wallaby Lane	QLD

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Acacia nilotica subsp. indica Prickly Acacia [6196]		Species or species habitat may occur within area
Cryptostegia grandiflora Rubber Vine, Rubbervine, India Rubber Vine, India Rubbervine, Palay Rubbervine, Purple Allamanda [18913]		Species or species habitat likely to occur within area
Jatropha gossypifolia Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Parthenium hysterophorus Parthenium Weed, Bitter Weed, Carrot Grass, False Ragweed [19566]		Species or species habitat likely to occur within area
Vachellia nilotica Prickly Acacia, Blackthorn, Prickly Mimosa, Black Piquant, Babul [84351]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

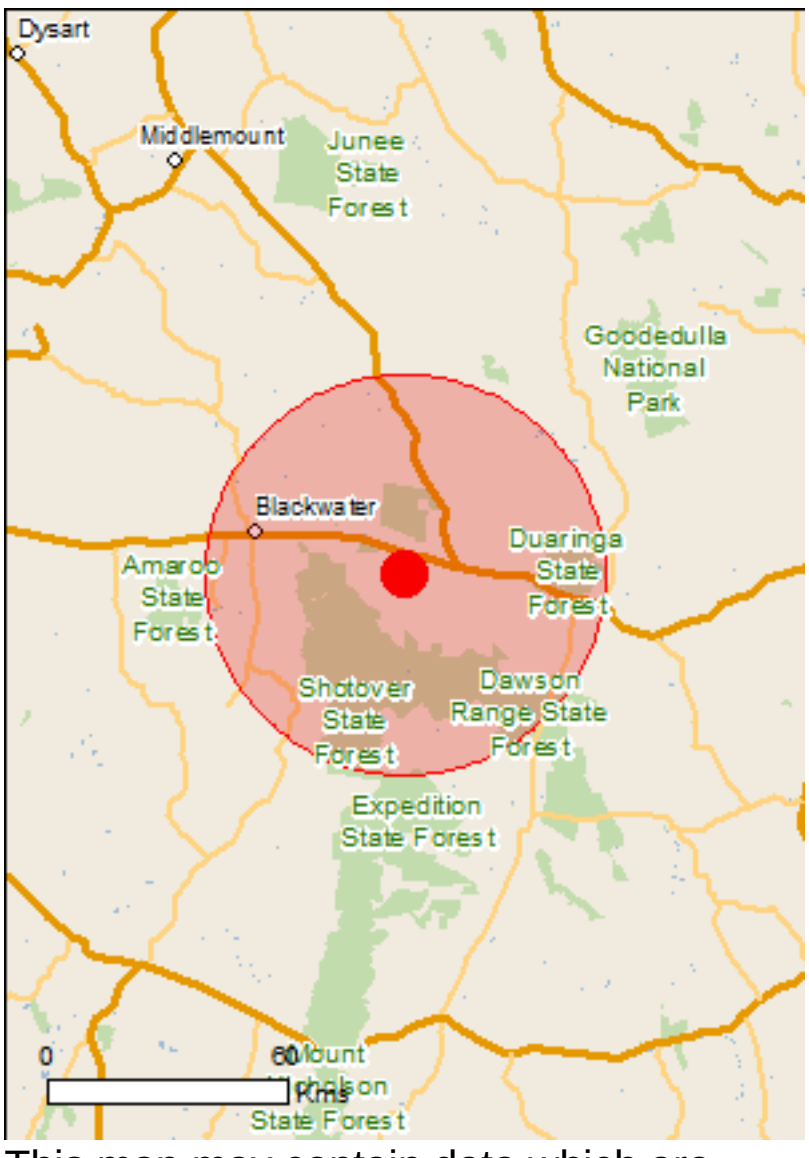
EPBC Act Protected Matters Report

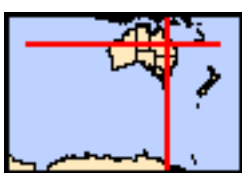
This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.



Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 03/06/19 09:45:56



Summary

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	5
Listed Threatened Species:	39
Listed Migratory Species:	16

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	1
Commonwealth Heritage Places:	None
Listed Marine Species:	22
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	5
Regional Forest Agreements:	None
Invasive Species:	27
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Brigalow (Acacia harpophylla dominant and co-dominant)	Endangered	Community known to occur within area
Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	Endangered	Community may occur within area
Natural Grasslands of the Queensland Central Highlands and northern Fitzroy Basin	Endangered	Community likely to occur within area
Semi-evergreen vine thickets of the Brigalow Belt (North and South) and Nandewar Bioregions	Endangered	Community likely to occur within area
Weeping Myall Woodlands	Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Geophaps scripta scripta Squatter Pigeon (southern) [64440]	Vulnerable	Species or species habitat known to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Neochmia ruficauda ruficauda Star Finch (eastern), Star Finch (southern) [26027]	Endangered	Species or species habitat likely to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Poephila cincta cincta Southern Black-throated Finch [64447]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Fish		
Maccullochella peelii		
Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Mammals		
Chalinolobus dwyeri		
Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat likely to occur within area
Dasyurus hallucatus		
Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Macroderma gigas		
Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Nyctophilus corbeni		
Corben's Long-eared Bat, South-eastern Long-eared Bat [83395]	Vulnerable	Species or species habitat may occur within area
Onychogalea fraenata		
Bridled Nail-tail Wallaby, Bridled Nailtail Wallaby [239]	Endangered	Species or species habitat known to occur within area
Petauroides volans		
Greater Glider [254]	Vulnerable	Species or species habitat known to occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT)		
Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Pteropus poliocephalus		
Grey-headed Flying-fox [186]	Vulnerable	Foraging, feeding or related behaviour may occur within area
Plants		
Acacia grandifolia		
[3566]	Vulnerable	Species or species habitat known to occur within area
Aristida annua		
[17906]	Vulnerable	Species or species habitat likely to occur within area
Bertya opponens		
[13792]	Vulnerable	Species or species habitat likely to occur within area
Cadellia pentastylis		
Ooline [9828]	Vulnerable	Species or species habitat likely to occur within area
Cycas ophiolitica		
[55797]	Endangered	Species or species habitat likely to occur within area
Daviesia discolor		
[3567]	Vulnerable	Species or species habitat likely to occur within area
Dichanthium queenslandicum		
King Blue-grass [5481]	Endangered	Species or species habitat may occur within area
Dichanthium setosum		
bluegrass [14159]	Vulnerable	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Eucalyptus raveretiana Black Ironbox [16344]	Vulnerable	Species or species habitat likely to occur within area
Homoranthus decumbens a shrub [55186]	Endangered	Species or species habitat known to occur within area
Logania diffusa [24159]	Vulnerable	Species or species habitat likely to occur within area
Macrozamia platyrhachis cycad [3412]	Endangered	Species or species habitat likely to occur within area
Phaius australis Lesser Swamp-orchid [5872]	Endangered	Species or species habitat known to occur within area
Solanum dissectum [75720]	Endangered	Species or species habitat known to occur within area
Solanum johnsonianum [84820]	Endangered	Species or species habitat may occur within area
Reptiles		
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat known to occur within area
Denisonia maculata Ornamental Snake [1193]	Vulnerable	Species or species habitat known to occur within area
Egernia rugosa Yakka Skink [1420]	Vulnerable	Species or species habitat known to occur within area
Elseya albagula Southern Snapping Turtle, White-throated Snapping Turtle [81648]	Critically Endangered	Species or species habitat known to occur within area
Furina dunmalli Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Rheodytes leukops Fitzroy River Turtle, Fitzroy Tortoise, Fitzroy Turtle, White-eyed River Diver [1761]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Marine Species		
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Hirundapus caudacutus		
White-throated Needletail [682]		Species or species habitat known to occur within area
Monarcha melanopsis		
Black-faced Monarch [609]		Species or species habitat likely to occur within area
Monarcha trivirgatus		
Spectacled Monarch [610]		Species or species habitat may occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca		
Satin Flycatcher [612]		Species or species habitat may occur within area
Rhipidura rufifrons		
Rufous Fantail [592]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]		Species or species habitat likely to occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Gallinago hardwickii		
Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Defence - BLACKWATER TRAINING DEPOT

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		

Name	Threatened	Type of Presence
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Anseranas semipalmata Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Breeding known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat likely to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Chrysococcyx osculans Black-eared Cuckoo [705]		Species or species habitat likely to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Species or species habitat may occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat likely to occur within area
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat known to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat likely to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species

Name	Threatened	Type of Presence
		habitat likely to occur within area
[Rhipidura rufifrons](#) Rufous Fantail [592]		Species or species habitat may occur within area
[Rostratula benghalensis (sensu lato)](#) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Reptiles		
[Crocodylus porosus](#) Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area

Extra Information

State and Territory Reserves [Resource Information]

Name	State
Blackdown Tableland	QLD
Blackwater	QLD
Ghungalu	QLD
Taunton	QLD
Wallaby Lane	QLD

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Acacia nilotica subsp. indica Prickly Acacia [6196]		Species or species habitat may occur within area
Cryptostegia grandiflora Rubber Vine, Rubbervine, India Rubber Vine, India Rubbervine, Palay Rubbervine, Purple Allamanda [18913]		Species or species habitat likely to occur within area
Hymenachne amplexicaulis Hymenachne, Olive Hymenachne, Water Stargrass, West Indian Grass, West Indian Marsh Grass [31754]		Species or species habitat likely to occur within area
Jatropha gossypifolia Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Lantana camara Lantana, Common Lantana, Kamara Lantana, Large-leaf Lantana, Pink Flowered Lantana, Red Flowered Lantana, Red-Flowered Sage, White Sage, Wild Sage [10892]		Species or species habitat likely to occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Parthenium hysterophorus Parthenium Weed, Bitter Weed, Carrot Grass, False Ragweed [19566]		Species or species habitat likely to occur within area
Prosopis spp. Mesquite, Algaroba [68407]		Species or species habitat likely to occur within area
Salvinia molesta Salvinia, Giant Salvinia, Aquarium Watermoss, Kariba Weed [13665]		Species or species habitat likely to occur within area
Tamarix aphylla Athel Pine, Athel Tree, Tamarisk, Athel Tamarisk, Athel Tamarix, Desert Tamarisk, Flowering		Species or species habitat likely to occur

Name	Status	Type of Presence
Cypress, Salt Cedar [16018] Vachellia nilotica		within area
Prickly Acacia, Blackthorn, Prickly Mimosa, Black Piquant, Babul [84351]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
animals	amphibians	Bufonidae	*Rhinella marina*	cane toad	Y			4
animals	amphibians	Hylidae	*Litoria latopalmata*	broad palmed rocketfrog		C		1
animals	amphibians	Hylidae	*Cyclorana alboguttata*	greenstripe frog		C		1
animals	amphibians	Hylidae	*Litoria caerulea*	common green treefrog		C		1
animals	amphibians	Limnodynastidae	*Limnodynastes tasmaniensis*	spotted grassfrog		C		1
animals	amphibians	Limnodynastidae	*Limnodynastes salmini*	salmon striped frog		C		1
animals	amphibians	Limnodynastidae	*Platyplectrum ornatum*	ornate burrowing frog		C		5
animals	birds	Acanthizidae	*Acanthiza nana*	yellow thornbill		C		1
animals	birds	Acanthizidae	*Smicrornis brevirostris*	weebill		C		3
animals	birds	Acanthizidae	*Gerygone olivacea*	white-throated gerygone		C		7
animals	birds	Accipitridae	*Milvus migrans*	black kite		C		1
animals	birds	Accipitridae	*Haliastur sphenurus*	whistling kite		C		3
animals	birds	Accipitridae	*Aquila audax*	wedge-tailed eagle		C		6
animals	birds	Aegothelidae	*Aegotheles cristatus*	Australian owlet-nightjar		C		2
animals	birds	Alaudidae	*Mirafra javanica*	Horsfield's bushlark		C		1
animals	birds	Anatidae	*Anas gracilis*	grey teal		C		1
animals	birds	Anatidae	*Cygnus atratus*	black swan		C		1
animals	birds	Anatidae	*Anas rhynchotis*	Australasian shoveler		C		1
animals	birds	Anatidae	*Aythya australis*	hardhead		C		2
animals	birds	Anatidae	*Dendrocygna arcuata*	wandering whistling-duck		C		1
animals	birds	Anatidae	*Anas superciliosa*	Pacific black duck		C		3
animals	birds	Anatidae	*Chenonetta jubata*	Australian wood duck		C		1
animals	birds	Anhingidae	*Anhinga novaehollandiae*	Australasian darter		C		1
animals	birds	Anseranatidae	*Anseranas semipalmata*	magpie goose		C		1
animals	birds	Ardeidae	*Egretta novaehollandiae*	white-faced heron		C		1
animals	birds	Ardeidae	*Nycticorax caledonicus*	nankeen night-heron		C		1
animals	birds	Ardeidae	*Ardea alba modesta*	eastern great egret		C		1
animals	birds	Ardeidae	*Ardea intermedia*	intermediate egret		C		1
animals	birds	Ardeidae	*Bubulcus ibis*	cattle egret		C		1
animals	birds	Ardeidae	*Ardea pacifica*	white-necked heron		C		2
animals	birds	Artamidae	*Cracticus tibicen*	Australian magpie		C		10
animals	birds	Artamidae	*Cracticus torquatus*	grey butcherbird		C		6
animals	birds	Artamidae	*Artamus leucorynchus*	white-breasted woodswallow		C		1
animals	birds	Artamidae	*Cracticus nigrogularis*	pied butcherbird		C		8
animals	birds	Artamidae	*Artamus cinereus*	black-faced woodswallow		C		3
animals	birds	Cacatuidae	*Cacatua galerita*	sulphur-crested cockatoo		C		3
animals	birds	Cacatuidae	*Eolophus roseicapilla*	galah		C		2
animals	birds	Cacatuidae	*Calyptorhynchus banksii*	red-tailed black-cockatoo		C		1
animals	birds	Campephagidae	*Lalage tricolor*	white-winged triller		C		1
animals	birds	Campephagidae	*Coracina novaehollandiae*	black-faced cuckoo-shrike		C		6
animals	birds	Campephagidae	*Coracina papuensis*	white-bellied cuckoo-shrike		C		1
animals	birds	Casuariidae	*Dromaius novaehollandiae*	emu		C		1
animals	birds	Charadriidae	*Vanellus miles*	masked lapwing		C		1
animals	birds	Charadriidae	*Elseyornis melanops*	black-fronted dotterel		C		2
animals	birds	Columbidae	*Ocyphaps lophotes*	crested pigeon		C		4
animals	birds	Columbidae	*Geophaps scripta scripta*	squatter pigeon (southern subspecies)		V	V	8

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
animals	birds	Columbidae	*Geopelia humeralis*	bar-shouldered dove		C		4
animals	birds	Columbidae	*Phaps chalcoptera*	common bronzewing		C		2
animals	birds	Columbidae	*Geopelia striata*	peaceful dove		C		5
animals	birds	Columbidae	*Geopelia cuneata*	diamond dove		C		1
animals	birds	Coraciidae	*Eurystomus orientalis*	dollarbird		C		3
animals	birds	Corcoracidae	*Struthidea cinerea*	apostlebird		C		5
animals	birds	Corcoracidae	*Corcorax melanorhamphos*	white-winged chough		C		2
animals	birds	Corvidae	*Corvus coronoides*	Australian raven		C		3
animals	birds	Corvidae	*Corvus orru*	Torresian crow		C		9
animals	birds	Cuculidae	*Chalcites basalis*	Horsfield's bronze-cuckoo		C		1
animals	birds	Cuculidae	*Chalcites lucidus*	shining bronze-cuckoo		C		1
animals	birds	Cuculidae	*Scythrops novaehollandiae*	channel-billed cuckoo		C		1
animals	birds	Cuculidae	*Cacomantis pallidus*	pallid cuckoo		C		1
animals	birds	Cuculidae	*Centropus phasianinus*	pheasant coucal		C		3
animals	birds	Cuculidae	*Eudynamys orientalis*	eastern koel		C		1
animals	birds	Dicruridae	*Dicrurus bracteatus*	spangled drongo		C		1
animals	birds	Estrildidae	*Taeniopygia guttata*	zebra finch		C		1
animals	birds	Estrildidae	*Taeniopygia bichenovii*	double-barred finch		C		9
animals	birds	Eurostopodidae	*Eurostopodus mystacalis*	white-throated nightjar		C		1
animals	birds	Falconidae	*Falco cenchroides*	nankeen kestrel		C		2
animals	birds	Falconidae	*Falco berigora*	brown falcon		C		4
animals	birds	Gruidae	*Grus rubicunda*	brolga		C		3
animals	birds	Halcyonidae	*Dacelo novaeguineae*	laughing kookaburra		C		7
animals	birds	Halcyonidae	*Todiramphus macleayii*	forest kingfisher		C		2
animals	birds	Halcyonidae	*Dacelo leachii*	blue-winged kookaburra		C		2
animals	birds	Halcyonidae	*Todiramphus pyrrhopygius*	red-backed kingfisher		C		1
animals	birds	Halcyonidae	*Todiramphus sanctus*	sacred kingfisher		C		1
animals	birds	Hirundinidae	*Petrochelidon nigricans*	tree martin		C		2
animals	birds	Hirundinidae	*Hirundo neoxena*	welcome swallow		C		1
animals	birds	Jacanidae	*Irediparra gallinacea*	comb-crested jacana		C		1
animals	birds	Maluridae	*Malurus cyaneus*	superb fairy-wren		C		1
animals	birds	Maluridae	*Malurus melanocephalus*	red-backed fairy-wren		C		7
animals	birds	Maluridae	*Malurus lamberti*	variegated fairy-wren		C		2
animals	birds	Megaluridae	*Cincloramphus mathewsi*	rufous songlark		C		1
animals	birds	Meliphagidae	*Manorina flavigula*	yellow-throated miner		C		3
animals	birds	Meliphagidae	*Gavicalis virescens*	singing honeyeater		C		3
animals	birds	Meliphagidae	*Lichmera indistincta*	brown honeyeater		C		3
animals	birds	Meliphagidae	*Philemon corniculatus*	noisy friarbird		C		7
animals	birds	Meliphagidae	*Ptilotula penicillata*	white-plumed honeyeater		C		1
animals	birds	Meliphagidae	*Manorina melanocephala*	noisy miner		C		5
animals	birds	Meliphagidae	*Myzomela sanguinolenta*	scarlet honeyeater		C		1
animals	birds	Meliphagidae	*Philemon citreogularis*	little friarbird		C		7
animals	birds	Meliphagidae	*Melithreptus albogularis*	white-throated honeyeater		C		11
animals	birds	Meliphagidae	*Plectorhyncha lanceolata*	striped honeyeater		C		2
animals	birds	Meliphagidae	*Entomyzon cyanotis*	blue-faced honeyeater		C		7
animals	birds	Meropidae	*Merops ornatus*	rainbow bee-eater		C		11

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
animals	birds	Monarchidae	*Grallina cyanoleuca*	magpie-lark		C		11
animals	birds	Monarchidae	*Myiagra inquieta*	restless flycatcher		C		3
animals	birds	Monarchidae	*Myiagra rubecula*	leaden flycatcher		C		3
animals	birds	Motacillidae	*Anthus novaeseelandiae*	Australasian pipit		C		2
animals	birds	Nectariniidae	*Dicaeum hirundinaceum*	mistletoebird		C		2
animals	birds	Neosittidae	*Daphoenositta chrysoptera*	varied sittella		C		1
animals	birds	Oriolidae	*Oriolus sagittatus*	olive-backed oriole		C		7
animals	birds	Oriolidae	*Sphecotheres vieilloti*	Australasian figbird		C		2
animals	birds	Otididae	*Ardeotis australis*	Australian bustard		C		5
animals	birds	Pachycephalidae	*Pachycephala rufiventris*	rufous whistler		C		5
animals	birds	Pachycephalidae	*Colluricincla megarhyncha*	little shrike-thrush		C		1
animals	birds	Pachycephalidae	*Colluricincla harmonica*	grey shrike-thrush		C		6
animals	birds	Pardalotidae	*Pardalotus striatus*	striated pardalote		C		11/1
animals	birds	Pelecanidae	*Pelecanus conspicillatus*	Australian pelican		C		1
animals	birds	Petroicidae	*Eopsaltria australis*	eastern yellow robin		C		1
animals	birds	Petroicidae	*Microeca fascinans*	jacky winter		C		4
animals	birds	Phalacrocoracidae	*Phalacrocorax varius*	pied cormorant		C		1
animals	birds	Phalacrocoracidae	*Microcarbo melanoleucos*	little pied cormorant		C		1
animals	birds	Phalacrocoracidae	*Phalacrocorax sulcirostris*	little black cormorant		C		1
animals	birds	Phasianidae	*Coturnix ypsilophora*	brown quail		C		1
animals	birds	Podicipedidae	*Tachybaptus novaehollandiae*	Australasian grebe		C		3
animals	birds	Podicipedidae	*Podiceps cristatus*	great crested grebe		C		1
animals	birds	Pomatostomidae	*Pomatostomus temporalis*	grey-crowned babbler		C		4
animals	birds	Psittacidae	*Trichoglossus chlorolepidotus*	scaly-breasted lorikeet		C		2
animals	birds	Psittacidae	*Trichoglossus haematodus moluccanus*	rainbow lorikeet		C		8
animals	birds	Psittacidae	*Aprosmictus erythropterus*	red-winged parrot		C		2
animals	birds	Psittacidae	*Melopsittacus undulatus*	budgerigar		C		1
animals	birds	Psittacidae	*Platycercus adscitus*	pale-headed rosella		C		7
animals	birds	Ptilonorhynchidae	*Ptilonorhynchus maculatus*	spotted bowerbird		C		5
animals	birds	Rallidae	*Porphyrio melanotus*	purple swamphen		C		1
animals	birds	Rallidae	*Fulica atra*	Eurasian coot		C		1
animals	birds	Rallidae	*Gallinula tenebrosa*	dusky moorhen		C		1
animals	birds	Recurvirostridae	*Himantopus himantopus*	black-winged stilt		C		1
animals	birds	Rhipiduridae	*Rhipidura leucophrys*	willie wagtail		C		10
animals	birds	Rhipiduridae	*Rhipidura albiscapa*	grey fantail		C		6
animals	birds	Strigidae	*Ninox boobook*	southern boobook		C		1
animals	birds	Threskiornithidae	*Threskiornis spinicollis*	straw-necked ibis		C		4
animals	birds	Threskiornithidae	*Threskiornis molucca*	Australian white ibis		C		1
animals	birds	Threskiornithidae	*Platalea regia*	royal spoonbill		C		1
animals	birds	Threskiornithidae	*Platalea flavipes*	yellow-billed spoonbill		C		1
animals	birds	Timaliidae	*Zosterops lateralis*	silvereye		C		1
animals	birds	Tytonidae	*Tyto delicatula*	eastern barn owl		C		3
animals	mammals	Bovidae	*Bos taurus*	European cattle	Y			1
animals	mammals	Canidae	*Vulpes vulpes*	red fox	Y			1
animals	mammals	Canidae	*Canis lupus dingo*	dingo				6
animals	mammals	Equidae	*Equus caballus*	horse	Y			1

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
animals	mammals	Felidae	*Felis catus*	cat	Y			3
animals	mammals	Hipposideridae	*Hipposideros ater aruensis*	eastern dusky leaf-nosed bat		C		1
animals	mammals	Leporidae	*Oryctolagus cuniculus*	rabbit	Y			2
animals	mammals	Leporidae	*Lepus europaeus*	European brown hare	Y			2
animals	mammals	Macropodidae	*Macropus dorsalis*	black-striped wallaby		C		5
animals	mammals	Macropodidae	*Onychogalea fraenata*	bridled nailtail wallaby		E	E	13
animals	mammals	Macropodidae	*Macropus giganteus*	eastern grey kangaroo		C		2
animals	mammals	Macropodidae	*Macropus robustus*	common wallaroo		C		1
animals	mammals	Macropodidae	*Wallabia bicolor*	swamp wallaby		C		1
animals	mammals	Miniopteridae	*Miniopterus schreibersii oceanensis*	eastern bent-wing bat		C		1
animals	mammals	Muridae	*Mus musculus*	house mouse	Y			5
animals	mammals	Muridae	*Pseudomys delicatulus*	delicate mouse		C		1
animals	mammals	Peramelidae	*Perameles nasuta*	long-nosed bandicoot		C		1
animals	mammals	Phalangeridae	*Trichosurus vulpecula*	common brushtail possum		C		4
animals	mammals	Phascolarctidae	*Phascolarctos cinereus*	koala		V	V	1
animals	mammals	Potoroidae	*Aepyprymnus rufescens*	rufous bettong		C		2
animals	mammals	Pseudocheiridae	*Petauroides volans volans*	southern greater glider		V	V	2
animals	mammals	Suidae	*Sus scrofa*	pig	Y			1
animals	mammals	Tachyglossidae	*Tachyglossus aculeatus*	short-beaked echidna		SL		4
animals	mammals	Vespertilionidae	*Nyctophilus gouldi*	Gould's long-eared bat		C		1
animals	mammals	Vespertilionidae	*Myotis macropus*	large-footed myotis		C		2
animals	ray-finned fishes	Terapontidae	*Leiopotherapon unicolor*	spangled perch				1
animals	reptiles	Agamidae	*Pogona barbata*	bearded dragon		C		2/1
animals	reptiles	Agamidae	*Diporiphora australis*	tommy roundhead		C		1/1
animals	reptiles	Boidae	*Aspidites melanocephalus*	black-headed python		C		1
animals	reptiles	Carphodactylidae	*Nephrurus asper*	spiny knob-tailed gecko		C		2/1
animals	reptiles	Diplodactylidae	*Lucasium steindachneri*	Steindachner's gecko		C		1
animals	reptiles	Diplodactylidae	*Oedura monilis*	ocellated velvet gecko		C		1/1
animals	reptiles	Diplodactylidae	*Strophurus taenicauda*	golden-tailed gecko		NT		3
animals	reptiles	Elapidae	*Demansia vestigiata*	lesser black whipsnake		C		2
animals	reptiles	Elapidae	*Demansia psammophis*	yellow-faced whipsnake		C		1
animals	reptiles	Elapidae	*Hoplocephalus bitorquatus*	pale-headed snake		C		1/1
animals	reptiles	Gekkonidae	*Gehyra catenata*	chain-backed dtella		C		1/1
animals	reptiles	Gekkonidae	*Gehyra dubia*	dubious dtella		C		32
animals	reptiles	Gekkonidae	*Heteronotia binoei*	Bynoe's gecko		C		6
animals	reptiles	Pygopodidae	*Lialis burtonis*	Burton's legless lizard		C		2
animals	reptiles	Scincidae	*Cryptoblepharus pulcher pulcher*	elegant snake-eyed skink		C		1
animals	reptiles	Scincidae	*Cryptoblepharus virgatus sensu lato*			C		1
animals	reptiles	Scincidae	*Carlia pectoralis sensu lato*			C		2/1
animals	reptiles	Scincidae	*Cryptoblepharus australis*	inland snake-eyed skink		C		1
animals	reptiles	Scincidae	*Cyclodomorphus gerrardii*	pink-tongued lizard		C		1
animals	reptiles	Scincidae	*Morethia taeniopleura*	fire-tailed skink		C		2
animals	reptiles	Scincidae	*Ctenotus taeniolatus*	copper-tailed skink		C		1
animals	reptiles	Scincidae	*Concinnia brachysoma*	northern bar-sided skink		C		1/1
animals	reptiles	Scincidae	*Morethia boulengeri*	south-eastern morethia skink		C		1
animals	reptiles	Scincidae	*Lygisaurus foliorum*	tree-base litter-skink		C		1

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
animals	reptiles	Scincidae	*Lerista fragilis*	eastern mulch slider		C		2
animals	reptiles	Scincidae	*Carlia rubigo*	orange-flanked rainbow skink		C		6
animals	reptiles	Scincidae	*Carlia vivax*	tussock rainbow-skink		C		1
plants	Equisetopsida	Acanthaceae	*Pseuderanthemum variabile*	pastel flower		C		1
plants	Equisetopsida	Amaranthaceae	*Alternanthera pungens*	khaki weed	Y			1/1
plants	Equisetopsida	Amaranthaceae	*Ptilotus polystachyus*			C		1/1
plants	Equisetopsida	Amaryllidaceae	*Crinum flaccidum*	Murray lily		C		1
plants	Equisetopsida	Apocynaceae	*Carissa ovata*	currantbush		C		20
plants	Equisetopsida	Apocynaceae	*Cerbera dumicola*			NT		2/2
plants	Equisetopsida	Apocynaceae	*Alstonia constricta*	bitterbark		C		10/1
plants	Equisetopsida	Apocynaceae	*Parsonsia straminea*	monkey rope		C		6
plants	Equisetopsida	Apocynaceae	*Cryptostegia grandiflora*	rubber vine	Y			1
plants	Equisetopsida	Apocynaceae	*Parsonsia eucalyptophylla*	gargaloo		C		1
plants	Equisetopsida	Asteraceae	*Blumea saxatilis*			C		1/1
plants	Equisetopsida	Asteraceae	*Parthenium hysterophorus*	parthenium weed	Y			1
plants	Equisetopsida	Asteraceae	*Cyanthillium cinereum*			C		5
plants	Equisetopsida	Asteraceae	*Coronidium glutinosum*			C		2/2
plants	Equisetopsida	Boraginaceae	*Ehretia membranifolia*	weeping koda		C		2
plants	Equisetopsida	Cactaceae	*Harrisia martinii*		Y			1
plants	Equisetopsida	Cactaceae	*Opuntia tomentosa*	velvety tree pear	Y			2
plants	Equisetopsida	Caesalpiniaceae	*Lysiphyllum hookeri*	Queensland ebony		C		1
plants	Equisetopsida	Caesalpiniaceae	*Lysiphyllum carronii*	ebony tree		C		1
plants	Equisetopsida	Caesalpiniaceae	*Cassia brewsteri*			C		21/1
plants	Equisetopsida	Capparaceae	*Capparis*			C		1
plants	Equisetopsida	Capparaceae	*Capparis mitchellii*			C		1
plants	Equisetopsida	Capparaceae	*Capparis loranthifolia*			C		1
plants	Equisetopsida	Capparaceae	*Capparis lasiantha*	nipan		C		5/1
plants	Equisetopsida	Capparaceae	*Capparis canescens*			C		5
plants	Equisetopsida	Casuarinaceae	*Allocasuarina luehmannii*	bull oak		C		1
plants	Equisetopsida	Casuarinaceae	*Casuarina cunninghamiana subsp. cunninghamiana*			C		1/1
plants	Equisetopsida	Celastraceae	*Elaeodendron australe var. integrifolium*			C		1
plants	Equisetopsida	Chenopodiaceae	*Maireana*			C		2
plants	Equisetopsida	Chenopodiaceae	*Sclerolaena*			C		1/1
plants	Equisetopsida	Chenopodiaceae	*Salsola australis*			C		1
plants	Equisetopsida	Chenopodiaceae	*Enchylaena tomentosa*			C		1
plants	Equisetopsida	Chenopodiaceae	*Maireana microphylla*			C		2/2
plants	Equisetopsida	Clusiaceae	*Hypericum gramineum*			C		1
plants	Equisetopsida	Colchicaceae	*Iphigenia indica*			C		2/2
plants	Equisetopsida	Combretaceae	*Terminalia oblongata*			C		7
plants	Equisetopsida	Commelinaceae	*Commelina diffusa*	wandering jew		C		1
plants	Equisetopsida	Convolvulaceae	*Evolvulus alsinoides*			C		2
plants	Equisetopsida	Convolvulaceae	*Evolvulus alsinoides var. decumbens*			C		2
plants	Equisetopsida	Crassulaceae	*Bryophyllum x houghtonii*		Y			1/1
plants	Equisetopsida	Crassulaceae	*Bryophyllum delagoense*		Y			9
plants	Equisetopsida	Cupressaceae	*Callitris glaucophylla*	white cypress pine		C		1
plants	Equisetopsida	Cyperaceae	*Cyperaceae*			C		1

Kingdom	Class	Family	Scientific Name	Common Name	I	Q	A	Records
plants	Equisetopsida	Cyperaceae	*Cyperus fulvus*			C		1/1
plants	Equisetopsida	Cyperaceae	*Fimbristylis aestivalis*			C		1/1
plants	Equisetopsida	Cyperaceae	*Cyperus conicus*			C		1/1
plants	Equisetopsida	Cyperaceae	*Cyperus alterniflorus*			C		2/1
plants	Equisetopsida	Dipterocarpaceae	*Shorea*			C		1/1
plants	Equisetopsida	Erythroxylaceae	*Erythroxylum australe*	cocaine tree		C		18/2
plants	Equisetopsida	Euphorbiaceae	*Mallotus philippensis*	red kamala		C		1/1
plants	Equisetopsida	Euphorbiaceae	*Euphorbia tannensis subsp. eremophila*			C		2
plants	Equisetopsida	Fabaceae	*Daviesia filipes*			C		1/1
plants	Equisetopsida	Fabaceae	*Jacksonia scoparia*			C		1
plants	Equisetopsida	Fabaceae	*Medicago polymorpha*	burr medic	Y			1/1
plants	Equisetopsida	Fabaceae	*Stylosanthes scabra*		Y			4
plants	Equisetopsida	Fabaceae	*Hovea linearis x Hovea planifolia*			C		1/1
plants	Equisetopsida	Fabaceae	*Desmodium macrocarpum*			C		1
plants	Equisetopsida	Fabaceae	*Jacksonia rhadinoclona*	Miles dogwood		C		1
plants	Equisetopsida	Fabaceae	*Macroptilium atropurpureum*	siratro	Y			1
plants	Equisetopsida	Fabaceae	*Daviesia filipes subsp. filipes*			C		1/1
plants	Equisetopsida	Fabaceae	*Crotalaria verrucosa*			C		1/1
plants	Equisetopsida	Goodeniaceae	*Goodenia rotundifolia*			C		2

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

CODES

I - Y indicates that the taxon is introduced to Queensland and has naturalised.

Q - Indicates the Queensland conservation status of each taxon under the *Nature Conservation Act 1992.* The codes are Extinct in the Wild (PE), Endangered (E), Vulnerable (V), Near Threatened (NT), Least Concern (C) or Not Protected ( ).

A - Indicates the Australian conservation status of each taxon under the *Environment Protection and Biodiversity Conservation Act 1999.* The values of EPBC are Conservation Dependent (CD), Critically Endangered (CE), Endangered (E), Extinct (EX), Extinct in the Wild (XW) and Vulnerable (V).

Records – The first number indicates the total number of records of the taxon for the record option selected (i.e. All, Confirmed or Specimens).
This number is output as 99999 if it equals or exceeds this value. The second number located after the / indicates the number of specimen records for the taxon.
This number is output as 999 if it equals or exceeds this value.

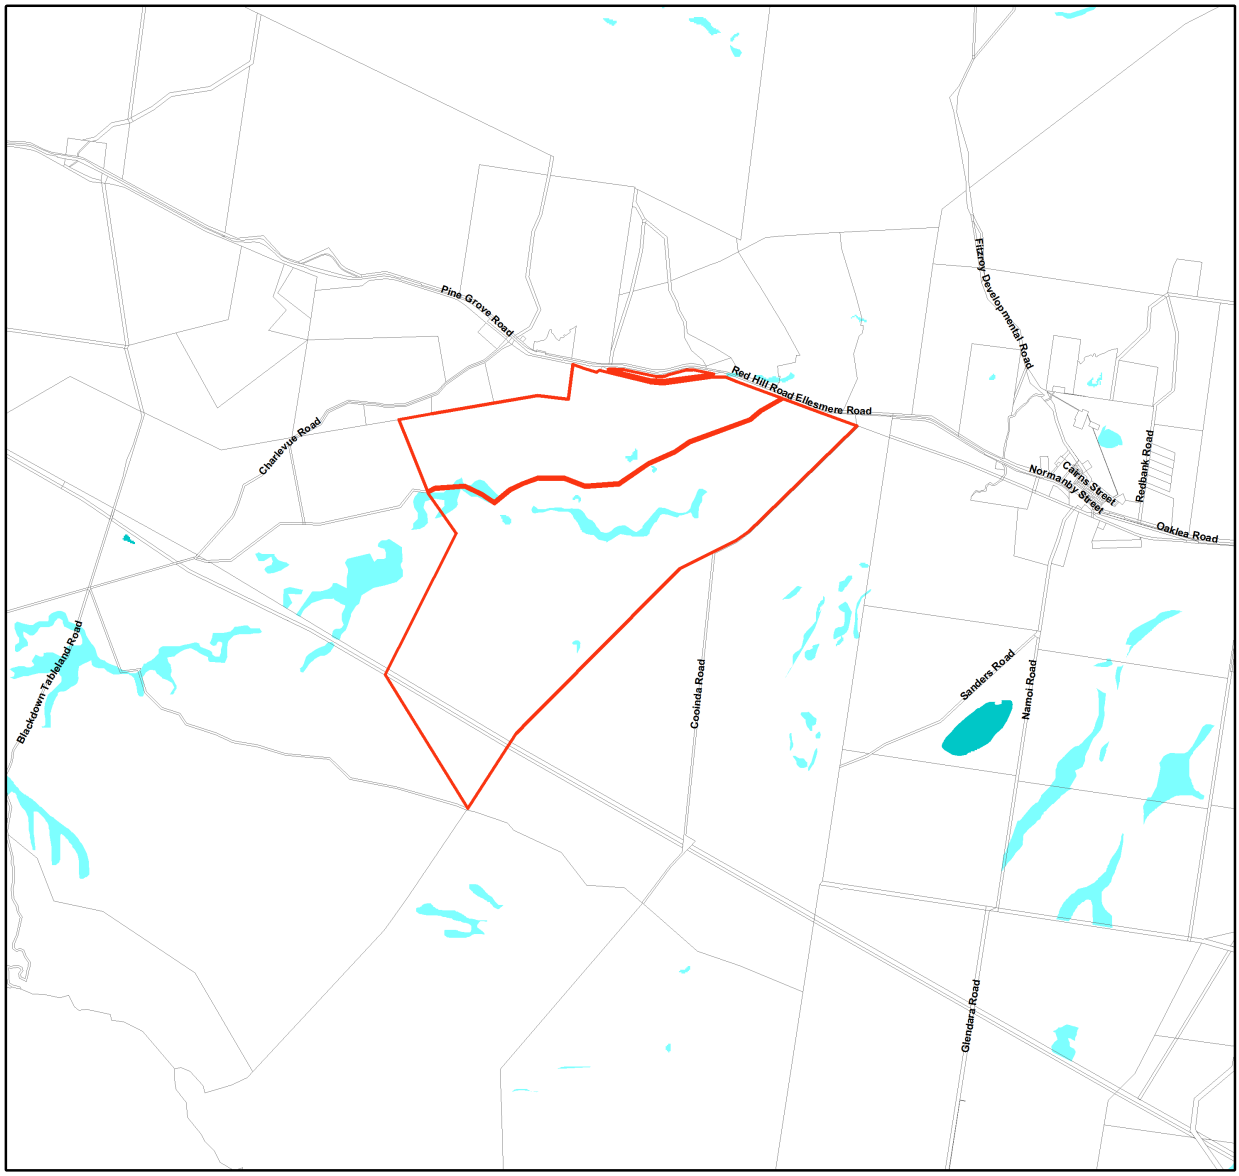
Note:
This map shows the location of wetland protection areas which are defined under the Environmental Protection Regulation 2008. Within wetland protection areas, certain types of development involving high impact earthworks are made assessable under Schedule 3 of the Sustainable Planning Regulation 2009.

The Department of State Development, Manufacturing, Infrastructure and Planning is the State Assessment Referral Agency (SARA) under Schedule 7 of the Sustainable Planning Regulation 2009 for assessable development involving high impact earthworks within wetland protection areas. The Department of Environment and Science is a technical agency.

The policy outcome and assessment criteria for assessing these applications are described in the State Development Assessment Provisions (SDAP) *Module 11: Wetlands and wild rivers.*

This map is produced at a scale relevant to the size of the lot on plan identified and should be printed at A4 size in portrait orientation. Consideration of the effects of mapped scale is necessary when interpreting data at a large scale.



For further information or assistance with interpretation of this product, please contact the Department of Environment and Science, email planning.support@des.qld.gov.au.

LOCALITY DIAGRAM

N

Note:
This map shows the location of wetlands on the Map of Referable Wetlands which are defined under the Environmental Protection Regulation 2008.

Wetlands are assessed for ecological significance using the environmental values for wetlands in section 81A of the Environmental Protection Regulation 2008. Wetlands are considered either High Ecological Significance (HES) or of General Ecological Significance (GES) for the purposes of the environmental values.

This map is produced at a scale relevant to the size of the lot on plan identified and should be printed at A4 size in portrait orientation. Consideration of the effects of mapped scale is necessary when interpreting data at a large scale.

Appendix B Likelihood of Occurrence for Threatened Ecological Communities (TEC)

Likelihood of Occurrence for Threatened Ecological Communities

Community Name	Database searches		Desktop likelihood determination
	PMST	Corresponding REs mapped within EPC	
Brigalow (A*cacia harpophylla* dominant and co-dominant)	**Known** to occur (0-10 km)	11.3.1	Likely Brigalow TEC is common throughout central QLD in small patches. It is known to occur within a 10 km buffer of the study area. One RE that corresponds to the TEC has been mapped by DES as occurring on the study area. It is likely that this TEC will be identified within the study area during RE mapping validation.
Natural grasslands of the Queensland Central Highlands and northern Fitzroy Basin	**May** occur (0-10 km)	None	Unlikely This TEC may occur within a 10 km buffer of the study area according to the PMST. There are no REs corresponding to this TEC mapped by DES within the study area.
Coolabah – Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	**May** occur (0-10 km)	None	Unlikely Search with PMST has identified that this TEC may occur within a 10 km buffer of the study area. None of the REs identified within the study area correspond with this TEC and therefore it is unlikely that this TEC will be found within the study area.
Weeping Myall Woodlands	**Likely** to occur (0-10 km)	11.3.2	Unlikely Weeping Myall TEC is uncommon and is only known to form minor components of two possible REs. It is considered likely to occur within a 0 – 10 km buffer of the study area. One RE that has the potential to contain minor components corresponding to this TEC has been mapped by DES as occurring on the study area. No records of *Acacia pendula* (Weeping Myall) were returned in a 50 km search of the Project using Wildlife Online. It is considered unlikely that this TEC will occur on the study area.
Semi-evergreen vine thickets of the Brigalow Belt (North and South) and Nandewar Bioregions	**Likely** to occur (10-50 km)	None	Unlikely Vine thicket TEC is not known to occur within 10 km of the study area and is only considered likely to occur within a 10 – 50 km buffer of the Project. No REs that correspond to the TEC have been mapped by DES as occurring on the study area.

Community Name	Database searches		Desktop likelihood determination
	PMST	Corresponding REs mapped within EPC	
Poplar Box Grassy Woodlands on Alluvial Plains	Not identified at time of search	11.3.2	Likely Poplar Box TEC was added to the list of TECs protected by the EPBC Act effective from 4 July 2019. One RE that corresponds to the TEC has been mapped by DES as occurring on the study area, *Eucalyptus populnea* woodland on alluvial plains (RE 11.3.2).

Appendix C Likelihood of Occurrence for Flora Species of Conservation Significance

Likelihood of Occurrence for Fauna Species of Conservation Significance

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Acacia grandiflora	V	LC	Species or species habitat **known** to occur within area (10 – 50 km)	6 *10 - 50 km*	*Acacia grandifolia* grows in hilly terrain on hillslopes of varying aspects and slope. The species also occurs on hillcrests, gullies and plains. Soil is usually shallow and well drained and is described as sandy loam to clay loam in texture derived from sandstones and acidic volcanics. Altitudes are predominantly between 200 and 370 metres. The vegetation is tall woodland or open forest with a range of floristic associations. The most frequently recorded tree species are *Eucalyptus crebra, Corymbia citriodora, C. trachyphloia, E. maculata* and *E. exserta* (QCRA/FRA, 1998; Queensland Herbarium 2011, cited in DES 2018b).	Unlikely This species has been recorded 6 times within 50 km of the Project. Potential suitable habitat is not likely to occur within the Project due to the elevation requirements of the species. The Project is located outside of the species distribution range.
Acacia storyi	-	NT	-	17 *10 - 50 km*	*Acacia storyi* typically grows on sandy and shallow skeletal soils over sandstone and grows in open forests. This species is associated with *Eucalyptus teriticornis* and *Aristida* spp. The species was considered occasional in two populations from Blackdown Tableland National Park, west of Rockhampton in central Queensland (DES 2018b).	Unlikely This species has been recorded 17 times within 50 km of the Project and potential habitat is likely to occur within the Project. However, the species range is very restricted, and the majority of the known populations protected within the Blackdown Tablelands NP, to the southwest of the Project.
Aristida annua	V	V	Species or species habitat **likely** to occur within area (10 – 50 km)	No Records	This species is restricted to Eucalypt woodland on black clay and basalt soils (DoEE 2018).	Unlikely This species was returned in the 50 km PMST search as likely to occur, however has no records within 50 km of the Project on Wildlife Online or Atlas of Living Australia database (ALA). Potential habitat is unlikely to occur within the Project due to the absence of suitable soil types.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Baeckea trapeza	-	NT	-	7 *10 - 50 km*	*Baeckea trapeza* grows at altitudes around 700 – 800m and on sandy soil in open Eucalyptus forest. This species is confined to the Blackdown Tableland (DES 2018b).	Unlikely This species has been recorded 7 times within 50 km of the Project and potential habitat is likely to occur within the Project. However, the species range is very restricted, and the majority of the known populations area protected within the Blackdown Tablelands NP, to the southwest of the Project.
Bertya opponens	V	V	Species or species habitat **likely** to occur within area (10 – 50 km)	No Records	Recorded growing in a variety of community types including mixed shrubland, Lancewood woodland, Mallee woodland, Eucalyptus / Acacia open forest with shrubby understorey, Eucalyptus / Callitris open woodland and semi-evergreen vine-thicket. Soils are recorded as generally shallow sandy loams or red earths associated mostly with sandstone, but also with rhyolite, shale and metasediments (DoEE 2018).	Potential This species was returned in the 50 km PMST search as likely to occur, however has no records within 50 km of the Project on Wildlife Online, ALA or Australian Virtual Herbarium (AVH). Due to the presence of Lancewood woodland within the study area and the proximity to the edge of the species distribution, the species potentially could be found within the study area.
Bertya pedicellata	-	NT	-	3 *10 - 50 km*	*Bertya pedicellata* grows on rocky hillsides in range of community types including eucalypt forest or woodland, Acacia woodland or shrubland and open heathland or vine thicket communities. The soils on which this species grow on are mainly skeletal to shallow sandy, sandy clay or clay loams overlaying rhyolite, trachyte or sandstone substrates (DES 2018b).	Potential This species has been recorded 3 times within 50 km of the Project. Even though there are no records of the species in the vicinity of the Project, this is located within the species distribution range. Potential suitable habitat may occur within the Project.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Cadellia pentastylis Ooline	V	V	Species or species habitat **likely** to occur within area (0-10 km)	4 *10 - 50 km*	Ooline occurs in a range of vegetation types including dry rainforest, semi-evergreen vine thickets and sclerophyll communities including, Brigalow-Belah, Poplar Box and Bendee communities (Pollock 1999; DEWHA 2008; cited in DES 2014b). Ooline often occurs on the edges of sandstone and basalt escarpments, 200 - 500m above sea level. Ooline grows on the moderately fertile soils preferred for agriculture and pasture development (Pollock 1999; DEWHA 2008; cited in DES 2014b).	Unlikely This species has been recorded four times within 50 km of the Project. Potential suitable habitat is not likely to occur within the Project due to the elevation requirements of the species. The Project is located outside of the species distribution range.
Cerbera dumicola	-	NT	-	2 *0 - 10 km* 6 *10 - 50 km*	*Cerbera dumicola* occurs across a range of habitats in central and southern Queensland. Associated vegetation and species include: sandstone hills in open *E. umbra subsp. carnea*; on plateaus, in woodland of *Acacia shirleyi* with *Corymbia dolichocarpa*; acidic soils in mine rehabilitation area; woodland of *A. catenulata* and *A. shirleyi* with *E. thozetiana* on a slope of sand/clay soil; semi-deciduous notophyll-microphyll vine forest of Brachychiton australis, *Gyrocarpus americanus, Flindersia australis, Pleiogynium timorense, Drypetes deplanchei* and *Sterculia quadrifida* on rhyolite hillslopes; open-woodland of *E. melanophloia* with occasional Acacia shirleyi, E. populnea and *E. brownii*; semi-evergreen vine thicket with *Corymbia citriodora* and *Corymbia aureola* emergents; woodland of *A. rhodoxylon* on brown, sandy loam; and in *Corymbia tessellaris - Acacia aneura* open woodland (Queensland Herbarium, 2011; cited in DES 2018).	Likely This species has been been recorded twice within 10 km of the Project, and six times within 50 km. Potential suitable habitat is likely to occur within the Project.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Commersonia pearnii	-	E	-	2 *10 - 50 km*	*Commersonia pearnii* occurs in open forests and woodlands with a range of canopy species. This species grows on sandstone escarpments and tablelands with shallow, medium to coarse-grained soils. This species is restricted to Blackdown Tableland in central Queensland (DES 2014b).	Unlikely This species is restricted to the Blackdown Tablelands NP. Potential suitable habitat is not likely to occur within the Project.
Corunastylis pedersonii	-	V	-	1 *0 - 50 km*	This species has been recorded in Queensland from a single location in the Blackdown Tableland NP, on coarse decomposed sandstone. Seepage area on rock ledge with sedges, moss and *Drosera* sp. (AVH 2019). Specimens from New South Wales were recorded from Undulating country. Reddish/brown sandy clay loam soil over sandstone. Shrubby *Eucalyptus crebra* woodland with *Melaleuca uncinata.*	Unlikely This species has been recorded once within 50 km of the Project, in the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the Project due to the absence of suitable soil types.
Corunastylis valida	-	V	-	1 *10 - 50 km*	This species has been recorded in Queensland from a single location in the Blackdown Tableland NP, on coarse decomposed sandstone. Sparse woodland dominated by Banksia sp. (AVH 2019).	Unlikely This species has been recorded once within 50 km of the Project, in the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the Project due to the absence of suitable soil types.

Cycas ophiolitica Marlborough blue	E	E	Species or species habitat **likely** to occur within area (10 – 50 km)	No Records	*Cycas ophiolitica* inhabits eucalypt open forest and woodland communities with a grassy understorey. They occur on hill tops or steep slopes, at altitudes of 80-620m above sea level. It grows on shallow, stony, red clay loams or sandy soils (DES 2018b).	Unlikely This species was returned in the 50 km PMST search as likely to occur, however has no records within 50 km of the Project on Wildlife Online or ALA. Potential suitable habitat is unlikely to occur within the Project.
Daviesia discolor	V	V	Species or species habitat **likely** to occur within area (10 – 50 km)	6 *10 - 50 km*	This species is distributed in three localities in Queensland; Blackdown Tableland NP, Mount Walsh area near Biggeden, and in Carnarvon National Park (north of Mount Playfair) (DoEE 2018; Queensland Herbarium 2012). *Daviesia discolor* typically occurs from coastal hills to mountain slopes and ridges and grows between 50 – 1100m in altitude, mostly on fine-textured soils, which may be derived from acid volcanic or metamorphic rocks. Specifically, on the Blackdown Tableland NP, this species occurs on sandy soil derived from sandstone and on lateritic clay at altitudes of 600 – 900m, in open eucalypt forest dominated by species such as *Eucalyptus sphaerocarpa* and *E. nigra* (Queensland Herbarium 2012, cited in DES 2018b).).	Unlikely This species has been recorded within 50 km of the Project in the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the Project due to the absence of suitable soil types and elevation.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Daviesia quoquoversus	-	V	-	2 *10 - 50 km*	*Daviesia quoquoversus* occurs in open forests on sandy soil derived from sandstone. This species is restricted to south-east Queensland and only found in Blackdown Tableland NP (Queensland Herbarium 2012, cited in DES 2018b).	Unlikely This species has been described as restricted to the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the study area due to the absence of suitable soil types.
Dichanthium queenslandicum King bluegrass	E	V	Species or species habitat **may** occur within area (10 – 50 km)	No Records	This species occurs on black cracking clay in tussock grasslands mainly in association with other species of Bluegrasses. It is mostly confined to the natural Bluegrass grasslands of central and southern Queensland (DoEE 2018).	Unlikely The species has not been recorded within 50 km of the Project. The species is mostly confined to natural Bluegrass grasslands and not in grazed land. The study area lacks on suitable habitat.
Dichanthium setosum Bluegrass	V	-	Species or species habitat **likely** to occur within area (0 – 10 km) Species or species habitat **likely** to occur within area (10 – 50 km)	No Records	Occurs in grassy woodland and open forests in inland Australia. Associated with heavy basaltic black soils and stony red-brown hard-setting loam with clay subsoil and is found in moderately disturbed areas such as cleared woodland, grassy roadside remnants, grazed land and highly disturbed pasture (DoEE 2018).	Unlikely The species has not been recorded within 50 km of the Project. The species is mostly confined to natural Bluegrass grasslands and not in grazed land. The study area lacks on suitable habitat.

	EPBC Act	NC Act	PMST	Wildlife Online Records		
Eucalyptus raveretiana Black ironbox	V	LC	Species or species habitat **likely** to occur within area (10 – 50 km)	No Records	Occurs on alluvial soils, loams, light clays or cracking clays in open forests and woodlands along watercourses and occasionally on river flats (DES 2018b).	Unlikely Potential suitable habitat may occur within the study area. This species was returned in the 50 km PMST search as likely to occur, however has not been recorded within 50 km of the Project. The species is unlikely to occur within the study area as it is only known from coastal regions of eastern Queensland, with the nearest records north and east of Coppabella.
Gastrodia crebrifolia	-	V	-	1 *10 - 50 km*	*Gastrodia crebriflora* is an orchid that grows in loose colonies on protected slopes in tall open forest, often close to fallen trees. This species occurs on soils that are sands derived from decomposed sandstone. Endemic to Queensland (Jones 1991 cited in DES 2018b).	Unlikely This species has been recorded once within 50 km of the study area, in the Blackdown Tableland NP. However, the study area is located outside the known distribution of the species.
Homoranthus decumbens	E	V	Species or species habitat **known** to occur within area (10 – 50 km)	No Records	*Homoranthus decumbens* occurs in tall shrubland or heath up to 800m above sea level. It occurs on the edge of sandstone cliffs or in shallow sandy soils containing lateritic (iron-rich) pebbles (Wang 1995).	Unlikely This species was returned in the 50 km PMST search as known to occur, however, it has not been recorded within 50 km of the Project on Wildlife Online or ALA. The closest record of the species is from near Taroom, over 200 km south of the Project. Potential suitable habitat is unlikely to occur within the study area.

	EPBC Act	NC Act	PMST	Wildlife Online Records		
Livistona fulva	-	V	-	12 *10 - 50 km*	*Livistona fulva* occurs mainly along sandstone cliff-lines, on rocky foot-slopes below cliffs, in shallow rocky gullies of the Blackdown Tableland NP, and in deep sandstone gorges below major waterfalls around the edge of the plateau. Grows in moderately tall eucalypt forest, typically dominated by *Eucalyptus sphaerocarpa*. Most occurrences are recorded at altitudes 300 – 600m above sea level (DES 2018b). This species is found in the Blackdown Tablelands NP.	Unlikely This species has been described as occur mainly in the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the study area due to the absence of suitable soil types and low elevation.
Logania diffusa	V	V	Species or species habitat **likely** to occur within area (0-10 km)	2 *10 - 50 km*	*Logania diffusa* occurs in heathland and eucalypt open forest. It grows in sandy or sandy clay soil with sandstone outcropping and loose surface stones on escarpments. This species grows at altitudes of 600 – 780m above sea level. This species is restricted to the Blackdown Tableland NP (DES 2014b).	Unlikely This species has been described as restricted to the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the Project due to the absence of suitable soil types and low elevation.
Macrozamia platyrhachis	E	E	Species or species habitat **likely** to occur within area (0-10 km)	30 *10 - 50 km*	*Macrozamia platyrhachis* is scattered locally and abundantly in eucalypt woodland or open forest at altitudes between 300 – 780m above sea level. Mid- and under-stories of the vegetation may be relatively dense but is variably dependent on fire history. This species grows on deep sandy soils, derived from sandstone and is mainly found on Blackdown Tableland NP and has occurrence recorded in areas slightly south of township of Dingo (DES 2018b).	Unlikely This species has been recorded mainly within 50 km of the Project, in the Blackdown Tableland NP. The study area with its highest elevation at 200m above sea level, lacks the suitable habitat for this species.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Melaleuca groveana	-	NT	-	4 *10 - 50 km*	*Melaleuca groveana* grows on exposed rocky ridges, high mountain slopes and the summit of mountains at altitudes 340 – 600m above sea level. This species typically occurs on in heaths and eucalypt woodlands and forests with heath understoreys. It is also found in tall open forest with a grassy understorey and in microphyll vine forests. It has been previously recorded growing on red sandy loams, brown loams, skeletal rocky soils and sandy soils over sandstone rock. This species is found in fragments from Port Stephens (NSW) to the Blackdown Tableland NP (DES 2014b).	Unlikely This species has been recorded within 50 km of the Project, in the Blackdown Tableland NP. The study area with its highest elevation at 200m above sea level, lacks the suitable habitat for this species.
Melaleuca pearsonii	-	NT	-	12 *10 - 50 km*	*Melaleuca pearsonii* occurs in Blackdown Tableland NP. Grows near rivers, in rocky gullies and in wallum vegetation in creek beds (Brophy *et al.* 2013).	Unlikely This species has been described as occurring in the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the study area.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Phaius australis	E	E	Species or species habitat **known** to occur within area (0-10 km)	3 *10 - 50 km*	*Phaius australis* grows in areas where soils are almost always damp, but not flooded for lengthy periods. Sands are generally the underlying soil type. *P. australis* are usually found in coastal habitats between swamps and forests or in suitable areas further inland. This includes swampy sclerophyll forest dominated by melaleucas, swampy forest that often have scleorphyll emergents, or fringing open forest and melaleuca swamp forest associated with rainforest species. *P. australis* has also been recorded in wallum, sedgeland, rainforest and closed forest. They often grow in deep shade but can also occur in full sun. This species occurs at higher altitudes in northern Queensland (Barker 1995).	Unlikely Despite being described from coastal habitats, this species has been recorded 3 times within 50 km of the study area in the Blackdown Tableland NP. Potential suitable habitat is not likely to occur within the Project.
Plectranthus blakei	-	NT	-	10 *10 - 50 km*	*Plectranthus blakei* has been only recorded from sandstone rock outcrops and ledges in association with *Hoya australis* and *Clandrina* in the Blackdown Tableland NP (JSTOR 2018).	Unlikely This species has only been recorded in the Blackdown Tableland NP. However, the study area is located outside the known distribution of the species.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Pseudanthus pauciflorus subsp. arenicola	-	NT	-	1 *10 - 50 km*	This species occurs in crevices on vertical or near vertical rock faces and sandstone cliffs within dry sclerophyll woodland (DSITI 2015) and is endemic to the Blackdown Tableland NP (DES 2018b).	Unlikely This species has been described as being endemic to the Blackdown Tableland NP. Potential suitable habitat does not occur within the study area.
Rutidosis glandulosa	-	NT	-	7 *10 - 50 km*	*Rutidosis glandulosa* is known from approximately 15 populations across six distinct localities, which includes Blackdown Tableland NP. This species mainly occurs on sandy or gravelly well drained soil in grassy open eucalypt woodland. Around Blackdown Tableland NP, this species appears to be growing in open forest dominated by *Eucalyptus interstans, E. sphaerocarpa* and *Angophora leiocarpa*. (DES 2018b).	Unlikely The study area is located outside of the species distribution, which extends from Stanthorpe to the Blackdown Tableland NP, to the west of the study area. Potential suitable habitat is not likely to occur within the Project.
Sannantha brachypoda	-	V	-	1 *10 - 50 km*	*Sannantha brachypoda* has been described from loamy, sandy or rocky soils and from gorges and creek lines (AVH 2019).	Unlikely This species has been recorded once within 50 km of the study area, in the Blackdown Tableland NP. Potential suitable habitat does not occur within the study area.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Solanum adenophorum	-	NT	-	10 *10 - 50 km*	*Solanum adenophorum* occurs mostly in brigalow woodland and on very gently inclined slopes. It also occurs in gidgee (*Acacia cambagei*) scrub on deep cracking clay soils (DES 2018e). Occurrence records show that this species is from south and south-west of Marlborough to Rockhampton and also found in small populations north and north-east of Wagga Wagga, NSW (ALA 2018).	Potential The Project is located south of the distribution range of the species. All records near the Project are located within Taunton NP. Potential suitable habitat may occur within the study area in small patches.
Solanum dissectum	E	E	Species or species habitat **known** to occur within area (0-10 km)	3 *10 - 50 km*	*Solanum dissectum* occurs in open forest and woodland of brigalow (Acacia harpophylla) or *Eucalyptus thozetiana* on solodic clay soils (Queensland Herbarium 2012, cited in DES 2018b).	Potential This species was returned in the 50 km PMST search as known to occur, however, the closest record of the species is from west of Blackdown Tableland NP. Potential suitable habitat may occur within the study area in small patches.
Solanum elachophyllum	-	E	-	1 *0 - 10 km* 14 *10 - 50 km*	*Solanum elachophyllum* grows on fertile cracking-clay soils in open forest of *Eucalyptus thozetiana, Acacia harpophylla,* with understorey *of Geijera parviflora, Casuarina cristata, Macropteranthes leichhardtii, Eucalyptus cambageana*, or woodland of *E. creba* and *E. tenuipes* (DES 2018b). Occurrence of this species has been recorded in areas from south-west of Mackay to south-west of Gladstone.	Likely The Project is located within the species distribution. Potential suitable habitat may occur within the study area in small patches.

C

Species Name Common Name	EVNT Listing		Database Searches		Preferred Habitat	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Solanum johnsonianum	E	E	Species or species habitat **may** occur within area (10 – 50 km)	No Records	*Solanum johnsonianum* is distributed within communities dominated or co-dominated by *Acacia harpophylla* (Brigalow), on heavy cracking soils. Other associated species include *Eucalyptus thozetiana* with understorey of *Geijera parviflora* (Bean, 2004; Queensland Herbarium, 2012, cited in DES 2018b).	Unlikely The Project is located south of the distribution of the species. Potential suitable habitat may occur within the study area in small patches. There are no records of the species within 50 km of the Project.

C

Appendix D Likelihood of Occurrence for Fauna Species of Conservation Significance

Likelihood of Occurrence for Fauna Species of Conservation Significance

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Amphibians						
Adelotus brevis Tusked frog	-	V	-	10 (10-50 km)	The Tusked frog Inhabits wet eucalypt forest, rainforest, and sometimes dry eucalypt forest, where it can be found in close proximity to suitable breeding habitat such as ponds and slow-moving sections of streams. Also recorded from dams and garden ponds in urban and peri-urban areas (Rowland 2013).	Potential The study area occurs within the vicinity of the known range of the Tusked frog and there is a possibly the study area provides areas of suitable habitat. However, the closest records of the species in the area are from Blackdown Tableland NP, located over 20km southwest of the study area.
Reptiles						
Delma torquate Adorned delma	V	V	Species or species habitat **likely** to occur within area (0-10 km)	1 (10-50 km)	The Collared Delma normally inhabits eucalypt dominated woodland and open forest where it is associated with suitable micro-habitats (exposed rocky outcrops). The ground cover is predominantly native grasses, such as Kangaroo Grass (*Themeda triandra*), Barbed-wire Grass (*Cymbopogon refractus*), Wiregrass (*Aristida* sp.) and Lomandra (*Lomandra* sp.) (Peck & Hobson, 2007, cited in TSSC 2008).	Potential This species was returned in the 10 km PMST search as may occur. This species is known to occur between 10 and 50 km, at the Blackdown Tablelands NP. However, desktop searches identified marginal suitable habitat for this species in the study area.
Denisonia maculate Ornamental snake	V	V	Species or species habitat **may** to occur within area (0-10 km)	2 (10-50 km)	The Ornamental Snake's preferred habitat is within, or close to, habitat that is favoured by its prey - frogs. The species is known to prefer woodlands and open forests associated with moist areas, particularly gilgai (melon-hole) mounds and depressions in Queensland Regional Ecosystem Land Zone 4, but also lake margins and wetlands (Agnew 2010 pers. comm.; Brigalow Belt Reptiles Workshop 2010; Wilson & Knowles 1988	Unlikely This species was returned in the 10 km PMST search as may occur, and as known to occur between 10 and 50 km. Desktop searches did not identify suitable habitat for this species.

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
					cited in DEE 2018). Gilgai formations are found where deep-cracking alluvial soils with high clay contents occur (Brigalow Belt Reptiles Workshop 2010, cited in DoEE 2018).	
Egernia rugosa Yakka skink	V	V	Species or species habitat **known** to occur within area (0-10 km)	No records	Dry open forests, woodlands and rocky areas in the Brigalow Belt, where it occurs in fallen timber, wood piles, uprooted trees, deep rock crevices, deeply eroded gullies or disused rabbit warrens (DoEE 2018).	Unlikely This species or species habitat was returned in the 10 km PMST search as known to occur, however no records were returned in the database and online searches. There nearest ALA records are from over 50km west of the study area. Some marginally suitable habitat may be found on the study area.
Furina dunmalli Dunmall's snake	V	V	Species or species habitat **may** occur within area (0-10 km)	No records	Dunmall's Snake inhabits a broad range of habitats including; Forests/woodlands on black alluvial cracking clay/clay loams. Dominant vegetation includes Brigalow *(Acacia harpophylla),* Wattles *(A. burowii, A. deanii, A. leioclyx),* native Cypress *(Callitris spp.) or* Bull-oak *(Allocasuarina luehmannii), Corymbia citriodora, Eucalyptus crebra* and *E. melanophloia, and Callitris glaucophylla* (DoEE 2018).	Unlikely This species was returned in the 10 km PMST search as may occur, however no records were returned in the database and online searches. There nearest ALA records are from over 50km west of the study area. Desktop searches identified potentially suitable habitat for this species on the study area.
Strophurus taenicauda Golden-tailed gecko	-	NT	-	10 (10-50 km)	The Golden-tailed Gecko inhabits dry sclerophyll forests featuring ironbarks, cypress pine and brigalow. It is described as an arboreal species sheltering behind loose dead bark, in hollows, or clinging to exposed slender branches in dapple sunlight (Wilson 2005).	Potential This species has been recorded within 50 km of the study area. The study area contains suitable habitat for this species.
Birds						
Actitis hypoleucos	Ma	SL	Species or species habitat	No records	Varied coastal and interior wetlands – narrow muddy edges of billabongs, river pools,	Unlikely

Common Sandpiper			**may** occur within area (0-10 km)		mangroves, among rocks and snags, reefs or rocky beaches (Morcombe 2002).	This species has not been recorded on the study area and has no records within 50 km of the study area on Wildlife Online or ALA. Suitable habitat for this species is unlikely to be available on the study area.
Anseranas semipalmata Magpie Goose	Ma	-	Species or species habitat **may** occur within area (0-10 km)	No records	The Magpie Goose occupies large seasonal wetlands and well-vegetated dams with rushes and sedges; wet grasslands and floodplains (Pizzey & Knight 2007).	<u>Unlikely</u> This species has not been recorded within 50 km or the study area. Some seasonal habitat may occur on the study area, however preferred habitat is distributed on coastal margins.
Apus pacificus Fork-tailed swift	Ma, Mi	SL	Species or species habitat **likely** to occur within area (0-10 km)	No records	Low to very high airspace over varied habitat, rainforest to semi-desert, most active just ahead of summer storm fronts (Morcombe 2002).	<u>Unlikely</u> This species has not been recorded within 50 km of the study area on Wildlife Online or ALA. Potential habitat may occur on the study area, however occurrence is highly concentrated on coastal margins, and sporadic through inland Australia.
Ardea alba Great egret	Ma	-	Species or species habitat **likely** to occur within area (0-10 km) Breeding **known** to occur within area (10-50 km)	No records	Common throughout Australia, with the exception of the most arid areas. Known to prefer shallow water, particularly when flowing, but may be seen on any watered area, including damp grasslands (Morcombe 2002).	<u>Potential</u> This species has not been recorded within 50 km of the study area on Wildlife Online or ALA. Seasonally suitable habitat is likely to occur on the study area and in the greater region.
Ardea ibis Cattle egret	Ma	-	Species or species habitat **may** occur within area (0-10 km)	No records	Widespread and common in north, north-eastern and south-eastern Australia. The species is found in grasslands, woodlands and wetlands, and is not common in arid areas. Utilises pastures and croplands, especially where drainage is poor. Will also	<u>Potential</u> This species has not been recorded within 50 km of the study area on Wildlife Online or ALA. Potential suitable habitat is

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
					forage in garbage dumps, and often associates with livestock (Morcombe 2002).	available on the study area and in the greater region.
Calidris acuminate Sharp-tailed sandpiper	Ma, Mi	SL	Species or species habitat **may** occur within area (0-10 km) Species or species habitat **likely** to occur within area (10-50 km)	No records	Fresh or salt wetlands – the muddy edges of wetlands and dams (Morcombe 2002). In Queensland, they are recorded in most regions, being widespread along much of the coast and are very sparsely scattered inland, particularly in central and south-western regions (DoEE 2018).	Potential This species was returned in the 10 km PMST search as may occur, and as likely to occur between 10 and 50 km. No records of presence were recorded within 50km of the study area. Species occurrence is concentrated on coastal margins, but still common throughout inland Australia where suitable habitat is available. Limited seasonal habitat may occur in the study area.
Calidris ferruginea Curlew sandpiper	CE, Mi, Ma	E	Species or species habitat **may** occur within area (0-10 km)	No records	Inhabiting wetland environments, the Curlew sandpiper is commonly found on sandy shores, lagoons, tidal mudflats, saltmarshes, swamps, lakes, and sewage farms (Pizzey and Knight 2007). They forage at the edge of shallow pools and can wade through water 15-60 mm deep (DoEE 2018). Whilst small numbers have been recorded living inland around ephemeral and permanent lakes, dams and bores, the majority reside along the coast roosting on dry shingle, sand, or shell beaches. This species is distributed around most of the coastline of Australia.	Unlikely Habitat within the study area is not suited for this species as the study area is not coastal and will not provide the resources required to sustain this species. Although this species has been recorded in association with inland waterbodies, it is very rare.
Calidris melanotos Pectoral sandpiper	Ma, Mi	SL	Species or species habitat **may** occur within area (0-10 km)	No records	Usually coast wetlands, both fresh and saline, but also inland on permanent and temporary wetlands; utilises sites with mudflats, fringing vegetation, swamps with heavy overgrowth of vegetation (Morcombe 2002).	Unlikely This species was returned in the 10 km PMST search as may occur, however as no records were returned in the database and online searches. The nearest ALA records are near Mackay and Yeppoon. Potentially

						marginal suitable habitat is likely to occur within the study area.
Calyptorhynchus lathami erebus Glossy black-cockatoo (northern)	-	V	-	19 (10-50 km)	The Glossy black-cockatoo (northern) prefers woodland areas dominated by she-oak Allocasuarina or open sclerophyll forests and woodlands with a stratum of Allocasuarina beneath Eucalyptus, Corymbia or Angophora. This species occurs in the north and central east coast of Queensland, including Blackdown Tableland (Glossy Black Conservancy 2010).	Potential Wildlife online records indicate 19 occurrences of this species within 10 to 50 km of the study area. The PMST did not identify this species as it is not listed under the EPBC Act. Suitable habitat occurs in the broader region but has not been mapped as present within the study area.
Cuculus optatus Oriental Cuckoo	Mi	SL	Species or species habitat **may** occur within area (0-10 km)	No records	Rainforest margins, monsoon forest, vine scrubs, riverine thickets, wetter, densely canopied eucalypt forests, paperbark swamps and mangroves (Morcombe 2002).	Unlikely This species was returned in the 10 km PMST search as may occur, however no records were returned in the database and online searches. Suitable habitat is unlikely to occur within the study area.
Chrysococcyx osculans Black-eared cuckoo	Ma	-	Species or species habitat **likely** to occur within area (0-10 km)	No records	This species inhabits areas of dry open forests, scrublands, mallee, mulga, lignum, and riverside thickets. This species is widespread across the mainland of Australia.	Potential This species was returned in the 10 km PMST search as likely to occur, however no records were returned in the database and online searches. Potential habitat for this species may occur within the study area.
Erythrotriorchis radiatus Red goshawk	V	E	Species or species habitat **known** to occur within area (0-10 km)	15 (10-50km)	The red goshawk prefers a mix of vegetation types with its habitat including tall open forest, woodland, lightly treed savannah and the edge of rainforest. In partly cleared parts of eastern Queensland, it is associated with gorge and escarpment country (DES 2018b).	Potential Wildlife Online records identify 15 occurrences of this species within 10 to 50 km. PMST identified species/species habitat as known to occur within 10 km of the study area.

	EPBC Act	NC Act	PMST	Wildlife Online Records		
Gallinago hardwickii Lathams snipe	Ma, Mi	SL	Species or species habitat **may** occur within area (0-10 km)	-	This species prefers open freshwarer wetlands, typically with low dense vegetation. Can be found in a variety of vegetation communities including but not limited to tussock grasslands, coastal and alpine heathlands, tea-tree scrub and open forests.	Unlikely This species was returned in the 10 km PMST search as may occur, no records were returned in the database and online searches. Limited suitable habitat is likely to occur within the study area.
Geophaps scripta scripta Squatter pigeon (southern)	V	V	Species or species habitat **known** to occur within area (0-10 km)	14 (0-10 km) 44 (10-50 km)	Open grassy woodlands on sandy soils interspersed with low gravelly ridges, never far from water (Morcombe 2002).	Likely This species has been recorded several times within 10 km of the study area. Suitable habitat exists within the study area. The species is typically locally abundant in areas where it is known from and not cryptic in nature.
Grantiella picta Painted honeyeater	V	V	Species or species habitat **may** occur within area (0-10 km)	3 (10-50 km)	The Painted honeyeater typically occupies habitats on deep, productive soils and is reliant on abundant mistletoes as a food source. It favours Acacia dominant woodlands (particularly Brigalow dominant) and often uses Belah and Bulloak woodlands and riparian woodlands of Black Box and River Red Gum. The species' breeding range is largely restricted to inland NSW and south of Roma.	Potential Thre records identified this species as occurring between 10 and 50 km from the study area. Desktop searches identified potential suitable habitat for this species along creek lines/watercourses within the study area.
Haliaeetus leucogaster White-bellied Sea-Eagle	Ma	-	Species or species habitat **likely** to occur within area (0-10 km)	No records	Coastal habitats (especially those close to the sea-shore) and around terrestrial wetlands. Habitat characterised by the presence of large areas of open water (larger rivers, swamps, lakes, the sea). Birds have been recorded in (or flying over) a variety of terrestrial habitats (DoEE 2018).	Unlikely This species was returned in the 10 km PMST search as likely to occur, but no records within 50 km of the study area. Seasonally suitable habitat may occur within the study area.

Hirundapus caudacutus White-throated needletail	Ma, Mi	SL	Species or species habitat **known** to occur within area (10-50 km)	No records	This species in Australia is primarily aerial but does show preferences for certain habitats. This species is found in associated with wooded areas, including open forests and rainforests.	Potential This species was returned in the 50 km PMST search as known to occur. Database searches did not identify any records of this species occurring within 50 km of the study area.
Lathamus discolor Swift parrot	CE	E	-	1 (10-50 km)	This species distribution covers eastern NSW, South-east Queensland, Victoria and Tasmania. This species migrates to south-eastern Queensland during Autumn and Winter. This species forages within eucalypt forests and woodlands.	Potential This species was not identified by the PMST. One record of this species exists within 10 to 50 km from the study area. Limited suitable habitat occurs for this species along the creek lines and watercourses within the study area. The study area occurs at the most upper limit of this species distribution.
Merops ornatus Rainbow bee-eater	Ma	-	Species or species habitat **may** occur within area (0-10 km)	No records	Open forests and woodlands, shrublands, various cleared or semi-cleared habitats, including farmland and areas of human habitation. Open, cleared or lightly timbered areas that are often located in close proximity to permanent water (DoEE 2018).	Potential This species was listed as may occur within 10 km on the PMST search. Database searches did not identify any records of this species occurring within 50 km of the study area. The study area is likely to contain suitable habitat for this species.
Monarcha melanopsis Black-faced monarch	Ma, Mi	SL	Species or species habitat **likely** to occur within area (0-10 km)	No records	Rainforests, mangroves, eucalypt forests and woodlands (Morcombe 2002).	Potential This species was returned in the 10 km PMST search as likely to occur, however has not been recorded in the 50 km Wildlife Online search. Suitable habitat potentially occurs within the study area.
Monarcha trivirgatus	Ma, Mi	SL	Species or species habitat	No records	Distribution is focused along the eastern coastline of Queensland and NSW. This	Unlikely

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Spectacled monarch			**may** occur within area (10-50 km)		species inhabits areas of wet forests and mangroves.	This species was returned in the 10 km PMST search as may occur, however has not been recorded in the 50 km Wildlife Online search. The study area occurs at the limit of this species range and its preferred habitat is unlikely to occur within the study area.
Motacilla flava Yellow wagtail	Ma, Mi	SL	Species or species habitat **may** occur within area (0-10 km)	No records	Open habitats, often near water; in Queensland it is usually coastal (Morcombe 2002).	Potential This species was returned in the 10 km PMST search as may occur, however no records were returned in the database and online searches. Suitable habitat has the potential to occur within the Project, though likely only seasonally.
Myiagra cyanoleuca Satin flycatcher	Ma, Mi	SL	Species or species habitat **may** occur within area (0-10 km)	No records	Forests and woodlands, mangroves, coastal heath scrubs; in breeding season favours dense, wet gullies of heavy eucalypt forests (Morcombe 2002).	Potential This species was returned in the 10 km PMST search as may occur, but no database records within 50 km. Limited suitable habitat may occur within the study area.
Neochmia ruficauda ruficauda Star finch	E	E	Species or species habitat **likely** to occur within area (0-10 km)	No records	The Star finch occurs in grasslands and grassy woodlands, near permanent water, and often in or near suburban areas (Curtis *et al.* 2012). The Star Finch is endemic to central Queensland (DoEE 2018).	Unlikely This species was returned in the 10 km PMST search as likely to occur, but no database records within 50 km. Limited to no suitable habitat for this species is likely to occur within in the study area.
Ninox strenua Powerful owl	-	V	-	3 (10-50 km)	This species prefers tall open woodlands and forests. Powerful owls require large hollows to nest. This species inhabits areas along watercourses.	Potential Three records of this species have been recorded between 10 and 50 km from the study area. This species is not listed under the EPBC Act as such did not come up in

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
						the PMST. This species is likely to use only marginal habitat features along major watercourses within the study area.
Numenius madagascariensis Eastern curlew	CE, Mi	E	Species or species habitat **may** occur within area (10-50 km)	No records	Tidal mudflats, sand spits of estuaries, mangroves, lake shores and ocean beaches (Morcombe 2002).	Unlikely This species has not been recorded within 50 km of the study area on Wildlife Online. Suitable habitat is unlikely to be present on the study area due to the study area lying outside suitable coastline environs, with only scattered records inland.
Pedionomus torquatus Plains wanderer	CE	V	-	1 (10-50 km)	The Plains wanderer is a ground-dwelling bird species that inhabits native grasslands. This species is often absent from areas that are too dense or sparse.	Potential This species was not identified in the PMST, and only one record of this species was identified within 10 to 50 km from the study area. Desktop searches identified no native grasslands within the study area boundary.
Psephotus pulcherrimus Paradise parrot	PE	EX	-	9 (10-50 km)	Historically this species occurred in central and southern Queensland. This species inhabited undulating river valleys in sparse open eucalypt woodlands and forests.	Unlikely This species is now extinct. Historic records are from over 50 years ago.
Poephila cincta cincta Black-throated finch (white-rumped subspecies)	E	E	Species or species habitat **may** occur within area (0-10 km)	4 (10-50 km)	This species inhabits open grassy woodlands and forests (Curtis *et al.* 2012), scrubby plains and Pandanus flats with deep cover of grasses. Its habitat is never far from water. It is known to occur south of Townsville, particularly around Townsville and Charters Towers (DoEE 2018).	Potential This species was returned in the 10 km PMST search as may occur. Wildlife Online records identify four occurrences of this species within 10 to 50 km.
Rhipidura rufifrons Rufous fantail	Ma	SL	Species or species habitat	No records	In east and southeast Australia, the Rufous Fantail mainly inhabits wet sclerophyll forests. They are also recorded from parks and	Unlikely

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
			may occur within area (0-10 km)		gardens when on passage. In north and northeast Australia, they often occur in tropical rainforest and monsoon rainforests, including semi-evergreen mesophyll vine forests, semideciduous vine thickets or thickets of Melaleuca spp. (DoEE 2018).	This species was returned in the 10 km PMST search as may occur, but no database records within 50 km. Limited suitable habitat is unlikely to occur within the study area.
Rostratula australis Australian painted snipe	E, Ma	V	Species or species habitat **may** occur within area (0-10 km)	No records	This species is found in shallow inland wetlands, either freshwater or brackish, which are either permanently or temporarily filled, throughout many parts of Australia (DoEE 2018).	<u>Unlikely</u> This species was returned in the 10 km PMST search as may occur, and as likely to occur between 10 and 50 km. No records of presence were recorded within 50 km of the study area. The study area is unlikely to provide potential habitat for this species.
Turnix melanogaster Black-breasted button-quail	V	V	Species or species habitat **may** occur within area (0-10 km)	7 (10-50 km)	The preferred habitat for the black-breasted button-quail includes vine thickets and rainforests that are periodically water-stressed such as semi-evergreen vine thicket, low microphyll vine forest, *Araucarian microphyll* or notophyll vine forest, Brigalow and Belah low thickets or woodlands with a dense understorey and little groundcover and littoral habitats.	<u>Potential</u> This species was returned in the 10 km PMST search as may occur, and as likely to occur between 10 and 50 km. Seven records of this species have been registered within 10 to 50 kms. Potential suitable habitat may occur within the study area.
Mammals						
Antechinus argentus Silver-headed antechinus	E	V	-	23 (10-50 km)	The silver-headed antechinus is known from three isolated subpopulations located in centraleastern Queensland - the plateau at the eastern escarpment of Kroombit Tops NP. located 70 km south-west of Gladstone; Blackdown Tableland National Park, located 220 km west of Gladstone (Mason *et al.* 2016); and Bulburin National Park (A Baker pers. comm. 2017b; H Hines pers. comm.	<u>Unlikely</u> Records of this species were reported from within 50 of the Project, however, this species is known from only 3 subpopulations located over 150 km south of the Project. The species was not returned in the PMST search as potential species or habitat occurring within the Project area.

D

					2017), located 80 km south-east of Gladstone (TSSC 2018).	
Chalinolobus dwyeri Large-eared pied bat	V	V	Species or species habitat **may** occur within area (0-10 km)	2 (10-50 km)	This species occurs in areas with extensive cliffs and caves, primarily in the Central Queensland sandstone belt. Suitable habitat consists of sandstone gorges in tall open eucalypt forest, dry sclerophyll forests and woodlands, rainforest edges, wet sclerophyll forest and *Callitris* dominant forest.	Potential This species was returned in the 10 km PMST search as may occur, and as likely to occur between 10 and 50 km. The study area potentially contains suitable habitat for this species.
Dasyurus hallucatus Northern quoll	E	-	Species or species habitat **likely** to occur within area (0-10 km)	No records	The northern quoll lives in a range of open woodland and open forest types preferring rocky areas. Northern quolls have also been recorded in vine forest, mangroves, sugarcane farms and urban areas. Their greatest breeding success is known to occur at sites near water (DES 2018b).	Unlikely This species was returned in the 10 km PMST search as likely to occur. The study area may contain small areas of suitable habitat for this species. No confirmed records of this species have been found to occur within 50 km of the study area.
Macroderma gigas Ghost bat	V	E	Species or species habitat **likely** to occur within area (0-10 km)	No records	Ghost bats currently occupy habitats ranging from the arid Pilbara to tropical savanna woodlands and rainforests. During the daytime they roost in caves, rock crevices and old mines. (TSSC 2016b). They occupy the northern tropical areas of Queensland, Northern Territory and Western Australia.	Unlikely This species was returned in the 10 km PMST search as likely to occur. The study is unlikely to contain suitable habitat for this species and is located outside of the species distribution. No confirmed records of this species have been found to occur within 50 km of the study area.
Nycophilus corbeni Corben's long-eared bat	V	V	Species or species habitat **may** occur within area (0-10 km)	No records	This species is found across semi-arid southern Australia to southern Queensland and inhabits a range of dry woodland and shrubland communities in arid and semi-arid regions. This bat species roosts mostly in tree hollows (Menkhorst & Knight 2011).	Unlikely This species was returned in the 10 km PMST search as may occur, however, the study area is located outside of the species distribution. No records of presence were recorded within 50 km of the study area. Based on desktop mapping investigations areas containing hollow bearing trees are

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence

						likely limited to along watercourses within the study area.
Onychogalea fraenata Bridled nail-tail wallaby	E	E	Species or species habitat **known** to occur within area (0-10 km)	15 (0-10 km) 41 (10-50 km)	Within Taunton National Park, bridled nailtail wallabies are found in open grassy eucalypt woodland dominated by poplar box (*Eucalyptus populnea*), dense acacia forest dominated by brigalow (*Acacia harpophylla*), transitional vegetation intermediate between the woodland and forest areas of very dense brigalow regrowth (Lundie-Jenkins, G., & J. Lowry 2005)	<u>Likely</u> Despite not being reported on the Wildlife online search for 10km, this species is known to occur in the Taunton NP. Desktop searches identified potential suitable habitat for this species in small isolated patches throughout the study area.
Petauroides Volans Greater glider	V	V	Species or species habitat **likely** to occur within area (0-10 km)	1 (0-10 km) 71 (10-50 km)	Eucalypt dominated habitats, ranging from low, open forests on the coast to tall forests in the ranges and low woodland westwards of the Dividing Range (DES 2018b).	<u>Likely</u> Based on desktop mapping investigations areas containing hollow bearing trees are likely limited to along watercourses within the study area. One Wildlife online records of presence was recorded within 10 km of the study area, and 71 records exist within 10 to 50 kms.
Phascolarctos cinereus Koala	V	V	Species or species habitat **likely** to occur within area (0-10 km)	1 (0-10 km) 14 (10-50 km)	The Koala inhabits Eucalypt forests and woodlands on the east coast of Australia (Curtis *et al.* 2012). Koalas require areas of eucalypt species that are highly connected, to ensure shelter from predators.	<u>Potential</u> The study area occurs within the known range of the Koala and provides possible areas of suitable habitat along a narrow strip of *Eucalyptus* spp following the watercourses in the study area. One Wildlife online record of presence was recorded within 10 km of the study area, and 14 records exist within 10 to 50 kms.

D

Scientific Name Common Name	Status		Database Searches		Habitat and Distribution	Desktop Likelihood of Occurrence
	EPBC Act	NC Act	PMST	Wildlife Online Records		
Pteropus poliocephalus Grey-headed flying-fox	V	-	Foraging, feeding or related behaviour **may** occur within area (10-50 km)	No records	Roost in native vegetation near water, including mangrove, rainforest, melaleuca or casuarina (Churchill 2008). Typically commute within 15 km to feed on flowering and fruiting plants, including blossoms of various species of eucalypt, angophora, tea-tree and banksia (DES 2018b).	Unlikely No records within 50 km of the study area on Wildlife Online or ALA. Seasonally suitable foraging habitat may exist within the study area, however, no known records or roosts occur within 50 km.

Appendix E Fauna Survey Sites

Site Name	DF01
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 727223 7381160
Habitat type	Habitat type 2
Associated RE	11.7.2
Habitat Description	*Acacia* spp. woodland with *Eucalyptus crebra* as emergent on lateritic duricrust.
Disturbance Present	Moderate to light grazing and evidence of old fire.
Dominant Vegetation Species	Dominant Trees: *Acacia sherleyi* (Lancewood)*, Acacia rhodoxylon (Rosewood)* and *Eucalyptus crebra* as emergent. Dominant Shrubs: *Erythroxylum australe,* and saplings of the canopy species. Dominant Ground Cover: *Calyptochloa gracilima* and *Aristida caput-medusae*

E

Site Name	DF02
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 727380 7382738
Habitat type	Habitat type 3
Associated RE	11.3.25
Habitat Description	*Eucalyptus tereticornis* open woodland in floodplain between main creek and drainage line.
Disturbance Present	Adjacent land cleared, moderate grazing, erosion nearby and invasive species (Parthenium weed, Rubber vine and Velvet tree pear).
Dominant Vegetation Species	Dominant Trees: *Eucalyptus tereticornis* and *Cassia brewsterii* Dominant Shrub: *Cassia brewsterii* Dominant Ground Cover: *Megathyrsus maximus*

E

Site Name	DF03
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 726387 7383525
Habitat type	Habitat type 1
Associated RE	11.5.2
Habitat Description	*Eucalyptus crebra* and *Acacia rhodoxylon* on sandy plains.
Disturbance Present	Moderate grazing, evidence of old fire and invasive species (Harrisia cactus and Velvet tree pear).
Dominant Vegetation Species	Dominant Trees: *Eucalyptus crebra* and *Acacia rhodoxylon* Dominant Shrubs: *Erythroxylum australe* Dominant Ground Cover: *Cleistochloa sp. (Duaringa K.B.Adison 42)* and *Aristida caput-medusae*

E

Site Name	DF04
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 729993 7383135
Habitat type	Habitat type 3
Associated RE	11.5.2/11.3.25
Habitat Description	Floodplain next to creek line with *Eucalyptus crebra* on the floodplain and *E. tereticornis* woodland by the creek line.
Disturbance Present	Tracks, erosion, moderate grazing and invasive species (Rubber vine)
Dominant Vegetation Species	Dominant Trees: *Eucalyptus tereticornis, Eucalyptus crebra* and *Bauhinia carronii* Dominant Shrubs: *Bauhinia carronii* and *Terminalia oblongata* Dominant Ground Cover: *Dichantium sericeum* and *Megathyrsus maximus*

E

Site Name	DF05
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 728432 7382299
Habitat type	Habitat type 3
Associated RE	11.3.25
Habitat Description	*Eucalyptus tereticornis* and *Bauhinia carronii* woodland on floodplain between creek lines.
Disturbance Present	Moderate grazing and invasive species (Velvet tree pear).
Dominant Vegetation Species	Dominant Trees: *Eucalyptus tereticornis* and *Bauhinia carronii* Dominant Shrubs: *Bauhinia carronii* and *Carissa spinarum* Dominant Ground Cover: *Cenchrus ciliaris*

E

Site Name	DF06
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 729350 7388339
Habitat type	Habitat type 2
Associated RE	11.7.2
Habitat Description	*Acacia rhodoxylon* woodland on undulating soil with ephemeral drainage lines.
Disturbance Present	Road nearby, dieback, invasive species (Velvet tree pear).
Dominant Vegetation Species	Dominant Trees: *Acacia rhodoxylon* Dominant Shrubs: *Owenia acidula, Erythroxylum australe* and *Carissa spinarum* Dominant Ground Cover: *Aristida caput medusae*

E

Site Name	DF07
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 729388 7387547
Habitat type	Habitat type 1
Associated RE	11.5.2
Habitat Description	*Eucalyptus crebra* and *Corymbia clarksoniana* on undulating terrain on top of hill besides an ephemeral drainage feature.
Disturbance Present	Agriculture (clearing prior 1986 pers. comm.), road nearby, evidence of fire (big fire around 2014 less than 100m away, across the road) and invasive species (Velvet tree pear).
Dominant Vegetation Species	Dominant Trees: *Eucalyptus crebra*, *Corymbia clarksoniana*, *Alphitonia excelsa*, *Acacia leiocalyx* subsp. *leiocalyx* and *Acacia rhodoxylon* Dominant Shrubs: *Petalostigma pubescens, Erythroxylum australe* and *Carissa spinarum* Dominant Ground Cover: *Cenchrus ciliaris* and native grasses

E

Site Name	DF08
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 728436 7387550
Habitat type	Habitat type 2
Associated RE	11.7.2
Habitat Description	*Acacia lanceolata* and *Acacia rhodoxylon* woodland with *Eucalyptus crebra* as emergent at foothill of a rocky scarpment.
Disturbance Present	Moderate disturbance due to a nearby track (not in use any longer because of erosion), some evidence of selective logging, moderate grazing and invasive species (Velvet tree pear)
Dominant Vegetation Species	Dominant Trees: *Eucalyptus crebra*, *Acacia shirleyi, Acacia rhodoxylon* Dominant Shrubs: *Psydrax forsteri* Dominant Ground Cover: *Calyptochloa gracilima*

E

Site Name	DF09
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 731322 7387731
Habitat type	Habitat type 1
Associated RE	11.5.2
Habitat Description	*Allocasuarina luehmannii* with *Eucalyptus crebra* and *Corymbia clarksoniana* on sand plains with ephemeral drainage features.
Disturbance Present	Tracks nearby, moderate grazing, clearing land nearby, evidence of fire and invasive species (Velvet tree pear).
Dominant Vegetation Species	Dominant Trees: *Eucalyptus crebra, Allocasuarina luehmannii* and *Corymbia clarksoniana* Dominant Shrubs: *Melaleuca nervosa* and *Petalostigma pubescens* Dominant Ground Cover: *Aristida calycina* and *Eragrostis lacunaria*

E

Site Name	DF10
Associated Project Site	Dingo West
Site Location (Zone, Easting, Northing)	55 K 727566 7386375
Habitat type	Habitat type 4
Associated RE	11.3.2
Habitat Description	*Eucalyptus populnea woodland on* alluvial plains.
Disturbance Present	Adjacent to dam for cattle, heavy presence of stock, tracks nearby, erosion on drainage features and invasive species (Harrisia cactus, Velvet tree pear and Mother of Millions (small infestation)).
Dominant Vegetation Species	Dominant Trees: *Eucalyptus populnea* Dominant Shrubs: *Erythroxylum australe, Archidendropsis basaltica* and *Carissa spinarum* Dominant Ground Cover: Poaceae sp. (grazed)

Dear Lucia

The botanical specimens received by the Queensland Herbarium on 22 May 2017 have been identified as:

DSO2.02; DS04.12; DSO8.12; DSO9,07	*Afrohybanthus stellarioides*
DQ11	#*Cerbera dumicola*, This species is listed as Near Threatened under Queensland's *Nature Conservation Act 1992.*
DSO3.05	*Capparis canescens*
DSO7.09	*Glycine tomentella*
DSO7.23	*Chamaecrista rotundifolia* var. *rotundifolia*
DSO4.16; DSO8.02	*Cyanthillium cinereum*
DSO4.05	*Cyanthillium cinereum*
DSO4.02	Possibly *Glycine* sp. (Marburg K.A.Williams 83006), flowers or fruits required for species confirmation
DSO4.21	*Ipomoea plebeia*
DSO2.05	**Parthenium hysterophorus*. This species is a Restricted Invasive Plant (Category 3) under the Queensland *Biosecurity Act 2014.*
DSO5.03	# *Iphigenia indica*
DSO5.07	*Hypericum gramineum*
DSO5.02	*Stylidium eriorhizum*
DSO7.21	**Senna occidentalis*
DSO4.15	#**Bidens pilosa*
DSO7.27	*Psydrax forsteri*
DSO7.06	#*Polycarpaea corymbosa* var. *minor*

Download a full version of Census of the Queensland Flora 2016
https://data.qld.gov.au/dataset/census-of-the-queensland-flora-2016

DSO7.14	*Melaleuca nervosa*
DSO4.07	Possibly *Paspalidium constrictum*, the specimen has been diseased.
DSO3.01	*Cleistochloa* sp. (Duaringa K.B.Addison 42)
DQ40	*Parsonsia eucalyptophylla*
DQ	*Acacia cretata*
DSO7.16	*Acacia cretata*
DSO8.15	#*Sida* sp. (Aramac E.J.Thompson+ JER192)

*Naturalised, non-native species
These specimens have been kept for incorporation into the Herbarium collection, with thanks.

There is a charge of $640.80 (6 hrs @ $106.80 per hr incl GST) for these identifications and a tax invoice and receipt are enclosed.

Yours sincerely

for G.P.Guymer
Director

TARINGA QLD 4068

Dear Lucia

The botanical specimens received by the Queensland Herbarium on 23 October 2017, have been identified as:

D 10-10	*Ehretia membranifolia*
D 10-11	**Sonchus oleraceus*
D 10-3	*Glycine tabacina*
DS 13-01	*Goodenia* sp.
DS 13-02	*Acacia leiocalyx* subsp. *leiocalyx*
DS 14-8	*Archidendropsis basaltica*, the fruit like structures on this specimen are insect galls
SD 14-4	*Sphaeromorphaea subintegra*

*Naturalised, non-native species

There is a charge of $165.82 (1.5 hrs @ $110.55 per hr incl GST) for these identifications. A tax invoice and receipt are enclosed.

Yours sincerely

G.P. Guymer
Director

TARINGA Qld 4068

Dear Lucia

The botanical specimens received by the Queensland Herbarium on 26 April 2018 have been identified as:

	Dingo Project
PCUS/1	**Sporobolus pyramidalis*. This species is a Restricted Invasive Plant (Category 3) under the Queensland *Biosecurity Act 2014*.
PS17-15	*Aristida gracilipes*
DS21-2	*Panicum effusum*
DS17-22	*Ehretia membranifolia*
DB-3	*Goodenia disperma*
DS17-5	*Eriochloa procera*
DB-1	*Laxmannia gracilis*
DS18-5	*Cyperus concinnus*
RCDS/1	*Cyperus trinervis*
DS17-1	*Enneapogon* sp. probably *Enneapogon lindleyanus*
DB-2	*Cyanthillium cinereum*
DB-4	*Murdannia graminea*
DS19-2	**Emilia sonchifolia* var. *sonchifolia*
DS16-6	Poaceae sp. indeterminate. Fertile material is required for complete identification.

*Naturalised, non-native species
There is a charge of $1216.05 (11 hrs @ $110.55 per hr incl GST) for these identifications.

Yours sincerely

G.P.Guymer
Director

This disclaimer does not limit any rights Balance! Environmental may have under the Copyright Act 1968 (Cth).

The Client acknowledges that the Final Report is intended for the sole use of the Client, and only to be used for the Intended Purpose. Any representation or recommendation contained in the Final Report is made only to the Client. Balance! Environmental will not be liable for any loss or damage whatsoever arising from the use and/or reliance on the Final Report by any third party.

Methods

Data received and post-processing

This survey was conducted at four sites over six consecutive nights, using two Anabat Express detectors (Titley Scientific, Brisbane) provided by *Balance! Environmental*. Table 1 provides a summary of detector log data, matched to site information provided by the client.

AnalookW (Corben 2015) was used to download the raw ZCA data and log files and to generate Anabat zero-crossing (ZC) call sequence files. This process yielded more than 68,000 sequence files.

Due the large size of the data set, and high noise-to-signal ratio evident in an initial manual scan of the data, a generic noise filter (after Corben 2009) was used to extract only those files that contained recognisable bat call sequences. This reduced the analysable data set to just under 1000 files containing potentially-identifiable bat calls.

Call identification

All sequence files that passed the noise filter were viewed in *AnalookW*, with species identification achieved manually by comparing the call spectrograms with those of reference calls from central and northern Queensland and with reference to published call descriptions (e.g. Reinhold *et al.* 2001; Pennay *et al*. 2004). Calls with fewer than four clearly-defined, non-fragmented pulses were excluded from the analysis.

Species' identification was also guided by considering probability of occurrence based on general distribution information (Churchill 2008; van Dyck *et al.* 2013) and/or *Atlas of Living Australia* on-line database records (http://www.ala.org.au).

Reporting standard

The format and content of this report follows Australasian Bat Society standards for the interpretation and reporting of bat call data (Reardon 2003), available on-line at http://www.ausbats.org.au/. Species nomenclature follows Reardon *et al.* (2015).

Results & Discussion

Detector log files indicate that both detectors recorded continuously from sunset to sunrise on each night of survey; however, no sequence files were retrieved from the raw data file recorded on Anabat-2 on the night of 9th May (second night at site FS03). The cause of this failure is not apparent from log data recorded by the detector.

At least thirteen and probably fourteen species were recorded during the Dingo survey of May 2017 (see Table 2).

The only species not positively identified was *Chalinolobus nigrogriseus*, which shares many call characteristics with *Scotorepens greyii*. The latter species was reliably identified for sites FS01, FS02 and FS03, but a number of calls from sites FS02 and FS03 had characteristics intermediate between these two species. All other species were positively identified from at least one call recorded during the survey; although all species were not recorded at every site.

Many calls could not be resolved to species level, due to similarities between the calls of several species that are likely to occur in the study area. These calls were allocated to species groups and each member of the group listed as "possible" unless other calls were unequivocally identified.

The species groups used in this analysis included:

- *Chalinolobus gouldii* / *Mormopterus ridei* / *Scotorepens balstoni*;
- *Chalinolobus nigrogriseus* / *Scotorepens greyii*;
- *Chalinolobus picatus* / *Scotorepens greyii;* and
- *Saccolaimus flaviventris* / *Chaerephon jobensis*.

None of the species recorded in this survey are listed as threatened under State or Commonwealth legislation; however, it was interesting to note the presence of three species that generally rely on subterranean roosts (*Rhinolophus megaphyllus, Vespadelus troughtoni* and *Miniopterus orianae oceanensis*). These three species were all recorded at FS03, with *M. o. oceanensis* also recorded at sites FS01 and FS02. A cursory survey of *Google Earth* imagery suggests that natural subterranean roosts are probably not present in the immediate vicinity of the study area, so it is assumed these bats are roosting in man-made structures (e.g. culverts and bridges along the nearby Capricorn Highway) and then commuting to the study area to forage. All three species are also present in Blackdown Tableland National Park, south of the study area, although it is unlikely that *R. megaphyllus* or *V. troughtoni* would commute 15-20km from there to forage in the study area.

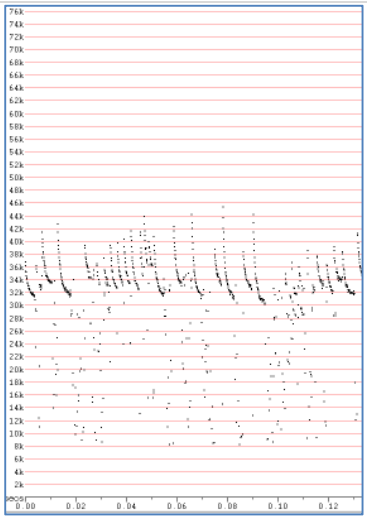
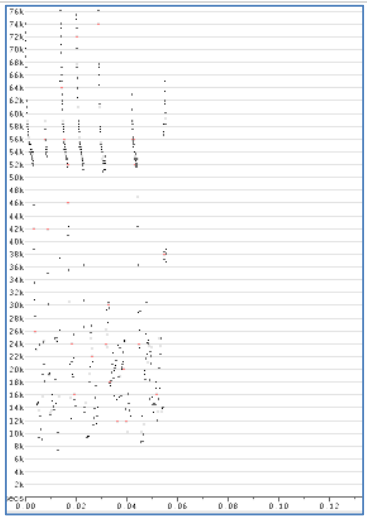
Glossary



Technical terms used in this report are described in the following table.

Approach phase	The part of a bat *call* emitted as the bat starts to home in on a detected prey item; a transitional series of *pulses* between the *search phase* and *feeding buzz*, that become progressively steeper and shorter in duration.
Call	Refers to a single bat call, made up of a series of individual sound *pulses* in one or more *phases* (*search, approach, feeding buzz*).
CF (=Constant Frequency)	A type of *pulse* in which the dominant component consists of a more-or-less 'pure tone' of sound at a Constant Frequency; with *shape* appearing flat on the sonogram. Often also contains a brief *FM* component at the beginning and/or end of the CF component (*viz.* FM-CF-FM).
Characteristic frequency (Fc)	The frequency of the flattest part of a *pulse*; usually the lowest frequency reached in the *qCF* component of a pulse. This is often the primary diagnostic feature for species identification.
Duration	The time period from the beginning of a *pulse* to the end of the pulse.
Feeding buzz	The terminal part of a *call*, following the *approach phase*, emitted as the bat catches a prey item; a distinctive, rapid series of very steep, very short-duration pulses.
FM (=Frequency Modulated)	A type of *pulse* in which there is substantial change in frequency from beginning to end; *shape* ranges from almost vertical and linear through varying degrees of curvature.
FC range	Refers to the range of frequencies occupied by the *characteristic frequency* section of *pulses* within a call or set of calls.
Frequency sweep or "band-width"	The range of frequencies through which a *pulse* sweeps from beginning to end; Maximum frequency (Fmax) – minimum frequency (Fmin).
Knee	The transitional part of a *pulse* between the initial (usually steeper) frequency sweep and the *characteristic frequency* section (usually flatter); time to knee (Tk) and frequency of knee (Fk) can be diagnostic for some species.
Pulse	An individual pulse of sound within a bat *call*; the *shape*, *duration* and *characteristic frequency* of a pulse are the key diagnostic features used to differentiate species.
Pulse body	The part of the *pulse* between the *knee* and *tail* and containing the *characteristic frequency* section.
Pulse shape	The general appearance of a *pulse* on the sonogram, described using relative terms related to features such as slope and degree of curvature. See also *CF, qCF* and *FM*.
qCF (=quasi Constant Frequency)	A type of *pulse* in which there is very little change in frequency from beginning to end; *shape* appears to be almost flat. Some pulses also contain an *FM* component at the beginning and/or end of the qCF component (*viz.* FM-qCF).
Search phase	The part of a bat *call* generally required for reliable species diagnosis. A consistent series of *pulses* emitted by a bat that is searching for prey or and/or navigating through its habitat. Search phase pulses generally have longer duration, flatter slope and more consistent shape than *approach phase* and *feeding buzz* pulses.
Sequence	Literally, a sequence of *pulses* that may be from one or more bats; but generally refers to a *call* or part (e.g. *phase*) of a call.
Tail	The final component of a *pulse*, following the *characteristic frequency* section; may consist of a short or long sweep of frequencies either upward or downward from the Fc; or may be absent.



Appendix 1 Representative call sequences from the Dingo survey, 5-11 May 2017.

Figure 1 *Bat detection sites in the Dingo survey area, 19-29 September 2017*

Data post-processing

Balance! Environmental received eighteen raw Anabat ZCA files and associated LOG files for post-processing and analysis. *AnalookW* (Corben 2015) was used to convert the ZCA files to 4365 Anabat call sequence files for use in species identification.

Call identification

All Anabat sequence files were viewed in *AnalookW*, with a subset of all call types recorded each night at each site selected for further analysis. Species identification was achieved manually by comparing the call spectrograms of the selected files with those of reference calls from central and southern Queensland and to published call descriptions (e.g. Reinhold *et al.* 2001; Pennay *et al*. 2004).

Calls with fewer than four clearly-defined, non-fragmented pulses were excluded from the analysis.

Species' identification was also guided by considering probability of occurrence based on general distribution information (Churchill 2008; van Dyck *et al.* 2013) and/or *Atlas of Living Australia* on-line database records (http://www.ala.org.au).

Reporting standard

The format and content of this report follows Australasian Bat Society standards for the interpretation and reporting of bat call data (Reardon 2003), available on-line at http://www.ausbats.org.au/.

Species nomenclature follows Jackson & Groves (2015). Note that this treatment of Australian mammal taxonomy elevates the sub-genus names proposed by Reardon *et al.* (2014) for the *Mormopterus* free-tailed bats to genus level, hence *Ozimops* (*O. lumsdenae, O. petersi, O. ridei*) and *Setirostris* (*S. eleryi*) are used herein.

Results & Discussion

Detection success

More than 75% of the sequence files (3374/4365) were recorded by Anabat 1 (SN434354), with sites FS08 and FS10 producing over half of the total recorded bat calls. The detector sensitivity setting was the same (115) on both detectors for all nights, so, assuming microphone equivalence and similar deployment set-up, this marked difference in call detection probably reflects a real difference in bat activity levels related to habitat suitability and, possibly, bat abundance.

Location data show sites sampled by Anabat 1 were near water (FS05 and FS10) or on lateritic escarpment with potential subterranean roosting habitat (FS08); whereas sites FS06, FS07 and FS09 (Anabat 2) were distant from water and in more open vegetation sites (see Figure 1). Proximity to water has been shown to be a key determinant in roost-selection and foraging activity of bats (e.g. see Kalcounis-Rüppell *et al.* 2005; Rainho & Palmeirim 2011; Blakey *et al.* 2017). Furthermore, a significant proportion of the calls recorded at site FS08 were from the Eastern Cave Bat, *Vespadelus troughtoni*, which roosts in shallow caves and overhangs (Parnaby *et al.* 2008), such as those observed by the client in the vicinity of FS08.

Species identified

Species identification was attempted on 227 call sequence files.

At least 14 and up to 19 species were recorded during these surveys (see Table 2). Thirteen call types were positively identified to individual species, while one type was reliably identified to the genus *Nyctophilus* but could not be further differentiated. Two *Nyctophilus* species potentially occur in the study area: *N. geoffroyi* and *N. gouldi*.

Some calls could not be reliably identified due to similarities in the call characteristics of several species that may occur in the study area. Where such unresolved calls were encountered, they were allocated to species groups. All group members are listed as "probable" in Table 1, unless additional calls of one or more group members were positively identified for the same site. The groups used in this analysis included:

- *Chalinolobus gouldii / Ozimops petersi / O. ridei;*
- *C. gouldii / Scotorepens balstoni;*
- *Chalinolobus picatus / Scotorepens greyii / Vespadelus baverstocki;*
- *Scotorepens greyii / Setirostris eleryi;*
- *Vespadelus troughtoni / Chalinolobus morio;* and
- *Taphozous troughtoni / Mormopterus lumsdenae*.

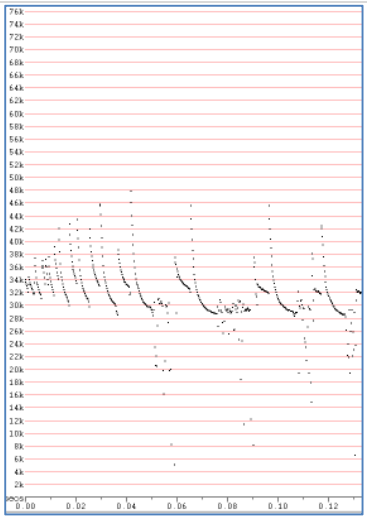
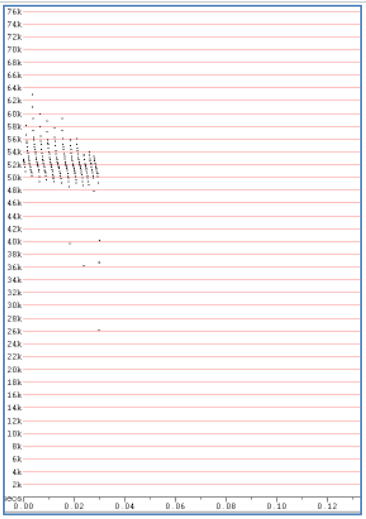
Glossary

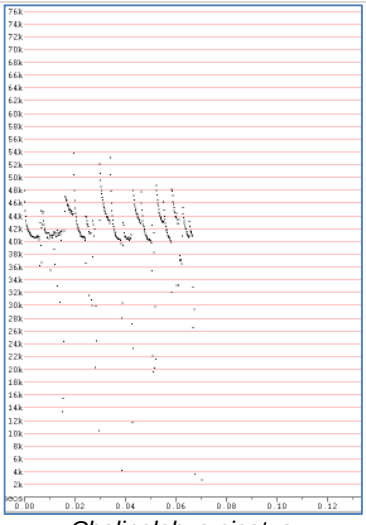


Technical terms used in this report are described in the following table.

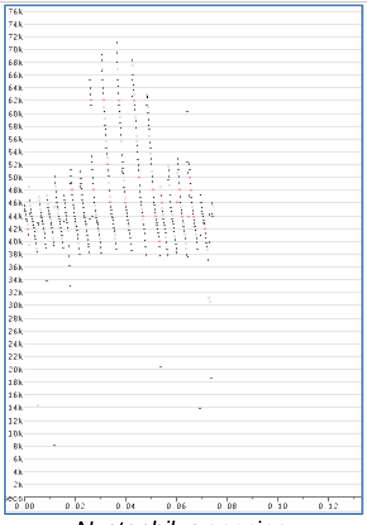
Approach phase	The part of a bat *call* emitted as the bat starts to home in on a detected prey item; a transitional series of *pulses* between the *search phase* and *feeding buzz*, that become progressively steeper and shorter in duration.
Call	Refers to a single bat call, made up of a series of individual sound *pulses* in one or more *phases* (*search, approach, feeding buzz*).
CF (=Constant Frequency)	A type of *pulse* in which the dominant component consists of a more-or-less 'pure tone' of sound at a Constant Frequency; with *shape* appearing flat on the sonogram. Often also contains a brief *FM* component at the beginning and/or end of the CF component (*viz.* FM-CF-FM).
Characteristic frequency (Fc)	The frequency of the flattest part of a *pulse*; usually the lowest frequency reached in the *qCF* component of a pulse. This is often the primary diagnostic feature for species identification.
Duration	The time period from the beginning of a *pulse* to the end of the pulse.
Feeding buzz	The terminal part of a *call*, following the *approach phase*, emitted as the bat catches a prey item; a distinctive, rapid series of very steep, very short-duration pulses.
FM (=Frequency Modulated)	A type of *pulse* in which there is substantial change in frequency from beginning to end; *shape* ranges from almost vertical and linear through varying degrees of curvature.
FC range	Refers to the range of frequencies occupied by the *characteristic frequency* section of *pulses* within a call or set of calls.
Frequency sweep or "band-width"	The range of frequencies through which a *pulse* sweeps from beginning to end; Maximum frequency (Fmax) – minimum frequency (Fmin).
Knee	The transitional part of a *pulse* between the initial (usually steeper) frequency sweep and the *characteristic frequency* section (usually flatter); time to knee (Tk) and frequency of knee (Fk) can be diagnostic for some species.
Pulse	An individual pulse of sound within a bat *call*; the *shape*, *duration* and *characteristic frequency* of a pulse are the key diagnostic features used to differentiate species.
Pulse body	The part of the *pulse* between the *knee* and *tail* and containing the *characteristic frequency* section.
Pulse shape	The general appearance of a *pulse* on the sonogram, described using relative terms related to features such as slope and degree of curvature. See also *CF, qCF* and *FM*.
qCF (=quasi Constant Frequency)	A type of *pulse* in which there is very little change in frequency from beginning to end; *shape* appears to be almost flat. Some pulses also contain an *FM* component at the beginning and/or end of the qCF component (*viz.* FM-qCF).
Search phase	The part of a bat *call* generally required for reliable species diagnosis. A consistent series of *pulses* emitted by a bat that is searching for prey or and/or navigating through its habitat. Search phase pulses generally have longer duration, flatter slope and more consistent shape than *approach phase* and *feeding buzz* pulses.
Sequence	Literally, a sequence of *pulses* that may be from one or more bats; but generally refers to a *call* or part (e.g. *phase*) of a call.
Tail	The final component of a *pulse*, following the *characteristic frequency* section; may consist of a short or long sweep of frequencies either upward or downward from the Fc; or may be absent.



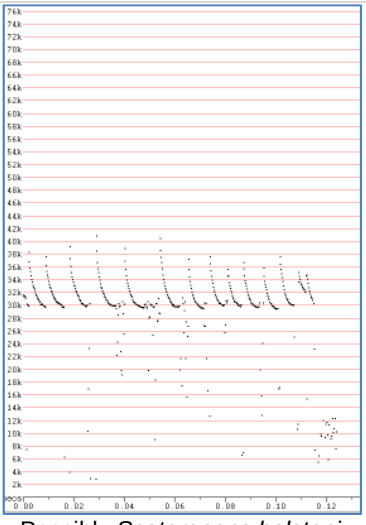
Appendix 1 Representative call sequences from the Dingo area survey, September 2017.
(AnalookW 'F7 compressed' display: x=time(s); y=frequency(kHz); time between pulses removed)



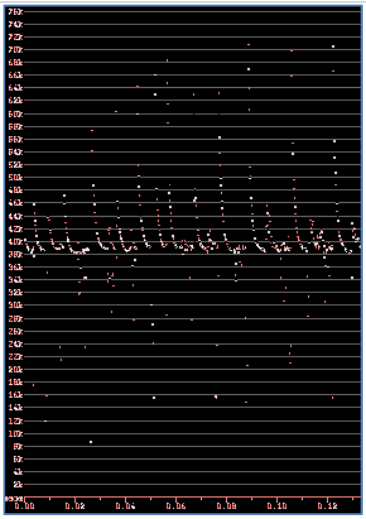
Rhinolophus megaphyllus



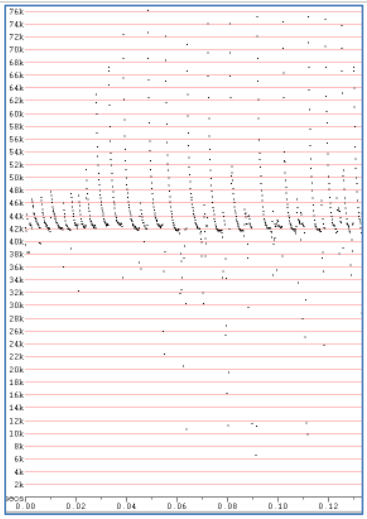
Chalinolobus gouldii



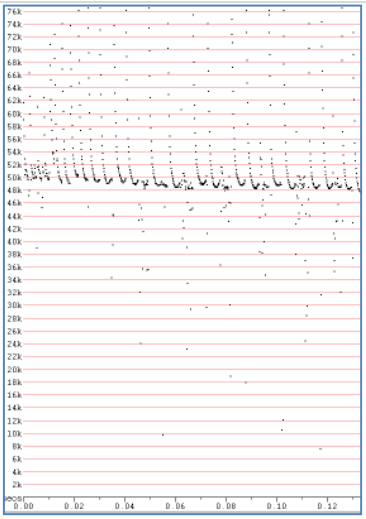
Chalinolobus morio



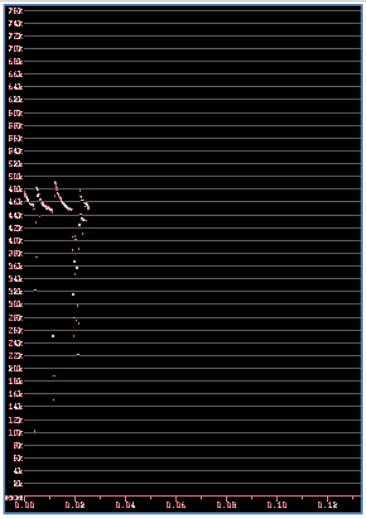
Chalinolobus picatus



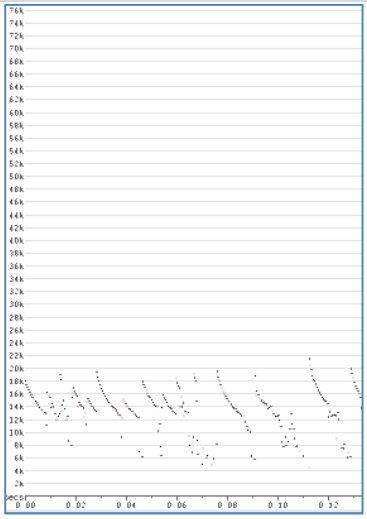
Nyctophilus species



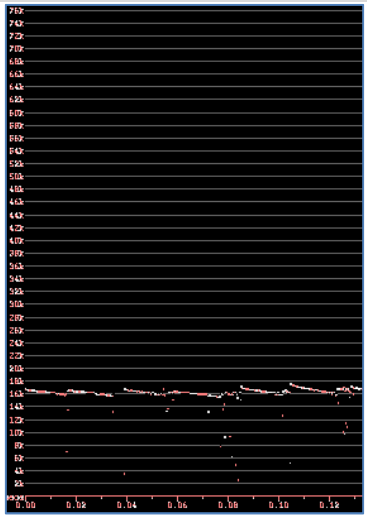
Possibly *Scotorepens balstoni*



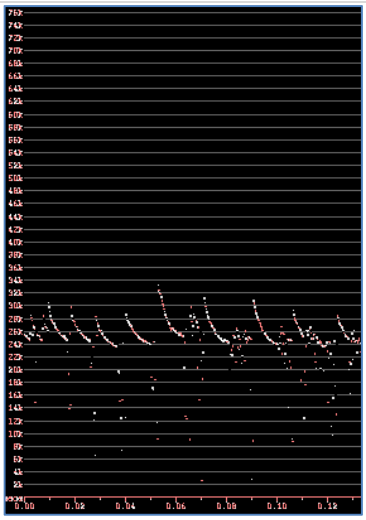
Scotorepens greyii



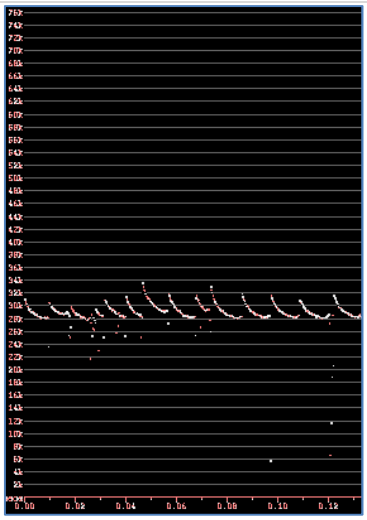
Probably *Vespadelus baverstocki*



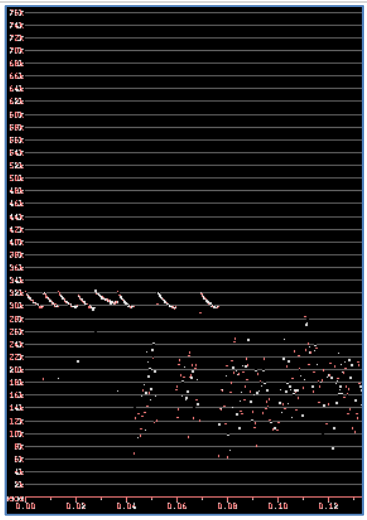
Vespadelus troughtoni



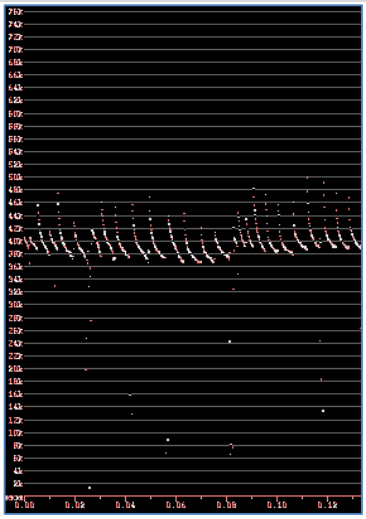
Miniopterus orianae oceanensis



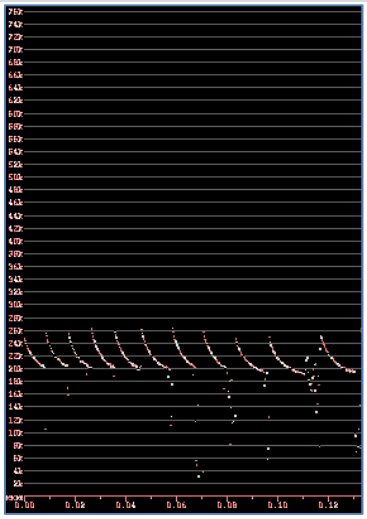
Austronomus australis



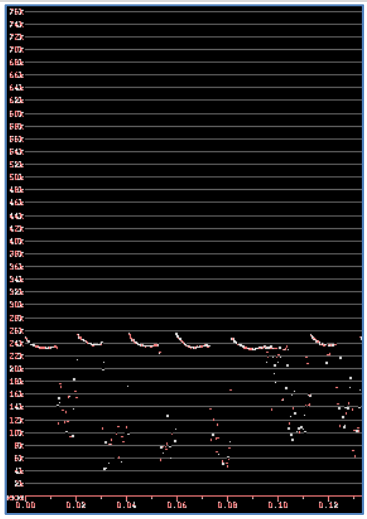
Chaerephon jobensis



Ozimops lumsdenae



Ozimops petersi



Ozimops ridei

Possibly *Setirostris eleryi*

Saccolaimus flaviventris

Possibly *Taphozous troughtoni*

Microbat Call Identification Report

Prepared for ("Client"):	AustralAsian Resource Consultants
Survey location/project name:	Dingo West Stage 3
Survey dates:	17-22 April 2018
Client project reference:	
Job no.:	AARC-1805
Report date:	30 May 2018

Methods

Survey summary

The survey was conducted at four sites (see Figure 1) over six consecutive nights, using Anabat Express detectors (Titley Scientific, Brisbane). Deployment details are summarised in Table 1.

Table 1 Deployment schedule for the Dingo West Stage 3 bat-detector survey, 17-22 April 2018.

Derived from detector LOG files and survey summary information provided by the client.

Site name	Coordinates		Detector Serial No.	Deployment date	Operating time	
	Latitude	Longitude			Start	Finish
FS11	-23.661	149.2592	SN434344	17-Apr	18:11:59	6:22:13
				18-Apr	18:11:16	6:22:47
				19-Apr	18:10:32	6:23:21

				22-Apr	18:08:12	6:24:59

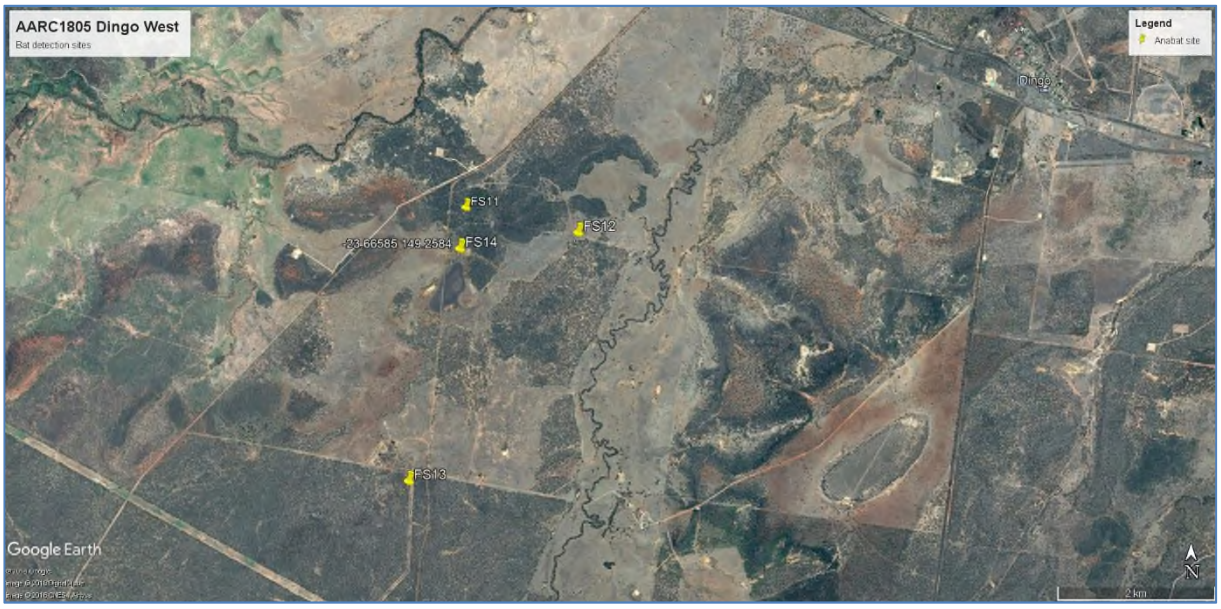

Figure 1 *Bat detection sites in the Dingo West survey area, 17-22 April 2018.*

Data post-processing

Balance! Environmental received 12 raw Anabat ZCA files and associated LOG files for post-processing and analysis. *AnalookW* (Corben 2017) was used to convert the ZCA files to Anabat call sequence files (ZC files). This process yielded 25,023 ZC files, which were passed through a generic noise filter in *AnalookW* to extract only those files that contained potentially-identifiable bat calls. This filtration process extracted 3588 ZC files for analysis.

Call identification

All Anabat sequence files that passed the noise filter were viewed in *AnalookW*, with a subset of all call types recorded at each site selected for further analysis. Species identification was achieved manually by comparing the call spectrograms of the selected files with those of reference calls from central and southern Queensland and to published call descriptions (e.g. Reinhold *et al.* 2001; Pennay *et al*. 2004).

Calls with fewer than four clearly-defined, non-fragmented pulses were excluded from the analysis.

Species' identification was also guided by considering probability of occurrence based on general distribution information (Churchill 2008; van Dyck *et al.* 2013) and/or *Atlas of Living Australia* on-line database records (http://www.ala.org.au).

Reporting standard

The format and content of this report follows Australasian Bat Society standards for the interpretation and reporting of bat call data (Reardon 2003), available on-line at http://www.ausbats.org.au/.

Species nomenclature follows Jackson & Groves (2015), which elevates the sub-genus names proposed by Reardon *et al.* (2014) for the *Mormopterus* free-tailed bats to genus level, hence *Ozimops* (*O. lumsdenae* and *O. ridei*) is used herein.

Results & Discussion

Species identification was attempted on 658 call sequence files.

Table 2 provides a summary of species recorded at each site. Twelve species were positively identified, with one further call type allocated reliably to the *Nyctophilus* genus, within which species' calls cannot be differentiated. Two *Nyctophilus* species probably occur in the study area: *N. geoffroyi*; and *N. gouldi*.

Nine call types could not be reliably identified due to similarities in the call characteristics of several species that may occur in the study area. These unresolved calls were allocated to species groups (see lower half of Table 2), most of which contained species that were also identified positively (see upper part of Table 2); however, two groups included species that were not otherwise identified in this analysis:

- *Taphozous troughtoni / Ozimops lumsdenae*
    - Calls similar in frequency and pulse-shape to those allocated to *O. lumsdenae*, but more uniform pulse-shape throughout sequence and often much flatter pulse-shape
- *Vespadelus troughtoni / Chalinolobus morio*
    - Just one call allocated to this group, with no other evidence of either species from the entire data set
    - Call was brief and somewhat fragmented, with indeterminate pulse shape

Table 2 Microbat species recorded during the Dingo West Stage 3 survey, 17-22 April 2018.

Number of calls allocated to each species or group

Site name:	FS11	FS12	FS13	FS14	Total calls for species
Species positively identified					
Rhinolophus megaphyllus	1				1
Chalinolobus gouldii	25	64	17	13	119

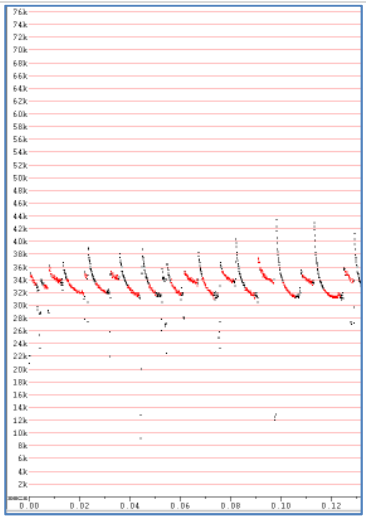
Glossary



Technical terms used in this report are described in the following table.

Approach phase	The part of a bat *call* emitted as the bat starts to home in on a detected prey item; a transitional series of *pulses* between the *search phase* and *feeding buzz*, that become progressively steeper and shorter in duration.
Call	Refers to a single bat call, made up of a series of individual sound *pulses* in one or more *phases* (*search, approach, feeding buzz*).
CF (=Constant Frequency)	A type of *pulse* in which the dominant component consists of a more-or-less 'pure tone' of sound at a Constant Frequency; with *shape* appearing flat on the sonogram. Often also contains a brief *FM* component at the beginning and/or end of the CF component (*viz.* FM-CF-FM).
Characteristic frequency (Fc)	The frequency of the flattest part of a *pulse*; usually the lowest frequency reached in the *qCF* component of a pulse. This is often the primary diagnostic feature for species identification.
Duration	The time period from the beginning of a *pulse* to the end of the pulse.
Feeding buzz	The terminal part of a *call*, following the *approach phase*, emitted as the bat catches a prey item; a distinctive, rapid series of very steep, very short-duration pulses.
FM (=Frequency Modulated)	A type of *pulse* in which there is substantial change in frequency from beginning to end; *shape* ranges from almost vertical and linear through varying degrees of curvature.
FC range	Refers to the range of frequencies occupied by the *characteristic frequency* section of *pulses* within a call or set of calls.
Frequency sweep or "band-width"	The range of frequencies through which a *pulse* sweeps from beginning to end; Maximum frequency (Fmax) – minimum frequency (Fmin).
Knee	The transitional part of a *pulse* between the initial (usually steeper) frequency sweep and the *characteristic frequency* section (usually flatter); time to knee (Tk) and frequency of knee (Fk) can be diagnostic for some species.
Pulse	An individual pulse of sound within a bat *call*; the *shape*, *duration* and *characteristic frequency* of a pulse are the key diagnostic features used to differentiate species.
Pulse body	The part of the *pulse* between the *knee* and *tail* and containing the *characteristic frequency* section.
Pulse shape	The general appearance of a *pulse* on the sonogram, described using relative terms related to features such as slope and degree of curvature. See also *CF, qCF* and *FM*.
qCF (=quasi Constant Frequency)	A type of *pulse* in which there is very little change in frequency from beginning to end; *shape* appears to be almost flat. Some pulses also contain an *FM* component at the beginning and/or end of the qCF component (*viz.* FM-qCF).
Search phase	The part of a bat *call* generally required for reliable species diagnosis. A consistent series of *pulses* emitted by a bat that is searching for prey or and/or navigating through its habitat. Search phase pulses generally have longer duration, flatter slope and more consistent shape than *approach phase* and *feeding buzz* pulses.
Sequence	Literally, a sequence of *pulses* that may be from one or more bats; but generally refers to a *call* or part (e.g. *phase*) of a call.
Tail	The final component of a *pulse*, following the *characteristic frequency* section; may consist of a short or long sweep of frequencies either upward or downward from the Fc; or may be absent.

Family	*Scientific Name*	Common Name	NC Act Status	EPBC Act Status	VC1	VC2	VC3	VC4
Mimosaceae	*Archidendropsis basaltica*	Red lancewood	LC	-				x
Mimosaceae	*Vachellia farnesiana*	Mimosa bush	I	-				
Moraceae	*Ficus opposita*	Sandpaper fig	LC	-			x	
Myrtaceae	*Corymbia clarksoniana*		LC	-	x	x	x	x
Myrtaceae	*Corymbia dallachiana*		LC	-				x
Myrtaceae	*Corymbia tesselaris*	Moreton bay ash	LC	-	x		x	x
Myrtaceae	*Eucalyptus* (sappling)		LC	-			x	
Myrtaceae	*E. crebra/E. populnea (hybrid)*		LC	-			x	
Myrtaceae	*Eucalyptus crebra*	Narrow-leaved red ironbark	LC	-	x	x	x	
Myrtaceae	*Eucalyptus exserta*	Queensland peppermint	LC	-	x			
Myrtaceae	*Eucalyptus melanophloia*		LC	-				x
Myrtaceae	*Eucalyptus populnea*	Poplar box	LC	-	x		x	x
Myrtaceae	*Eucalyptus tereticornis*	River blue gum	LC	-			x	x
Myrtaceae	*Melaleuca* sp.			-			x	
Myrtaceae	*Melaleuca nervosa*		LC	-	x			
Nyctaginaceae	*Boerhavia dominii*	Tarvine	LC	-				x
Oleaceae	*Jasminum didymum*		LC	-				x
Oxalidaceae	*Oxalis corniculata*	Yellow wood sorrel	I	-	x	x	x	
Pentapetaceae	*Melhania oblongifolia*		LC	-				x
Phyllanthaceae	*Phyllanthaceae sp.*							
Phyllanthaceae	*Phyllanthus virgatus*		LC	-	x	x	x	x
Picrodendraceae	*Petalostigma pubescens*	Quinine tree	LC	-	x	x	x	x
Poaceae	*Alloteropsis cimicina*		LC	-	x		x	
Poaceae	*Aristida* sp.			-	x			
Poaceae	*Aristida calycina*		LC	-	x	x		x
Poaceae	*Aristida caput-medusae*		LC	-	x	x	x	
Poaceae	*Aristida gracilipes*		LC	-				x

Family	*Scientific Name*	Common Name	NC Act Status	EPBC Act Status	VC1	VC2	VC3	VC4
Poaceae	*Aristida jerichoensis*		LC	-	x		x	
Poaceae	*Aristida perniciosa*		LC	-				x
Poaceae	*Aristida pruinosa*		LC	-				
Poaceae	*Bothriochloa decipiens*		LC	-	x		x	
Poaceae	*Bothriochloa ewartiana*	Desert bluegrass	LC	-			x	x
Poaceae	*Bothriochloa pertusa*		I	-			x	
Poaceae	*Calyptochloa gracilima*		LC	-	x	x	x	
Poaceae	*Cenchrus ciliaris*	Buffel grass	I	-	x	x	x	x
Poaceae	*Chrysopogon fallax*		LC	-	x	x	x	
Poaceae	*Cleistochloa sp. (Duaringa K.B.Adison 42)*		LC	-	x	x		
Poaceae	*Cymbopogon refractus*	Barbed-wire grass	LC	-	x			
Poaceae	*Cynodon dactylon*	Native couch	I	-	x			x
Poaceae	*Dichanthium sericeum*	Queensland bluegrass	LC	-			x	
Poaceae	*Digitaria brownii (dead)**		LC	-	x			
Poaceae	*Digitaria diminuta*		LC	-		x	x	
Poaceae	*Digitaria divaricatissima*	Spreading umbrella grass	LC	-			x	
Poaceae	*Digitaria sp* (not enough material for a positive ID)				x			
Poaceae	*Dinebra ligulata*		LC	-		x		
Poaceae	*Enneapogon lindleyanus*		LC	-		x	x	x
Poaceae	*Enteropogon acicularis*	Curly windmill grass	LC	-	x			
Poaceae	*Entolasia stricta*	Wiry panic	LC	-		x	x	
Poaceae	*Eragrostis sp. (not enough material to ID)*				x			
Poaceae	*Eragrostis elongata*		LC	-	x			
Poaceae	*Eragrostis lacunaria*	Purple lovegrass	LC	-	x	x	x	x
Poaceae	*Eragrostis sororia*	Woodland lovegrass	LC	-	x		x	x
Poaceae	*Eriachne mucronata*		LC	-	x			

Family	*Scientific Name*	Common Name	NC Act Status	EPBC Act Status	VC1	VC2	VC3	VC4
Poaceae	*Eriochloa procera*	Slender cupgrass	LC	-				x
Poaceae	*Eulalia aurea*	Silky browntop	LC	-	x			
Poaceae	*Heteropogon contortus*	Black spear grass	LC	-		x	x	x
Poaceae	*Megathyrsus maximus*		I	-	x		x	
Poaceae	*Melinis repens*	Red natal grass	I	-	x		x	x
Poaceae	*Panicum decompositum*		LC	-			x	
Poaceae	*Panicum effusum*		LC	-			x	x
Poaceae	*Paspalidium caespitosum*	Brigalow grass	LC	-	x	x		x
Poaceae	*Paspalidium constrictum**		LC	-			x	
Poaceae	*Paspalidium* sp.				x			
Poaceae	*Perotis rara*	Comet grass	LC	-	x		x	
Poaceae	*Sporobolus caroli*	Fairy grass	LC	-	x	x	x	x
Poaceae	*Sporobolus creber*	Western rat's tail Grass	LC	-				x
Poaceae	*Themeda triandra*	Kangaroo grass	LC	-			x	x
Poaceae	*Urochloa mosambicensis*	Sabi grass	LC	-	x	x	x	x
Poaceae	*Urochloa* sp.				x		x	
Poaceae	*Poaceae sp. (grazed)*				x			x
Polygonaceae	*Duma florulenta*		LC	-				x
Portulacaceae	*Portulaca bicolor*		LC	-				
Portulacaceae	*Portulaca filifolia*		LC	-			x	
Portulacaceae	*Portulaca pilosa*		I	-				
Proteaceae	*Grevillea striata*	Beefwood	LC	-	x		x	
Pteridaceae	*Cheilanthes sieberi subsp sieberi*	Poison rock fern	LC	-			x	
Pteridaceae	*Cheilanthes* sp.							
Rhamnaceae	*Alphitonia excelsa*	Soap tree	LC	-	x	x	x	x
Rhamnaceae	*Ventilago viminalis*	Supplejack	LC	-				
Rubiaceae	*Coelospermum reticulatum*		LC	-	x	x	x	
Rubiaceae	*Everistia vacciniifolia*		LC	-	x		x	

Family	*Scientific Name*	Common Name	NC Act Status	EPBC Act Status	VC1	VC2	VC3	VC4
Rubiaceae	*Psydrax forsteri*		LC	-	x	x		
Rubiaceae	*Psydrax johnsonii*		LC	-			x	x
Rubiaceae	*Psydrax oleifolia*		LC	-		x		
Rubiaceae	*Spermacoce brachystema*		LC	-	x		x	
Rubiaceae	*Coelospermum reticulatum*		LC	-				x
Rutaceae	*Flindersia dissosperma*		LC	-				
Rutaceae	*Rutaceae* sp.							x
Sapindaceae	*Atalaya hemiglauca*	Whitewood	LC	-			x	x
Scrophulariaceae	*Myoporum acuminatum*	Coastal boobialla	LC	-				
Stylidiaceae	*Stylidium eriorhizum*		LC	-				
Verbenaceae	*Glandularia aristigera*	Mayne's pest	I	-				
Violaceae	*Afrohybanthus stellarioides*		LC	-	x	x	x	
Violaceae	*Afrohybanthus enneaspermus*		LC	-				x

Appendix I Fauna Species List

Family	*Scientific Name*	Common Name	NC Act/LP Act	EPBC Act	2017 - Autumn						2017 - Spring							2018 - Autumn						
					OPPS	DF01	DF02	DF03	DF04	Total	OPPS	DF05	DF06	DF07	DF08	DF09	DF10	Total	OPPS	DF11	DF12	DF13	DF14	DF15	Total
Amphibians																									
Bufonidae	*Rhinella marina*	Cane toad	I	-			5		8	13		13	4				8	25			5	1		10	16
Hylidae	*Litoria rubella*	Naked tree frog	LC	-						0		1						1			1				1
Hylidae	*Litoria caerulea*	Common green tree frog	LC	-			7		2	9								0			1			1	2
Hylidae	*Litoria latopalmata*	Broad-palmed frog	LC	-			1			1								0							0
Hylidae	*Litoria inermis*	Bumpy rocket frog	LC	-	1					1	1							1			1		2	6	9
Limnodynastidae	*Limnodynastes salmini*	Salmon-striped frog	LC	-						0		1						1							0
Limnodynastidae	*Limnodynastes tasmaniensis*	Spotted grass frog	LC	-						0		2						2			2		3		5
Limnodynastidae	*Platyplectrum ornatum*	Ornate burrowing frog	LC	-			249	2	25	276		1						1			3		5		8
				TOTAL AMPHIBIANS	**1**	**0**	**262**	**2**	**35**	**300**	**1**	**18**	**4**	**0**	**0**	**0**	**8**	**31**	**0**	**0**	**13**	**1**	**10**	**17**	**41**
Reptiles																									
Elapidae	*Cryptophis boschmai*	Carpentaria snake	LC	-						0				2				2					1		1
Elapidae	*Demansia psammophis*	Yellow-faced whip snake	LC	-						0		1						1							0
Elapidae	*Furina ornata*	Orange-naped snake	LC	-						0							1	1							0
Elapidae	*Hoplocephalus bitorquatus*	Pale-headed snake	LC	-					1	1								0							0
Elapidae	*Pseudonaja textilis*	Eastern Brown snake	LC	-	1					1	1	1						2							0
Pythonidae	*Aspidites melanocephalus*	Black headed python	LC	-																					
Agamidae	*Pogona barbata*	Bearded dragon	LC	-		1				1	1							1		1		1			2
Agamidae	*Diporiphora australis*	Tommy roundhead	LC	-						0				2		4		6				3			3
Varanidae	*Varanus tristis orientalis*	Freckled monitor	LC	-						0							1	1							0
Carphodactylidae	*Nephrurus asper*	Prickly knob-tailed gecko	LC	-						0					1			1							0
Diplodactylidae	*Diplodactylus vittatus*	Eastern stone gecko	LC	-						0				1				1							0
Diplodactylidae	*Lucasium steindachneri*	Box-patterned gecko	LC	-						0						2		2							0
Gekkonidae	*Heteronotia binoei*	Bynoe's gecko	LC	-		1		4	2	7			1	2	2	1	2	8		1					1
Gekkonidae	*Gehyra dubia*	Dubious dtella	LC	-				1	1	2					1		1	2						1	1
Pygopodidae	*Lialis burtonis*	Burton's legless lizard	LC	-		1				1								0							0
Scincidae	*Carlia munda*	Shade-litter rainbow skink	LC	-						0								0			1				1
Scincidae	*Carlia rubigo*	Orange-flanked rainbow-ski	LC	-		4	1	4	3	12		3		3	3			9				2			2
Scincidae	*Cryptoblepharus pulcher*	Elegant snake-eyed skink	LC	-				1		1			1					1							0
Scincidae	*Morethia boulengeri*	South-eastern morethia	LC	-						0		1						1							0
Scincidae	*Ctenotus robustus*	Eastern striped skink	LC	-						0								0		1			2	2	5
Scincidae	*Morethia taeniopleura*	Fire-tailed skink	LC	-				2		2								0							0
Scincidae	*Pygmaescincus timlowi*	Dwarf litter-skink	LC	-						0				1				1			2				2

Appendix J Weed Species and Management Plans

Department of Agriculture and Fisheries
Biosecurity Queensland

Restricted invasive plant

Harrisia cactus

Moonlight cactus

Harrisia martinii, Harrisia tortuosa and *Harrisia pomanensis*

Harrisia cactus can form dense infestations that will reduce pastures to a level unsuitable for stock. Harrisia cactus will choke out other pasture species when left unchecked.

The spines are a problem for stock management, interfering with mustering and stock movement.

Harrisia cactus produces large quantities of seed that is highly viable and easily spread by birds and other animals. As well as reproducing from seed, harrisia cactus has long trailing branches that bend and take root wherever they touch the ground. Any broken-off portions of the plant will take root and grow.

Legal requirements

Harrisia cactus (*Harrisia martinii, Harrisia tortuosa* and *Harrisia pomanensis*) are restricted invasive plants under the *Biosecurity Act 2014*. It must not be given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

Queensland Government

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Description

Harrisia cactus is a perennial. The spiny fleshy stems are jointed and form tangled mats about half a metre high. Many branches often lie flat and take root where they touch the ground. Each section is ribbed lengthwise with six ribs; each rib has low, thick, triangular humps at regular intervals. These humps have cushions of grey felty hairs, three to five short spines lying flat, and one to three erect, stiff, very sharp spines 2.5–3 cm long.

The large flowers open at night. Flowers are pink and funnel-shaped with a tinge of white. These grow singly near the ends of the stems on a scaly but spineless slender grey-green tube 12–15 cm long.

Round, red fruits 4–5 cm across have scattered bumps with hairs and spines. Numerous small black seeds are embedded in the white, juicy pulp of the fruit, which splits open when ripe.

Harrisia cactus roots are of two types. Shallow feeding roots up to 3 cm thick and 30 cm to 2 m long grow mostly horizontally off a crown, up to 15 cm below ground level. Swollen tuberous storage roots descend to a depth of 15–60 cm.

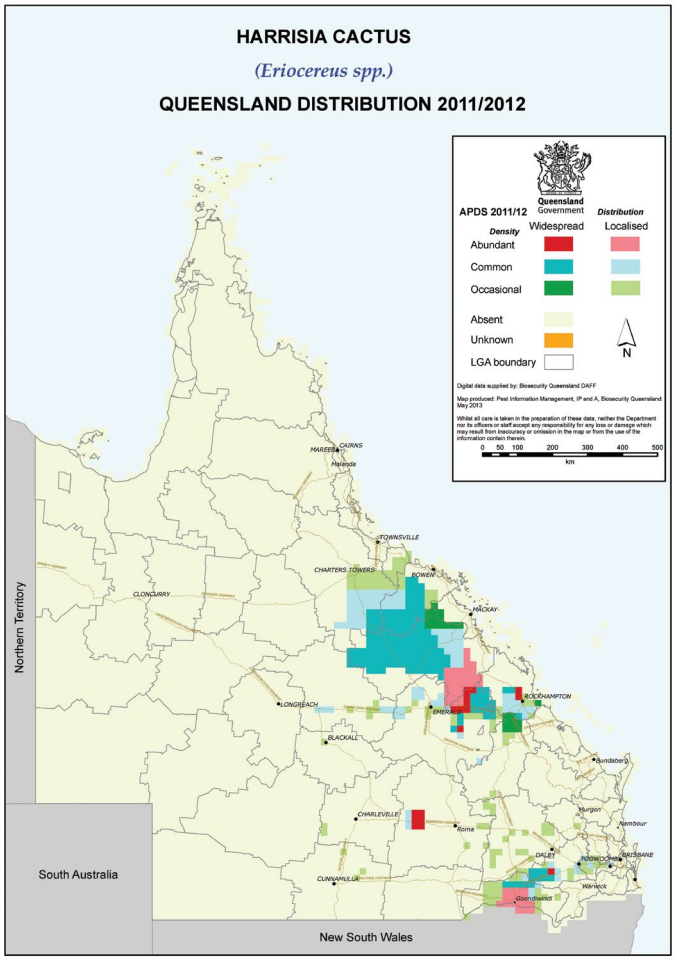
Life cycle

Harrisia cactus bears a bright red fruit containing 400–1000 small black seeds. Plants are easily established from seed and germinate soon after rain.

Seedlings quickly produce a swollen tuberous food storage root that develops as the plant grows. Branches take root where they touch the ground and new plants will grow from broken branches and sections of underground tubers.

Counts of tubers in dense cactus infestations have shown over 125 000 per hectare. Each plant houses many dormant underground buds that are all capable of reshooting when the tip growth dies; any small portion of the tuberous root left in the soil will grow.

Methods of spread



Fruit and seed are readily eaten by birds, mammals and to a lesser extent by feral pigs.

Habitat and distribution

Harrisia cactus is a native of Argentina and Paraguay, South America. It was introduced to Australia as a pot plant in the 1890s. In 1935 it was first recognised as a serious pest in the Collinsville district and by the 1950s was rapidly spreading south.

Harrisia cactus is mainly a pest of brigalow and associated softwood country. However, infestations are now appearing in box and ironbark stands and also in pine forests.

Map 1. Distribution of harrisia cactus in Queensland

The cactus is shade tolerant and reaches its maximum development in the shade and shelter of brigalow scrub, though established infestations can persist once scrub is pulled.

Harrisia cactus is found in the Collinsville, Nebo, Moranbah, Dingo, Blackwater and Goondiwindi districts, with minor infestations occurring at Millmerran, Greenmount, Gatton, Ipswich, Rockhampton, Rannes, Mount Morgan, Alpha and Mitchell.

Control

Managing harrisia cactus

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by harrisia cactus. This fact sheet provides information and some options for controlling harrisia cactus.

Control of this plant is difficult as it has a deep underground tuberous root system and use of a combination of physical, biologic and herbicide controls is recommended.

Physical control

Dig out plants completely and burn. Ensure that all tubers that can grow are removed and destroyed.

Ploughing is not considered an effective means of control unless followed by annual cropping.

Biological control

Two introduced insects have become established in the field:

- a stem-boring longicorn beetle (*Alcidion cereicola)*
- a mealy bug (*Hypogeococcus festerianus*).

The stem-boring beetle only attacks older woody stems. In the Collinsville area, large beetle colonies developed and contributed to the collapse of dense areas of cactus. Populations of *Alcidion cereicola* have declined with the reduction in the cactus in recent years.

The most successful biological control agent is the mealy bug *Hypogeococcus festerianus* which is now present in harrisia cactus in Collinsville, Dingo, Moranbah, Blackwater, Nebo, Charters Towers and Goondiwindi districts, with small colonies established at Alpha, Capella, Rannes, Gatton, Greenmount, Millmerran and Rockhampton.

How mealy bug works

The mealy bug aggregates and feeds in the tips of stems and buds, where it limits growth and causes distortion. This results in the knotting of the stem. The plant's response is to utilise energy reserves within the tuber system to produce new growth. Eventually the plant dies, as it is unable to support the continuous high energy demands.

Dry weather reduces the effectiveness of the mealy bug. When dry, the plant's tuber system becomes dormant. Consequently, mealy bug damage does not result in new growth and the energy reserves within the plant are not affected. Instead the bug may damage all vegetative parts and eventually die out. The tuber will remain dormant until adequate moisture returns, when it will reshoot.

How to spread the bug

Mealy bug disperses naturally via wind, although landholder assistance is necessary for its continuous spread, particularly between patches. The bug is manually spread by cutting infected stems and placing them into healthy plants. The best pieces for starting new colonies are large knobs of twisted and distorted cactus that contain many mealy bugs well protected inside knots. Stem tips covered by white, woolly masses of bug are also good. To collect the bug, cut infected stems approximately 15 cm from the distorted knob and place segments in green, plump sections of the healthy plant. Avoid placing mealy bug in stressed or dried out stems. Small cactus plants require at least one large knot, with larger plants requiring three knots per plant. Where possible, landholders should infest every cactus clump as this ensures a rapid reduction in growth and fruiting potential. When cactus infestations are light, chemical control may be a preferable option.

Cut pieces can be transported in boxes or open vehicles. They are not delicate, but are best kept in the shade. Avoid keeping them in large heaps, in direct sunlight, under tarpaulins or in closed containers for long periods. Such conditions will promote rotting of the stems, leading to poor results or failures. Ideally, stems should be put out within three days and a maximum of five days.

When to infest

Best results come by infesting new areas during spring and early summer, from September to December. Maximum growth and spreading occurs in the summer months of December to February. During the drier and colder months of April to August the mealy bug does not die, but little growth and multiplication occurs. Introduction of mealy bug during autumn and winter will not be lost, but little effect is seen until the following summer.

How soon to expect results

Mealy bugs are generally more active and effective on harrisia cactus growing underneath shrubs and trees, so results will be seen more quickly in these areas than in cactus growing in the open. Best results are obtained when infesting plants that have actively growing new shoots.

During wet summers in northern and central Queensland, the growing points of stems will begin to curl after about six weeks.

By the end of the first summer, damage (severe twisting) will be widespread in infested plants. If the initial infestation was sufficiently heavy, no fruit or growth will occur during the second year, and the cactus will begin to die during the third year. Seedlings and regrowth shoots will continue to be present but by the end of the fourth year there should be very little cactus left.

In the southern portion of the state, where temperatures are lower, the mealy bug still provides control but the process takes longer. However, the mealy bug will do better on cactus in the open, rather than in the shade, as temperatures are higher in the open.

Herbicide control

Foliar application of registered herbicides provides effective control, but can be costly over large areas. Before using any herbicide always read the label carefully. All herbicides must be applied strictly in accordance with the directions on the label (see to Table 1).

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Table 1. Herbicides for the control of harrisia cactus

Situation	Herbicide	Rate	Comments
Non-crop land and rights-of-way	Dichlorprop as K salt (600 g/L)	1 L/60 L water	Good soil moisture essential Spray plant when actively growing to run-off point A follow-up treatment may be necessary
Native pastures, rights-of-way, commercial and industrial areas	Metsulfuron-methyl (600 g/kg) (e.g. Brush-Off®)	20 g/100 L water + surfactant	Spray plant when actively growing to run-off point A follow-up treatment may be necessary
Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr as butotyl (240 g/L) + Picloram as ioe (120 g/L) (e.g. Access®)	1 L/60 L diesel	Spray plant when actively growing Apply as overall spray, wetting all areas of the plant to ground level
Non-agricultural areas (native pastures), commercial and industrial areas and rights-of-ways	Aminopyralid as K salt 375 g/kg + Metsulfuron methyl 3 g/kg (e.g Stinger)	40 g/100 L water	Spray to thoroughly wet using 1000 to 1400 L/ha Follow-up treatment may be necessary
Commercial and industrial areas, around buildings and rights-of-way	Triclopyr as butotyl 75 g/L + Metsulfuron-methyl 28 g/L (e.g. Zelam Brush Weed®)	500 mL/100 L	Spray to thoroughly wet using 1000 to 1500 L/ha Follow-up treatment may be necessary
Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	Triclopyr as tea 200 g/L + Picloram as tipa 100 g/L (e.g. Slasher) or Triclopyr as tea 200 g/L + Picloram as tipa 100 g/L + Aminopyralid 25 g/L (e.g. Tordon RegrowthMaster) (e.g. Tordon DSH®)	2.5 L/100 L water	Spray plant when actively growing (September–March) Treat all stems thoroughly

Read the label carefully before use. Always use the herbicide in accordance with the directions on the label.

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture and Fisheries (DAF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

Biosecurity Queensland

Invasive plant

Mimosa bush

Acacia farnesiana

Mimosa bush can spread readily and grow quickly. As it often forms thorny thickets, it can be a considerable nuisance during mustering and can also hinder stock access to water.

Mimosa does offer shade in open downs country and can be useful as a supplement to grass during the dry season. It may therefore be a useful plant in some areas if its spread can be controlled to prevent thicket formation. The maintenance of healthy pasture competition is the best mechanism to achieve this.

Legal requirements

Mimosa bush is not a prohibited or restricted invasive plant under the *Biosecurity Act 2014*. However, by law, everyone has a general biosecurity obligation (GBO) to take reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control.

Local governments must have a biosecurity plan that covers invasive plants and animals in their area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Queensland Government

Description

Mimosa bush is a rounded shrub or small tree generally growing 2 to 3 m high, occasionally to 5 m. It often forms thorny thickets, and is nearly always multi-stemmed. The branches grow in a zigzag shape and are usually a grey-brown colour with prominent white spots.

Leaves are a ferny type, with 1–6 pairs of leaf 'branches' each with 5–20 pairs of narrow, rounded leaflets 4–8 mm long. Leaves are sometimes more of a yellowish green than a pure green. Thorns are found in pairs at the base of each leaf and can grow up to 10 cm long.

Golden yellow to orangeish flowers are ball-shaped, about 1 cm across, and grow on stalks, usually two stalks at the base of each leaf. Flowers develop into clusters of cigar-shaped pods, slightly curved and up to 6 cm long. The pods are dark brown or black and woody at maturity, with seeds embedded in the pith. Pods do no split open and tend to stay on the plant for a length of time.

Mimosa bush can be confused with the declared weeds mesquite (*Prosopis* spp.) and prickly acacia (*Vachellia nilotica*), particularly when young (see the 'identification of prickle bushes' fact sheet from www.biosecurity.qld.gov.au).

Distribution

Mimosa bush, a native of central and south America, is naturalised in Australia. Mimosa bush is widespread in Queensland, and found in all but the wettest and driest parts of the State. Seeds sprout readily and plants grow rapidly. Mimosa bush does well in dry localities and on loamy or sandy soils, forming thickets along watercourses. Mimosa bush withstands drought well, is readily eaten by stock, and has good regrowth after grazing.

Mimosa bush is not a long-lived plant. It is readily attacked by many native insects and is prone to dieback on an irregular basis. In some parts of the world mimosa bush is cultivated for perfume production.

Control

Basal bark spray

For stems up to 15 cm diameter, carefully spray completely around base of plant to a height of 30 cm above ground level. Thoroughly spray into all crevices. Larger trees may be controlled by spraying to a greater height, up to 100 cm above ground level.

The best time for treatment is during autumn when plants are actively growing and soil moisture is good.

Cut stump treatment

At any time of year, cut stems off horizontally as close to the ground as possible. Immediately (within 15 seconds) swab cut surface with herbicide mixture.

Bore drains

Channels and drains must be empty of water. Spray a one metre strip into the mud in channel or drain. Wait at least three days for diuron to bond to mud before slowly allowing water in again. Water must not be used in domestic water supply or supplied to desirable shade trees for 7–14 days after re-opening the drain.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Table 1. Herbicides for the control of mimosa bush

Situation	Herbicide	Rate	Optimum time	Comments
Basal bark/ cut stump	Fluroxypyr eg. Starane Advanced®, etc Triclpyr + picloram e.g. Access®	Refer to product label	Basal bark: for plants up to 5 cm basal diameter	
	Triclpyr + picloram e.g. Access®	1 L/60 L diesel	Basal bark: for plants up to 5 cm basal diameter	Ensure all stems on multi-stemmed plants are treated.
Soil application	Tebuthiuron (PERMIT 13891) e.g. Tebulan 200GR herbicide®, Graslan herbicide®, etc	2.0 g/m2 or 20 kg/ha		For use in pastures, roadside and rights of way. Application just prior to rainfall gives best results. Avoid damage to off target species – refer to herbicide label for product restraints and critical comments.
High volume spray	500 g/L clopyralid present as the triisopropanol amine (PERMIT 11638) e.g. Lontrel herbicide®, Nufarm Archer®, Farmoz Victory herbicide®, etc	500 mL of product per 100 L of water (plus non-ionic surfactant at 0.1%)	Spray when plants are actively growing and in full leaf	For use in pastures, rights of way, powerline areas. Full covering of foliage with spray is essential. Withholding period: do not graze treated areas, or cut for stock feed, for seven days after application.
Bore drains	Diuron e.g. Diuron 500SC®, etc	Refer to product label	Do not apply between 1 December and 30 March each year.	Do not apply more than once per calendar year. Do not open drains for 72 hours following treatment. Do not apply if heavy rains are predicted within three days of application. Application should be limited to 1 m strips along the sides of bore drains. Withholding period – do not allow animals to drink water from treated bore drains for three days, before slaughter for human consumption

Read the label carefully before use. Always use the herbicide in accordance with the directions on the label.

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture and Fisheries (DAF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. Biosecurity Queensland

Restricted invasive plant

Mother-of-millions

Bryophyllum delagoense (syn. *B. tubiflorum*, *Kalanchoe delagoensis*) and *Bryophyllum × houghtonii*

Mother-of-millions are native to Madagascar and are escaped ornamental plants. Five species are commonly naturalised in Queensland. It is well adapted to dry areas because of its succulent features.

As the name suggests, one plant can reproduce a new generation from masses of embryoids (plantlets) that are formed on the leaf edges. This makes these plants hard to eradicate and follow up controls are essential.

These plants, especially their flowers, are poisonous to stock and occasionally cause a significant number of cattle deaths. The plant flowers from May to October (during the drier months of the year) and the scarcity of feed at this time may cause cattle to consume lethal amounts of mother-of-millions.

Legal requirements

Mother-of-millions is a restricted invasive plant under the *Biosecurity Act 2014*. It must not be given away, sold, or released into the environment without a permit.

Bryophyllum pinnatum (resurrection plant, live-leaf) is not a restricted invasive plant. However the Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

Queensland Government

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Description

Mother-of-millions are erect, smooth, fleshy succulent plants growing to 1 m or more in height.

All species form tall flower spikes in winter with clusters of bell-shaped flowers. Each species has a distinctive leaf shape, but all produce small plantlets along the edges of the leaves. These plantlets drop readily, develop roots and establish quickly to form a new colony.

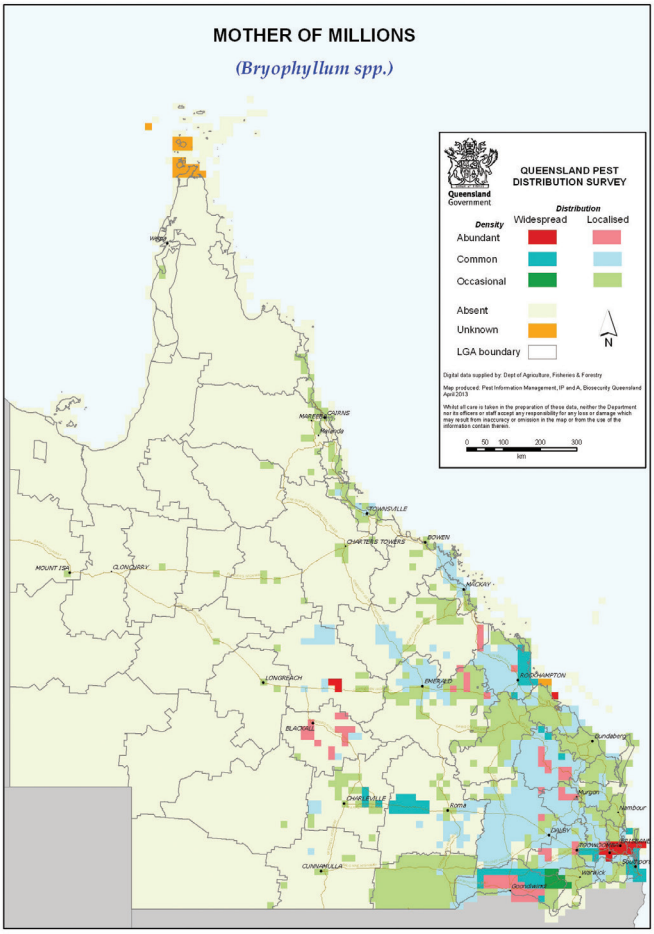
Bryophyllum delagoense syn. *B. tubiflorum* and *Kalanchoe delagoensis* (common mother-of-millions, mission bells, Christmas bells) has grey-brown, fleshy, tubular-like leaves with up to seven projections at the tip of each leaf. The flowers are orange-red and occur in a cluster at the top of a single stem. Seeds can germinate for some years.

Bryophyllum × *houghtonii* syn. *B. daigremontianum* × *B. delagoense, Kalanchoe* × *houghtonii* (hybrid or crossbred mother-of-millions) has similar flowers arranged in a branched cluster at the top of the stem. Its leaves are boat shaped with thick stalks and notches along the edges of the leaves.

A third species, *Bryophyllum pinnatum (*resurrection plant, live-leaf) has yellow-green, oval, fleshy leaflets with wavy edges and up to five leaflets per leaf. Its flowers are yellowish-green, often tinged with pink, and occur in loose clusters on stalks growing at intervals along the upper portion of the stem.

Life cycle

Mother-of-millions flowers in Winter and reproduces by seed and by tiny plantlets that are produced at the tips of its fleshy (succulent) leaves. Dislodged leaves and broken leaf parts can also take root and give rise to new plants.



Methods of spread

Mother-of-millions is commonly spread by garners and in garden waste. The tiny seeds are probably wind and water dispersed and its leaves and plantlets may also be dislodged and spread by animals, vehicles, machinery, soil and slashers.

Habitat and distribution

Native to Madagascar, these popular succulent garden plants have escaped culitvation and spread in various areas of Queensland. They have become a problem in pasture lands in the central highlands around Clermont, Emerald and Dingo, and the Burnett, Moreton and Darling Downs scrub regions. The plants establish well in leaf litter or other debris on shallow soils in shady woodlands, and often grow on roadsides, along fence lines and around old rubbish dumps. They can spread from these areas, especially in flood, and establish if pastures are run down.

Map 1. Distribution of mother-of-millions in Queensland

They are adapted to dry conditions and can survive long periods of drought.

Toxicity

These plants are toxic, especially their flowers, and occasionally cause a significant number of cattle deaths. When cattle are under stress or in unusual conditions they are more likely to eat plants that they would not normally eat. Shifting cattle to new paddocks, moving stock through infested rubbish dumps and wastelands, and reduction of availability of feed due to flood or drought can all contribute to cattle eating mother-of-millions and being poisoned.

Poisoned cattle show signs of dullness, loss of appetite, diarrhoea and heart failure. Some cattle may drool saliva or dribble urine. There are two responses to poisoning:

- acute—where cattle die within a day
- chronic—where cattle may take up to five days to die.

Some cattle may make a slow recovery if insufficient plant material was eaten.

Poisoned cattle must be treated within 24 hours of consuming the plant. The treatment is intense and needs to be given by a veterinarian, or under their direction, because of the drugs and materials used.

Control

Managing mother-of-millions

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by mother-of-millions. This fact sheet provides information and some options for controlling mother-of-millions.

Prevention and early detection

The best form of weed control is prevention. Always treat weed new infestations when small—do not allow weeds to establish. Weed control is not cheap, but it is cheaper to do it now rather than next year, or the year after. Proper planning ensures better value for each dollar spent.

Permanent control of mother-of-millions infested areas is best ensured by establishing more desirable plants in that location to compete successfully with future mother-of-millions seedlings and plantlets. This is best achieved through soil preparation, replanting, fertilising and using the area more productively.

Ensure scattered infestations and small dumping areas on properties are regularly checked and cleaned up. Day-today hygiene management will help prevent establishment of these weeds.

Co-operative control upstream and downstream of problem areas will help prevent re-infestation from other areas.

To prevent poisoning, keep stock (especially hungry stock) away from infested areas until the plants are controlled.

Mechanical control

For small areas, pull up plants by hand and burn on a wood heap. Alternatively, bag the plants and dump them in a bin, the contents of which are buried at council refuse tips rather than being recycled into mulch.

Fire

When suitable (e.g. after grading firebreaks), burn infestations and the accompanying debris on which mother-of-millions plants thrive. This is the most economical form of control, encourages grass competition and lessens the problem for following years, requiring only spot spraying with selective herbicides.

Biological control

The South African citrus thrip is present in Queensland and is quite widespread through the south of the state. The thrip damages the outer tissue of the mother-of-millions plant and also lays its eggs under the outer tissue. Where high populations of thrips exist, the number of viable plantlets and flowers forming on mother-of-millions is reduced.

The thrips populations vary from year to year, according to mother-of-millions populations and climate. The South African citrus thrips should not be seen as a long term control strategy—only a control option to complement other techniques such as herbicide treatment and burning.

The department is undertaking further research to identify potential biological control agents to support with management.

Herbicide control

Before using any herbicide always read the label carefully. All herbicides must be applied strictly in accordance with the directions on the label. Where the addition of a wetting agent is recommended, always use a commercial wetting agent or surfactant.

Mother-of-millions may be controlled with herbicides at ny time of the year, but infestations are easiest to see in winter when the plants are in flower. Treating infestations at this time of year also has the benefit of preventing new seeds from developing on common mother-of-millions.

Table 1 details the herbicides registered for mother-of-millions control.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Bryophyllum x *houghtonii* (left) and *Bryophyllum delagoense* (right)

South African citrus thrips damage to mother-of-millions

Table 1. Herbicides for the control of mother-of-millions

Situation	Herbicide	Rate	Comments
Pastures and non-crop land	2,4-D acid (e.g. Affray 300)	7 L/1000 L water per ha 70 mL/10 L water	High volume foliar spray (handgun) High volume foliar spray (knapsack)
Pastures, rights-of-way and industrial	2,4-D amine 700 g/L (e.g. Amicide Advance 700)	360 mL/100L water	Hand gun and knapsack only. Thorough coverage is essential. Use a surfactant (e.g. Nufarm Activator) (consult label).
Pastures, rights-of-way, non-crop land, forests, non-agricultural land and commercial and industrial areas	Triclopyr 300 g/L + Picloram 100 g/L (e.g. Conqueror) or Triclopyr 300 g/L + Picloram 100 g/L + Aminopyralid 8 g/L (e.g. Grazon Extra)	500 mL/100 L water 50 mL/10 L water	High volume foliar spray (hand gun, knapsack). Always add a wetting agent (e.g. BS-1000 or Chemwet 1000) at 100 mL/100 L water. Apply at flowering.
	Fluroxypyr 200 g/L (e.g. Flagship 200)	600 mL/100 L water + sufactant (consult label)	Apply to seedlings and young plants before flowering.
	Fluroxypyr 333 g/L (e.g. Starane Advanced)	360 mL/100 L water + sufactant (consult label)	
	Fluroxypyr 400 g/L (e.g. Comet 400)	300 mL/100 L water + sufactant (consult label)	

Notes
Thorough, even coverage of leaves and plantlets is necessary.
Note that many 2,4-D products are not registered for control of mother-of-millions in Queensland. Only use products registered for the purpose.

Read the label carefully before use. Always use the herbicide in accordance with the directions on the label.

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture and Fisheries (DAF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

Department of Agriculture and Fisheries
Biosecurity Queensland

Restricted invasive plant

Parthenium

Parthenium hysterophorus

Parthenium is a vigorous species that colonises weak pastures with sparse ground cover. It will readily colonise disturbed, bare areas along roadsides and heavily stocked areas around yards and watering points. Parthenium can also colonise brigalow, gidgee and softwood scrub soils. Its presence reduces the reliability of improved pasture establishment and reduces pasture production potential.

Parthenium is also a health problem as contact with the plant or the pollen can cause serious allergic reactions such as dermatitis and hay fever.

Parthenium is listed as a Weed of National Significance.

Legal requirements

Parthenium is a restricted invasive plant under the *Biosecurity Act 2014*. It must not be given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Queensland Government

Description

Parthenium is an annual herb with a deep tap root and an erect stem that becomes woody with age. As it matures, the plant develops many branches in its top half and may eventually reach a height of 2 m.

Its leaves are pale green, deeply lobed and covered with fine soft hairs.

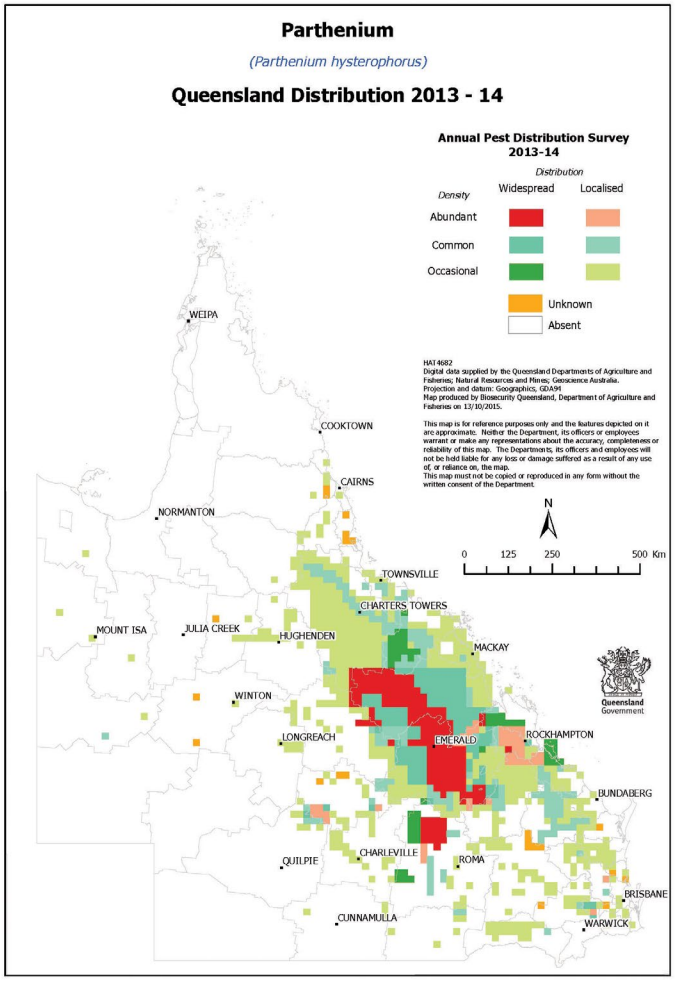
Small creamy white flowers occur on the tips of the numerous stems. Each flower contains four to five black seeds that are wedge-shaped, two millimetres long with two thin, white scales.

Life cycle

Parthenium normally germinates in spring and early summer, produces flowers and seed throughout its life and dies around late autumn. However, with suitable conditions (rain, available moisture, mild temperatures), parthenium can grow and produce flowers at any time of the year. In summer, plants can flower and set seed within four weeks of germination, particularly if stressed.

Methods of spread

Parthenium seeds can spread via water, vehicles, machinery, stock, feral and native animals and in feed and seed. Drought conditions aid the spread of seed with increased movements of stock fodder and transports.



Habitat and distribution

Parthenium is capable of growing in most soil types but becomes most dominant in alkaline, clay loam soils.

The plant is well established in Central Queensland and present in isolated infestations west to Longreach and in northern and southern Queensland.

Infestations have also been found in northern and central parts of New South Wales and it is capable of growing in most states of Australia.

Map 1. Distribution of parthenium in Queensland

Control

Managing parthenium

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by parthenium. This fact sheet provides information and some options for controlling parthenium.

Prevention and weed seed spread

Pastures maintained in good condition, with high levels of grass crown cover, will limit parthenium colonisation. Drought, and the subsequent reduced pasture cover, creates the ideal window of opportunity for parthenium colonisation when good conditions return.

Vehicles and implements passing through parthenium infested areas should be washed down with water. Particular care should be taken with earthmoving machinery and harvesting equipment. The wash down procedure should be confined to one area, so that plants that establish from dislodged seed can be destroyed before they set seed.

Extreme caution should be taken when moving cattle from infested to clean areas. Avoid movement during wet periods as cattle readily transport seed in muddy soil. On arrival, cattle should be held in yards or small paddocks until seed has dropped from their coats and tails prior to their release into large paddocks. Infestations around yards can be easily spotted and controlled whereas infestations can develop unnoticed in large paddocks.

Particular care should be taken when purchasing seed, hay and other fodder materials. Always keep a close watch for the emergence of parthenium or other weeds on areas where hay has been fed out.

Property hygiene is important. Owners of clean properties should ensure that visitors from infested areas do not drive through their properties. If your property has parthenium on it, ensure that it is not spread beyond the boundary or further within the property.

Manual control

Hand pulling of small areas is not recommended. There is a health hazard from allergic reactions and a danger that mature seeds will drop off and increase the area of infestation.

Pasture management

Grazing management is the most useful method of controlling large-scale parthenium infestations. Maintain pastures in good condition with high levels of ground and grass crown cover. This may require rehabilitation of poor pastures, followed by a sound grazing maintenance program.

Sown pasture establishment—Poor establishment of sown pastures can allow parthenium colonisation.

Pasture agronomy—Aerial seeding prior to scrub pulling is normally beneficial.

Overgrazing—High grazing pressure caused by drought or high stock numbers decreases the vigour and competitiveness of pastures and allows the entry and spread of parthenium. Maintenance of correct stock numbers is most important in controlling parthenium.

Pastures spelling—In situations of serious infestation, pasture spelling is essential for rehabilitation. Total spelling is much more effective than simply reducing the stocking rate. However, overgrazing of the remainder of the property must be avoided.

The most appropriate time for pasture spelling is the spring–summer growing period, with the first 6–8 weeks being particularly important. If the condition of perennial grasses (native or sown) is low, spelling for the entire growing season may be required or introduced grasses may need to be re-sown. Herbicide treatment can hasten the rehabilitation process by removing a generation of parthenium seedlings and allowing grass seedlings to establish without competition. In the presence of parthenium, grass establishment is poor.

Grazing during winter should not increase the parthenium risk. Most tropical grasses are dormant and can tolerate moderate grazing during this period. However, parthenium may germinate and grow at this time.

Fencing—One of the main problems in controlling parthenium is the large paddock size and the variability of country within paddocks. The resulting uneven grazing pressures encourage parthenium to colonise the heavily grazed country. Ideally, similar land types should be fenced as single units. Fencing can be used to great effect to break up large paddocks, allowing more flexible management such as pasture spelling or herbicide application, options not available previously.

Burning—Burning is not promoted as a control strategy for parthenium. However, research suggests that burning for pasture management (e.g. woody weed control) should not result in an increased infestation if the pasture is allowed to recover prior to the resumption of grazing. Stocking of recently burnt areas known or suspected to contain parthenium decreases pasture competition and favours parthenium, ultimately creating a more serious infestation.

Biological control

The combined effects of biological control agents reduced the density and vigour of parthenium and increased grass production.

There are currently a number of insect species and two rust pathogens that have been introduced to control parthenium—a selection of these are outlined below. *Epiblema strenuana* is a moth introduced from Mexico established in all parthenium areas. The moth's larvae feed inside the stem, forming galls that stunt the plant's growth, reduce competitiveness and seed production.

Listronotus setosipennis is a stem-boring weevil from Argentina but is of limited success in reducing parthenium infestations.

Zygogramma bicolorata is a defoliating beetle from Mexico which is highly effective where present. It emerges in late spring and is active until autumn.

Smicronyx lutulentus (Mexico) lays eggs in the flower buds where the larvae feed on the seed heads. *Conotrachelus albocinereus* (stem-galling weevil from Argentina) produces small galls and is still becoming established in Queensland.

Bucculatrix parthenica (leaf mining moth from Mexico) larvae feed on leaves, leaving clear windows in the leaf. *Carmentia ithacae* is a stem boring moth from Mexico which is becoming established at favourable sites in the northern Central Highlands.

Puccinia abrupta is a winter rust from Mexico that infects and damages leaves and stems. It is currently established over a wide area from Clermont south. It requires a night temperature of less than 16 degrees and 5–6 hours of leaf wetness (dew). Sporadic outbreaks occur where weather conditions are suitable.

Puccinia melampodii is a summer rust from Mexico that weakens the plant by damaging the leaves over the summer growing season. It is currently established and spreading at a number of sites from north of Charters Towers to Injune in the south.

Herbicide control

Non-crop areas

Parthenium should be sprayed early before it can set seed. A close watch should be kept on treated areas for at least two years.

Small and/or isolated infestations should be treated immediately. Herbicide control will involve a knockdown herbicide to kill plants that are present and a residual herbicide to control future germinations. Repeated spraying may be required even within the one growing season to prevent further seed production.

Extensive infestations will require herbicide treatment in conjunction with pasture management. Timing of spraying is critical so that parthenium is removed when plants are small and before seeding has occurred. Grasses should be actively growing and seeding so that they can recolonise the infested area.

Table 1. shows the herbicides registered for parthenium control and application rates. All herbicides must be applied strictly in accordance with the directions on the label.

Cropping areas
Controlling parthenium in cropland requires selective herbicide use and/or crop rotations. For further information on parthenium control in crops consult your local biosecurity officer.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Table 1. Herbicides for the control of parthenium

Situation	Herbicide	Rate	Comments
Pastures, rights-of-way and industrial land	2,4-D as amine 625 g/L (e.g. Ken-Amine 625)	320 mL/100 L water	Spot spray Apply to young actively growing plants, ensuring thorough coverage
	2,4-D as amine 700 g/L (e.g. Amicide Advance 700)	285 mL/100L water	
Non agricultural areas (native pastures), commercial and industrial areas, rights-of-way	Aminopyralid 375 g/kg plus metsulfuron-methyl 300 g/kg (Stinger)	10 g/100 L water plus wetting agent Consult label	Spray to thoroughly wet all foliage but not to cause run-off
Fields and fallow, various crops (see label)	Atrazine 500 g/L (e.g. Kenso Atrazine 500)	3.6–6 L/ha Rate varies with situation Consult label	Boom spray. Pre and post emergent application Restrictions apply. Consult label for details of specific conditions. Max 3 kg a.i./ha/yr
Roadside and rights-of-way		6 L/ha	Boom spray. Pre and post emergent application Restrictions apply. Consult label for details of specific conditions. Max 3 kg a.i./ha/yr
Fields and fallow, various crops (see label)	Atrazine 900 g/kg (e.g. Atradex WG)	2–3.3 kg/ha Rate varies with situation Consult label	Boom spray. Pre and post emergent application Restrictions apply. Consult label for details of specific conditions. Max 3 kg a.i./ha/yr
Roadside and rights-of way		3.3 kg/ha	Boom spray. Pre and post emergent application. Restrictions apply. Consult label for details of specific conditions. Max 3 kg a.i./ha/yr
Non-crop areas, commercial and industrial areas, pastures and rights-of-way	2,4-D 300 g/L + picloram 75 g/L (e.g. Tordon 75-D)	125 mL/100 L	Spot spray during rosette stage Use at least 3000 L/ha in dense infestations Consult label
		3 L/ha	Boom spray during rosette stage Consult label
Native pastures, rights-of-way, commercial and industrial land	metsulfuron methyl 600g/L (e.g. Associate)	5 g/100 L water + wetter	Hand gun. Spray to thoroughly wet all foliage but not to cause runoff
		7 g/ha + wetter	Boom spray. For pastures only. Treat in rosette stage. Consult label for details
Wheat, barley, triticale and cereal rye		5–7 g/h	Boom spray. Lower rate up to 4-leaf stage, higher rate 4-leaf stage to rosette
Native pastures, rights-of-way, commercial and industrial land	Triclopyr 75 g/L + metsulfuron-methyl 28 g/L (e.g. Zelam Brush Weed)	125 mL/100 L water	Spot spray plants from rosette to flowering Consult label for critical comments
Commercial and industrial areas, rights-of-way, around agricultural buildings	Hexazinone 750 g/kg (e.g. Velpar DF)	1 kg/ha 2 g/10 L/20 m^2	Boom spray or spot spray
Around agricultural buildings	Hexazinone 250 g/L (e.g. Velpar L)	3.5 L/ha or 7 L/10 L/20 m^2	
Grass pastures, fallows, various crop and non-crop situations (consult label for details	Dicamba 500 g/L (e.g. Kamba 500) Dicamba 700 g/kg	Rates vary with situation Consult label	Boom spray or spot spray Consult label for details and critical comments

A number of the listed herbicides are available as different formulations, but some may not be registered for parthenium. Check the label for registration, rate and critical comments. Only use products that list parthenium on the label. The registered rates are for non-crop uses. Consult label for in-crop recommendations. For power hand spray or knapsack use, spray plants to the point of runoff.

Read the label carefully before use. Always use the herbicide in accordance with the directions on the label.

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture and Fisheries (DAF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

Department of Agriculture and Fisheries
Biosecurity Queensland

Restricted invasive plant

Opuntioid cacti

Austrocylindropuntia, *Cylindropuntia* and *Opuntia* species

Three types (genera) of opuntioid cacti have naturalised in Australia and are now considered Weeds of National Significance: *Austrocylindropuntia, Cylindropuntia* and *Opuntia*. They are drought resistant because of their succulent nature, their lack of leaves and their thick, tough skins. These features result in plants that use the majority of their internal tissues for water storage and their outer parts to reduce water loss and damage by grazing and browsing animals. They can remain vigorous in hot, dry conditions that cause most other plants to lose vigour or even die. Some species develop underground bulbs that enable the plant to resist fire and mechanical damage.

Dense infestations compete with native vegetation, limiting the growth of small shrubs and groundcover species. The plant's sharp spines or barbs can cause injury to stock and native animals and contaminate wool and hides, reducing or preventing grazing activities and productivity.

Large stands of cacti provide harbour for pest animals, such as foxes and rabbits and, due to their spiny nature, can limit access for stock mustering and recreational activities. The spines are capable of causing serious injury to animals and humans.

Queensland Government

Legal requirements

All Cholla cacti (*Cylindropuntia* spp.) and prickly pear (*Opuntia* spp.) not listed below are prohibited invasive plants and the *Biosecurity Act 2014* requires that all sightings to be reported to Biosecurity Queensland within 24 hours. By law, everyone has a general biosecurity obligation (GBO) to take all reasonable and practical steps to minimise the risk of these cacti spreading until they receive advice from an authorised officer.

The following species are restricted invasive plants under the Act. The Act requires that all sightings of these cacti must be reported to Biosecurity Queensland within 24 hours of the sighting. By law, everyone has a GBO to take all reasonable and practical steps to minimise the risk of spread of these cacti until they receive advice from an authorised officer.

- Hudson pear (*Cylindropuntia rosea* and *C. trunicata*)
- Jumping cholla (*Cylindropuntia prolifera*)
- Bunny ears (*Opuntia microdasys*)
- Riverina pear (*Opuntia elata*)

The following species are restricted invasive plants under the *Biosecurity Act 2014*. They must not be given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

- Cane cactus (*Austrocylindropuntia cylindrical*)
- Eve's pin cactus (*Austrocylindropuntia subulata*)
- Coral cactus (*Cylindropuntia fulgida*)
- Devil's rope pear (*Cylindropuntia imbricata*)
- Snake cactus (*Cylindropuntia spinosior*)
- Common pest pear, spiny pest pear (*Opuntia stricta* Syn. *O. inermis)*
- Drooping tree pear (*Opuntia monacantha* Syn. *O. vulgaris*)
- Tiger pear (*Opuntia aurantiaca*)
- Velvety tree pear (*Opuntia tomentosa*)
- Westwood pear (*Opuntia streptacantha*)

Indian fig (*Opunia ficus-indica*) is not prohibited or restricted invasive plant.

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Description

Opuntioid cacti vary significantly in their form and habit, ranging from low-growing shrubs under 50 cm to erect trees up to 8 m tall.

Plants are normally leafless succulent shrubs. Stems are divided into segments (pads or joints) that are flat and often incorrectly called leaves.

Young shoots have true leaves resembling small fleshy scales that fall off as the shoot matures.

Flowers are large, normally seen during spring and can be yellow, orange, red, pink, purple or white depending on the species. Fruits vary between species and can be red, purple, orange, yellow or green.

Areoles (spots with clusters of spines) are found on both the pads (joints, segments) and fruit. In addition to spines, areoles often have clusters of sharp bristles (glochids) and tufts of fibre ('wool'). Each areole contains a growing point that can produce roots or shoots.

Hudson pear *(Cylindropuntia rosea and C. tunicata)*

Densely branched cactus up to 1.5 m tall and 3 m wide. Spines are extremely sharp, 4.5 cm long, enclosed in whitish papery sheaths. Spines on *C. rosea* are white and *C. tunicata* are brown. Flowers on *C. rosea* are pink-purple, and on *C. tunicata* they are pink-yellow, 5 cm wide. Stem segments are green to grey-green, cylindrical, 90 cm long, 4 cm wide. Fruit is oval-shaped, up to 4.5 cm long, yellow when ripe.

Jumping cholla (*Cylindropuntia prolifera*)

Low shrub 0.4 to 1 m tall. Spines 7–11, 1–2 cm long, light to dark brown, interlacing, white to light tan sheath firmly attached. Flowers are rose to magenta, 25–30 mm wide. Stem segments are dull green to greenish grey, whorled or subwhorled, cylindrical, 4–15 cm long, 4–5 cm wide, waxy flaky surface when dry. Prominent tubercles and segments easily detached. Fruit obovoid to globose, solitary or forming chains, up to 20–50 mm long, green. Seed not seen in Australia.

Bunny ears *(Opuntia microdasys)*

Dense shrub 40–60 cm tall, occasionally more. Stems are pad-like, 6–15 cm long, 4–12 cm wide. No central stem, pads always grow in pairs, giving appearance of bunny ears. Has no spines, but instead has numerous white or yellow glochids (hair-like prickles), 2–3 mm long, in dense clusters. Flowers are yellow, 3 cm wide. Fruits are fleshy, globular, 3 cm long, red-purple.

Riverina pear *(Opuntia elata)*

Branched shrub with erect branches to 2 m tall. Spines absent or 1–3 short spines, whitish yellow present at some areoles. Flowers are orange, 3–4 cm wide. Stem segments are glossy green, sometimes with a purple tinge (especially around the areoles and margins). Often more than 2 cm thick, 5–25 cm long. Fruit club shaped, up to 6 cm long, purplish red.

Cane cactus *(Austrocylindropuntia cylindrica)*

Dark green shrub, 0.5–1.5 m tall. Branches 35–40 mm diameter. Leaves on new growth, deciduous, 3–5 mm long, but up to 10 mm on regrowth. Spines without papery sheath, 3–6 major ones per areole, 9–25mm long, and 3–4 minor ones, to 5.5 mm long. Flowers are red to red-orange. Fruit solitary or in small chains of 2–4. 30–60 mm long, dark green to yellow-green.

Eve's pin cactus *(Austrocylindropuntia subulata)*

Robust shrub to 3 m tall. Branches 40–50 mm diameter. Spines without papery sheath, 1 per areole on new growth, additional smaller ones (up to five) developing in successive years, mostly 35–70 mm long. Flowers are pink. Stem segments are glossy green, sometimes with a purple tinge (especially around the areoles and margins). Often more than 2 cm thick, 5–25 cm long. Fruit large, solitary or in small chains of 2–4, green, 50–135 mm long.

Coral cactus *(Cylindropuntia fulgida)*

Coral cactus grows as a branching shrub 1–1.5 m high. The stems of coral cactus are divided into green cylinder-like pads that are fist-like and obtuse at their apex. Mature coral cactus pads widen, become distorted and wavy, and resemble a piece of coral. Areoles along the pads have a number of short white spines.

Coral cactus produces small (1–2 mm wide) scarlet flowers. The fruit is yellow-green and 2–5 cm wide.

Devil's rope pear *(Cylindropuntia imbricata)*

This open-branching shrub grows 1.5–3 m high. The stems are divided into hairless, dull green, cylindrical pads that vary up to 37 cm in length and are 3.5–5 cm thick. The pads have a series of short raised ridges that give them a twined, rope-like appearance. The areoles are found on these ridges and produce 3–11 pale yellow or white spines, with the longest being 2.5 cm long. Papery sheaths cover these spines.

The flowers are a dull, red-purple colour and found at the ends of pads. The yellow fruit resembles a small, 5 cm wide custard apple and has a spineless areole at the top.

Snake cactus *(Cylindropuntia spinosior)*

This open-branching shrub grows 1–2 m high. The stems are divided into hairless, dull green, cylindrical pads that vary up to 20 cm in length and are 3.5–5 cm thick. The pads have a series of short raised ridges that give them a twined rope-like appearance. The areoles are found on the bottom of these ridges and produce 5–10 pale yellow to brown spines, with the longest being 3 cm long.

The flowers are light red to dark rose and commonly 5–7 cm wide. Snake cactus produces fruit that is yellow and 2–5 cm wide.

Common pest pear, Spiny pest pear *(Opuntia stricta)*

This bushy, spreading plant grows up to 1.5 m high and forms large clumps. The stems are divided into oval, blue-green spineless pads 20 cm long and 10 cm wide. Areoles are in diagonal lines along the pads 2.5 cm to 5 cm apart and have a cushion of brown wool containing bristles but usually no spines. When spines occur they are stout, yellow and up to 4 cm long.

Flowers that are 7.5 cm wide, bright lemon yellow and green at the base. The fruit is oval-shaped, has a deep cavity on one end and tapers at the other. It is purple, 6 cm long and 3 cm wide, with carmine-coloured (dark red) seeds and a fleshy pulp.

Drooping tree pear *(Opuntia monacanta)*

This erect succulent shrub with fibrous roots grows up to 5 m high but is usually 2–3 m high. The branches are divided into glossy light green pads up to 45 cm long, 15 cm wide and 1.5 cm thick. The dark grey trunk grows up to 25 cm in diameter. Drooping tree pear gets its name because the upper segments tend to droop. The areoles on the older pads have 1–5 sharp spines about 5 cm long.

Small, scale-like leaves are found on areoles of very young pads and are quickly shed as the pad grows. Drooping tree pear produces yellow flowers that are 6 cm wide and have red markings on the back. The fruit is pear-shaped and 4–7 cm long with a green skin. The flesh of the fruit is red and pulpy and contains round seeds that are yellow or pale brown. The fruits have areoles with tufts of fine, barbed bristles.

Tiger pear *(Opuntia aurantiaca)*

This succulent low shrub with underground tubers usually grows 30–60 cm high. The stems are divided into very spiny, slightly flattened pads that are 1–30 cm long and 1–5 cm wide. The stems are dark green to purple and red in colour. The areoles have 3–7 brown barbed spines up to 4 cm long surrounded by tufts of short, fine bristles. The pads detach easily and are transported on the skins of animals. Small and scale-like leaves are found on areoles of immature pads.

Tiger pear produces 6 cm wide yellow flowers. The rarely formed fruits are pear-shaped and about 2.5 cm long. When ripe, they are red with purple markings.

Velvety tree pear *(Opuntia tomentosa)*

This tree-like plant forms a central woody trunk over 40 cm wide and grows up to 5 m high. The stems are divided into oblong pads that are dull green and velvety to touch due to the dense covering of short fine hairs. The pads are 15–35 cm long, 8–12 cm wide and 1.5–2 cm thick.

Young plants have 2–4 white or pale yellow spines located in the areoles with one spine reaching a length of 2.5 cm. The areoles usually become spineless as the plant matures. A more spiny variety does exist and has more than 50 spines in each areole on the trunk.

The flowers are a deep orange. The fruit is egg-shaped, about 5 cm long and 3 cm wide, and dull red. The top of the fruit is saucer-shaped with circular lines that meet in the centre and give the fruit a shrivelled appearance. The fruit produces many seeds within a reddish pulp.

Westwood pear or Cardona pear *(Opuntia streptacantha)*

Westwood pear is a shrub-like or tree-like plant that forms clumps by branching from the base and is usually 2–4 m high. The stems are divided into almost circular dull green pads, 25–30 cm long and 15–20 cm wide. The areoles have white spines that vary in number and size when the plant matures.

Young pads have 2–5 white spines 1–2 cm long, accompanied by two hair-like spines 0.5 cm long in the lower part of the areole. Spines increase in number (up to 20) and size (5 cm long) in areoles along the trunk of the plant.

The flowers are yellow and fruits are barrel-shaped, 6 cm long and 5 cm wide with a flat top. The fruit has a purple skin and a rind that is 1 cm thick. Fruits contain red seeds buried in a dark red (carmine) pulp.

Habitat and distribution

Native to the Americas, Opuntioid species are found throughout most Australian states and territories and there is potential for further spread.

In Queensland Opuntioid species are mainly found in low rainfall areas but can be are found in gardens,along beaches and on off shore island.

Life cycle

Opuntioids reproduce both sexually and asexually. Birds and other animals readily eat the many seeded fruits and deposit seeds in their droppings. The seeds have hard seed coats that allow them to survive heat and lack of water. Asexual reproduction (cloning) of cacti occurs when pads (joints, segments) or fruits located on the ground take root and produce shoots.

Methods of spread

Animals and floods move broken pads long distances. These pads can survive long periods of drought before weather conditions allow them to set roots. People can spread cacti for ornamental plantings.

Control

Managing opuntioid cacti

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by opuntioid cacti. This fact sheet provides information and some options for controlling opuntioid cacti.

Mechanical and fire control

Mechanical control using machinery is difficult because prickly pear pads can easily re-establish. A hot fire is an effective control method for dense prickly pear infestations. Before burning, consult Biosecurity Queensland to see if this practice is suitable for your pasture and land management practices.

Biological control

Investigations into biological control agents against prickly pear began in 1912. Over 150 insect species were studied throughout the world, with 52 species selected for transport to Queensland. Following intensive host specificity testing, 18 insects and one mite were released in Queensland. Nine insects and the mite remain established in Queensland. These species are:

Cactoblastis cactorum, a stem-boring moth

- *Dactylopius ceylonicus*, a cochineal mealy bug
- *Dactylopius opuntiae*, a cochineal mealy bug
- *Dactylopius confusus*, a cochineal mealy bug
- *Dactylopius tomentosus*, a cochineal mealy bug
- *Dactylopius austrinus*, a cochineal mealy bug
- *Chelinidea tabulata*, a cell-sucking bug
- *Tucumania tapiacola*, a stem-boring moth
- *Archlagocheirus funestus*, a stem-boring beetle
- *Tetranychus opuntiae*, prickly pear red spider mite.

These biological control agents continue to keep several prickly pear species under control. It is important to remember not all the agents attack all species.

The most successful of these agents were the moth *Cactoblastis cactorum* and five cochineal mealy bugs—*Dactylopius ceylonicus, D. opuntiae, D. confusus, D. tomentosus* and *D. austrinus*. The other agents are still around but not in sufficient numbers to provide control.

Cactoblastis cactorum (cactoblastis moth)

Larvae of this moth were introduced from Argentina in 1925. Cactoblastis proved to be the most effective agent against the common and spiny pest pears, destroying massive infestations in Australia. Larvae keeps these two pest pears controlled to an acceptable level most of the time, although it is less effective in some coastal and far western areas.

The larvae collectively eat out the contents of the pads, leaving empty pad skins and piles of mushy droppings. The orange and black larvae are occasionally observed on the outsides of pads. Cactoblastis also attacks most types of prickly pear but is not effective against them.

Dactylopius spp. (cochineal insects)

All female cochineal insects are small, sessile mealy bugs that spend their adult lives permanently attached to their host plants sucking plant juices. They are covered by a fine, white, waxy secretion and when crushed yield a carmine colouring. The adult males are small, free-flying insects that do not feed.

Dactylopius ceylonicus (monacantha cochineal, Argentine cochineal)

This South American mealy bug was released in 1914 and 1915 to control drooping tree pear. It destroyed the dense infestations existing at that time. It is specific to drooping tree pear and today remains the only effective biological control agent for drooping tree pear. This insect needs to be distributed manually.

Dactylopius opuntiae (prickly pear cochineal)

This mealy bug was introduced from Mexico and southern United States between 1920 and 1922. It is effective against common pest pear, spiny pest pear, velvety tree pear and Westwood pear and remains the main biological control agent against velvety tree pear and Westwood pear. This insect spreads slowly in nature and can be assisted manually.

Dactylopius confusus (prickly pear cochineal)

This mealy bug was introduced from Florida and released in 1933 against spiny pest pear. It remains effective against spiny pest pear in central Queensland but spreads slowly. This insect can be spread manually.

Dactylopius tomentosus (devil's rope pear cochineal)

This mealy bug was introduced from southern United States in 1925 and 1926. It is effective against devil's rope pear but works slowly.

Dactylopius austrinus (tiger pear cochineal)

This mealy bug was introduced from Argentina in 1932. It is specific to and effective against tiger pear. It rapidly reduces tiger pear populations but dies out in a paddock after the destruction of tiger pear. It needs to be reintroduced after tiger pear regrows.

Chelinidea tabulata (prickly pear bug)

This plant-sucking bug was introduced from Texas in 1921. It was effective against dense common pest pear before *Cactoblastis cactorum* was but is now relatively ineffective. This insect also attacks most other prickly pears. The adult is a pale brown bug up to 20 mm long that leaves characteristic round bleached spots on the surface of the cactus.

Tucumania tapiacola (prickly pear moth-borer)

This moth was introduced from Argentina in 1934 against tiger pear. Its solitary larvae feed internally and eat out tiger pear pads with limited effect. It has been observed attacking common pest pear and harrisia cactus.

Archlagocheirus funestus (tree pear beetle)

This stem-boring beetle was introduced from Mexico in 1935. It was effective against velvety tree pear and Westwood pear but has become rare since the dense stands of these prickly pears have gone.

Tetranychus opuntiae (prickly pear spider mite)

This mite was introduced from southern United States and Mexico in 1922. It was effective against common pest pear but is now rare and difficult to find. It causes distinctive scar tissue formation around areoles.

Distributing biological control agents

Cactoblastis

Cactoblastis can be spread manually by distributing eggs or larvae. Cactoblastis moths lay chains of eggs (eggsticks) on prickly pear pads from January to February and from September to November. The eggsticks are distinguished from spines by their curved appearance.

1. Collect the fragile eggsticks carefully.
2. Glue single eggsticks to small pieces of paper using a starch-based adhesive.
3. Pin the egg papers to prickly pear pads. (Eggs take up to one month to hatch.)
4. Collect pads or plants in which larvae are obviously still active.
5. At a release site place all the collected plant material in a small part of the infestation.
6. Subsequent generations of moths will disperse through the infestation.
7. Follow up the biological control with either herbicide or mechanical treatment.

Cochineals

Because several cochineal insects affect some prickly pears and not others, it is essential to know what prickly pear you wish to control.

1. Identify your prickly pear type.
2. Find the same prickly pear type which is being attacked by a cochineal.
3. Collect pads of the prickly pear with the insects.
4. Place affected pads against unaffected prickly pears at the release site.
5. Follow up the biological control with either herbicide or mechanical treatment.

Tiger pear cochineal

Tiger pear cochineal is easy to multiply quickly after collection.

1. Carefully collect a reasonable quantity of unaffected tiger pear in a container (box or bucket).
2. Place a few pieces of cochineal-affected tiger pear into the same container.
3. Cover the container with a cloth and store under cover for a few weeks.
4. Check the cactus occasionally.
5. When most of the tiger pear in the container has cochineal, it is ready to distribute.
6. At the release site place affected pads against unaffected prickly pears.
7. Follow up the biological control with either herbicide or mechanical treatment.

Note: It is best to multiply tiger pear cochineal before release.

Herbicide control

Herbicide options available for the control of optuntioid cacti in Queensland are shown in Table 1.

Landholders and contractors should check if the property is in a hazardous area as defined in the *Agricultural Chemicals Distribution Control Act 1966* prior to spraying.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Table 1. Herbicides for the control of opuntioid cacti

Pest name	Situation	Herbicide	Rate	Method
Common prickly pear	Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + picloram 120 g/L (e.g. Access)	1 L/60 L diesel	Basal bark/cut stump Apply as an overall spray, wetting all areas of plant to ground level
	Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	Triclopyr 300 g/L + picloram 100 g/L (e.g. Conqueror) or Triclopyr 300 g/L + picloram 100 g/L + aminopyralid 8g/L (Grazon Extra)	500 mL/100 L	Apply as a thorough foliage spray
		Triclopyr 600 g/L) e.g. Garlon 600)	3 L/100 L or 0.8 L/60 L diesel	
Coral cactus	Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + picloram 120 g/L (e.g. Access)	1 L/60 L diesel	Basal bark/cut stump Apply as an overall spray, wetting all areas of the plant to ground level
	Pastures, rights-of-way, commercial/industrial areas	Triclopyr 240 g/L + picloram 120 g/L (e/g/ Access)	1 L/60 L diesel See permit PER13812 (expires 30/11/2017)	Paint stump immediately after cutting or spray basal bark
Tiger pear	Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + picloram 120 g/L (e.g. Access)	1 L/60 L diesel	Basal bark/cut stump Apply as an overall spray, wetting all areas of plant to ground level
	Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	Triclopyr 600 g/L (e.g. Garlon 600)	3 L/100 L water or 0.8 L/60 L diesel	Apply as a thorough foliage spray
Drooping tree pear	Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr 300 g/L + picloram 100 g/L (e.g. Conqueror) or Triclopyr 300 g/L + picloram 100 g/L + aminopyralid 8g/L (Grazon Extra)	500 mL/100L water	
	Non-crop areas around buildings, commercial and industrial areas, domestic and public service areas, rights-of-way	Amitrole 250 g/L + ammonium thiocyanate 220 g/L (e.g. Amitrole T)	1 mL/3 cm (inject) or 1 L/25 L (small plants/regrowth)	Tree pears may take up to 12 months to die Resparying may be needed in some cases Consult label
Velvety tree pear	Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + picloram 120 g/L (e.g Access)	1 L/60 L diesel	Basal bark/cut stump Apply as an overall spray, wetting all areas of plant to ground level
	Non-crop areas around buildings, commercial and industrial areas, domestic and public service areas, rights-of-way	Amitrole 250 g/L + ammonium thiocyanate 220 g/L (e.g. Amitrole T)	1 mL/3 cm (inject) or 1 L/25 L (small plants/regrowth)	Tree pears may take up to 12 months to die Resparying may be needed in some cases Consult label
Spiny pest pear Westwood pear Devil's rope pear Snake cactus	Agricultural non-crop areas, commercial and industrial areas, fence lines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + picloram 120 g/L (e.g. Access)	1 L/60 L diesel	Basal bark/cut stump Apply as an overall spray, wetting all areas of plant to ground level

Snake cactus (*Cylindropuntia spinosior*)

Coral cactus (*Cylindropuntia fulgida*)

Hudson pear (*Cylindropuntia rosea*)

Jumping cholla (*Cylindropuntia prolifera*)

Prickly pear (*Opuntia stricta)*

Bunny ears (*Opuntia microdasys*)

Tiger pear (*Opuntia aurantiaca*)

Riveria pear (*Optunia elata*)

Devil's rope pear (*Cylindropuntia imbricata*)

Drooping tree pear (*Opuntia monacanta*)

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture and Fisheries (DAF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

Restricted invasive plant

Rubber vine

Cryptostegia grandiflora and *Cryptostegia madagascarensis*

Rubber vine's ability to quickly spread and colonise areas makes it a threat to many areas of northern Australia. Due to this ability, rubber vine is listed as a Weed of National Significance.

Rubber vine generally invades waterways first, where the seeds germinate in moist silt layers after rain. The plant smothers riparian vegetation and forms dense, sometimes impenetrable, thickets.

This decreases biodiversity and prevents access to both stock and native animals. It also creates habitat for feral animals. Infestations expand outward from waterways, hillsides and pastures, resulting in loss of grazing land and increased difficulty in mustering stock.

Rubber vine is poisonous to stock, though seldom eaten. Most deaths due to rubber vine occur after stock have been stressed, or when other feed is scarce.

Queensland Government

Legal requirements

Rubber vine (*Cryptostegia grandiflora*) and ornamental rubber vine (*Cryptostegia madagascarensis*) are restricted invasive plants under the *Biosecurity Act 2014*. They must not be given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Description

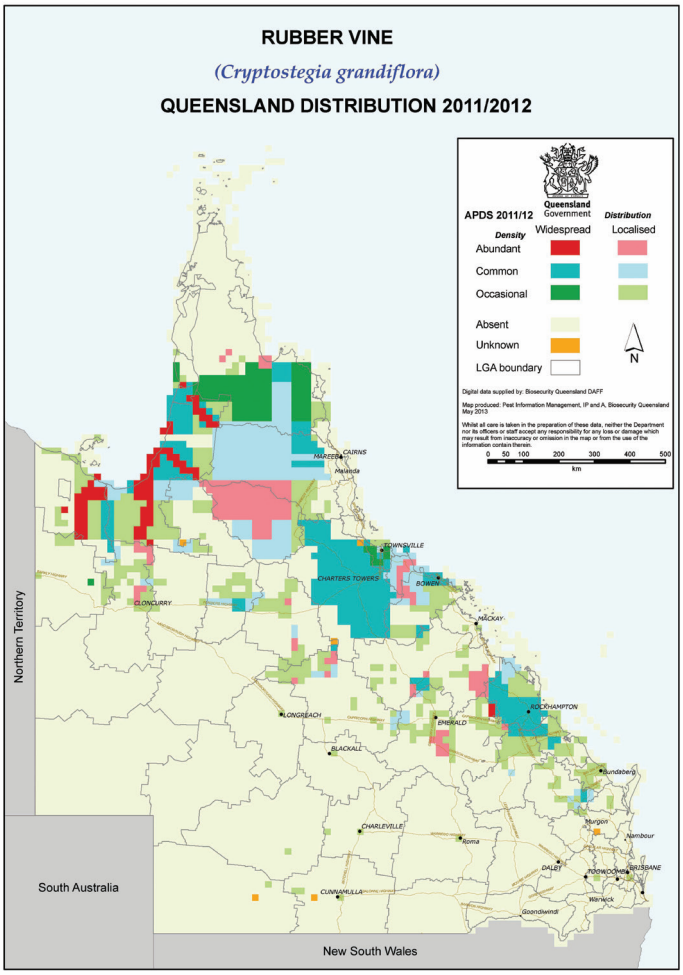
Rubber vine is a vigorous climber with twining, whip-like shoots that can grow unsupported as an untidy, multi-stemmed shrub 1–2 m high, or it can scramble up to 30 m high in trees. The stems, leaves and unripe pods exude a white, milky sap when broken or cut.

Leaves are dark green and somewhat glossy, 6–10 cm long, 3–5 cm wide, and in opposite pairs.

Flowers are large and showy, with five white to light purple petals arranged in a funnel shape.

The seed pods are rigid and grow in pairs at the end of a short stalk. The pods are 10–12 cm long, 3–4 cm wide and each can contain up to 450 brown seeds. Each seed has a tuft of long, white, silky hairs, which enable easy dispersal by wind and water.

Ornamental rubber vine (*Cryptostegia spilanthoides*) is a shrub up to 3 m tall, if unsupported and stems can climb to 10 m if supported. Bark is sparsely dotted with corky patches. Leaves are dark green, glossy, with pale underside, 2–11 cm long, 1.5–5.5 cm wide, arranged in opposite pairs. Plant produces milky latex sap when leaves, fruit or branches are cut.



Flowers are pink-purple, 4–6 cm long, found near branchlet ends. Pods are 7–9 cm long, contain seeds 5–5.9 mm long, 1.8–3.5 mm wide, topped with silky tuft of white hairs.

Life cycle

Rubber vine flowers at any time of year if sufficient moisture is available. Usually, June and July are the only non-flowering months. Plant stem diameter must be approximately 20 mm before flowering can occur.

Seed pod formation occurs from spring to late autumn, with peak seed production corresponding to maximum flowering. Eventually, pods dry out and split open, with pod-splitting occurring approximately 200 days after formation.

Map 1. Distribution of rubber vine in Queensland

Seeds are scattered by wind, but also carried downstream by water. Approximately 95% of seed is viable, although germination requires favourable temperature and soil moisture conditions.

Methods of spread

Rubber vine seeds spread by wind and water.

Habitat and distribution

Rubber vine is native to Madagascar, but is now widely distributed throughout tropical and subtropical regions of the world.

The plant was introduced to Australia as an ornamental shrub in 1875 or earlier, and was popular in north Queensland mining settlements due to its luxuriant growth even under harsh conditions. Weedy infestations were recorded around Charters Towers early this century.

Rubber vine prefers areas where annual rainfall is 400–1400 mm, and is well adapted to a monsoonal climate.

Infestations of rubber vine are now found throughout river systems of southern Cape York and the Gulf of Carpentaria, south along the coast to the Burnett River, and isolated infestations occur as far south as Gatton and as far west as the Northern Territory border.

Infestations are common throughout central Queensland, while in western Queensland there are infestations in the Mount Isa, Longreach and Aramac areas. Isolated infestations have been reported in Western Australia.

Control

Managing rubber vine

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by rubber vine. This fact sheet provides information and some options for controlling rubber vine.

Effective control of rubber vine can be achieved by a number of methods, alone or in combination depending on the situation and the severity of infestation. All areas treated must be periodically checked and any regrowth treated or the initial treatment efforts will be wasted.

Rubber vine seed is most commonly spread by wind and running water.

It is thus difficult to prevent seed coming onto uninfested land if there is rubber vine anywhere in the area. Your goal should be to prevent rubber vine from establishing and forming dense infestations. It is essential to regularly inspect all areas of your property, paying particular attention to creeks and gullies.

This is most important where prevailing winds are known to blow from infested areas, or where infestations occur upstream.

Any isolated plants located should be treated promptly.

All control of rubber vine will require follow-up treatments to keep your property clean. As rubber vine spreads quickly, small infestations should be controlled first to prevent them from becoming major problem areas. Dense infestations are difficult and costly to treat.

Follow-up treatment must be budgeted for within the overall control program. Techniques need to be integrated for successful rubber vine management. Consideration should be given to coordinating control over a catchment area.

Five suggested strategies for controlling rubber vine in scattered, medium, and dense infestations are outlined in Table 2.

Fire

Rubber vine infestations can be very effectively controlled by burning. Preparing and managing fuel load prior to burning, and following up in a timely manner after the fires, are critical to the overall success of the program.

It is recommended that you perform two successive annual burns. The first fire will open up the infestation to increase grass growth (fuel load) while killing rubber vine plants. The second fire will clean up the regrowth that occurs after the first fire.

An appropriate fire regime is an effective tool for managing rubber vine over the long term, as well as being an effective follow-up to other control methods.

Mechanical control

Several mechanical techniques are effective in controlling rubber vine. The type of infestation will determine the technique required.

- Scattered or medium-density infestations: Where possible, repeated slashing close to ground level is recommended.
- Dense infestations: During winter, stick-raking or blade-ploughing reduces the bulk of the infestation. Pasture should be sown and windrows burned to kill residual seed. Follow-up treatment is essential. It is important to comply with the relevant state and/or local government native vegetation legislation, and it should be noted that causing even accidental death of vegetation can be a breach of this legislation.

Biological control

Two biological control agents are successfully established, and their impact depends on abundance. Both agents cause abnormal defoliation, creating an ‘energy sink’, which appears to reduce seed production. These agents usually do not kill established rubber vine plants.

Diseases

Rubber vine rust (*Maravalia cryptostegiae*) is established over a wide area. Yellow spores form under the leaves and are spread mainly by the wind.

It is most active over summer, abundance being directly related to leaf wetness, which is dependent on rainfall and dew. Over summer, a generation is completed every seven days. Rust activity is reduced over the dry season.

Continued heavy infection causes defoliation, appears to reduce seed production, can kill small seedlings and causes dieback of the whip-like stems. Established plants are not killed.

Insects

Also established is the moth *Euclasta whalleyi*, whose larvae are leaf feeders. Observation indicates the moth prefers stressed plants, either from limited soil moisture or high levels of rust infection.

The moth’s period of activity is the dry season. A native fly parasite and a disease can reduce the localised abundance of the *Euclasta* larvae.

The larvae are tapered at both ends, grow up to 30 mm long, and are grey-brown with orange dots along their sides. Fine silken threads and black, bead-like droppings are often found near the larval feeding damage.

The creamy-brown moths are active at night and rest at a 45° angle from a surface, with their wings folded. The life cycle from egg to adult takes 21–28 days.

Defoliation reduces the smothering effect on other vegetation and causes an increase in leaf litter and promotes increased grass growth amongst rubber vine, increasing fuel loads required for fire management. Decreased flower and pod production should reduce the ability of rubber vine to spread.

Herbicide control

Basal bark spray

This method gives a high level of control although it is not as effective on multi-stemmed plants as it is difficult to spray each stem completely around the base.

Thoroughly spray around the base of the plant to a height of 20–100 cm above ground level, spraying higher on larger plants.

Optimum results are attained when the plant is actively growing.

Cut stump treatment

This is the most successful method of herbicide control, but also the most labour intensive. The following points should be followed carefully:

- cut the stem off as close to the ground (within 15 cm) as possible; for smaller plants use a machete or similar; larger plants may require a chainsaw
- make sure the cut is horizontal
- immediately spray or swab the cut surface
- a cost-effective method for scattered to medium-density infestations is the use of a brush-cutter.

Soil application

Because of the high risk of killing non-target vegetation, including trees and pasture plants, soil-applied herbicides play a role in controlling rubber vine only in specific situations.

It is important to comply with the relevant state and/or local government native vegetation legislation, and it should be noted that causing even accidental death of vegetation can be a breach of this legislation.

The following points should be followed carefully:

- do not use residual herbicides within a distance of two or three times the height of desirable trees
- do not use Graslan along waterways or land with greater than a 20^0 slope
- a minimum of 50–80 mm of rainfall is required before residual herbicides are taken up by the plant.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Table 1. Herbicides for the control of rubber vine

Situation	Herbicide	Rate	Comments
Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	Triclopyr 300 g/L + Picloram 100 g/L + Aminopyralid 8 g/L (Grazon Extra) or Triclopyr 300 g/L + Picloram 100 g/L (e.g. Conqueror)	350–500 mL/ 100 L water	High volume spray Actively growing plants not infected with rust Use the higher rate for dense stands higher than 1.5 m tall at flowering (consult label)
Native pastures, rights-of-way, commercial and industrial areas	Metsulfuron-methyl 600 g/kg (e.g. Associate, Ken-Met 600)	15 g/100 L water	High volume spray on actively growing plants Apply to actively growing bushes up to 3 m tall, October through April Wetting agent is critical Complete coverage is essential May damage pasture legumes (consult label)
Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	2,4 D 300 g/L + Picloram 75 g/L (e.g. Tordon 75-D, Commander 75-D)	1.3 L/100 L water	Treat actively growing plants Thoroughly wet leaves and soil around base of plant Less effective than other treatments
Around agricultural buildings and other farm non-crop situations, commercial, industrial, and public service areas, rights-of-way and waster land, away from desirable vegetation	Imazapyr 250 g/L (e.g. Unimaz 250 SL)	4 mL/L water	High volume application to actively growing plants (consult label)
Non agricultural areas (native pastures) commercial and industrial areas and rights-of-way	Aminopyralid 375 g/kg plus Metsulfuron-methyl 300 g/kg (e.g. Stinger)	30 g/100L water plus wetting agent (consult label)	Apply to bushes up to 3 m in height Apply from October to April when bushes are actively growing. Ensure thorough spray coverage of all foliage and leaders Incomplete coverage will result in regrowth
Native pastures, rights-of-way, commercial and industrial areas	Triclopyr 75 g/L + Metsulfuron-methyl 28 g/L (e.g. Zelam Brush Weed)	375 mL/100L	Spray actively growing plants up to 3 m tall, from October to April. Thoroughly spray all foliage and leaders. Incomplete coverage will result in regrowth
Agricultural non-crop areas, commercial and industrial areas, fencelines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + Picloram 120 g/L (e.g. Access)	1 L/60 L diesel	Basal bark plants up to 5 cm basal diameter Treat at any time Thoroughly spray around base of plant
Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	Triclopyr 600 g/L (e.g. Garlon 600, Triclopyr 600)	1 L/60 L diesel	Basal bark Treat at any time Thoroughly spray around base of plant
Agricultural non-crop areas, commercial and industrial areas, fencelines, forestry, pastures and rights-of-way	Triclopyr 240 g/L + Picloram 120 g/L (e.g. Access)	1 L/60 L diesel	Cut stump Apply immediately cut is made
Agricultural non-crop areas, commercial and industrial areas, forests, pastures and rights-of-way	Triclopyr 600 g/L (e.g. Garlon 600, Triclopyr 600)	1 L/60 L diesel	Basal bark size and larger plants
Non-crop areas, including: native vegetation, conservation areas, gullies, reserves and parks	Picloram 44.7 g/L + aminopyralid 4.47 g/L (Vigilant II)	Undiluted	Cut stump as close to the ground as possible. Apply immediately according to label instructions
Pastures, rights-of-way and industrial	2,4-D as amine 700 g/L (e.g. Amicide Advance 700)	145 mL/10L water	Cut stump Apply immediately
Other formulations of 2,4-D are also registered for cut-stump treatment of rubber vine. Consult labels for registration details, rates and critical comments.			
	Hexazinone# 250g /L (e.g. Bobcat®SL, Velpar®L)	2 mL/spot, 3 spots for each bush (tree)	Soil application# prior to rain See warning below. #Must place spots around bush. Less effective on sandy soils
	Tebuthiuron# 200 g/kg (e.g. Graslan, Tebuthiuron 200)	1.5 g/m^2	Soil application# prior to rain Application prior to rain by hand or backpack spreader
	Triclopyr 300 g/L + Picloram 100 g/L+ Aminopyralid 8 g/L (Grazon Extra) or Triclopyr 300 g/L + Picloram 100 g/L (e.g. Conqueror, Grass-up)	3–5 L/ha	Aerial application (helicopter only) to actively growing plants Triclopyr 300 g/L + Picloram 100 g/L
	Tebuthiuron# 200 g/kg registered for aerial application (e.g. Graslan)	7.5–15 kg/ha	Aerial application prior to rain Triclopyr 300 g/L + Picloram 100 g/L

Warning: Soil testing is highly recommended prior to application of these herbicides, as rate and efficacy are dependant on soil type.
DO NOT USE SOIL APPLIED HERBICIDES (HEXAZINONE AND GRASLAN) WITHIN A DISTANCE OF TWO TO THREE TIMES THE HEIGHT OF DESIRABLE TREES.
DO NOT USE GRASLAN NEAR WATERWAYS OR LAND WITH GREATER THAN A 20° SLOPE.

Read the label carefully before use. Always use the herbicide in accordance with the directions on the label.

Table 2. Suggested strategies for the control of rubber vine

Situation	Initial treatment	Follow-up	Comments
Scattered infestations	Basal bark/ cut stump	Follow-up with basal bark/ cut stump as necessary	Cut stump method preferred where possible
	Foliar spray	Follow-up basal bark/ cut stump/foliar spray as necessary	Only foliar spray when there is nil to little rust on the leaves of the plants
	Fire	Follow-up basal bark/ cut stump/foliar spray as necessary	For scattered infestations usually recommended only if herbicides not desired, or if have other weeds can be controlled by fire or if fire is utilised to improve pastures
	Repeated slashing		
Medium infestations	Foliar spray	Treat regrowth, seedlings with basal bark/cut stump/ foliar spray	Fire and follow-up with basal bark/cut stump/foliar spray as necessary
	Fire	Fire 1 year later and follow-up basal bark/cut stump/ foliar spray as necessary	If fuel load is sufficient **CAUTION:** There are some native tree species which are susceptible to fire Check before burning
	Repeated slashing		
Dense infestations previously cleared areas	Stick rake or blade plough	Sow pasture – basal bark/ foliar spray – fire and basal bark/cut stump/foliar spray as necessary	First treatment clears bulk of rubber vine and kills roots; any regrowth or seedlings can then be treated; when grass growth allows fuel build up, fire used as control and individual plants later treated
	Fire	Fire one year later and follow-up basal bark/ cut stump/foliar spray as necessary	If fuel load is sufficient **CAUTION:** There are some native tree species which are susceptible to fire Check before burning
	Aerial spray	Fire 1–2 years later or follow-up with basal bark spray	Bulk of rubber vine killed with aerial spray; allow build up of fuel for fire or treat remaining plants with basal bark spray Contact 13 25 23 before use of this method
	Graslan		Where situation and soil type are suitable
Dense infestations along creeks and rivers	Basal bark/ cut stump	Fire or basal bark/cut stump/foliar spray	When bulk of rubber vine killed, allow fuel build up for fire or treat remaining plants individually
	Fire and sow pasture	Fire one year later and follow-up basal bark/cut stump/foliar spray as necessary	If there is a sufficient fuel load to carry a fire, it can open up dense infestations **CAUTION:** There are some native tree species which are susceptible to fire Check before burning

Appendix K Pest Species and Management Plans

Department of Agriculture and Fisheries
Biosecurity Queensland

Invasive animal

Cane toad

Bufo marinus

The cane toad is not a declared pest in Queensland, so there is no legal requirement to control them.

Their original introduction in 1935 was to control agricultural pests, but they proved ineffective.

For the past 60 years, cane toads have been expanding their territory in Australia, and are capable of colonising at least four of the mainland Australian states.

As the toad's geographical range continues to expand, concern has increased about their detrimental environmental effects, particularly on the wetlands of the Northern Territory.

Studies into the feasibility of biological control have commenced.

Legal requirements

The cane toad is not a prohibited or restricted invasive animal under the *Biosecurity Act 2014,* however everyone has a general biosecurity obligation (GBO) to take reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control.

Local governments have a biosecurity plan that covers invasive plants and animals in their area and may require additional actions to be taken on certain species; some of these may be applied under local laws. Refer to your local government for more information.

Queensland Government

History of introduction and spread

The cane toad or giant toad is an amphibian, native to Central and South America. Cane toads have been introduced throughout the world as a biological control for insect pests of agriculture, most notably sugarcane.

A consignment of cane toads from Hawaii was released into Queensland cane fields in 1935. The introduction was surrounded by controversy as to the potential costs and benefits to Australia.

It was hoped that the toad would control Frenchi and greyback beetles—pests of economic importance to the sugarcane industry.

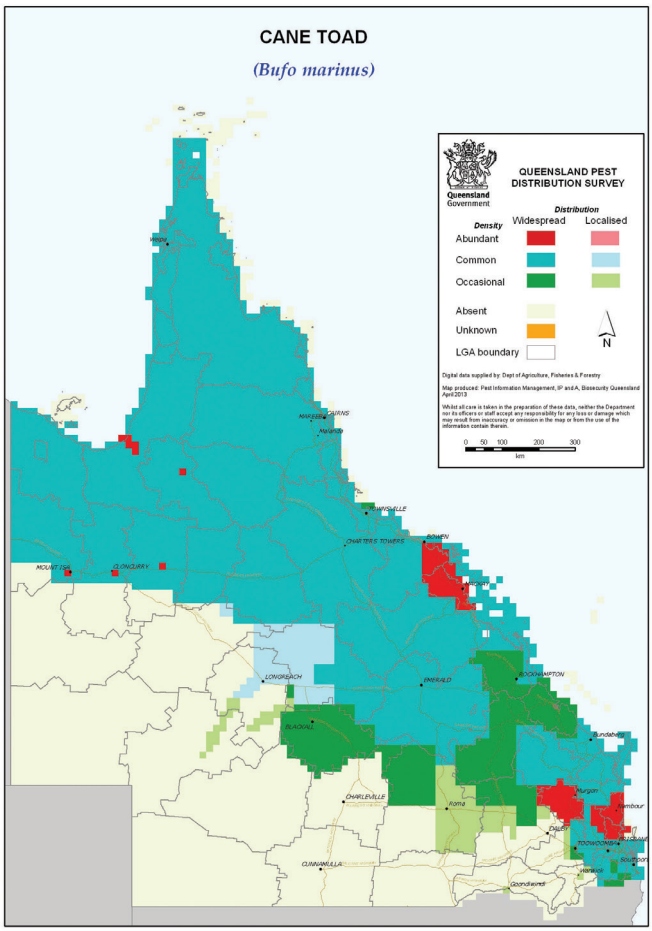
By 1941, however, it had become evident that the cane toad was exerting only limited control over its intended prey. There were two main reasons for this:

- Greyback beetles are only rarely in contact with the ground and Frenchi beetles invade cane fields at a time when the toads are absent due to a lack of protective cover.
- The cane toad has a wide-ranging and indiscriminate diet, and it was not solely dependant upon its intended prey.

The unlimited food source, suitable environment and low rates of predation allowed dynamic reproduction and spread. Toads were recorded in Brisbane only 10 years after release. The toad continues to thrive and has now invaded the Northern Territory and New South Wales (see Map 1).

Map 1. Distribution of the cane toad in Australia

The cane toad's advance is only limited by environmental factors, such as the availability of water for breeding, tolerable temperatures, suitable shelter and availability of food.



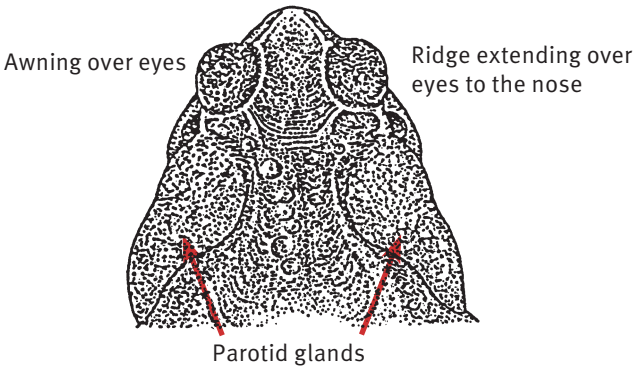
Toads at the frontier of their range of expansion may be larger than those in established populations. This is most probably due to greater food supply, combined with a lower incidence of disease.

Description

In comparison with native frog and toad species, adult cane toads have a distinctive head and face, and are large and heavily built creatures (adults may grow to 20 cm).

Following their aquatic larval stages (eggs and tadpoles), cane toads are generally encountered at night near any

Map 2. Distribution of the cane toad in Queensland



source of light. Cane toads are ground-dwelling—they are poor climbers and unable to jump very high.

A definite visor or awning extends over each eye and a high angular bony ridge extends from the eyes to the nose.

The parotid glands (see Figure 1) are perhaps the most characteristic feature of the adult cane toad. These glands are large, protuberant, and are situated on the head behind each ear. These glands carry a toxin.

Figure 1. Distinguishing features of the cane toad

The cane toad's hands and feet are relatively small and lack discs at the tips of the digits. Webbing is absent between the fingers but is distinct and leathery between the toes.

Colouring on the dorsal (upper) surface may be brown, olive-brown or reddish-brown. The ventral (under) surface varies from white to yellow and is usually mottled with brown.

Warts are present on all cane toads; however, males possess more than females. Warts are dark brown at the caps.

Mating

Mating can occur at any time of the year and depends only on available food and permanent water. The mating call is a continuous purring trill that sounds like a running motor.

In situations where females are scarce or absent, male cane toads may have the ability to undergo a sex change to become fertile females; however, this has not been proved.

Eggs

Both cane toads and native frogs spawn in slow-moving or still water, but their eggs can be easily distinguished.

Cane toad eggs are laid in long, gelatinous 'strings' with the developing tadpoles appearing as a row of small black dots along the length. The strings are unique to cane toads, generally appearing as blobs of jelly attached to water plants or debris. Native frogs generally produce egg clusters as mounds of foam floating on the water surface.

Compared with native species, cane toad egg production is dynamic and a single clutch can contain up to 35 000 eggs. Remove any cane toad eggs found in the water and allow to dry out.

Figure 2. Drawing of toad spawn from Wildlife of greater Brisbane

Tadpoles

The cane toad is the only species in Australia that has a pure black tadpole. Native frogs have lighter-coloured undersides with a great range of colours and markings—cane toad tadpoles may turn paler colours to almost transparent at night.

Cane toad tadpoles are small and usually congregate in vast, slow-moving shoals. This 'shoaling' behaviour is uncharacteristic of most native species.

Unlike cane toad tadpoles, native species develop lungs at an early stage and periodically rise to the surface in order to exchange their lung gasses. Large groupings of tadpoles that do not break the water surface for air indicate cane toads.

Young toads

Following emergence from the water, the young toadlets usually congregate around the moist perimeter of the water body for about a week before they eventually disperse.

Young toads are very difficult to distinguish from the native *Uperoleiea* species, which also have parotid glands, but all *Uperolelea* species have bright red patches in the groin area.

Under ideal conditions toadlets may reach adult size within a year.

Toxicity

Bufo marinus produce venom in glands occurring in most of the skin on their upper surface. The venom is concentrated in the parotid glands as a creamy-white solution, which is released when the animal experiences extreme provocation or direct localised pressure (e.g. grasped by the mouth of a predator).

The parotid solution is highly toxic and when ingested it produces drastic acceleration of the heartbeat, shortness of breath, salivation and prostration. It is extremely painful if accidentally rubbed into the eye.

Ingestion of toads by domestic and most native animals can result in death. In some recorded cases, death has occurred within 15 minutes.

Field observations suggest that some predatory Australian species have learned how to feed safely on cane toads.

Birds have been observed flipping toads over to avoid the parotid glands. Predatory reptiles may have more trouble adapting, being unable to remove a toad from the mouth once they start feeding.

Impacts on wildlife

The cane toad is poisonous at all stages of its life cycle and most native frog larvae and many aquatic invertebrates are dramatically affected by their presence.

Cane toads are voracious feeders that consume a wide variety of insects, frogs, small reptiles, mammals and even birds. Perhaps the only limiting factor to the prey taken is the width of the cane toad's mouth.

It has been suggested that cane toad competition for food and breeding grounds has been responsible for reducing the populations of some native frogs. However, many native frogs are arboreal (tree-dwelling) and occupy different niches. Cane toads don't have the native frogs' ability to 'shut down' during dry seasons when resources are limited.

Pressure from cane toads may displace native animals (frogs and other species) where they are already suffering due to manipulation of their habitat by humans and grazing animals. Animals that use waterholes as retreat sites during the dry season are especially vulnerable—toads will congregate here in large numbers.

Public health

Cane toads readily eat animal and human faecal material and, in areas of poor hygiene, they have been known to transmit disease such as salmonella.

Control

Control of cane toads is not enforced as there is currently no available effective broad scale control. Individuals and community groups have carried out removal campaigns to decrease numbers and slow the invasion front.

Fencing is recommended to keep toads out of ponds intended for native fish and frogs; a height of 50 cm is sufficient. Bird wire with 1 cm holes may keep toads out of an area.

Research indicates that spread can be delayed in semi-arid areas by blocking access to water holes.

Individual toads may be killed relatively humanely using a commercial spray available from hardware stores or may be stunned and decapitated (only by experienced operators). The removal of eggs from small water bodies such as frog ponds can be effective.

Researchers have successfully mitigated impacts in recently colonised areas by 'training' predators however, large scale application of this technique is difficult.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Restricted invasive animal

Dingo

Canis familiaris dingo

The dingo is a primitive canid related to wolves and coyote. The dingo was not a part of the ancestral fauna of Australia. Though its origins are not clear, it is thought to have arrived in Australia 3500–4000 years ago.

It is the largest mammalian carnivore remaining in mainland Australia, and as such fills an important ecological niche. Females weigh about 12 kg and males 15 kg.

The dingo has been regarded as a serious predator of domestic stock since early European settlement in Australia.

Since European settlement domestic dogs have been released or escaped into the environment to cross with dingoes. These hybrids or crosses are colloquially call wild dogs (*Canis lupus familiaris*). Often the term wild dog covers both dingoes and dingo hybrids.

Wild dogs predate on livestock, native fauna and domestic pets.

Queensland Government

Legal requirements

The dingo is a restricted invasive animal under the *Biosecurity Act 2014*. It must not be moved, kept, fed, given away, sold, or released into the environment without a permit. The wild dog must not be moved, fed, given away, sold, or released into the environment without a permit.

The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO).

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Description

Red, ginger and sandy-yellow are the dominant coat colours, though dingoes can also be pure white, black and tan or solid black.

It is not difficult to distinguish between most dingoes and hybrids. The presence of domestic genes is suggested by broken colours—brindling and patchiness in the normally pure white feet and chest patch and sable colouration (black hairs along the back and sides).

Dingoes have a more heavily boned skull and larger teeth (especially the canine) than domestic dogs of similar size.

Life cycle

Dingoes have only one breeding season per year (usually April to June), whereas domestic bitches have two or more oestrus cycles per year. However, unless seasons are particularly favourable, or human sources of food are intentionally or inadvertently provided, feral domestic dogs are unlikely to successfully rear two litters per year.

After a nine-week gestation, dingo pups (usually four to six) are born in a hollow log or cave den. Bitches tend to use the same den each year. Pups are suckled at four to six weeks and generally weaned at four months. When large enough to travel, pups are taken from the den to kills, and other dens many be used. The range of pups is increased as they are moved from den to den. In this way the pups are gradually moved around the bitch's home range.

Independence may occur as early as six months of age when parents abandon them, but this results in high juvenile mortality. Pups that become independent around 12 months appear to disperse voluntarily. Being larger and more experienced, mortality is then usually low.

Where dingoes live alone or in small groups (most pastoral and semi-settled areas), mature females will breed successfully each year.

By contrast, dominant female infanticide results in only one litter being successfully raised each year within groups containing several adult females (e.g. undisturbed areas such as the Simpson Desert). The dominant (alpha) female will kill all pups of the other females, and then use subordinate females to suckle and rear her litter.

Methods of spread

Dingoes in an undisturbed area generally belong to discrete packs (3–12 members), which occupy long-term, non-overlapping territories. The group rarely moves as a pack—rather, members meet and separate again throughout the day. Dingoes are most gregarious during the breeding season.

There is overlap of home ranges within a group. In contrast, boundaries between groups are more rigid, actively defended and infrequently crossed.

Olfactory communication (smell) is important in dingo social organisation. Dingo droppings are deposited along pads in specific areas where other dingoes will encounter them (creek crossings, intersections of roads and fences).

These 'scent posts' appear to delineate the home range boundary and act as a warning to neighbouring groups and individuals.

This strong site attachment of dingoes is contrary to the notion commonly held by property owners that dingoes will travel large distances to kill stock.

Habitat and distribution

Dingo numbers are believed to be higher today than in pre-European times. This is thought to be due to increased food availability via the introduced rabbit and cattle carcasses, and the development of permanent waters in arid areas of the state.

Dingoes/wild dogs are present in all parts of the state.

The distribution of the wild dog in relation to purebred dingoes varies throughout the state. In far western areas, most dingoes sighted appear to be 'pure', with characteristic white points and broad heads. Closer to settled areas a greater number of feral domestic dogs produce a generally hybrid population. It has been estimated that dingoes are 50% pure in south-eastern Queensland and 90–95% pure in south-western and central Queensland.

Radio tracking studies show dingoes occupy a discrete area known as a 'home range'. The dingo visits the edge of this area frequently.

The home range can vary in size according to the productivity of the country—from 9 km² in rainforest areas to 300 km² on the Nullarbor Plain.

The edge of the home range is commonly associated with a major topographic feature (e.g. an escarpment, a major ridge or stream).

The home range is not used uniformly. Activity is centred on areas with highest food density.

Hunting movement is slow and exploratory, in contrast to frequent rapid movement around the home range boundary.

Pads follow well defined paths and are most likely associated with sociality and home range boundary maintenance. Activity is highest at dusk and dawn.

Diet

Dietary research of stomach content and faecal scats has shown dingoes are opportunistic predators.

Medium-size animals such as kangaroos, wallabies, rabbits and possums consistently form the major part of the dingo diet.

Studies by the Western Australia Agriculture Protection Board show dingoes in undisturbed refuge areas killed and ate kangaroos strictly according to need.

On grazing country, however, 'dingoes harassed, bit or killed sheep in large numbers, often without eating any'. The consumption of these sheep carcasses was the exception rather than the rule. Even kangaroos in these areas were sometimes killed in 'play' type behaviour rather than for food.

Such dietary studies could suggest dingo predation of domestic stock is low. There is, however, a need for caution in using such studies to assess dingo impact on stock.

Grouping increases foraging efficiency and appears necessary to exploit larger prey. Dingoes cooperating in groups are more successful in hunting kangaroos than lone dingoes are. While lone dingoes can easily kill sheep, it is less likely a solitary dingo would successfully attack a calf in the presence of a defending cow.

Disease threat

Dingoes are vectors of canid diseases (e.g. distemper, parvovirus) and parasites. The hydatid parasite *Echinococcus granulosus* is a major problem of dogs and domestic stock. It can cause illness and occasionally death in humans.

The dingo could pose a serious risk if the exotic disease rabies was introduced to Australia.

Beneficial considerations

The establishment of watering points during post-European settlement has resulted in a huge increase in the kangaroo population, with consequent strong pasture competition with domestic livestock.

Though it is widely accepted that sheep production is near impossible in the presence of dingoes, many cattle producers will tolerate dingoes because of their believed suppression of kangaroo numbers.

Research has shown that in some cases the dingo has the potential to mitigate population growth of native species during abundant seasons and it could also be an important limiting factor for many feral animal populations (e.g. feral pigs and goats).

There is some evidence that destruction of the dingo could cause increases in other pests to the grazing industry and result in widespread degradation of environmentally sensitive areas. However, this has not been proven.

Restricted invasive animal

Feral cat

Felis catus

A descendant of the African wild cat (*Felis silvestris lybica*), the common 'house' cat (*Felis catus*) has now been domesticated for about 4000 years. Although the domestic cat has a long history of association with humans, it retains a strong hunting instinct and can easily revert to a wild (feral) state when abandoned or having strayed from a domestic situation.

Semi-feral cats live around dump sites, alleys or abandoned buildings, relying on humans by scavenging rubbish scraps and sheltering in abandoned structures. The true feral cat does not rely on humans at all, obtaining its food and shelter from the natural environment.

Legal requirements

The feral cat is a restricted invasive animal under the *Biosecurity Act 2014*. This is a cat that is not domesticated. The feral cat must not be moved, fed, given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

Queensland Government

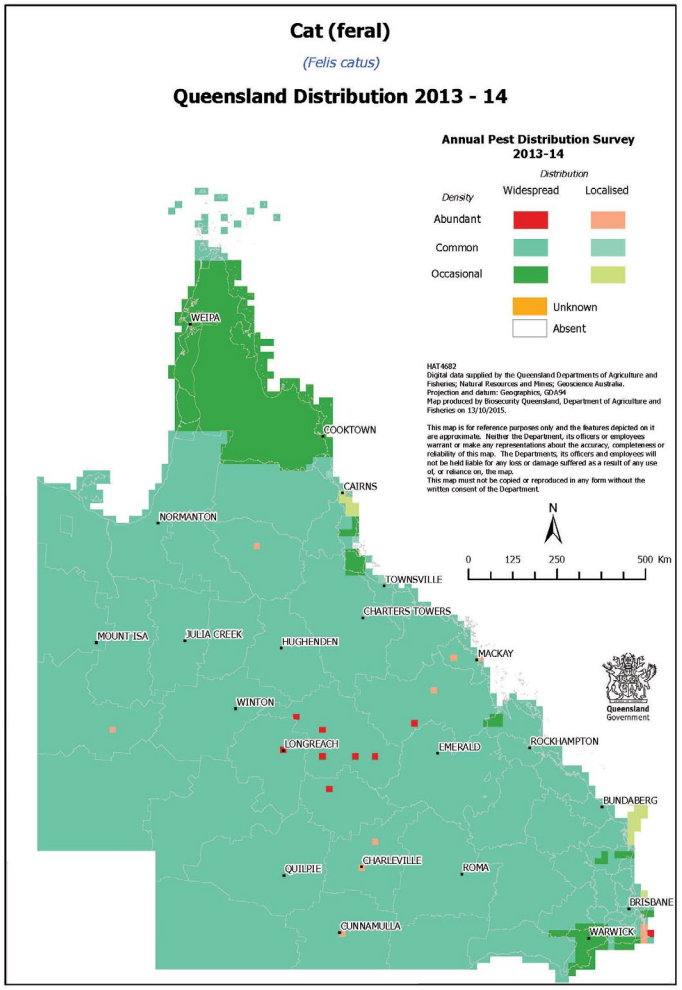
At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Description

The feral cat differs little in appearance from its domestic counterpart; however, when in good condition, the feral cat displays increased overall muscle development, especially noticeable around the head, neck and shoulders, which gives the animal a more robust appearance. The average body weight of male feral cats is 3–6 kg, while females weigh 2–4 kg. Body weights vary with condition, with some extremely large specimens documented.

Australian feral cats are predominantly short-haired, with coat colours that range between ginger, tabby, tortoiseshell, grey and black. White markings may be present on the feet, belly, chest and throat; completely white feral cats are extremely rare. In established populations, coat colours are the result of a natural, genetically selective process. Terrain, predators and the ability to capture prey limit coat colours to those that provide the most suitable camouflage and cause a predominance of these colours in subsequent offspring. Ginger cats are more likely to be found in the semi-arid and desert areas, while grey and black specimens generally predominate in scrub and more heavily timbered habitats.

The feral cat is most active at night, with peak hunting activity occurring soon after sunset and in the early hours before sunrise. At night the cat displays a distinctive green eyeshine under spotlight, making it easily distinguishable from other animals. During the day it will rest in any number of den sites, which may include hollow logs, dense clumps of grass, piles of debris, rabbit burrows, and even the hollow limbs of standing trees.



The most obvious and characteristic field signs of feral cats are their scats (droppings). Unlike the domestic cat, the feral cat does not bury its scats, but leaves them exposed at prominent sites to warn other cats of its territorial boundary.

Life cycle

Male cats attain sexual maturity at about 12 months, whereas females are capable of reproduction at approximately seven months. Annually, and under ideal conditions, an adult female can produce up to three litters—each of usually four kittens, but varying from two to seven.

As the breeding instinct is triggered by the increasing length of daylight, litters are less frequent in winter. Most reproduction occurs during the spring and summer months, and is generally limited to two litters per year. Birth follows a gestation period of 65 days, and kittens may be reared in a single den site or may be frequently shifted to other sites within the female's home range. Family and litter bonding begin to break down when the

Map 1. Distribution of feral cats in Queensland

kittens are approximately seven months old. The female's ability to bear litters does not decrease with age, so reproduction continues for the course of her life.

Habitat and distribution

There is some evidence to suggest that the cat was present in Australia long before European settlement. This may have occurred as a result of Dutch shipwrecks and regular visits to northern Australia by early South-East Asian vessels as long as 500 years ago.

Post-settlement dispersal resulted from cats straying from areas of early colonisation. In the late 19th and early 20th centuries, large numbers of cats were purposely released in many rural areas to combat plague numbers of rabbits. Unwanted cats continue to be released into urban and rural areas by irresponsible pet owners.

The feral cat is now present Australia-wide, thriving under all climatic extremes and in vastly different types of terrain.

Feral cats maintain stable home ranges, the sizes of which depend upon the relative abundance of food and the availability of suitable den sites. Dominant male cats may have territories of up to 8 km^2, while the territories of females are smaller and may even be halved while kittens are being reared.

Scent glands are present on the chin, at the corners of the mouth, and in the anal region. Territorial boundaries are maintained by scent marking with the cheek glands,

pole-clawing, urinating and leaving exposed faecal deposits.Although feral cats are often thought of as being solitary animals, studies show this behaviour is generally limited to hunting activities. At other times feral cats display a degree of social interaction that peaks during the breeding season. Group behaviour has been observed in semi-feral populations, and it has been suggested that such behaviour is exhibited also in feral populations.

Groups usually comprise several related adult females, their young of both sexes, and an adult male—whose range may include other groups of females. Young females usually remain in a group, while young males either leave or are driven from the group as they reach sexual maturity.

Impacts

Effects on wildlife

The energy expended by an adult male cat requires it to consume 5–8% of its body weight in prey per day, while females raising kittens require 20%. Based on these figures, one study concluded that 375 feral cats on Macquarie Island would consume 56 000 rabbits and 58 000 sea birds per year. Where present on the mainland, rabbits may comprise up to 40% of a feral cat's diet. Cats are successful as a control mechanism only when rabbit densities are low. At other times cat predation does little to halt the build-up or spread of rabbit populations; rabbits merely help to support a larger number of cats. When seasonal shortages of rabbits occur there is a corresponding rise in the number of native animals taken by cats.

The feral cat is an opportunistic predator, and dietary studies have shown that small mammals, birds, reptiles, amphibians, insects and even fish can be taken as prey. Cat predation is particularly harmful in island situations, and a number of species have become extinct due to the introduction of cats by early sealers and lighthouse keepers. On the mainland, native animals—which already suffer due to the destruction of their habitats by man and other introduced animals—may be endangered further by cat predation. Actual competition for prey can cause a decline in the numbers of native predatory species such as quolls, eagles, hawks and reptiles. Not only do native animals bear the brunt of predation, but they also suffer the effects of a parasite that reproduces only in the intestine of the cat. This disease (toxoplasmosis) is particularly harmful to marsupials, which may develop blindness, respiratory disorders, paralysis, and suffer the loss of offspring through abortion and stillbirths.

Exotic disease—rabies

Due to their widespread distribution, feral cats may prove to be a major vector for this fatal viral disease if it ever enters Australia. Overseas studies have revealed that wounds inflicted by rabid cats are more dangerous than those caused by rabid dogs. While the bites of rabid dog are generally inflicted on the arms and legs, the cat attacks the head of its victim, biting and clawing viciously. These head and facial bites reduce the time taken for the virus to enter the central nervous system, lessening the chance of success from subsequent remedial treatment.

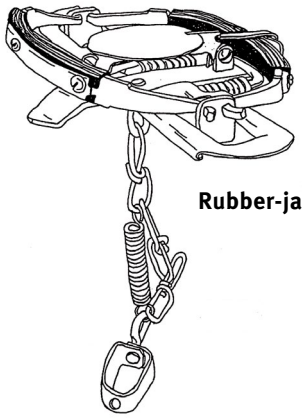
Control

Managing feral cats

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by feral cats. This fact sheet provides information and some options for controlling cats.

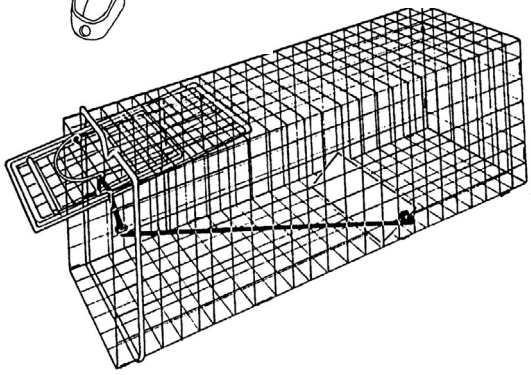
Exclusion fencing

Fencing is the only feasible method of control when special areas need protection from cats. Feral cats have been successfully prevented from climbing over netted fences that use an electrified wire mounted 15 cm from the top and 10 cm outward from the fence. Non-electrified fencing should incorporate a netted ceiling, or a curved overhang, which prevents the cat from climbing straight up and over the fence.



Trapping

Rubber-jawed, leg-hold traps (see below) can be laid in the same manner as they are laid for dingoes and foxes. Leg-hold traps can work well with true feral cats, which would normally avoid the live-capture box traps.



Ideal sites are those where territorial markers, such as faecal deposits and pole-clawing, are noticed. Tuna fish oil has shown some success as an attractant; however, feral cats seem more readily attracted to a site by some visual stimulus such as a bunch of bird feathers hung from a bush or stick.

Semi-feral urban cats are easily trapped in wire 'treadle-type' box traps (see diagram at right). Attractants/lures may be of meat or fish and should be placed so that they cannot be reached through the wire and be retrieved by clawing.

A number of local governments hire cat traps for the purpose of removing stray and feral cats in urban situations.

Rubber-jawed leg-hold trap

Treadle box trap

Lures

Audible recorded lures for feral cats and other predators are available through a number of sources. These recordings mimic the distress call of a small animal and can be used to draw a predator to a bait or trap site.

Shooting

Night shooting is assisted by the cat's distinctive, green eyeshine. Cats have been successfully attracted by the use of a fox whistle.

Poisoning

Fresh meat baits containing 1080 may be used for controlling feral cats under APVMA PERMIT14015.
To obtain a copy of this permit visit www.apvma.gov.au.

Only authorised persons can supply 1080 baits to landholders.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

This fact sheet is developed with funding support from the Land Protection Fund.

Fact sheets are available from Department of Agriculture and Fisheries (DAF) service centres and our Customer Service Centre (telephone 13 25 23). Check our website at www.biosecurity.qld.gov.au to ensure you have the latest version of this fact sheet. The control methods referred to in this fact sheet should be used in accordance with the restrictions (federal and state legislation, and local government laws) directly or indirectly related to each control method. These restrictions may prevent the use of one or more of the methods referred to, depending on individual circumstances. While every care is taken to ensure the accuracy of this information, DAF does not invite reliance upon it, nor accept responsibility for any loss or damage caused by actions based on it.

Restricted invasive animal

Feral pig

Sus scrofa

Pigs were introduced to Australia by early settlers. Subsequent accidental and deliberate releases resulted in the wild (feral) population establishing throughout Australia.

Feral pigs cause environmental and agricultural damage, spread weeds and can transmit exotic diseases such as leptospirosis and could spread foot-and-mouth disease.

Legal requirements

The feral pig is a restricted invasive animal under the *Biosecurity Act 2014*. It must not be moved, fed, given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

An animal ceases being considered an invasive restricted animal (feral) if a person is keeping it and has become a registerable biosecurity entity (RBE) to keep that designated animal. Feral pigs can be considered as designated animals if a person keeps them.

Description

Feral pigs are typically smaller, leaner and more muscular than domestic pigs with well developed shoulders and necks, and smaller, shorter hindquarters.

The body is usually covered in sparse, coarse hair and they have a longer, larger snout, longer tusks, a straighter tail and narrower back than domestic pigs. Feral pigs are mostly black, buff-coloured or spotted black and white.

Growth potential is similar to domestic pigs, although harsh environmental conditions tend to stunt development. Adult female feral pigs usually weigh 60–75 kg, while males usually weigh 90–110 kg. Older boars (razorbacks) can have massive heads and shoulders and a raised and prominent back bone that slopes steeply down to small hams and short hind legs. Some boars develop a crest or mane of stiff bristles extending from their neck down the middle of their back.

Life cycle

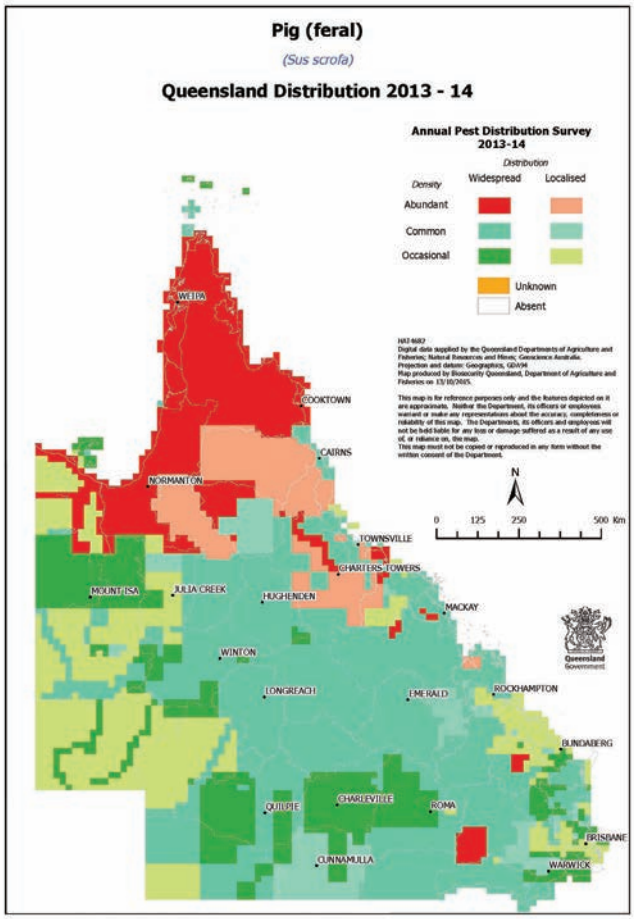
Under good seasonal conditions, breeding occurs all year and sows can produce two litters per year. Adult females have a 21–day oestrus cycle, with a gestation period of about 113 days, producing a litter of 4–10 piglets. Sows can make nests of available vegetation just before farrowing. Nests sometimes have a domed roof and are usually less than 2 km from available water. Piglets normally spend the first 1–5 days of life inside the nest, with the sow nearby. Weaning occurs after 2–3 months. Sexual maturity is reached when sows weigh about 25 kg, usually around six months of age.

Mortality of juveniles is high if the mother's dietary protein intake is low (up to 100% mortality in dry seasons). Adult mortality does not vary as much with seasonal conditions, but few animals live more than five years.

Social behaviour

Feral pigs are generally nocturnal, spending daylight hours sheltering in dense cover. Pigs are omnivorous, eating plants and animals and are extremely opportunistic feeders, exploiting any temporarily abundant food.

They prefer green feed and will eat grains, sugarcane and other crops, fruit and vegetables. They root extensively for tubers, worms and soil invertebrates.



Feral pigs have relatively high energy and protein requirements, particularly during pregnancy and lactation and often move to other parts of their home range during pregnancy.

Habitat and distribution

Feral pigs are found in all habitat types in Queensland. The greatest concentrations of feral pigs are on the larger drainage basins and swamp areas of the coast and inland. In hot weather, pigs need to remain near water.

Population estimates can be achieved by spotlighting, aerial survey or the use of motion cameras.

Map 1. Distribution of feral pigs in Queensland

Evidence of feral pigs includes fresh digging or rooting of the ground, tracks and faeces on and off pads, mud or hair at holes in fences where pigs have pushed through, wallows, tusk marking and mud rubs on trees and fence posts and nests in vegetation made by sows before farrowing.

Female and juvenile pigs usually live in small family groups with a home range of 2–20 km^2. Adult males are typically solitary, with a home range of 8–50 km^2. Range size varies with season, habitat, food availability and disturbance. Herds of 400 pigs have been recorded in Cape York.

Impacts

Pigs can damage almost all crops from sowing to harvest, starting with uprooting seed and seedlings to feeding on or trampling mature crop.

They feed on seed, sugar cane and grain crops (except safflower), fruit (especially banana, mango, papaw, macadamia and lychee) and vegetable crops. Research has shown feral pigs can take up to 40% of lambs.

Pastures are damaged by grazing and rooting and pigs can also transport weeds. Wallowing pigs damage and foul the water in tanks and bore drains and silt up troughs. They can also damage fences and dam walls.

Pig activity degrades water quality and the habitat for small terrestrial and aquatic animals. It also creates erosion and allows exotic weeds to establish. Predation of native fauna does occur and examination of faeces has shown remains of marsupials, reptiles, insects, and ground-nesting birds and their eggs.

Feral pig wallow

Feral pig rooting

Feral pig damage to river banks

Feral pig damage to sugar cane

Diseases and parasites

Feral pigs can carry many infectious diseases and internal and external parasites. Some are endemic (already present), while others are exotic to Australia.

Many of the diseases can spread to domestic pigs, other livestock and humans. Feral pigs can transmit sparganosis, melioidosis, leptospirosis, Q fever and brucellosis to humans.

To prevent contracting these diseases it is advisable to either avoid handling feral pigs or use suitable protective clothing (mask, goggles, strong rubber gloves and plastic apron and boots) to minimise contamination with blood, urine and faeces. Rare or undercooked meat should not be eaten; thoroughly cook meat to avoid contracting pathogens. Raw feral pig meat and offal should not be fed to dogs as dogs can be infected with swine brucellosis. Dogs infected with swine brucellosis can also transmit the disease to humans.

Control

Managing feral pigs

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by feral pigs. This fact sheet provides information and some options for controlling feral pigs.

Feral pigs are difficult to control because they are primarily nocturnal, breed rapidly, are generalist omnivores and have large home ranges and thus control programs need to be conducted over a wide area (often including several properties) to be effective.

Effective control requires an integrated, collaborative approach where all stakeholders participate in planning, implementation and evaluation of the actions taken.

Fencing

Though an expensive option, fencing can offer successful pig control especially for high value crops grown on small areas. Research has indicated that the most successful pig-proof fences are also the most expensive.

The most effective pig-proof fences use fabricated sheep mesh held close to the ground by plain or barbed wire and supported on steel posts.

Electrifying a conventional fence greatly improves its effectiveness if used before pigs have established a path through the fence.

Pigs will often charge an electric fence and unless the fence incorporates fabricated netting they often successfully breach the fence.

For crop protection or to avoid lamb predation, pig-proof fences need to be constructed before the pigs become a problem. Once pigs have adjusted to feeding on grain or lambs in a particular paddock fencing may be ineffective.

Trapping

Trapping is an important technique that is most useful in populated areas, on smaller properties (‹5000 ha), and where there are low pig numbers. Trapping can be particularly useful in 'mopping up' survivors from baiting programs. It is most successful when food resources are limited.

Trigger mechanisms for pig traps can be made pig-specific and therefore pose little danger to wildlife or domestic animals.

Advantages

- This is the safest form of control and can be safely undertaken on closely populated areas.
- It's flexible and can be incorporated into routine property activities, making economical use of labour and materials.
- Carcasses can be safely disposed.
- Traps can be moved and re-used; good trapping makes use of opportunities as they arise.
- Normal pig behaviour is not altered, which allows a greater number of the total population in an area to be targeted.
- More humane to pigs and non-target species.
- The number of animals removed can be easily monitored.

Disadvantages

- Can be time consuming and expensive to construct and maintain.
- Must be checked regularly.
- Not practical for large-scale control.
- Some pigs are trap shy.

Tips

- Stop all activities that will disturb normal feeding (i.e. do not undertake any shooting or dogging).
- Pre-feeding (i.e. ensure that pigs are visiting trap and consuming bait) prior to activating traps is an essential part of successful trapping.
- Feeding sites should be placed where feral pigs are active (i.e. water points, holes in fences, areas containing old carcasses on which pigs have been feeding).
- Bait for traps must be food that pigs usually eat in that area. Pigs feeding on one crop (e.g. sugarcane) will often not take to alternative foods. However, new, novel baits are sometimes attractive (e.g. fermented grains).
- The trap can be built around the feeding site, with feeding within the trap undertaken for several nights before it is set.
- Set the trap every night and check each day. If the trap cannot be checked daily then shade and water must be provided.
- Continue to trap until no more pigs are caught. A change of bait can be tried. Again, feed for one or two nights before re-setting the trap.
- Traps may be left permanently in locations used by pigs and can be utilised when fresh signs of pigs appear.
- If the trap is to be moved, start feeding at the new site before re-locating the trap.

Design

There are several trap designs but all are principally an enclosed area with one-way gates (see Figure 1).

The main area of the trap can be any shape and be made from materials on the property. The best material is steel mesh with a grid 100 × 100 mm, with a minimum height of at least 1.5 m. Star pickets need to be placed no more than 1.5 m apart and imbedded far enough to ensure that adult pigs cannot push them over or lift them up out of the ground.

Alternative trap entrances

Funnel entrance

Formed by the two ends of the mesh forming a funnel, the ends are tied together at the top with wire or rope. The pig moves through the funnel forcing the bottom of the mesh ends apart and once it is in the trap the ends spring back together (see Figures 1 and 2).

Tripped gate entrance

A side-hinged gate is pulled shut by springs and is held open by many systems that can be triggered to allow the gate to swing shut. Often trip wires or other systems are used; most of these systems are not selective for feral pigs and can be triggered by any animal attracted to the bait. Once triggered the trap is no longer effective in trapping pigs.

Pig-specific trigger

By far the simplest and most effective trigger system has the gate held open by a bar (often a branch or piece of wood) which is hooked over the wire on the gate and on the side panel (see Figure 3). For a close up of the pig specific trigger (see Figure 4).

Pigs rooting for feed in the trap lift the bar allowing the gate to swing shut. The specific feeding habit of pigs insures they are the only animals that lift the trigger bar.

The gate may be latched to prevent pigs from opening the door once triggered. However, this will prevent more pigs pushing their way in to join those inside.

Shooting

Shooting pigs by helicopter is effective in areas where pigs exist in reasonable numbers and are observable from the air.

Ground shooting is not effective in reducing the pig population unless intense shooting is undertaken on a small, isolated and accessible population of pigs.

Poisoning

Poisoning is the most effective control method available that can quickly reduce a pig population.

Sodium fluoroacetate (1080) can only be supplied by people approved under the Health (Drugs & Poisons) Regulation 1996 for the purpose of controlling declared pest animals. Your local government office should be able to assist you.

Pre-feeding is the most important step in ground-based poisoning operations. Free feeding with non-poisoned bait should be performed for several days prior to laying poisoned baits.

By selecting bait wisely, landholders can be species-selective in their poisoning program and avoid many of the unintentional effects of secondary poisoning.

Bait material such as fermented grains are very attractive to pigs. It is a good idea to establish a free feeding routine so that pigs are the only animals feeding, which helps to keep other non-targets away from the feeding site.

Other options (like pig-specific feeders) are now commercially available, and can assist in reducing non-target species access to bait. Other options include burying baits; feral pigs are one of the few animals that will dig up bait.

Aerial poisoning is also available and typically used for broadscale control in western and northern regional areas. Bait is distributed from an aircraft. This is particularly useful for covering large, remote, areas or restricted ground access. Aerial poisoning is a proven and cost-effective method for reducing pig populations.

A phosphorous-based poison is also available for use in Queensland.

Further information

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Restricted invasive animal

Rabbit

Oryctolagus cuniculus

Rabbits are one of Australia's major agricultural and environmental animal pests, costing the country between $600 million and $1 billion annually. They compete with native animals, destroy the landscape and are a primary cause of soil erosion by preventing regeneration of native vegetation.

Legal requirements

The rabbit is a restricted invasive animal under the *Biosecurity Act 2014*. It must not be moved, kept, fed, given away, sold, or released into the environment without a permit. The Act requires everyone to take all reasonable and practical steps to minimise the risks associated with invasive plants and animals under their control. This is called a general biosecurity obligation (GBO). This fact sheet gives examples of how you can meet your GBO.

At a local level, each local government must have a biosecurity plan that covers invasive plants and animals in its area. This plan may include actions to be taken on certain species. Some of these actions may be required under local laws. Contact your local government for more information.

Queensland Government

Pet rabbits

Introducing and selling rabbits in Queensland is not permitted (penalties apply). Limited numbers of permits for domestic rabbits are only available from Biosecurity Queensland for research purposes, public display, magic acts or circuses. Before a permit is granted, a number of guidelines need to be fulfilled.

Description

Rabbits are small mammals around 34–45 cm in length usually grey brown with pale belly fur, other colours include piebald, black and ginger. They have long ears 10 cm long and big eyes. They have long hind legs with hind feet measuring 9–11 cm and shor t front legs. The tail is fluffy brown with white underneath, 4–8 cm. Adult rabbits usually weigh around 1–2.1 kg. The male is called a buck, the female a doe and her young are called kittens.

Life cycle

Does (females) are pregnant for 28–30 days, but are able to mate within hours of giving birth. The average litter is 3–4 kittens but varies from two in a young doe, up to eight or more in a mature doe, and depends on the amount and quality of food available.

Five to six litters are possible in a good season. Young does can breed at four months of age if conditions are suitable.

Habitat and distribution

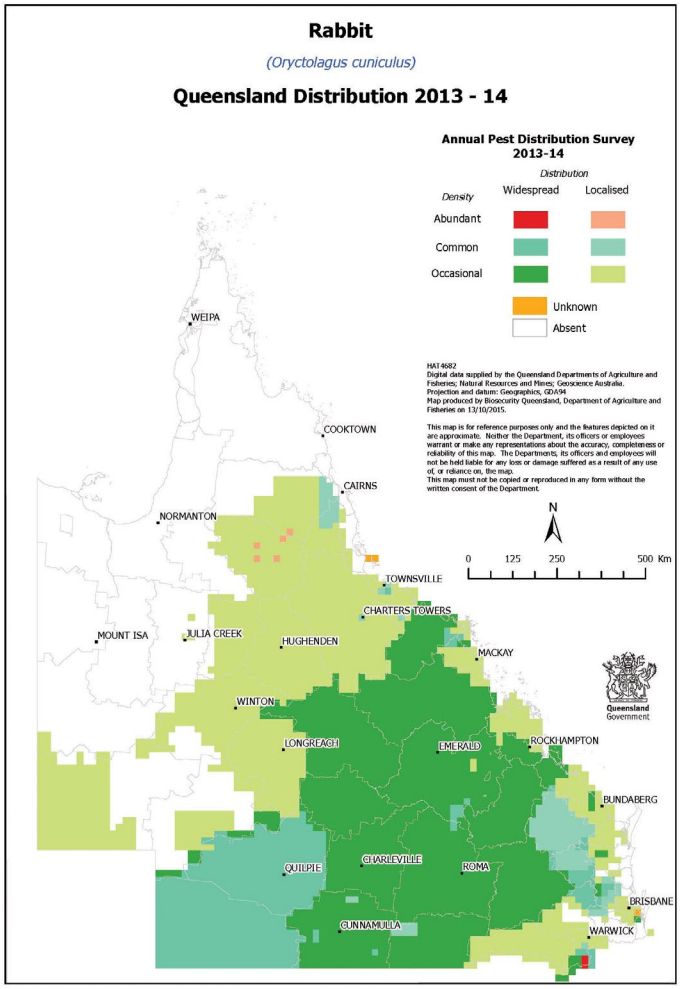
Rabbits prefer to live in warrens as protection against predators and extremes in temperature. However, they will sur vive in above-ground harbours such as logs, windrows and dense thickets of scrub (e.g. blackberr y and lantana) or under built harbour, old sheds and machiner y etc.

In newly colonised areas without warrens, rabbits tend to live in 'scrapes' (or 'squats')

Rabbits are adaptable and sometimes live in close association with people. They live in built environments such as:

- in and under buildings
- old machinery and storage containers
- in old dumps.

In rural environments rabbits frequently live in:



- felled timber and associated windrows
- tussock grasses and rocky areas
- warrens (if soils are easy to dig).

Control

Managing rabbits

The GBO requires a person to take reasonable and practical steps to minimise the risks posed by rabbits. This factsheet information and some options for controlling rabbits.

Map 1. Distribution of rabbits in Queensland

Effective rabbit control cycle

Rabbit control is best done as a joint exercise involving all land managers in the district. Integrated control methods, such as fumigating, ripping warrens and harbour destruction, are essential for the continued long-term reduction of rabbit numbers. Cost-effective, long-term results can be achieved in rabbit control by following a combination of the methods outlined below.

Prevention and early detection

Rabbits will generally eat around 15% of their body weight per day—approximately 250 g. This compares dramatically with the averages for stock—sheep and cattle eat around 3% of their body weight per day. So even a low number of rabbits can be removing large amounts of livestock feed.

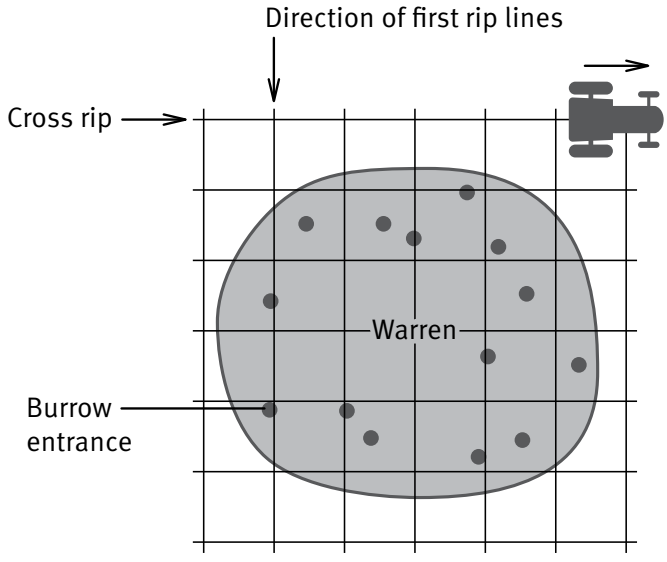
For effective long-term rabbit control, concentrate on destroying source areas. Source areas will all have well-established warrens or ready-made structures that are cool and provide protection from predators. A source area must also have a good supply of green feed during the cooler seasons.

Manual control

Harbour destruction

Where there is abundant surface harbour, a high proportion of rabbits may live above ground rather than in underground warrens. Rabbits can make their homes in windrows, dense thickets of shrubs (such as blackberries and lantana) and even in old machinery.

To eliminate these above-ground breeding areas, it may be necessary to:



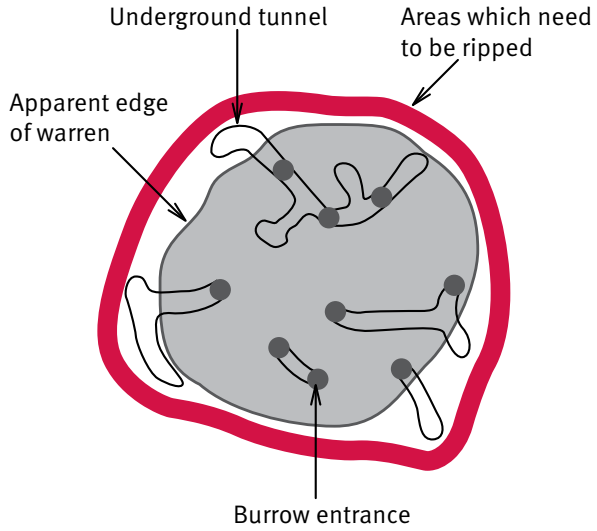
- burn windrows and log piles
- remove noxious weeds through chemical and physical control
- remove movable objects (such as old machinery) from paddocks.

Sometimes removing harbour can expose warrens underneath. If this happens, the warrens need to be ripped.

Mechanical control

Warren ripping

In areas where rabbits live in warrens, ripping is the most effective method of long-term control. Ripping is so successful because warrens can rarely be reopened and rabbits are unable to recolonise these areas.



Direction to rip warrens (illustration courtesy Will Dobbie)

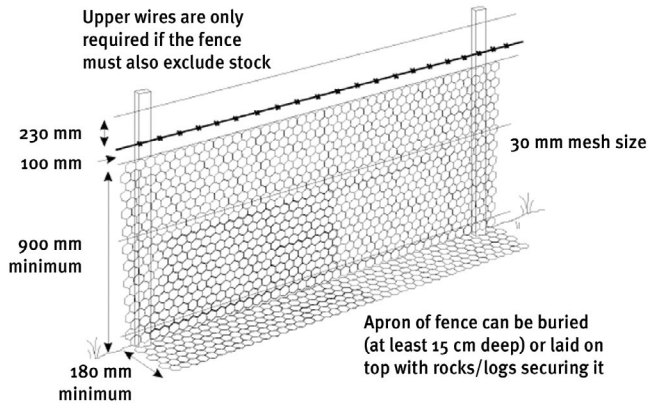
Tyne for ripping warrens (photo courtesy Mark Ridge)

To get the best results it is important to chase as many of the rabbits inside the warren as possible. Dogs can be used to drive rabbits into the warren before ripping starts.

The aim of ripping is to completely destroy the warren. It involves using a tractor with a tyned (sharp-pronged) implement—one tyne or many—that rips through the warren and collapses it. Larger tractors and dozers are more appropriate for properties with many warrens as they are able to move faster and rip wider.

Extent to rip warrens (illustration courtesy Will Dobbie)

Obviously, ripping is not suitable for warrens located underneath buildings or on steep rocky country. In such cases, other methods (poison baiting, releasing virus or fumigating burrows) should instead be used to reduce rabbit numbers. Warrens should then be either filled in or covered to stop rabbits from re-establishing. Burrows can be blocked with small boulders or rocks.



Rock blocking rabbit hole

Exclusion fencing

Rabbit exclusion fences are built with the aim of keeping rabbits out of a particular area. It is appropriate for small, high-value areas that require protection. A fully fenced area will only remain rabbit-free in the long term if all rabbits are removed from the enclosed area after fencing and the fence is regularly maintained and checked for holes.

Electric fencing is a cheaper alternative, but it is not a complete physical barrier and is also prone to damage from other pest animals and stock.

Exclusion fence for rabbits (illustration courtesy DEWHA)

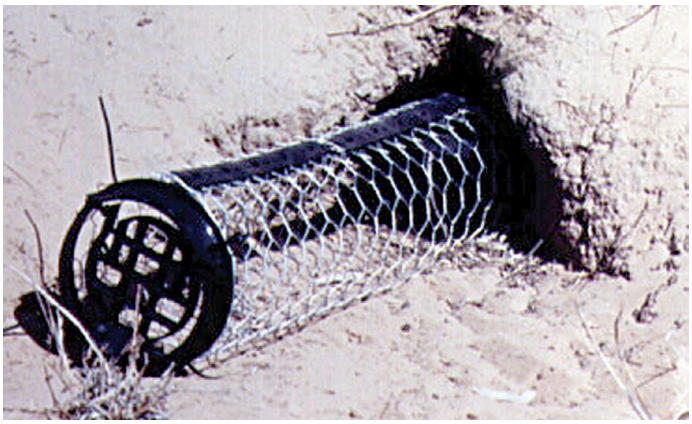
A rabbit-proof fence should be made of wire mesh netting (40 mm or smaller) and needs to be at least 900 mm high. The netting should also be buried to depth of at least 150 mm. Gates into the fenced area need to be rabbit-proof as well.

Trapping

Trapping is an extremely labour-intensive control method and requires a skilled operator to set the traps to successfully capture rabbits.

If you do plan to trap rabbits on your property, common sense and respect for animal welfare are essential. While there are currently no strict guidelines for the use of traps in Queensland, it is an area of growing concern for animal welfare advocates.

Cage trap



A cage trap has a lever that closes the cage when a rabbit steps on it. The rabbits are lured into the cage with bait—usually diced carrot. Traps need to be disabled and left open for two or three nights with bait leading into the cage. This entices rabbits to enter. A trap can be set once a rabbit has consumed a trail of bait all the way into that trap. Traps should be checked and emptied regularly—usually a couple of times a night.

This effective and humane technique is most useful for removing any remaining rabbits from places like hay sheds and after the shed has been fenced to prevent additional rabbits from entering and leaving. Free-feed then trap, and keep the shed rabbit-proof to prevent rabbits recolonising.

Barrel trap

A barrel trap is designed specifically for rabbits. It is cylindrical, made of light mesh, and is about 1 m long and 15 cm in diameter. The trap has one open end with two hinged trap doors along its side. The open end is placed in the burrow, and the hinged gates close and trap the rabbit after it enters from the burrow.

The trap can be left in the burrow entrance for a number of days. However, it must be checked at least daily so that if a rabbit has been caught it does not suffer and animal welfare responsibilities are met.

Barrel rabbit trap in hole

Biological controls

Rabbit hemorrhagic disease virus (also known as rabbit calicivirus disease)

RHDV is a virus specific to rabbits which works by infecting the lining of the throat, lungs, gut and liver.

RHDV relies primarily on direct rabbit-to-rabbit contact in order to spread. High rabbit numbers are therefore needed before this control method will be effective.

After RHDV has infected an area, it is important to use another method for follow-up control to increase the likelihood that the population is eradicated before it is able to develop resistance and increase its numbers again.

Resistance to RHDV depends primarily on the age of the rabbit. Therefore, it is better for RHDV to go through a rabbit population after rabbits have bred and the young are old enough to be affected by the virus. Rabbits that survive RHDV develop antibodies against the virus. Breeding females can also pass these antibodies on to the young (through antibodies in their milk), conferring temporary protection on rabbits up to 12 weeks old.

Myxomatosis

Myxomatosis is no longer produced as a laboratory strain but field strains are still known to recur and affect rabbit populations.

RHDV1-K5

Recent research by state and federal agencies has identified a new strain of RHDV (called RHDV-K5) that will aid in controlling rabbits that have immunity to current strains.

Shooting

Shooting is most useful when used to ‘mop up’ after other control methods (such as ripping). To get the best results, shoot at the time of day when rabbits are active. This is usually in the early morning, late afternoon or at night. The best and most economical firearm to use is a .22 calibre rifle.

If your property is within an urban area, you will need to comply with local government regulations and the *Police Powers and Responsibilities Act 2000*, which restrict the use of firearms.

Poison baiting

Baiting is not effective as a sole control method and will not eradicate an entire rabbit population. Numbers will quickly increase again, and you will have to continue baiting year after year with no permanent overall change in the rabbit population.

Rabbits can also become 'bait shy' and this method becomes less and less effective over time. Ideally, baiting is best used either before ripping/fumigation to reduce a population, or after ripping/fumigation as a 'mop-up'.

Baiting works best when rabbits are not breeding. During breeding season the majority of the population feeds over a larger-than-normal area, and it is the young rabbits that are most likely to take baits. While numbers will be reduced, animals of breeding age are not likely to be affected.

1080—sodium fluouroacetate

Pre-feeding is required when using 1080 because rabbits will not readily take new feed. The poison-free bait should be laid at least three times over a one-week period before the poisoned bait is laid. (1080-impregnated carrot baits are the most common form of bait used.) The practice helps to ensure that, when the poisoned bait is laid, it will be eaten by most of the rabbit population.

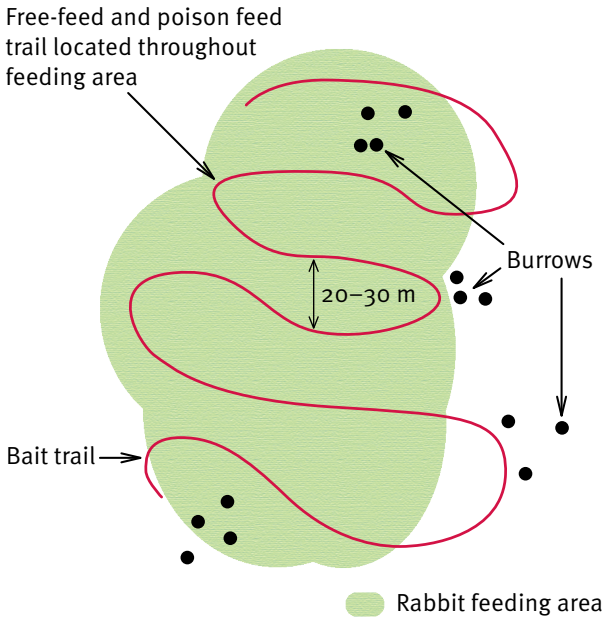
1080 can only be supplied through persons authorised under the Health Act. Your local Biosecurity officer or your local government office should be able to assist you.

Pindone

Pindone is an anticoagulant registered for rabbit control. This poison works by preventing blood from clotting. In Queensland, it is not recommended for broadacre use and is mainly used in urban areas and near farm buildings.

Pindone works best when given as a series of small doses/feeds over a period of three days. Although pre-feeding is not essential, it does enhance the bait uptake by shy rabbits as they get used to the feed prior to any poison bait being laid. To be effective, pindone requires multiple feeds so that the poison can build up to fatal levels in the rabbit's body. Feeding over a number of nights provides plenty of opportunity for most of the rabbit population to consume the required lethal dose. Rabbits poisoned with pindone will usually die within 10–20 days.

Pindone baiting does not work well when there is a lot of green pick around for rabbits.



Poison bait trails

It is important that bait trails are laid properly to ensure the best results. 'Baitlayers' make it easier to put out bait trails at the correct rate, and they can be towed behind most 4WD vehicles, quad bikes and tractors.

When scratching and laying a trail, consider the following:

- Rabbits like freshly scratched/disturbed soil—this may be because rabbits are territorial and inspect newly disturbed soil, and/or the disturbed vegetation smell attracts them.
- Lay trails around warrens and in the areas where rabbits most often feed.
- Laying trails on slopes and hills requires care—it can cause erosion in some soils types (e.g. granite and traprock). Trails are best laid in a zigzag pattern in steep terrain to minimise erosion.
- A trail that has been scratched for the first feed is easy to follow for the rest of the baiting program.
- The soil should be turned only enough to scratch the surface—don't plough the ground.
- A trail that has been scratched too deep will spook the rabbits because they will not have full sight of their predators.
- Where vegetation is thick, or it is difficult to find the main feeding areas, lay bait trails in a grid pattern across the site.

As a general rule, avoid crossing the bait trail—it can cause confusion when you try to follow the same trail on subsequent occasions.

Method for laying a bait trail (illustration courtesy Animal Control Technologies)

Bait trials will be most effective if you follow these guidelines:

- Use good quality, non-contaminated bait material. (Simple rule: if you wouldn't eat it, the rabbit won't either.)
- Use enough feed to bait all the rabbits in the area. (The pre-feed will give an indication of the potential bait take.)
- Expect a greater uptake of pre-feed and bait material when vegetation is scarce, dried off or soured.
- Ensure that all the preparation equipment is clean and free of any chemical residues or smells—rabbits can be very shy of unusual odours.
- When there are kittens in a warren, lay the bait trail close to the warrens.

Fumigation

Fumigation is labour intensive and time consuming, and is not usually an effective method if used alone. However, as a 'mop-up' technique or control method for use in areas

where ripping is not practical (e.g. steep and rocky terrain), it may be a good alternative.

Because this technique relies on directly affecting the rabbits, and does not affect the structure of the warren, it is crucial that as many rabbits as possible are underground when fumigation is carried out. Rabbits usually take refuge in their burrows from mid-morning to mid-afternoon and during hot weather so these are the best times to fumigate. Dogs can also be used to drive rabbits into their warrens.

For best results, fumigation should be carried out in two stages—initially, before the breeding season starts (as this reduces the breeding stock), and then again during the breeding season.

There are two types of warren fumigation—static and pressure. In Queensland, static fumigants are a more popular and safer option for controlling rabbits and will be explained below.

Static fumigation

This method is easy to use, and time- and cost-effective. Static fumigation comes in the form of aluminium phosphide (phosphine) tablets, which can be purchased from most agricultural suppliers. These tablets are small and round (about the size of a marble), and weigh 3 g. Trade names for phosphine include Pestex®, Quickphos® and Gastion®. General directions for the use of phosphine tablets appear below, but always refer to the manufacturer's specific recommendations for use.

To fumigate warrens using phosphine tablets:

1. Find all warren entrances—both active and inactive.
2. Cut back the warren entrance at right angles using a shovel.
3. Separately wrap two tablets in moistened absorbent paper (toilet paper/paper towels).
4. Insert the tablets as far down into the entrance as possible (polypipe and a push rod can be used to help push the tablets down).
5. Push some scrunched-up newspaper down the hole to block the entrance and then cover it up with soil and, if possible, a rock.
6. Treat all entrances to the warren (active and inactive) the same way.
7. Check warrens about a week after fumigation and re-fumigate any reopened entrances.

Once in the warren, the moistened tablets react with air to release a toxic gas, which spreads quickly throughout the warren. The phosphine gas itself is invisible and odourless but leakages from the warren can be detected by the smell of ammonia. (This is a safety mechanism that is built into the tablet.) Any leakages need to be blocked immediately.

Shooting

Shooting is most useful when used to 'mop up' after other control methods (such as ripping). To get the best results, shoot at the time of day when rabbits are active. This is usually in the early morning, late afternoon or at night. The best and most economical firearm to use is a .22 calibre rifle.

If your property is within an urban area, you will need to comply with local government regulations and the *Police Powers and Responsibilities Act 2000*, which restrict the use of firearms.

Further information

For further detailed reading information on specific rabbit control techniques or costing your rabbit control please refer to Rabbit control in Queensland; a guide for land managers. Download from the Biosecurity Queensland website at www.biosecurity.qld.gov.au

Further information is available from your local government office, or by contacting Biosecurity Queensland on 13 25 23 or visit www.biosecurity.qld.gov.au.

Dear Lloyd,

GEMINI MINE FEASIBILITY STUDY
STABILITY ANALYSIS OF FINAL VOID SEDIMENTARY SEQUENCE FOR RESPONSE TO DES

INTRODUCTION

Following a Magnetic South and Cartledge Mining and Geotechnics (CM&G) meeting, Magnetic South requested that CM&G prepare a response to the Department of Environment and Science's (DES) query relating to the stability of the Final Void shell for their Gemini Project. The Gemini Project is located in the Bowen Basin in Central Queensland. Magnetic South completed a Feasibility Study for the project in 2020 and is currently responding to DES's queries to progress the project to the next stage of development.

The query from DES concerns the geotechnical stability of the Cenozoic sediments for the final void. Maconochie (2020) indicates that the Cenozoic sediments comprise a surficial layer (up to about 5 m in thickness) of Quaternary aged sandy alluvium underlain by up to 50 m of Tertiary aged clays and sandy units. The current design adopts an overall slope angle for these soils of 22°. CM&G are to provide a stability assessment of this unit within the final void shell. If the design does not satisfy the Factor of Safety (FoS) requirement of 1.5 for long-term slopes, then CM&G will provide alternative options to achieve the required FoS.

Purpose

The purpose of this letter is to provide advice regarding the long-term stability of the Cenozoic sediments within the final void footprint to support Magnetic South's response to DES concerning their Feasibility Study.

Information Provided

The following information was provided to CM&G and utilised in this study:

- 5171.004 Magnetic South_Coal Resource Project_Gemini Project_FINAL 10072...
- gts-gem-013-20-1 – FINAL
- DW_Pits.dwg

METHODOLOGY

Limit equilibrium analysis was completed using the proprietary software Slide2 v9.008 by Rocscience Pty Ltd. One (No.) cross-section was cut through the proposed final void where the inferred maximum depth of Cenozoic soils occurred (i.e. worst-case scenario), see Figure 1.

Stabilty analyses were conducted on the cross-section, and where the required FoS could not be achieved, alternative concept designs were developed and analysed to achieve the required FoS.

Maconochie (2020) adopted typical material properties for the Bowen Basin in their study. To improve the veracity of these analyses, CM&G adopted material parameters for the soils from experience at similar sites within the Bowen Basin. To do this, CM&G compared the results of the Atterberg Limits tests presented in Maconochie (2020) against those for similar sites. The results for both sites were comperable with the average Plastic Limit (PL) for the Gemini Project; 27.5 versus 29 for similar sites. CM&G adopted the following non-linear strength envelopes for the analyses after Mesri (1993, 2003):

- Peak strength
- Fully softened strength

The subsurface stratigraphic profile and groundwater conditions were inferred based on information provided in Maconochie (2020). No geological structure was considered in this stability assessment.

STABILITY ANALYSIS

The Spencer and GLE-Morgenstern Price methods of limit equilibrium analysis were adopted after Sloan (2013). A non-circular failure path utilising the Cuckoo Search method was adopted. A copy of the typical cross-seciton analysed, and the material properties, is presented in Figure 2.

A minimum required FoS of 1.5 was adopted for long-term stability.

Material Name	Color	Unit Weight (kN/m3)	Strength Type	Cohesion (kPa)	Phi (deg)	Shear Normal Function	Water Surface	Hu Type
Unconsolidated Sediments		19	Shear Normal function			Alluvium	Water Surface	Automatically Calculated
Weathered Perm		22	Mohr-Coulomb	70	30		Water Surface	Automatically Calculated
Permian		24	Mohr-Coulomb	450	42		Water Surface	Automatically Calculated
Tertiary Saturated		20	Shear Normal function			Tertiary Saturated	Water Surface	Automatically Calculated

Figure 2. A screenshot of cross-section analysed for Base Case scenario.

Where the results of the stability analyses did not achieve the required FoS, the following alternative concept options were analysed to achieve the required FoS:

- Reduce the overall slope angle
- Construct a rockfill buttress at the slope toe

Analysis Assumptions

The following assumptions were adopted as part of this analysis:

- The base case analyses assumed the groundwater depth is 30 metres below ground level (mbgl)
- The depth of alluvium is 4 m
- The thickness of Tertiary clays is 40 m
- The initial slope geometry for the soil profile was 22°
- Typically adopted Bowen Basin parameters for Weathered and Fresh Permian
- Stability analyses were conducted on the soil profile only
- A minimum failure depth of 15 m was adopted to ignore surficial sloughing failures. These failure types are discussed in more detail in Surface Water Management.

- No seismic loads or any other transient loads were considered in this analysis. Transient loading is not considered critical to long-term stability of this slope as they are expected to have a nominal impact on slope stability.
- The rockfill buttress is constructed out of Fresh Permian and has the following material strength parameters: unit weight = 19 kN/m3, frictional angle = 40°, cohesion = 0 kPa.
- The batter angle for the rockfill buttress is 37°

Analysis Results

The results for the Base Case scenario returned a FoS of 1.3, refer to Figure 3. The results for the concept options that achieved a FoS of 1.5 were:

- Reduce overall slope angle – 18°
- Minimum buttress dimensions - 20 m wide at the toe and 20 m vertical height

Schematics showing the concept option dimensions are provided in Figure 4 and Figure 5 and a copy of results outputs are attached.

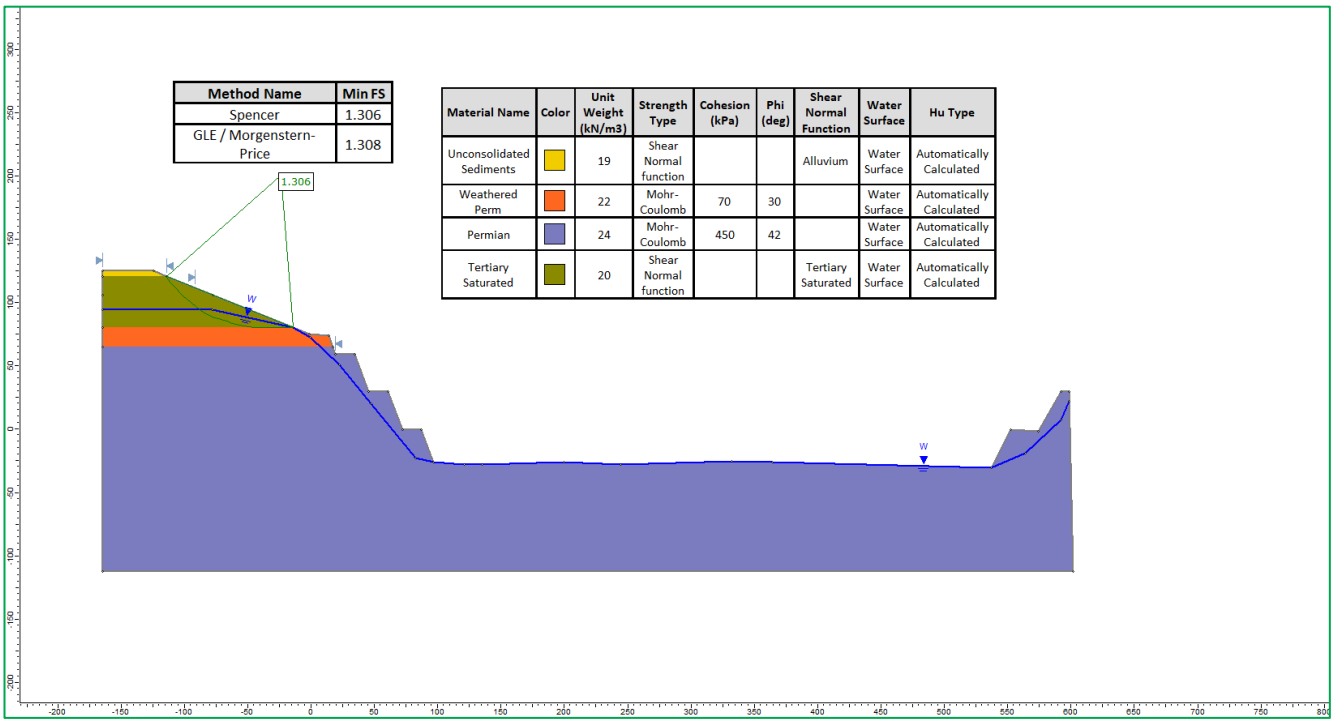

Figure 3. Stability analysis for the base case scenario (slope angle = 22°).

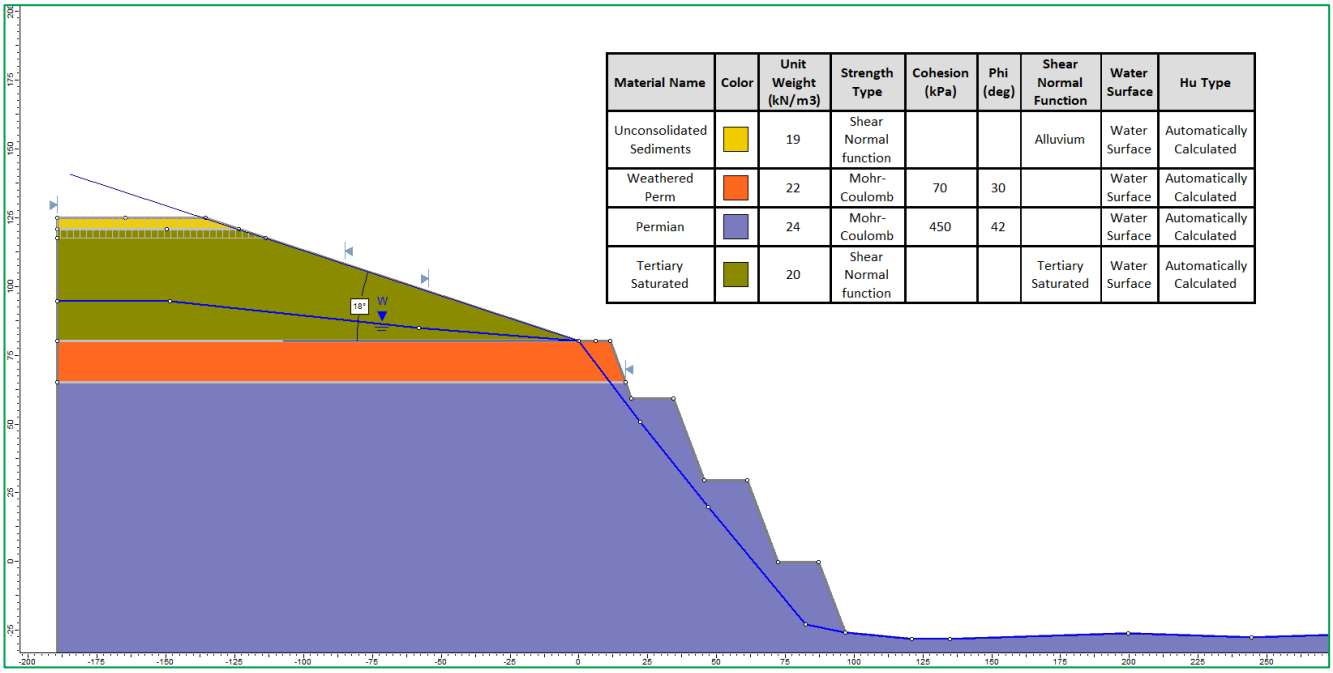

Figure 4. A schematic diagram to show an 18° slope angle.

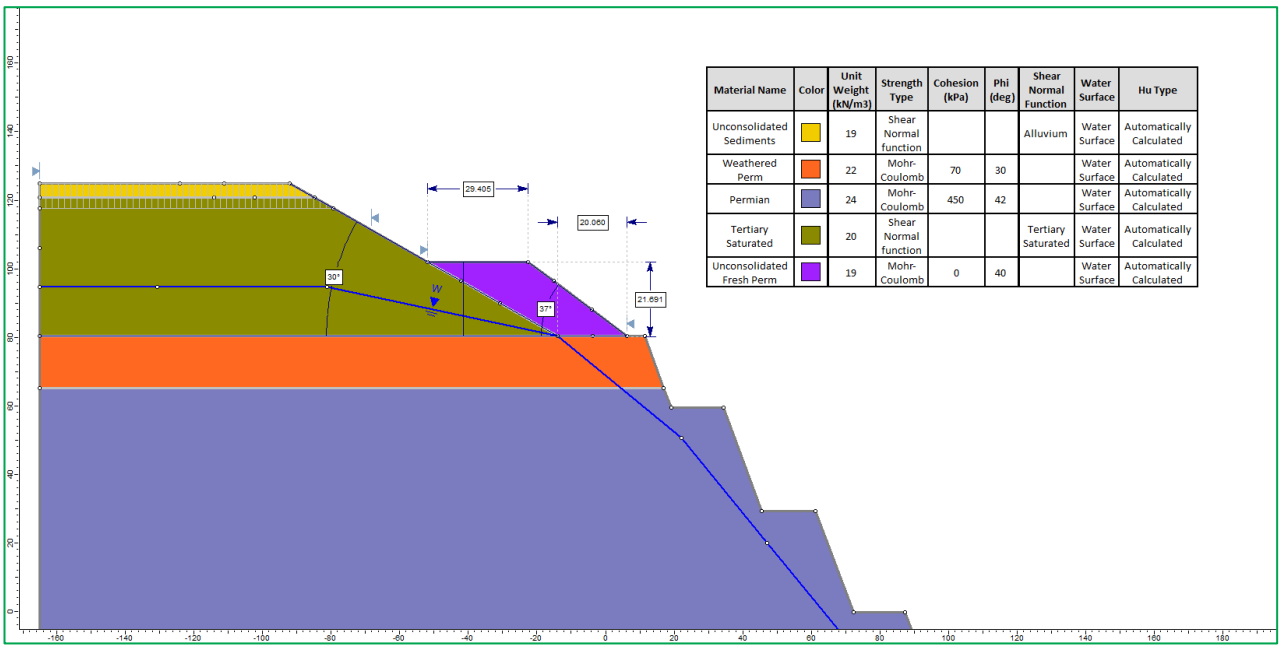

Figure 5. A schematic diagram to show a 30° slope angle of the tertiary material with a rockfill buttress at the toe.

MINE PLANNING IMPLICATIONS

Due to the depth of alluvium at this site, the initially adopted overall slope angle for this unit is not suitable for long-term stability for the final void provided. Alternative options considered to obtain the required FoS returned the following geometries:

- Reduce the overall slope angle to 18°

Cartledge Mining and Geotechnics

info@cmandg.com.au | +61 407 503 474 | www.cmandg.com.au

- Do not modify the original soil profile and construct a rockfill buttress to the geometry shown in Figure 5

Due to the limited availability of data at this stage of the project, it is recommended that the slope design for the final void soil profile be reviewed as additional data becomes available.

Surface Water Management

Management of surface water is critical in preventing ponding water near slope crests. Ponding facilitates the infiltration of meteoric waters into the subsurface, resulting in slope instability due to the temporary reduction of shear strength of the critical unit.

Sloughing failures are shallow surficial failures caused by saturation of these layers due to rainfall. Construction of surface water drainage is critical to reducing the likelihood that such failures will occur by reducing the volume of water moving across the slopes.

Surface water management is critical to ensure the long-term stability of the soil slope and minimisation of erosion and deterioration of the slope condition.

1.0 INTRODUCTION

Magnetic South Pty Ltd is the project proponent and the applicant for the Mining Lease (ML) and Environmental authority (EA) to develop the Gemini Project, a greenfield open cut mine to produce Pulverised Coal Injection (PCI) coal and Coking Coal products for export for steel production. The Project term is anticipated to be 25 years from grant of the ML with this term including initial construction, mine operation and rehabilitation activities. Mining at the Gemini Project is projected to occur over approximately 20 years as a truck and shovel operation at an average of 1.8 million tonnes per annum (Mtpa) ROM coal.

The Project is located approximately 150 km to the east of Rockhampton and 8 km west of the town of Dingo and is accessed by the Capricorn Highway, which transects the northern part of the tenement (Figure 1-1).

This report provides a comprehensive assessment of:

- The regional and mine-scale geology and hydrogeology;
- The installation of a groundwater monitoring bore network that has been designed to provide water level and water quality data from all groundwater units at site;
- A program of hydraulic testing that has been carried out on the groundwater monitoring bores at site in order to provide site-specific hydraulic conductivity data for groundwater modelling;
- Water level and water quality data obtained to date from the site groundwater monitoring bores;
- Regional groundwater occurrence and use;
- A conceptual groundwater model for the site; and,
- Groundwater modelling that has been undertaken to provide predictions of:
    - the rate of groundwater inflow to the mined voids; and
    - the extent of groundwater level impacts from mining, which are used to provide prediction of the potential for impact on sensitive environmental receptors such as landholder bores and groundwater dependent ecosystems (GDEs).

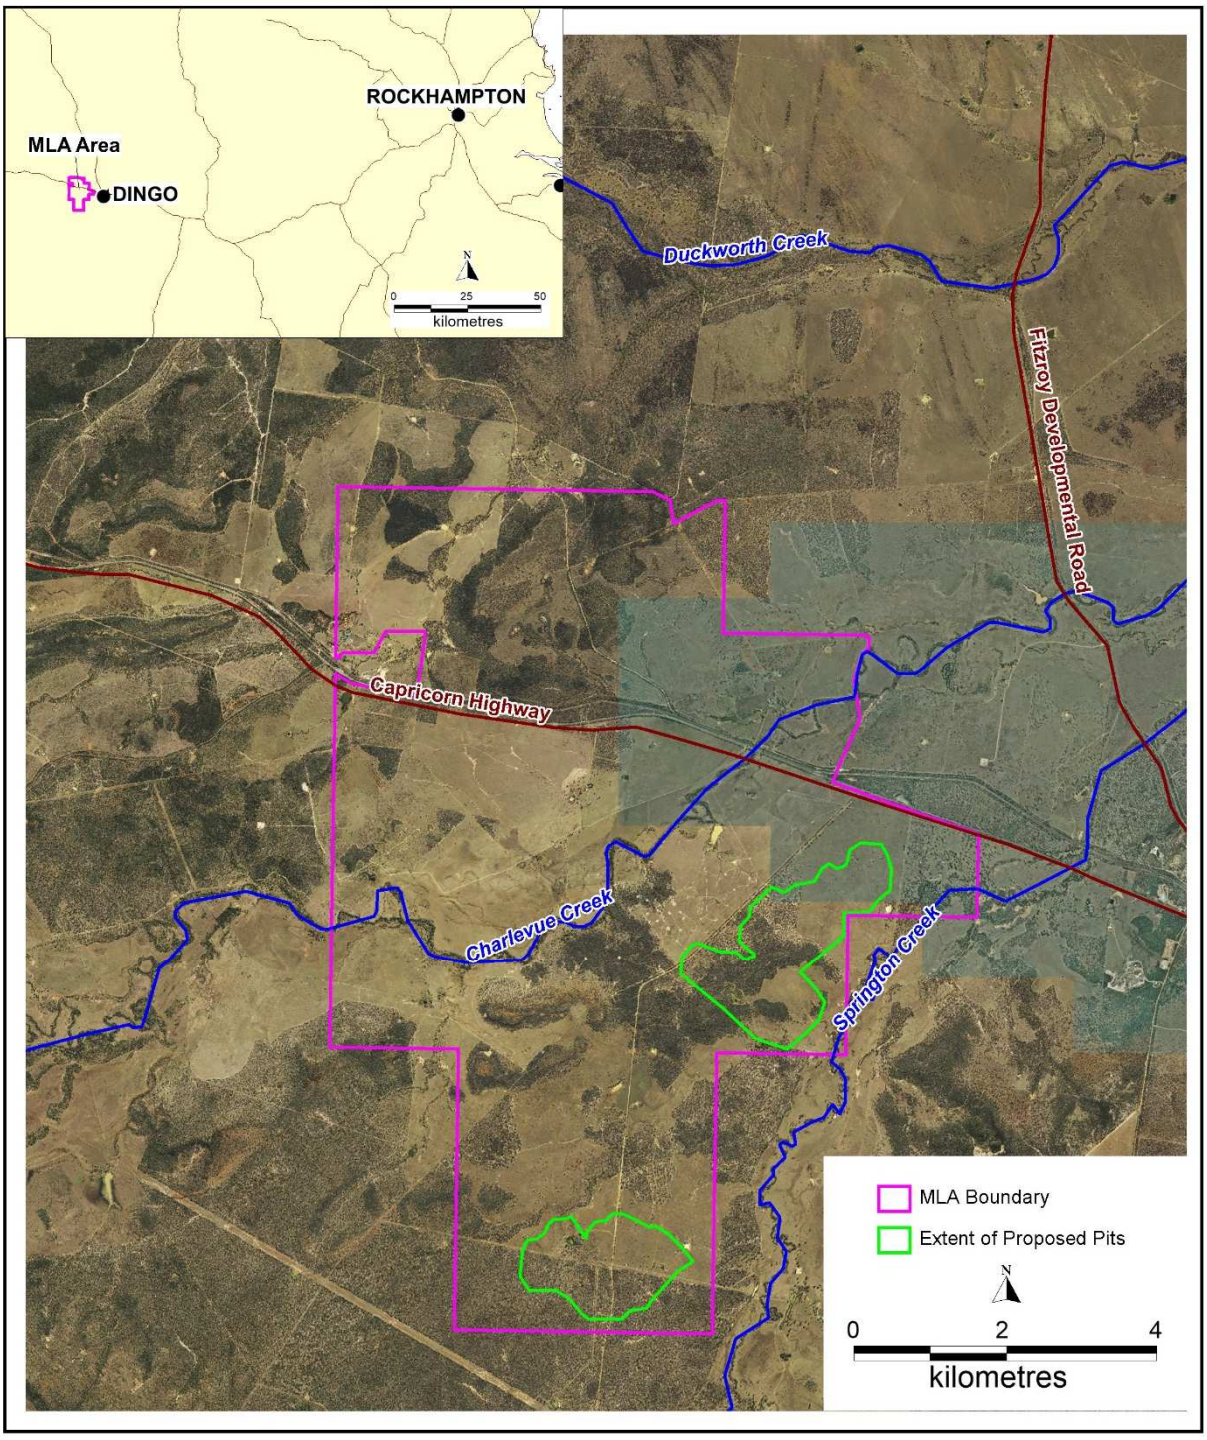

Figure 1-1: Project Location

2.0 CLIMATIC DATA

The climatic description of the region in which the project site is located has been compiled using data from the DNRM SILO Data Drill. The Data Drill accesses grids of climate data available from surrounding Bureau of Meteorology (BoM) point observations and then creates interpolated climate values for the requested location. The SILO climate data was obtained for coordinates that correspond to the approximate centre of the Gemini Project site.

Summary data for rainfall and evaporation is shown in Table 2-1 and indicates that:

- Mean annual rainfall for the site is approximately 678 mm; and,
- Mean annual evaporation is approximately 2024 mm and exceeds rainfall for every month of the year.

The data has been utilised to produce a climatograph for the Gemini Project site (Figure 2-1), which shows that:

- rainfall is highly seasonal, with the dry season from April to September-October, and a wet season from November through to March;
- The coldest month of the year is July, with a mean minimum temperature of 7.7 ºC and a mean maximum temperature of 23.2 ºC; and,
- The hottest month of the year is January, with a mean minimum temperature of 21.6 ºC and a mean maximum temperature of 33.8 ºC.

Figure 2-2 shows the total monthly rainfall for the period 2000 to July 2019 and also presents a rainfall residual mass (RRM) curve for the data. The RRM is calculated by subtracting the long-term average monthly rainfall from the actual monthly rainfall, to provide a monthly "departure" from average conditions. If the monthly rainfall is above average, the resulting rainfall departure number is positive, whereas if the rainfall is below average, the number is negative. A number of below-average rainfall months will result in a falling RRM curve, while a number of above average rainfall months will result in a rising RRM curve. The RRM curve is used extensively in groundwater investigations due to the strong correlation in many locations between the RRM and groundwater level trends. The RRM curve shows a downward trend from 2000 to 2007, an upward trend from 2008 to 2013 and a relatively stable trend from 2013 to present. The downward trend from 2013 to present indicates a potential for falling groundwater levels over that period for shallow aquifers where rainfall recharge is the dominant factor that affects water level rise and water levels tend to fall during periods of below-average rainfall.

Table 2-1: Average Monthly Rainfall and Evaporation (SILO Data)

Month	Average Rainfall (mm)	Average Evaporation (mm)
January	109.9	229.5
February	105.7	186.5
March	76.0	184.2

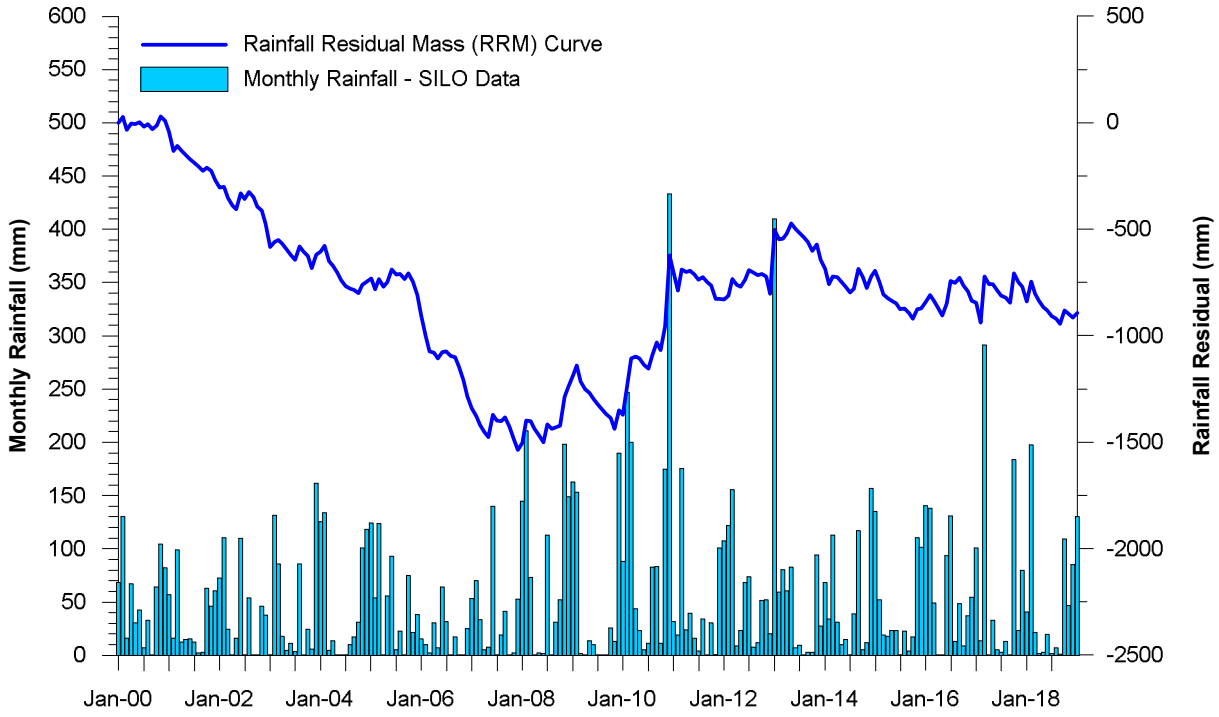

Figure 2-2: Monthly Rainfall and Rainfall Residual Mass Curve

3.0 GEOLOGY AND HYDROGEOLOGY

3.1 Stratigraphy

The Gemini coal deposit is hosted within the Permian Rangal Coal Measures and within the Yarrabee Structural Zone. Seven seams or seam groups have been identified at the Gemini Project site, which belong to either the Rangal Coal Measures or the underlying Burngrove Formation (Boyd 2019). In descending stratigraphic order the seams include the Aries, Castor, Pollux, Orion, Pisces, Virgo and Leo seams. The seams contain a number of individual plies that have identified for mining at site; the main coal seams that are encountered at site and their typical thickness are shown below in Table 3-1.

The surface geology at site is shown in Figure 3-1. It predominantly comprises sediments of the Tertiary Duaringa Formation and Quaternary alluvium associated with ephemeral creeks including Charlevue Creek and Springton Creek. At one location north of Pit C a small area of remnant basalt has been identified from drilling, measuring approximately 600 m long and 200 m wide with a thickness of approximately 20 m (JTB 2019). Bore DW7105W1 (Section 4.1) is located within the basalt and is dry.

Figure 2-2 shows the project location in relation to the underlying Bowen Basin solid geology (i.e. the surficial unconsolidated Quaternary and Tertiary units have been removed, revealing the relationship between the underlying Triassic and Permian sediments as well as the prevalence of regional-scale faults). The two mining areas (A-B Pit and C Pit) are located in areas where folding has brought the coal seams close to surface at depths that can be economically mined. Figures 3-1 and 3-2 also show the locations of east-west cross sections through each mining area and a long section through both mining areas. Data from these sections has been utilised to create cross sectional groundwater models, which are discussed below in Section 6.0.

Table 3-1: Summary of Regional and Site Stratigraphy

Geological Age	Unit	Coal Seams	Description	Typical Thickness at Site (m)
Quaternary	Alluvium		Unconsolidated soil, silt clay, sand and gravel associated with current surface drainage systems, e.g. Charlevue Creek and Springton Creek	1.5
Tertiary	Duaringa Formation		Mudstone, sandstone, conglomerate, siltstone	15 - 30
	Basalt		Minor basalt at one location north of Pit C.	20
Triassic	Rewan Group		Lithic sandstone, pebbly lithic sandstone, green to reddish brown mudstone and minor volcanilithic pebble conglomerate at base	0 - 50
Permian	Rangal Coal Measures	Aries Upper	Feldspathic and lithic sandstone, carbonaceous mudstone, siltstone, tuff and coal seams. Includes the Aries, Castor and Pollux Coal Seam, which are the target coal seam for mining at the Gemini Project	2.1
		Aries Lower		4
		Castor Upper		1.6
		Castor Lower		2
		Pollux Upper		1.9
		Pollux Lower Upper		2.9
		Pollux Lower Lower		3.5
		Orion		6.1
		Pisces Upper		1.7
		Yarrabee Tuff		0.9
		Pisces Lower		0.7
	Burngrove Formation	Virgo	Mudstone, siltstone, sandstone, coal, tuff	2.8
		Leo		4.4
	Gyranda Formation		Siltstone and shale with minor tuff and volcanilithic sandstone and rare coal	0 to 100 m+

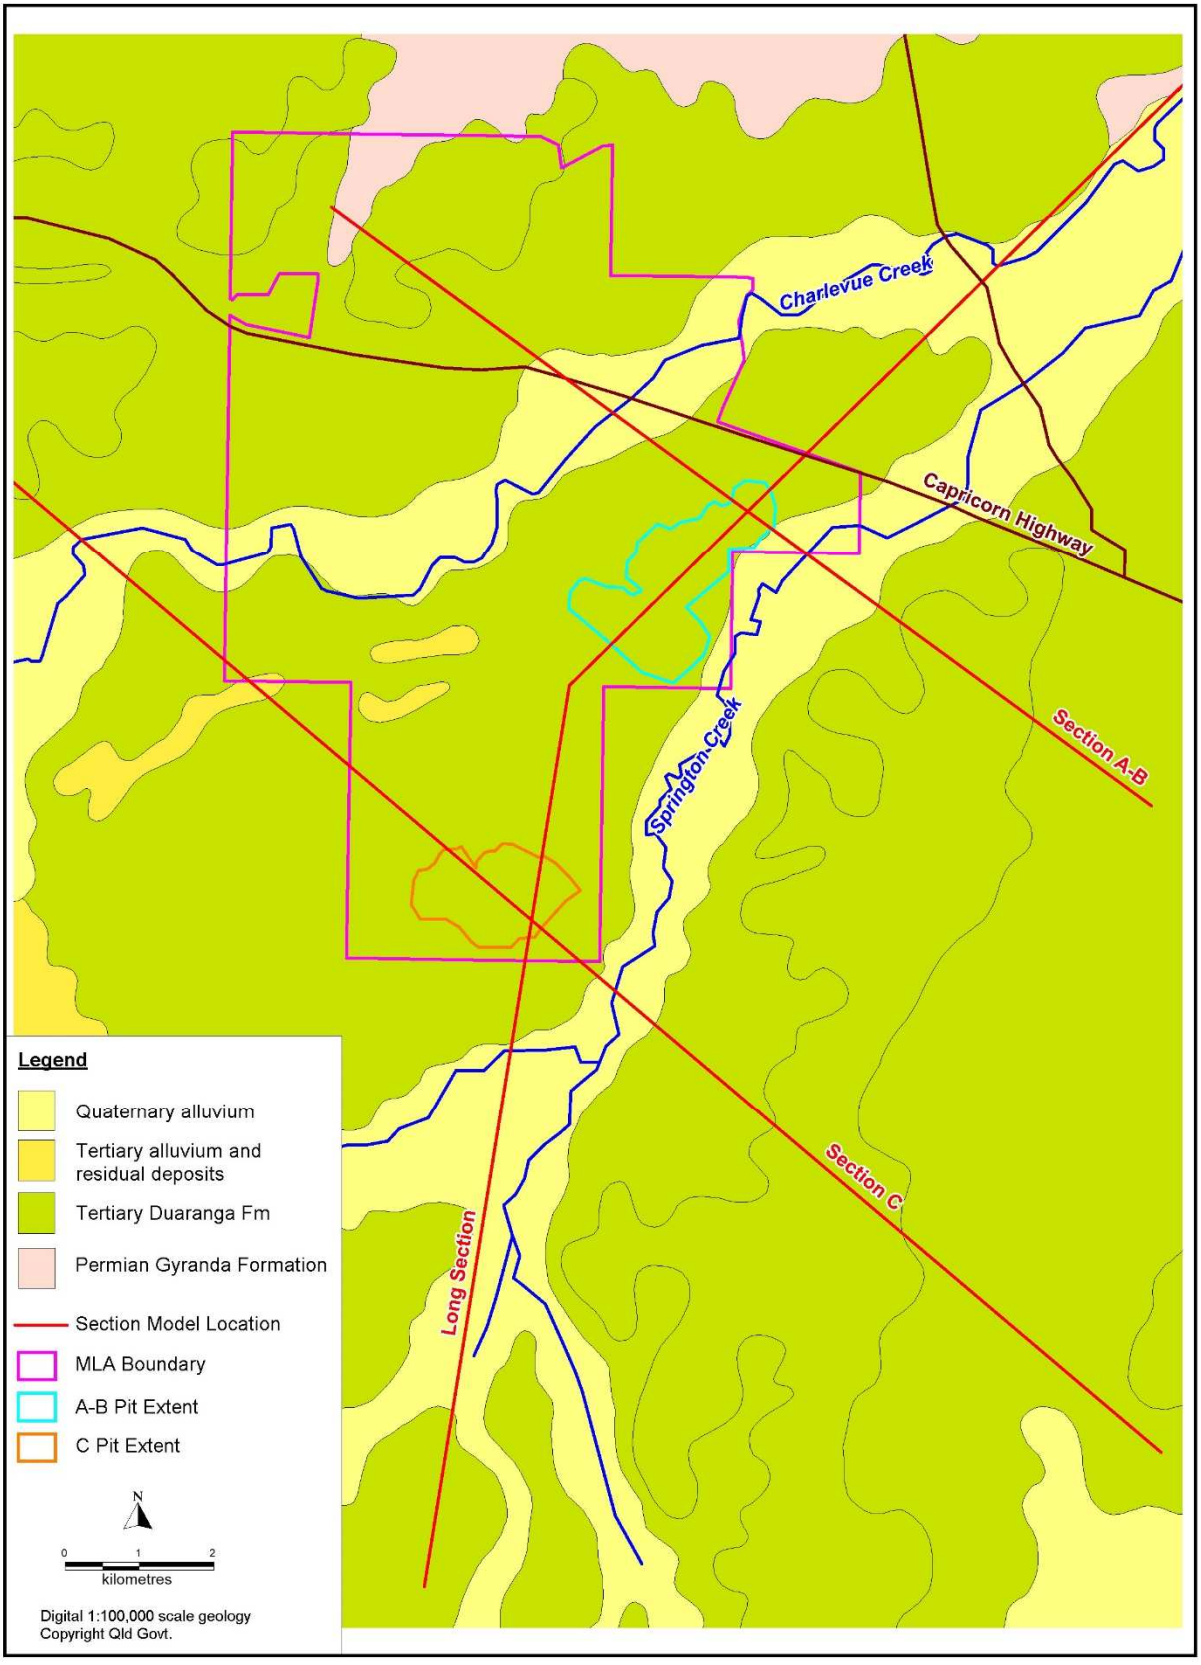

Figure 3-1: Project Location and Surface Geology (1:100,000 Scale Digital Geology)

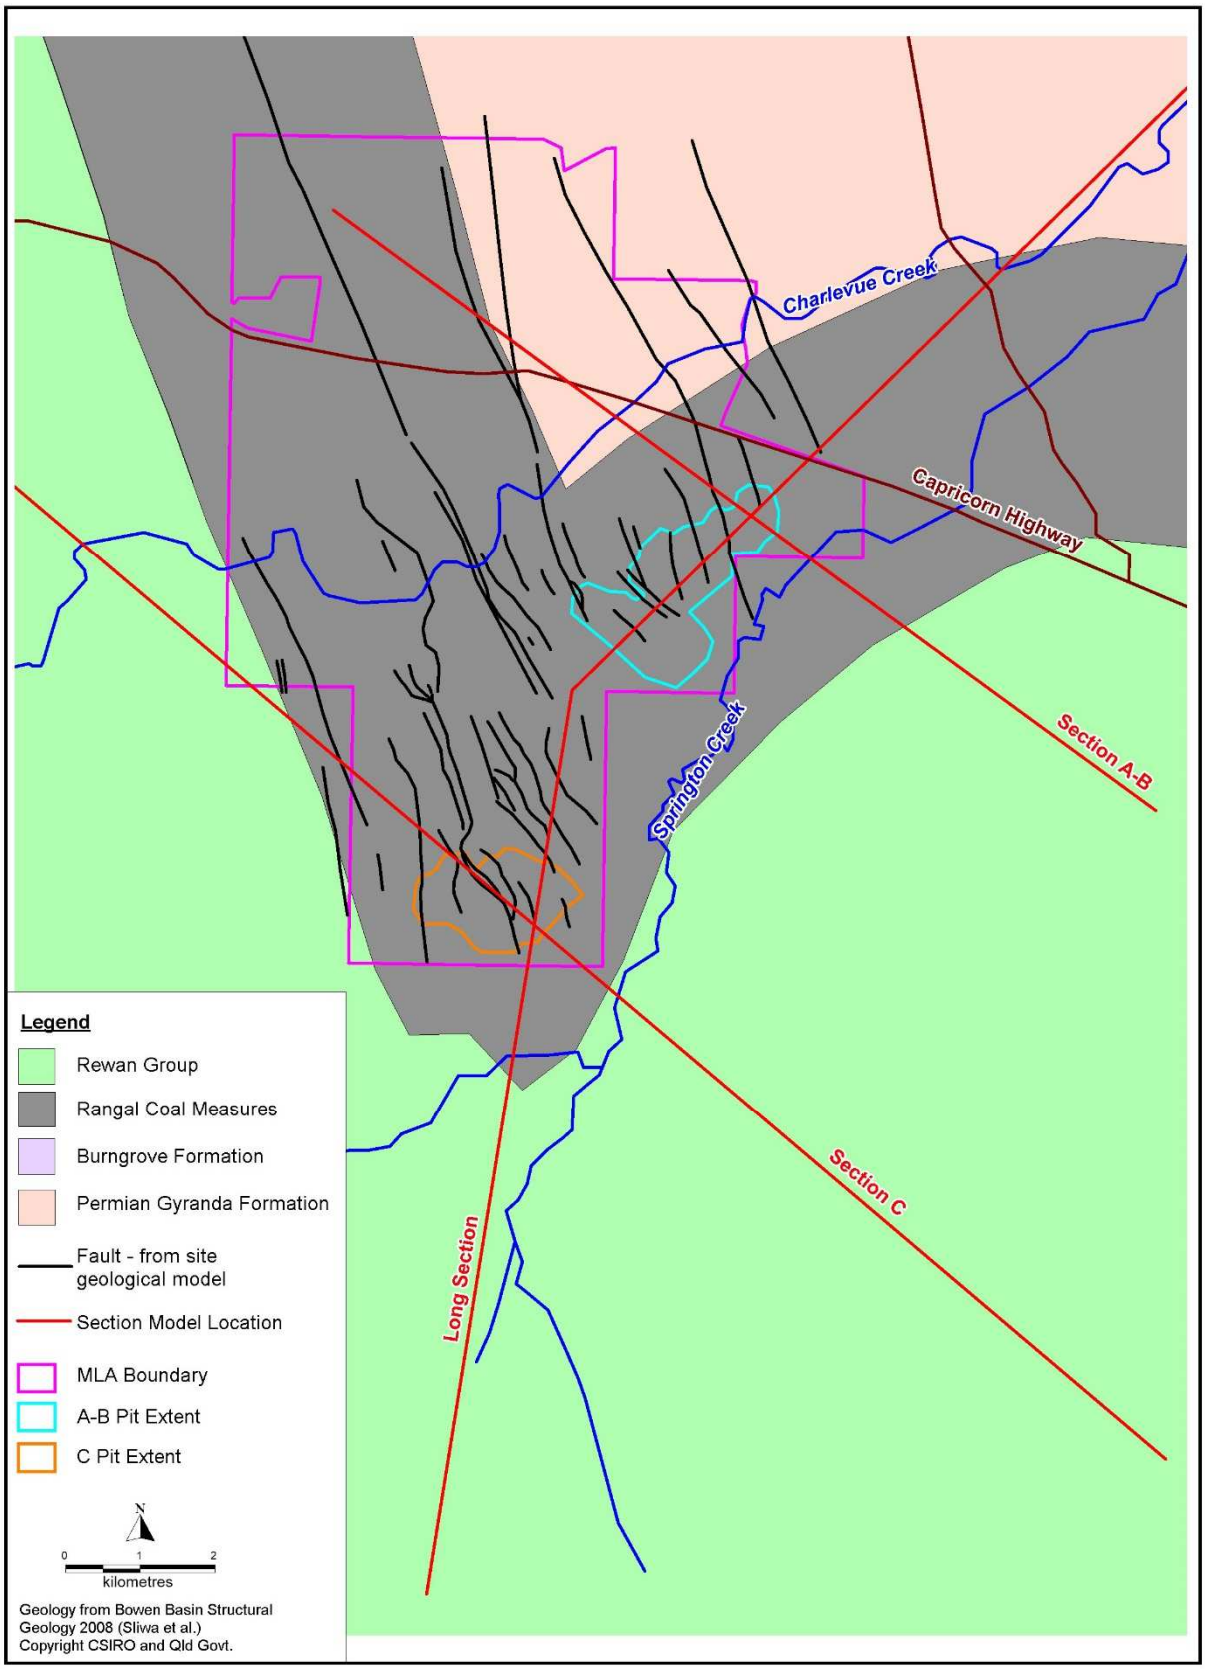

Figure 3-2: Project Location and Bowen Basin Solid Geology

3.2 Igneous Rocks and Intrusions

A minor occurrence of Tertiary basalt has been identified from geological drilling to the north of Pit C. The area of basalt is approximately 600 m long, 200 m wide and 20 m thick and has been interpreted as a localised basalt paleochannel (JTB 2019). One groundwater monitoring bore has been located within the basalt (bore DW7105W1, Section 4.1, Figures 4-1 and 4-2); the bore is 23 m deep and the basalt is dry at the bore location. The basalt flow is interpreted to be dry (as it is above the regional groundwater level) and of limited extent and is therefore not an important groundwater feature within the project area.

Extensive geological drilling across the project area has shown no other evidence of basaltic flows or intrusions (JTB 2019).

3.3 Structure

The Permian coal measures have undergone intense structural deformation, resulting in folding and faulting of the unit. Multiple reverse angle faults are present within the deposit, with displacements on some faults estimated to be in excess of 100 m (Boyd 2019). The location of mapped faults that are included in the site geological model are shown in Figure 3-2. With respect to the potential for impacts on groundwater occurrence and movement, the potential impacts are assessed to be:

- The fault zones may provide localilsed increases in hydraulic conductivity and storage that is associated with the shear zones of each fault; and,
- The faults may act as barriers to groundwater flow at locations where the faults disrupt individual coal seams, which are the main conduits for groundwater flow, especially at locations where the entire thickness of coal is displaced so that the coal seam terminates against lower-permeability interburden (the impacts of faults on groundwater are discussed further in Sections 4.6, 6.0 and 6.4).

4.0 GROUNDWATER INVESTIGATIONS AND DATA

4.1 Groundwater Monitoring Bores

The groundwater monitoring bore network at the Project site comprises 38 monitoring bores at 17 sites; bore locations are shown below in Figure 4-2, with summary details for the bores provided in Table 4-1. The monitoring bore network was designed to allow hydraulic testing as well as water level and water quality monitoring of all groundwater units encountered at site and includes:

- Two (2) bores within Quaternary alluvium;
- Ten (10) bores within Tertiary deposits (9 bores within Tertiary sediments and 1 bore (DW7105W1) in Tertiary basalt;
- Twenty-three (23) bores within Permian coal seams; and,
- Three (3) bores within the Permian overburden/interburden sediments that occur above/between the coal seams.

Bore construction logs for the monitoring bores are provided in Appendix A.

The development and utilisation of the monitoring bore network is summarised as follows:

- The network has been developed in two stages, comprising:
  - Stage 1 – installation of 11 bores at 5 sites (Sites 1 to 5 – refer Figure 4-2 and Table 4-1), with the bores installed in April 2018; and,
  - Stage 2 – Installation of a further 27 bores at 12 sites (Sites 6 to 17), with the bores drilled from May to June 2019.
- The bores at sites 1 to 5 have been monitored for water level and water quality on approximately a monthly basis since December 2018, with data available for this report from 8 sampling events between December 2018 and August 2019. Water level and water quality data is summarised below in Sections 4.2 and 4.3 respectively.
- Bores at Sites 6 to 17 were utilised for hydraulic testing (falling-head slug tests). Hydraulic tests were performed on a total of 25 bores, which provided data for all groundwater units present at site. Results from the hydraulic testing program are presented and discussed in Section 4.4.

* RL (mTOC) = elevation in mAHD of the top of bore casing; mbgl = metres below ground level; gravel pack and slotted interval from/to = from/to mbgl

4.2 Groundwater Levels

Available groundwater level data from the site groundwater monitoring bores is summarised as follows:

- For bores at sites 1 to 5 (refer Table 4-1), data is available to date for 9 sampling events between December 2018 and August 2019;
- For bore DW7076W, which is constructed within Quaternary alluvium adjacent to Charlevue Creek (Figure 4-2), a data logger has been fitted to the bore that records data at 3-hourly intervals. A barometric logger is also installed at the site to allow barometric correction of the data;
- For bores at sites 6 to 17, which were drilled in May/June 2019, water level data is available from field testing that was undertaken in July/August 2019.

Table 4-1 provides the most recent water level data (July/August 2019) for all monitoring sites and is summarised as follows:

- Six of the monitoring bores are dry; five of these bores are constructed within Tertiary units at depths of between 14 and 23 m and one bore is constructed with the Aries seam at a depth of 31.6 m;
- Available data for bores within the Tertiary sediments are shown below in Figure 4-2, which is summarised as follows:
    - Data shown in Figure 4-2 includes contours for RL base of Tertiary (mAHD), bore ID, water level (mAHD) and base of bore (mAHD);
    - At a number of sites where the bore is dry, the bore has not been constructed to the full depth of Tertiary sediments. These sites include DW7075W, DW7072W, DW7066W;
    - Two sites that are dry (DW7105W1 and DW7264W1) have been drilled to base of Tertiary, indicating that the Tertiary is dry at these locations. Bore DW7105W1 is constructed within the small area of remnant basalt north of C Pit that has been identified from geological drilling (section 3.1); the bore is 23 m deep and is dry;
    - There is a significant reduction in the level of the base of Tertiary to the west and north-west of AB Pit, where the level of base of Tertiary reduces from approximately 100 mAHD to 70-80 mAHD. The bores within the lower elevation area of base of Tertiary tend to record water levels in the order of 90 to 95 mAHD, whereas the bores in the range of 105 to 113 mAHD; and,
    - The presence of dry bores within the Tertiary, as well as the variation in water level between the topographically elevated base of Tertiary and topographically lower base of Tertiary, suggest that a continuous water surface does not exist in the Tertiary sediments and that the elevation of the base of Tertiary will be a control on the presence of groundwater within the sediments. From review of available data it is assessed that it is probable that the Tertiary sediments are dry above 120 mAHD and likely dry above 110 mAHD (refer Figure 4-2).
- Available data for bores within the coal seams is also shown below in Figure 4-2. In summary:
    - From the data shown in Table 4-1 it is evident that, where multiple coal seam bores exist at the one location, the water level (as mAHD) is almost identical. This suggests that there is no significant trend for upward or downward movement of groundwater between the coal seams at this location;
    - Figure 4-2 also shows groundwater level contours for the coal measures; these indicate a trend for groundwater movement within the coal seams from the southwest to the northeast, and also from the northwest to the southeast, towards a depression that is centred on the area where the AB Pit is proposed to be developed.

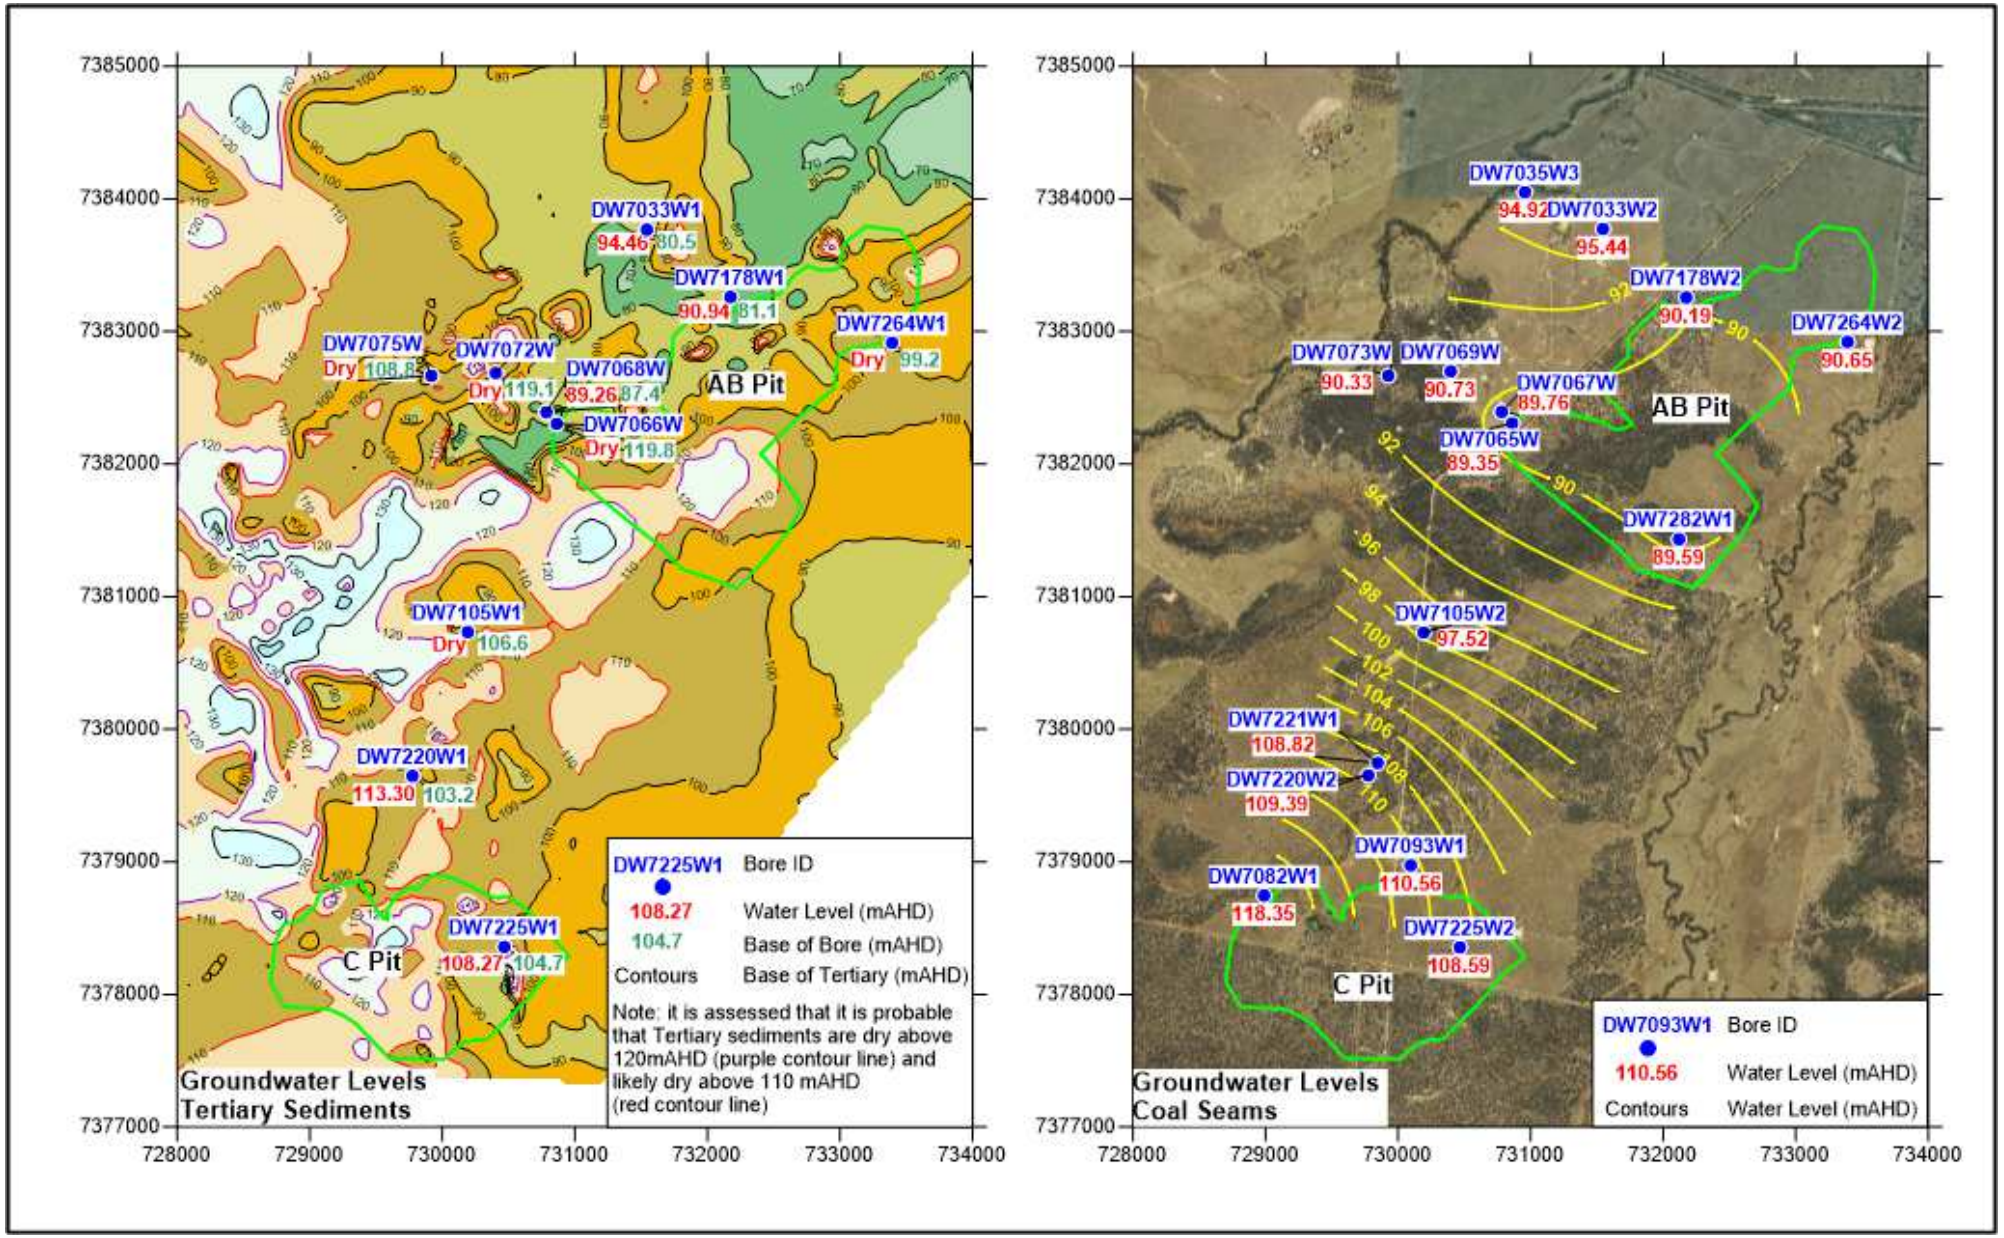

Figure 4-2: Water Level Data for Coal Seam and Tertiary Groundwater Units

For bores at Sites 1 to 5, where water level data is available from December 2018 to August 2019, the data is plotted on bore hydrographs. These are presented below and are summarised as follows:

- The bores shown on the plots below are located to the west of the AB Pit (Figure 4-2);
- When presented as water elevation data (i.e. as water level in mAHD) the data plots within a relatively tight range between approximately 88 to 90 mAHD;
- When presented as depth to water (m below ground level - mbgl), the range is from approximately 33 to 47 mbgl. This serves to highlight that the variability in the depth to groundwater is mainly related to the variation in surface topography, with the groundwater elevation in a particular area being relatively consistent; and,
- Figure 4-2 shows the location of bore DW7073W to the west of the AB Pit. This site also includes bore DW7074W, which is not shown in Figure 4-2. This is because only one coal seam bore was selected for generation of the water level contours shown in Figure 4-2, due to the similarity between the water levels within different coal seams at each site (refer water level data in Table 4-1). This relationship is highlighted in the water level data for bores DW7073W and DW7074W in the depth to water plot below; for these bores it can be seen that the water level is the same (within 0.1 m) for each monitoring event.

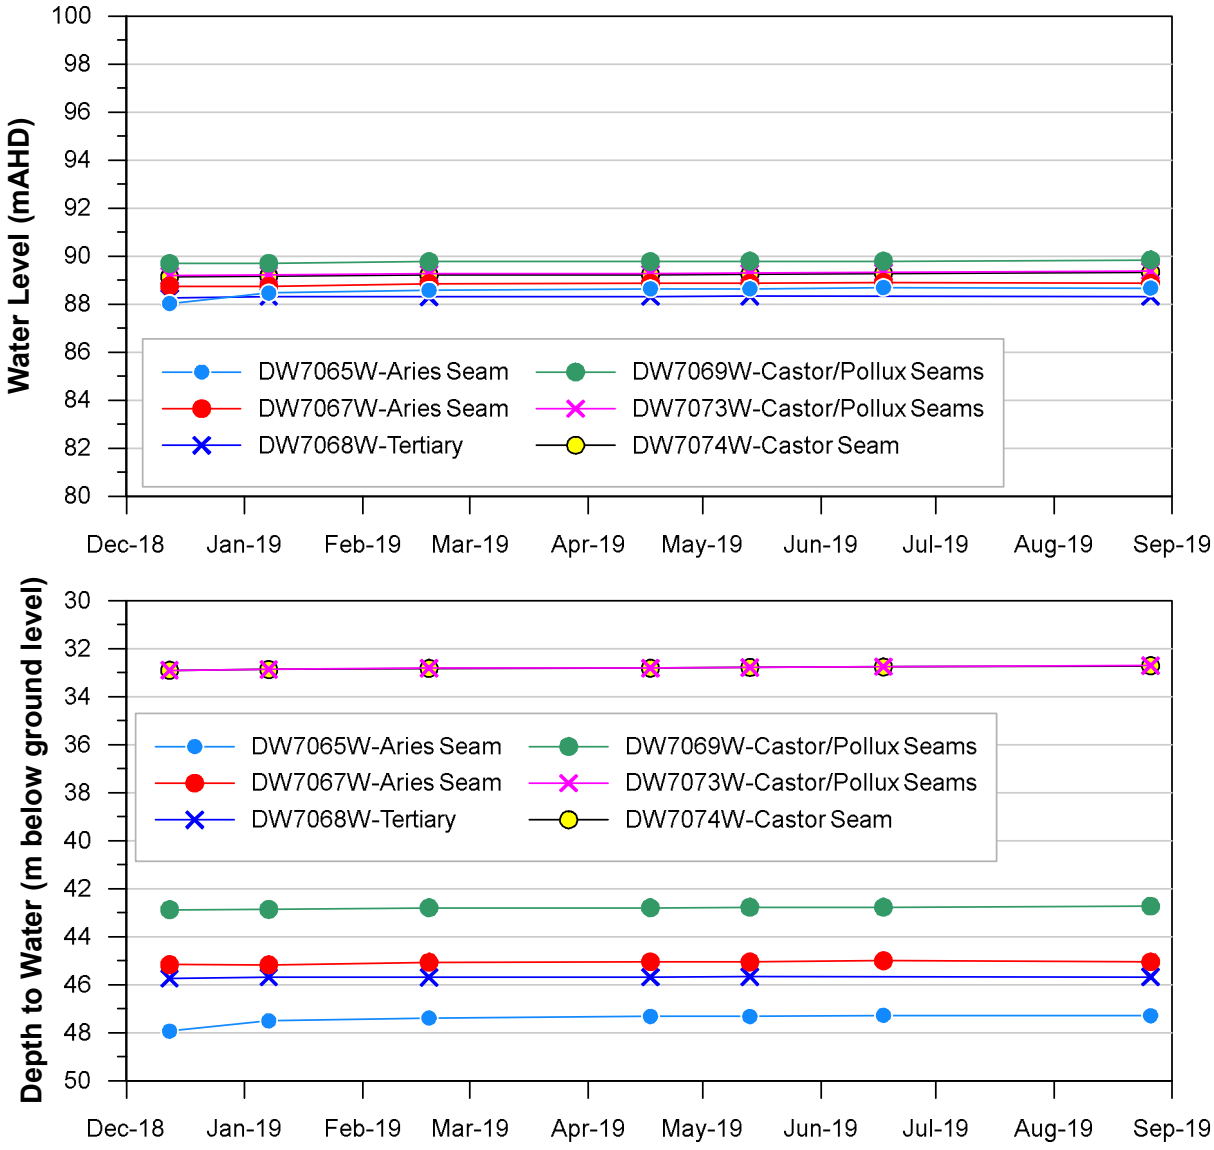

Figure 4-3: Water Level as Elevation (mAHD-top plot) and Depth to Water (mbgl-bottom plot)

Bore DW7076W (refer Figure 4-1 for bore location) is screened within Quaternary alluvium adjacent to Charlevue Creek. The bore has been fitted with a data logger that records water level at 3-hourly intervals, to allow the relationship between creek flow and water level to be established over time. To date the water level has been relatively stable, displaying a slightly downward water level tend between 9 and 10 mbgl. It is uncertain at this stage whether the reduction in water level is related to the ongoing removal of groundwater from the bore during sampling events (with the reduction in water level following sampling being evident in the bore hydrograph. Further data will be required at this site to establish the long-term water level trend.

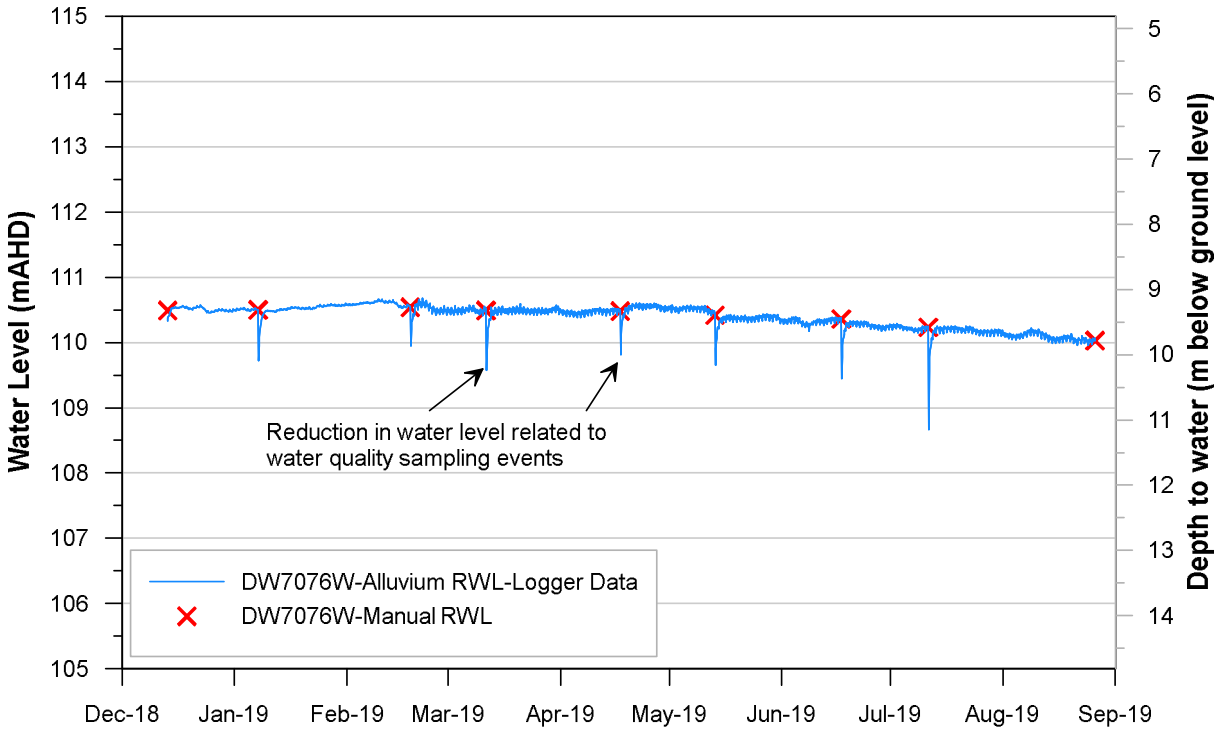

Figure 4-4: Water Level Data for Quaternary Alluvium Bore DW7076W

4.3 Groundwater Quality

Groundwater quality data is available for 8 sampling events that have occurred at approximately monthly intervals between December 2018 and August 2019. Available data includes:

- pH (field and laboratory data);
- Electrical Conductivity (EC – field and laboratory data);
- Total Dissolved Solids (TDS);
- Major ions (sodium, calcium, magnesium, potassium, chloride, sulphate, alkalinity); and,
- Total and dissolved metals/metalloids (aluminium, arsenic, barium, beryllium, boron, cadmium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, uranium, vanadium, zinc).

Available data is included as summary tables in Appendix B. Observations from review of the data area summarised as follows:

- pH (Field)
  - Quaternary alluvium - the pH ranges from 7.05 to 7.49, with a mean of 7.30 and median of 7.33;

- Tertiary sediments - the pH ranges from 6.78 to 7.06, with a mean of 6.93 and median of 6.94; and,
- Coal seams - the pH ranges from 6.21 to 6.84, with a mean of 6.44 and median of 6.42.

- Electrical Conductivity (EC – lab)
  - Quaternary alluvium - the EC at bore DW7076W (Charlevue Creek alluvium) ranges from 15,200 µS/cm to 16,600 µS/cm, with a mean of 15,788 µS/cm and median of 15,700 µS/cm (8 samples). A single field value from bore DW7292W1 (Springton Creek alluvium) recorded an EC of 5,948 µS/cm;
  - Tertiary sediments - the EC ranges from 20,200 µS/cm to 21,900 µS/cm, with a mean of 20,843 µS/cm and median of 20,800 µS/cm; and,
  - Coal seams - the EC ranges from 22,100 µS/cm to 28,500 µS/cm, with a mean of 25,693 µS/cm and median of 25,600 µS/cm.
- Sulphate (SO_4). Due to the high salinity of the groundwater, samples are also relatively high in sulphate, especially for the coal seams, with data summarised as:
  - Quaternary alluvium - the sulphate concentration ranges from 204 mg/L to 249 mg/L, with a mean of 217 mg/L and median of 212 mg/L;
  - Tertiary sediments - the sulphate concentration ranges from 291 mg/L to 635 mg/L, with a mean of 367 mg/L and median of 334 mg/L; and,
  - Coal seams - the sulphate concentration ranges from 341 mg/L to 841 mg/L, with a mean of 622 mg/L and median of 642 mg/L.
- Dissolved metal/metalloid data has been analysed with reference to the ANZECC 2000 95% freshwater ecosystem protection trigger values for parameters where guideline values exist; these include aluminium, arsenic, boron, cadmium, copper, lead, mercury, nickel, selenium, silver and zinc. Observations of note include:
  - All groundwater samples are above the guideline limit for boron of 0.37 mg/L, with data summarised as:
    - Quaternary alluvium – the boron concentration ranges from 0.56 to 4.56 mg/L, with mean of 3.50 mg/L and median of 3.81 mg/L;
    - Tertiary sediments – the boron concentration ranges from 1.14 to 1.52 mg/L, with mean of 1.28 mg/L and median of 1.26 mg/L; and,
    - Coal seams - the boron concentration ranges from 0.88 to 1.49 mg/L, with mean of 1.23 mg/L and median of 1.25 mg/L.
  - The majority of groundwater samples are above the guideline limit for copper of 0.0014 mg/L, with data summarised as:
    - Quaternary alluvium – the copper concentration ranges from 0.002 to 0.023 mg/L, with mean of 0.013 mg/L and median of 0.011 mg/L (9 samples, all samples >LOR);
    - Tertiary sediments – the copper concentration ranges from 0.001 to 0.014 mg/L, with mean of 0.004 mg/L and median of 0.003 mg/L (7 samples, 4 samples >LOR); and,
    - Coal seams - the copper concentration ranges from 0.001 to 0.081 mg/L, with mean of 0.011 mg/L and median of 0.003 mg/L (45 samples, 25 samples >LOR).
  - The majority of groundwater samples are above the guideline limit for zinc of 0.008 mg/L, with data summarised as:

- Quaternary alluvium – the zinc concentration ranges from 0.007 to 0.028 mg/L, with mean of 0.014 mg/L and median of 0.011 mg/L (9 samples, 7 samples >LOR);
- Tertiary sediments – the zinc concentration ranges from 0.017 to 0.096 mg/L, with mean of 0.049 mg/L and median of 0.035 mg/L (7 samples, all >LOR); and,
- Coal seams - the zinc concentration ranges from 0.025 to 0.21 mg/L, with mean of 0.086 mg/L and median of 0.075 mg/L (45 samples, all >LOR).

o A number of samples exceed the guideline values for aluminium, arsenic, lead and nickel.

The samples collected to date represent background water quality for the site. It can therefore be summarised that:

- Groundwater at site records very high EC for all groundwater units (Quaternary alluvium, Tertiary sediments and Permian coal measures). It is noted that the ANZECC 2000 livestock limit for beef cattle is 4,000 mg/L; this corresponds to an EC of approximately 6,000 µS/cm at a conversion factor of EC (µS/cm) x 0.67 = TDS (mg/L) (ANZECC 2000). It is therefore concluded, based on EC data, that groundwater at site is unsuited to stock watering; and,
- Groundwater at site is above the ANZECC 2000 freshwater ecosystem protection trigger value (95% species protection) for boron (all samples), copper and zinc (majority of samples) as well as aluminium, arsenic, lead and nickel (a number of samples for each analyte).

4.4 Hydraulic Conductivity data from Monitoring Bores

Falling head (slug) tests were undertaken on 25 monitoring bores in order to obtain site-specific hydraulic conductivity (K) data from all groundwater units that are encountered at site. The results for each bore are shown below in Table 4-2. Summary data for each groundwater unit are discussed further below and are provided in Table 4-3 and the slug test analysis sheets are included in Appendix C.

Table 4-2: Hydraulic Conductivity and Air Lift Yield Data for Monitoring Bores

Hole	Groundwater Unit	Centre of Screened Interval (mbgl)	SWL (mBTOC)	Hydraulic Conductivity (K) (m/day)	Air Lift Yield (L/s)*

DW7033W3	Interburden	80.3	29.97	0.002	2.250
DW7093W2	Interburden	98.5	29.54	0.001**	

* Air Lift Yield data was obtained from the base of bore prior to bore construction and therefore represents the yield of the entire open interval

** Data could not be analysed due to lack of recovery over test period – K set at low value of 0.001 m/day

The data was also reviewed in association with data from air-lift yield testing of the groundwater monitoring bores, which was undertaken at the completion of drilling (i.e. at the base of the hole) and prior to bore construction. From review of the combined dataset of hydraulic conductivity data and air-lift yield data, and with reference to information contained in Table 4-2, Table 4-3 and Figure 4-2, the following observations are made:

- A total of 17 slug tests were performed on bores that are screened within the coal seams. From review of the data it is evident that the K decreases with depth and that the difference becomes apparent when comparing data for coal seam bores that are screened at a depth of less than 80 metres below ground level (mbgl) to data for bores that are screened at a depth greater than 80 mbgl;

- Table 4-3 contains summary statistics (minimum value, maximum value and geometric mean) for the K of the coal seams, which is summarised as follows:
  - For data for all coal seams (17 data points), the K range is from 0.002 to 5.4 m/day, with a geometric mean of 0.13 m/day
  - For coal seam bores that are screened above 80 mbgl (11 data points) the K range is from 0.012 to 5.4 m/day, with a geometric mean of 0.37 m/day
  - For coal seam bores that are screened below 80 mbgl (6 data points) the K range is from 0.002 to 0.24 m/day, with a geometric mean of 0.02 m/day;
- The relationship between hydraulic conductivity and depth is shown graphically in Figure 4-2. Of particular interest is the data for the coal seam bores, where the trend for the lower K with depth is shown via the trend line and the 95% confidence interval that has been applied to the data (curves have been automatically fit within the software program Grapher).

Table 4-3: Summary of Hydraulic Conductivity and Air-Lift Yield Data per Groundwater Unit

Groundwater Unit	No. of Tests	Hydraulic Conductivity (m/day)			Average Air-Lift Yield (L/s)
		Min	Max	Geometric Mean	
Quaternary Alluvium	1	0.097		-	-
Tertiary	5	0.027	3.805	0.27	0.548
Permian Coal Seams	17	0.002	5.387	0.13	1.185
Coal Seams <80 mbgl	11	0.012	5.387	0.37	1.578
Coal Seams >80 mbgl	6	0.002	0.245	0.02	0.320
Permian Interburden	2	0.001	0.002	-	-

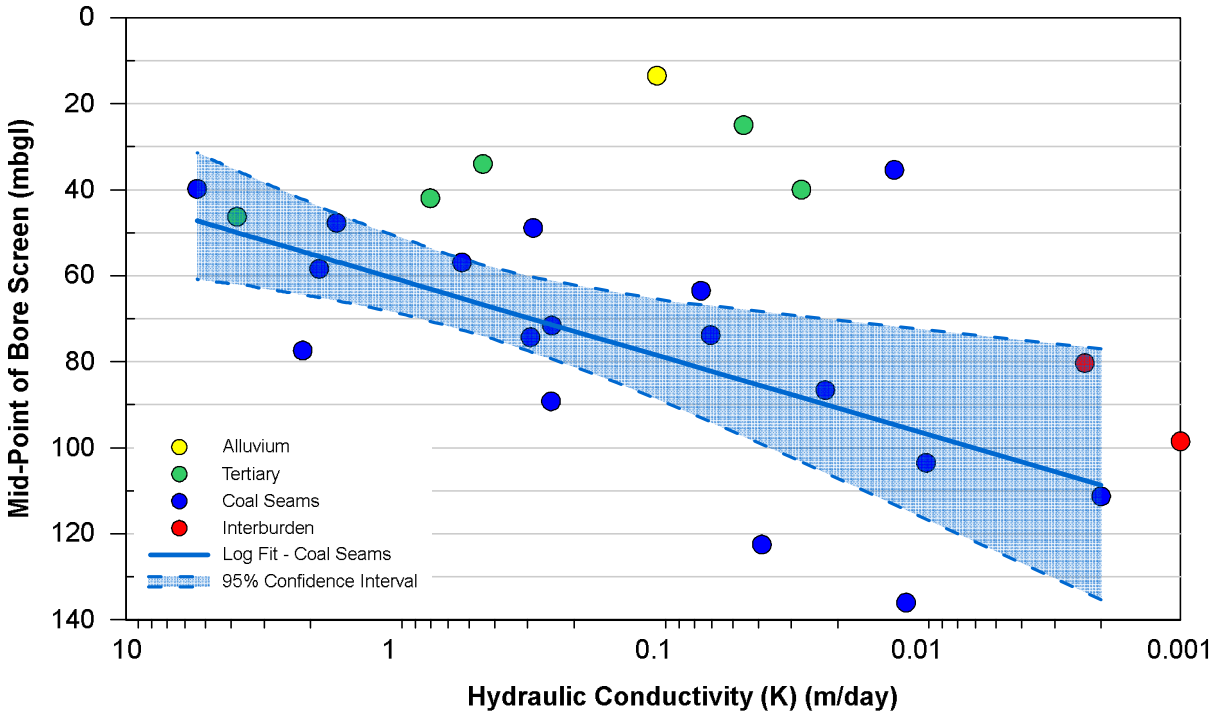

Figure 4-5: Relationship between Hydraulic Conductivity and Depth

4.5 Use of Groundwater Quality Data for Estimating Groundwater Recharge

Groundwater data from site has been utilised to provide an estimate of groundwater recharge based on the chloride mass balance (CMB) method, which utilises the concentration of chloride in rainfall and the concentration of chloride in groundwater to provide an estimate of the net recharge rate to groundwater. The CMB equation is given as:

$$R = \frac{PCp}{Cg}$$

Where:

R = Recharge (mm/year).

P = Rainfall (mm/year).

Cp = Chloride concentration in rainfall (mg/L).

Cg = Chloride concentration in groundwater (mg/L).

Utilising the above formula, the recharge rates for each groundwater unit were calculated using the following input data:

- Mean annual rainfall for the Gemini project site of 678 mm (from SILO data).
- Mean chloride concentration in rainfall for the Gemini project site of 4.9 mg/L (CSIRO 2014[1]).
- Mean chloride concentration of groundwater (refer Appendix B) of:
  - 4,088 mg/L for the alluvium;
  - 7,440 mg/L for Tertiary sediments; and,
  - 9,081 mg/L for the Permian coal seams.

The calculated recharge rates to groundwater are very low, being less than 1 mm of rainfall recharge for each groundwater unit at site and corresponds to approximately 0.05 to 0.12% of average annual rainfall reporting as recharge to the groundwater units.

While the calculated recharge rates are assessed to be low, the low recharge rates are consistent with the high salinity of the groundwater, which is observed for even the shallow alluvial units at site.

Table 4-4: Calculated Recharge via CMB Method

Parameter	Description	Groundwater Unit		
		Alluvium	Tertiary	Coal Seams
Cg	Chloride concentration in groundwater (mg/L)	4088	7440	9081
Cp	mg/L chloride in rainfall	4.9	4.9	4.9
P	Annual average rainfall (mm)	678	678	678
R	Annual average recharge (mm)	0.78	0.43	0.35
	Recharge as % of average annual rainfall	0.12	0.07	0.05

[1] CSIRO 2014 - Australian Chloride Deposition Rate https://doi.org/10.4225/08/545BEE54CD4FC

4.6 Summary of Observations from Site Data

The main observations from review of site data are as follows:

- Groundwater occurs within three main groundwater units at site, including:
  - Quaternary alluvium associated with Charlevue Creek and Springton Creek;
  - Tertiary sediments of the Duaringa Formation; and,
  - The Permian coal measures, where groundwater occurs preferentially within the coal seams.
- The site is heavily faulted and the faults may act to influence groundwater occurrence and movement as follows:
  - Shear zones associated with faulting may act as a store of water and as locally higher hydraulic conductivity zones. As discussed below, recharge to the groundwater system is assessed to be low; therefore the faults may provide initial relatively high inflow rates to the workings (in the order of several L/s), but the total storage within the faults is anticipated to be relatively low, with the initial rates of inflow not able to be sustained in the long-term; and,
  - Where the faults completely disrupt the coal seams, especially for cases where the coal seam terminates against lower-hydraulic conductivity interburden, the faults will act to disrupt groundwater flow.
- Available hydraulic conductivity and air-lift yield data indicates that there is notable reduction in hydraulic conductivity and bore yield for bores that are deeper than 80 mbgl compared to bores that are shallower than 80 mbgl.
- Groundwater level data at site are summarised as:
  - The water level within the alluvium ranges from 8.77 m to 11.19 m below ground level for bores adjacent to the creek channels;
  - The water level with the Tertiary sediments ranges from dry (5 bores, ranging in depth from 14 to 23 m) to 15.38-44.74 mbgl (where water is present). The presence of water within the Tertiary sediments is related to the RL of the base of Tertiary and from review of available data it is assessed that it is probable that the Tertiary sediments are dry above 120 mAHD and likely dry above 110 mAHD; and,
  - The water level in the coal measures ranges from 16.91 to 46.62 mbgl for bore depths of between 38.4 and 136.7 m, with one bore dry at a depth of 31.59 m.
- Groundwater quality data is summarised as:
  - All groundwater units at site record high EC groundwater, as follows:
    - Quaternary alluvium – bore DWDW7076W (Charlevue Creek alluvium) records an EC range from 15,200 µS/cm to 16,600 µS/cm (8 samples). A single field value for bore DW7292W (Springton Creek alluvium) records an EC of 5,948 µS/cm;
    - Tertiary sediments - the EC ranges from 20,200 µS/cm to 21,200 µS/cm; and,
    - Coal seams - the EC ranges from 22,100 µS/cm to 28,500 µS/cm.
  - Groundwater at site is above the ANZECC 2000 freshwater ecosystem protection trigger value (95% species protection) for boron (all samples), copper and zinc (majority of samples) as well as aluminium, arsenic, lead and nickel (a number of samples for each analyte).
  - All groundwater samples collected to date are assessed to represent the background water quality for the site.

- The recharge rate to the groundwater units at site, which has been calculated via the chloride mass balance method, indicates an extremely low recharge rate of less than 1 mm/year for each groundwater unit. The low rate of calculated recharge is consistent with the observation of highly saline groundwater at site, which is present for even the shallow alluvial units.
- The observation of a low recharge rate for groundwater suggests that, even though relatively high rates of groundwater inflow may be observed from faults/shear zones as mining progresses, the inflow rates are likely to be of short duration due to the relatively low volume that can be stored within fractures/faults and the very low rates of recharge observed at site (i.e. once the fault storage is depleted the faults are unlikely to be recharged).
- Because the faults may act as conduits for groundwater movement, the control of surface water around the site will be of particular importance (i.e. water that ponds at surface may recharge the underlying sediments and report as seepage to the pits via movement along faults/fractures. This type of flow would represent infiltrated surface water rather than groundwater.

4.7 Regional Groundwater Use

Data from DNRM groundwater database within a distance of 10 km from the EPC boundary is shown below in Figure 4-6 and summary data is provided in Table 4-4. With reference to the information in Table 4-4 and Figure 4-6 the following observations are made:

- There are 48 registered bores within 10km of EPC881 that are listed as being either existing or abandoned by useable.
- The majority of bores are screened within Tertiary units (26 bores) or Permian coal measures (15 bores).
- The right-hand plot in Figure 4-6 shows the available data classed according to EC range, being:
  - Bores that record an EC <1000 µS/cm. This includes four bores in Tertiary sediments to the east or south of the project area;
  - Bores that record an EC between 1,000 and 6,000 µS/cm. A limit of 6,000 µS/cm was assessed as this EC equates to 4,000 mg/L[2], which is the ANZECC 2000 livestock drinking limit for beef cattle (assessed to the most likely stock use for the area); and,
  - Bores that record an EC >6,000 µS/cm (assessed to be of limited or no use for stock watering).
- The majority of Tertiary bores outside the tenement area record an EC of < 6,000 µS/cm, whereas the majority of bores within or close to the tenement area record and EC in excess of 6,000 µS/cm (from Table 4-4 it is noted that the EC of groundwater within the Tertiary Duaringa Formation is often in excess of 10,000 µS/cm and at some sites in excess of 20,000 µS/cm; this observation is consistent with water quality data from site).

Data from private groundwater bores is discussed further in Sections 7.1 and 7.2.1.

5.0 CONCEPTUAL GROUNDWATER MODEL

Essential elements of the conceptual model that have informed numerical modelling include:

- Quaternary alluvium is present within ephemeral water courses to the east and west of the mining area (Springton Creek and Charlevue Creek respectively);
- Tertiary deposits are present across the project area that comprise mainly sediments of the Duaringa Formation. The Tertiary sediments are variably saturated the elevation of the base of Tertiary being a control on the occurrence of water within the sediments; it is assessed that Tertiary sediment above approximately 110 mAHD are likely to be unsaturated;
- A minor area of Tertiary basalt is present to the north of Pit C; the basalt is interpreted to be dry and of limited extent and is therefore not considered as a groundwater unit at site;
- Recharge to alluvium and Tertiary sediments is via direct rainfall recharge. The rate of recharge to the alluvium and Tertiary sediments is calculated by the chloride mass balance method (Section 4.5) to be in the order of 0.4 to 0.8 mm/year (0.07 to 0.12 % of annual average recharge respectively). The low rate of recharge is consistent with the observation of elevated salinity in the shallow sediments, with an EC range for alluvial sediments from 15,200 µS/cm to 16,600 µS/cm and for Tertiary sediments from 20,200 µS/cm to 21,200 µS/cm. The high EC that is recorded for the shallow sediments (alluvium and Tertiary) is interpreted to be reflective of a low rate of groundwater recharge as well as high residence times for groundwater;
- The coal measures are heavily faulted and folded and mining occurs where folding and faulting has brought the coal seams close to surface, as shown below in Figures 6-2 to 6-6;
- The coal seams are recharged in subcrop areas where the coal seams directly underlay Tertiary and/or Quaternary sediments. The rate of recharge to the coal seams has been calculated by the CMB method (Section 4.5) to be in the order of 0.05% of average annual rainfall. The extremely high salinity of groundwater within the coal measures (range from 22,100 µS/cm to 28,500 µS/cm) supports an interpretation of a low rate of recharge and high groundwater residence times for these units;
- Within the Permian coal measures the coal seams are the primary conduits for groundwater flow. This interpretation is supported by hydraulic conductivity data from site testing, which indicates a much lower hydraulic conductivity of interburden/ overburden units relative to the hydraulic conductivity of the coal seams;
- Hydraulic conductivity data (from testing of completed monitoring bores) and air-lift yield data (from air-lift testing undertaken at the base of the bore on completion of drilling and prior to bore construction) indicates that the shallow coal seams (shallower than approximately 80 mbgl) have a higher hydraulic conductivity and are higher yielding than the coal seams below 80 mbgl;
- The relatively high rates of groundwater flow (from air-lift yield testing) for bores shallower than 80 m may be related in some cases to proximity to faults, as the hydraulic conductivity calculated for some of the coal seams (in excess of 1.5 m/day at four sites) is assessed to be greater (by approximately an order of magnitude) than the geometric mean of the coal seam data;
- However, taken together with the interpreted low rate of recharge and high groundwater salinity it is interpreted that, while the faults may locally increase hydraulic conductivity and storage within the secondary porosity of the shear zones, the faults also act to compartmentalise the groundwater system (for example by truncating the coal seams so that they terminate against lower hydraulic

conductivity interburden); this leads to high residence times for groundwater that contributes to the elevated groundwater salinity;

- The direction of groundwater flow within the coal seams is generally from southwest to northeast; and,
- It is interpreted that a continuous water surface does not exist in the Tertiary sediments and that the elevation of the base of Tertiary will be a control on the presence of groundwater within the sediments. From review of available data it is assessed that it is probable that the Tertiary sediments are dry above 120 mAHD and likely dry above 110 mAHD.

6.0 GROUNDWATER MODELLING

6.1 Choice of Numerical Model

To estimate the extent of water level impact from the proposed project, 2-dimensional seepage modelling has been undertaken using the program Seep/W. The choice of model code has been based on an assessment of the model platform that would be appropriate to the study requirements.

A number of factors are assessed when choosing the appropriate modelling platform for a particular groundwater modelling study. Factors that are relevant to the Gemini Project include:

- The ability of the model to represent the essential elements of the conceptual groundwater model. At the Gemini Project this includes the ability of the model to accurately represent the complexity of the geology including faulting of strata, which acts to compartmentalise the geological and hydrogeological units, as faulting has the potential to significantly impact groundwater occurrence and flow; and,
- The ability of the model to adequately address the requirements of the scope of work. At the Gemini Project this includes assessment of the extent of groundwater level impact from mining, assessment of the potential impact of groundwater level changes on any groundwater dependant ecosystems, and assessment of the rate of groundwater inflow to the active mining area and final voids.

Based on assessment of the model requirements, including representation of the essential elements of the conceptual groundwater model, it was concluded that 2-dimensional cross-section modelling would be appropriate for the Gemini project and on that basis the model Seep/W was selected. The use of a 2-dimensional Seep/W cross-section model was assessed to be appropriate to this investigation for the following reasons:

- The geology of the mining area is complex, and includes a number of local-scale and regional-scale faults which significantly disrupt the strata (refer Figure 2-2 for solid geology). It is possible within a 2-dimensional model to reproduce complex cross-sectional geology, whereas such detail could not be included practically within a 3-dimensional model;
- Seep/W is designed to simulate flow in both the saturated zone and the unsaturated zone. When mining occurs below the phreatic surface[1] an unsaturated zone is induced in the pit walls as seepage to the excavation occurs. Seep/W is well suited to investigation of groundwater level impacts resulting from seepage to open pits, particularly for projects such as Gemini where mine dewatering via bores does not occur, and seepage to the excavation is the only means via which the mine removes water from the groundwater system;
- In open cut mines groundwater storage conditions transition from confined to unconfined in the zone adjacent to the pit walls. Seep/W models the rate of drainage to an excavation via a property called the volumetric water content (refer Section 6.3.2), which is able to accurately account for the rate of groundwater flow and the rate of change of the phreatic surface as groundwater conditions transition from confined to unconfined and gravity drainage of groundwater occurs to the excavation;
- One of the main purposes of the model is to investigate the rate and extent of groundwater level drawdown in response to mining, especially in areas of potentially connected surface water and

[1] The phreatic surface is a line of zero pore water pressure below which all pore spaces are saturated with water, and is analogous to the water table. The term phreatic surface is used throughout this report for consistency with Seep/W modelling terminology.

groundwater systems. This can be readily (and potentially more accurately) achieved through the use of a 2-dimensional cross-section models that are able to accurately represent faulting, relatively thin coal seams and seepage conditions within the mined void;

- The use of 2-dimensional models is valid in cases where the section can be oriented along a groundwater flow line so that all groundwater flow is along the section rather than across it. In open-cut mines where mining occurs below the water table, groundwater flow towards the excavation tends to dominate over the previous regional flow patterns, making it possible to orient a section along a groundwater flow line. Therefore the use of 2-dimensional cross-section models is assessed to be valid for the purposes of this investigation.

The selected modelling platform (Seep/W) is an industry-standard finite-element model capable of modelling groundwater movement and pressure distribution within the saturated/unsaturated zone of porous materials such as soil and rock. Seep/W has been used in this study to predict the rate and extent of change to the phreatic surface in response to the ongoing mining of the already approved Central North Mine, as well as the proposed extension of the operation into the extension area.

Three models were prepared for this study including west-east cross-sectional models through each of the AB and C Pits as well as a long section model that is orientated approximately north-south and represents mining at both pits; the models are described below in Section 6.2. Other details of the models (e.g. hydraulic parameters, boundary conditions, representation of faulting etc.) are discussed in subsequent sections.

6.2 Model Locations and Scenarios

Three models were generated for the study, including:

- A west-east cross section through the C Pit;
- A west-east cross section through the AB Pit; and,
- A long section that runs through the final void of both the C Pit and the AB Pit.

The locations of the sections are shown on Figures 3-1 and 3-2 as well as in Figure 6-1 below.

The models include representation of the mining schedule, including progressive backfilling of the mined areas with spoil, development of the final voids, partial backfilling of the final voids with spoil, and development of the pit void lakes to a level as modelled by WRM (2019). Selected stages in mining are shown below in Figure 6-1 and include:

- Year 1 – Mining commences in the AB Pit in the southwest region of the mining area, with mining progressing to approximately RL-45 in the deepest area, representing a depth of mining of approximately 165 m;
- Year 5 – Mining of the AB Pit has progressed from west to east, to a deepest mined level of approximately -65 mAHD, representing a depth of mining of approximately 185 m. Progressive backfilling of the mined area with spoil has occurred, in conjunction with the development of an out of pit dump;
- Year 9 – Mining of the AB Pit has progressed to the north, with the southern area of mining backfilled with spoil and progressively rehabilitated. The deepest mined area is approximately -65 mAHD, representing a depth of mining of approximately 185 m;
- Year 12 - Mining of the AB Pit has reached the full extent to the north and the floor of the pit is at a level of approximately -45 mAHD, representing a depth of mining in that area of approximately 165 m. Mining of the C Pit has commenced in the west of the mining area;

- Year 16 – Mining of the AB Pit is complete and the final landform has been developed. The final landform includes the partial backfilling of the final void area to a level of approximately 42 mAHD, representing a depth below original ground level of approximately 75 m. Development of the C Pit has progressed to the east and north and the floor is at approximately -50 mAHD, representing a depth below original ground surface of approximately 190 m at that location. Backfilling of the mined area with spoil and development of an out of pit dump has been progressively occurring; and,
- Final Landform (Years 18-20). The final voids are developed for each pit area. The final void levels for the AB Pit are as described above. The final void for C Pit has been partially backfilled with spoil to approximately 65 mAHD, representing a depth below original ground level of approximately 65 m.

The representation of mining in the Seep/W section models is shown on figures from the models and includes:

- Figure 6-2 shows detail of the long section model in the location of the AB Pit, from start of mining to Year 7. Detail from Figure 6-2, which is common to each section model, includes:
  - The coal seams are represented as distinct material types in the model, with the average thickness of each seam represented;
  - Faults are included in the model as they are shown in the sections from the geological model. As discussed in Sections 4.6 and 6.4, the main impact of the faults on groundwater flow occurs when the faults completely truncate the coal seams so that they terminate against lower hydraulic conductivity interburden;
  - The coal measures and overburden are progressively removed from the models in accordance with the mining schedule; and,
  - The mined voids are backfilled with spoil at the rate defined by the mining schedule.
- Figure 6-3 shows detail of the long section model in the location of the AB Pit, from mining Year 8 to end of mining and the final landform. Detail from Figure 6-3, which is common to all model stages that that simulate the final void and final landform, include:
  - The final void is partially backfilled with spoil as a means of reducing groundwater inflow to the final void and reducing the long-term impact on regional groundwater levels (as the water level adjacent to the final void will be to the groundwater level within the spoil and/or final void lake, rather than long-term groundwater drawdown to the base of the final void); and,
  - The average modelled water level within the AB final void of 53.7 mAHD (WRM 2019) has been included as a boundary condition for the post-mining period.
- Figure 6-4 shows detail of the long section model in the location of the C Pit, from commencement of mining in Mining Year 12 to end of mining and the final landform. Detail shown in the model is as described above, with the exception that the final void water level for the C Pit is represented at the average modelled water level of 70.3 mAHD (WRM 2019).
- Figure 6-5 shows the modelled mining sequence at the location of the west-east cross section model through Pit AB, with model detail as described above.
- Figure 6-6 shows the modelled mining sequence at the location of the west-east cross section model through Pit C, with model detail as described above.

6.3 Hydraulic Properties

6.3.1 Hydraulic Conductivity

Based on review and analysis of data discussed in Section 4-4, hydraulic conductivity values have been applied to the base-case model as shown below in Table 6-1.

Table 6-1: Hydraulic Properties Used in Model

Groundwater Unit	K (m/day)	Comment
Quaternary Alluvium	0.1	Value from slug test of bore DW7292W1.
Tertiary	0.27	Geometric mean of data from slug tests (Section 4.4)
Rewan Group	0.002	Estimated K value from other Bowen Basin projects. The Rewan Group is not present in over most of the tenement area but is present in the model area
Coal Seams <80 mbgl	0.37	Geometric mean of slug test data from bores with screened intervals less than 80mbgl
Coal Seams >80 mbgl	0.02	Geometric mean of slug test data from bores with screened intervals greater than 80mbgl
Permian Interburden <80 mbgl	0.01	Value set an order of magnitude higher than the value for interburden below 80 mbgl
Permian Interburden >80 mbgl	0.001	Estimate based on values from slug testing of DW7033W3 (0.002 m/day) and DW7093W2 (recovery rate so slow that the test data could not be analysed)
Mined Spoil	1	Estimate based on professional experience

6.3.2 Volumetric Water Content

6.3.2.1 Specific Yield

Seep/W represents the water content and drainage properties modelled units via a property called volumetric water content, which describes the transition from fully saturated porosity to fully drained porosity. Total porosity comprises specific yield (the volume that will drain from a material under gravity) and specific retention (the volume that will remain within the material following gravity drainage). The specific yield applied to each model unit is shown below in Table 6-2; the specific yield component of the volumetric water content curve is significant for areas close to the open cut void, as previously confined aquifers (such as the Permian coal measures) become unconfined as they drain to the mined void.

Table 6-2: Specific Yield Values used in Model

Lithology	Specific Yield (Sy)
Quaternary Alluvium	0.08 (8%)
Duaringa Formation	0.01 (1%)
Rewan Group	0.01 (1%)
Permian Overburden (weathered)	0.01 (1%)
Permian Overburden (unweathered)	0.01 (1%)
Coal Seams	0.02 (2%)
Permian Interburden	0.01 (1%)
Burngrove Formation and Gyranda Subgroup	0.01 (1%)
Mined Spoil	0.08 (8%)

6.3.2.2 Specific Storage

In Seep/W the specific storage (*Ss*) of the aquifer is accounted for via a related property called the coefficient of volume compressibility (*mv*). In areas where groundwater is draining to the pit void, the

model utilises the specific yield (*Sy*) portion of the volumetric water content curve (as discussed above). With increasing distance from the pit wall the groundwater storage conditions become increasingly confined, Seep/W automatically transitions from unconfined to confined conditions (i.e. from the portion of the volumetric water content curve where pore pressures are at or below atmospheric pressure (and draining to the pit void) to the portion of the curve where pore pressures are positive) using the properties of the Coefficient of Volumetric Compressibility (*mv*). The relationship between the coefficient of volume compressibility (*mv*) and specific storage (*Ss*), can be established from the following equation (Geoslope 2012):

$$S_S = \rho_w g(\alpha + n\beta) = \rho_w g(mv)$$

Where:

Ss	=	Specific Storage
mv	=	Coefficient of volume compressibility
ρw	=	The density of water
g	=	Acceleration due to gravity
α	=	Compressibility of the aquifer skeleton
n	=	The porosity of the aquifer
β	=	Compressibility of water

The value for *mv* generally ranges from 1 x 10^{-6}/ kPa to 1 x 10^{-3}/kPa and for confined aquifers a value of 1 x 10^{-5}/kPa is generally appropriate (Geoslope 2012). An *mv* of 1 x 10^{-5}/kPa has therefore been applied to all groundwater units in the model.

6.4 Representation of Faulting

Faults are represented in the models as follows:

- The site geological model conforms to the solid geology as shown in Figure 2-2. For areas of the model that are beyond the boundaries of the site geological model the solid geology, including fault locations, is consistent with the geology shown on the solid geology map (Figure 2-2).
- Where faults are shown on the sections produced from the site geological model or regional geological data, the location of the faults has been accurately reproduced in the Seep/W models;
- The faults have not been assigned any hydraulic properties, as no quantitative data exists to indicate whether individual faults act as groundwater conduits or as barriers to groundwater flow. Rather, the faults will act as described above, i.e. to allow transmission of groundwater across the fault if more permeable units are connected (such as coal seam to coal seam), and will tend to act as barriers to flow if a conductive unit such as a coal seam is terminated against lower permeability interburden material.

6.5 Boundary Conditions

6.5.1 Recharge

The recharge rate that was applied to the model was based on the recharge calculated via the chloride mass balance (CMB) method, as described above in Section 4.5. The recharge value used was equivalent to 0.1% of average annual rainfall, as an average of the CMB-calculated values for Quaternary sediments of 0.12% of average annual rainfall and the Tertiary sediments of 0.07% of average annual rainfall.

Recharge was applied to transient models as a flux boundary condition applied to the upper layer of the model (representing the ground surface). Rainfall was applied uniformly to the surface formation

(alluvium and Tertiary). Rainfall was not applied to the steady-state model as the starting phreatic surface was generated based on fixed head boundary conditions at the edges of the model.

Rainfall was applied at a rate of 0.678 mm/year, which corresponds to 0.1% of average annual rainfall of 678 mm/year, so that the flux was assigned as:

- 678 mm/year x 0.1% = 0.678 mm/year of recharge = 1.86 x 10^{-6} m/day

6.5.2 Starting Phreatic Surface

The initial phreatic surface was generated in the steady state model by applying fixed heads at the boundaries of the model. The boundaries were set at a distance of approximately 10 km from the edge of mining in order that the boundary conditions did not interfere with the groundwater response to mining, with the boundary conditions set to place the water level within the Tertiary sediments at levels observed from the groundwater monitoring bores for each mining area.

6.5.3 Groundwater Seepage to Voids

Seep/W requires the setting of seepage face review boundary conditions to allow water to leave the model and flow to the mine void. The seepage face boundary a flux boundary with total flux (Q) set at 0 m/day. The area of the mined void is set as a material type with no hydraulic properties; in practice the void is modelled as a zone into which groundwater flow can occur unimpeded through the seepage face boundaries.

6.6 Model Results

6.6.1 Groundwater Level Impacts

The modelled drawdown at the end of mining is shown in Figure 6-7, with the extent of drawdown at post-mining equilibrium (i.e. steady-state post-mining drawdown) shown in Figure 6-8. The contours are shown as the extent of 5 m and 2 m drawdown, based on extrapolation of data points from each of the cross section models (with the location of the data points also shown on Figures 6-7 and 6-8).

These contours have been utilised (refer Section 7.1) to estimate the potential impact on existing groundwater users, based on the definition of bore trigger thresholds for the Queensland *Water Act 2000*. The *Water Act* defines a "bore trigger threshold" (section 362) as *a decline in the water level in the aquifer that is-*

(a) If a regulation prescribes the bore trigger threshold for an area in which the aquifer is situated – the prescribed threshold for the area; or

(b) Otherwise-

i. For a consolidated aquifer – 5 m; or

ii. For an unconsolidated aquifer – 2 m.

The potential for impact on existing groundwater users is discussed in Section 7.1.

The potential for water level impact on environmental values (e.g. groundwater dependent ecosystems) is discussed in Section 7.2.

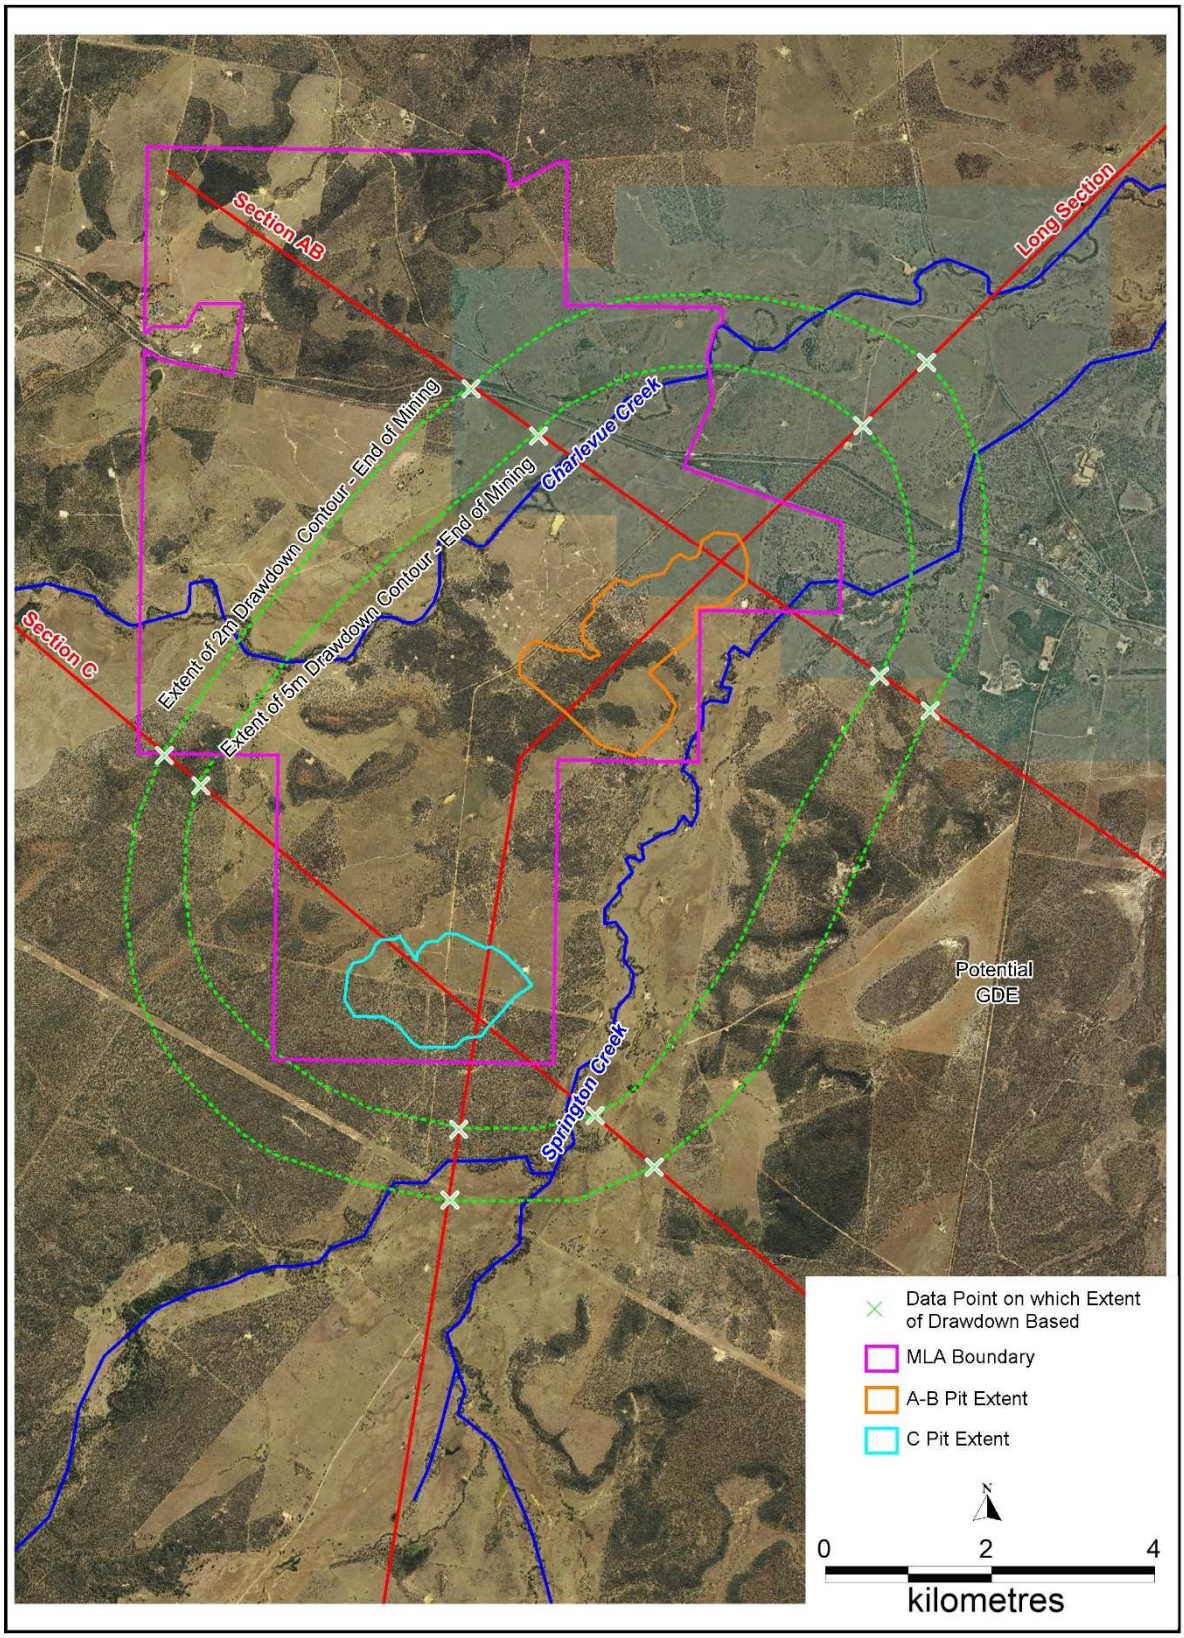

Figure 6-7: Extent of 2 m and 5 m Water Level Drawdown – End of Mining

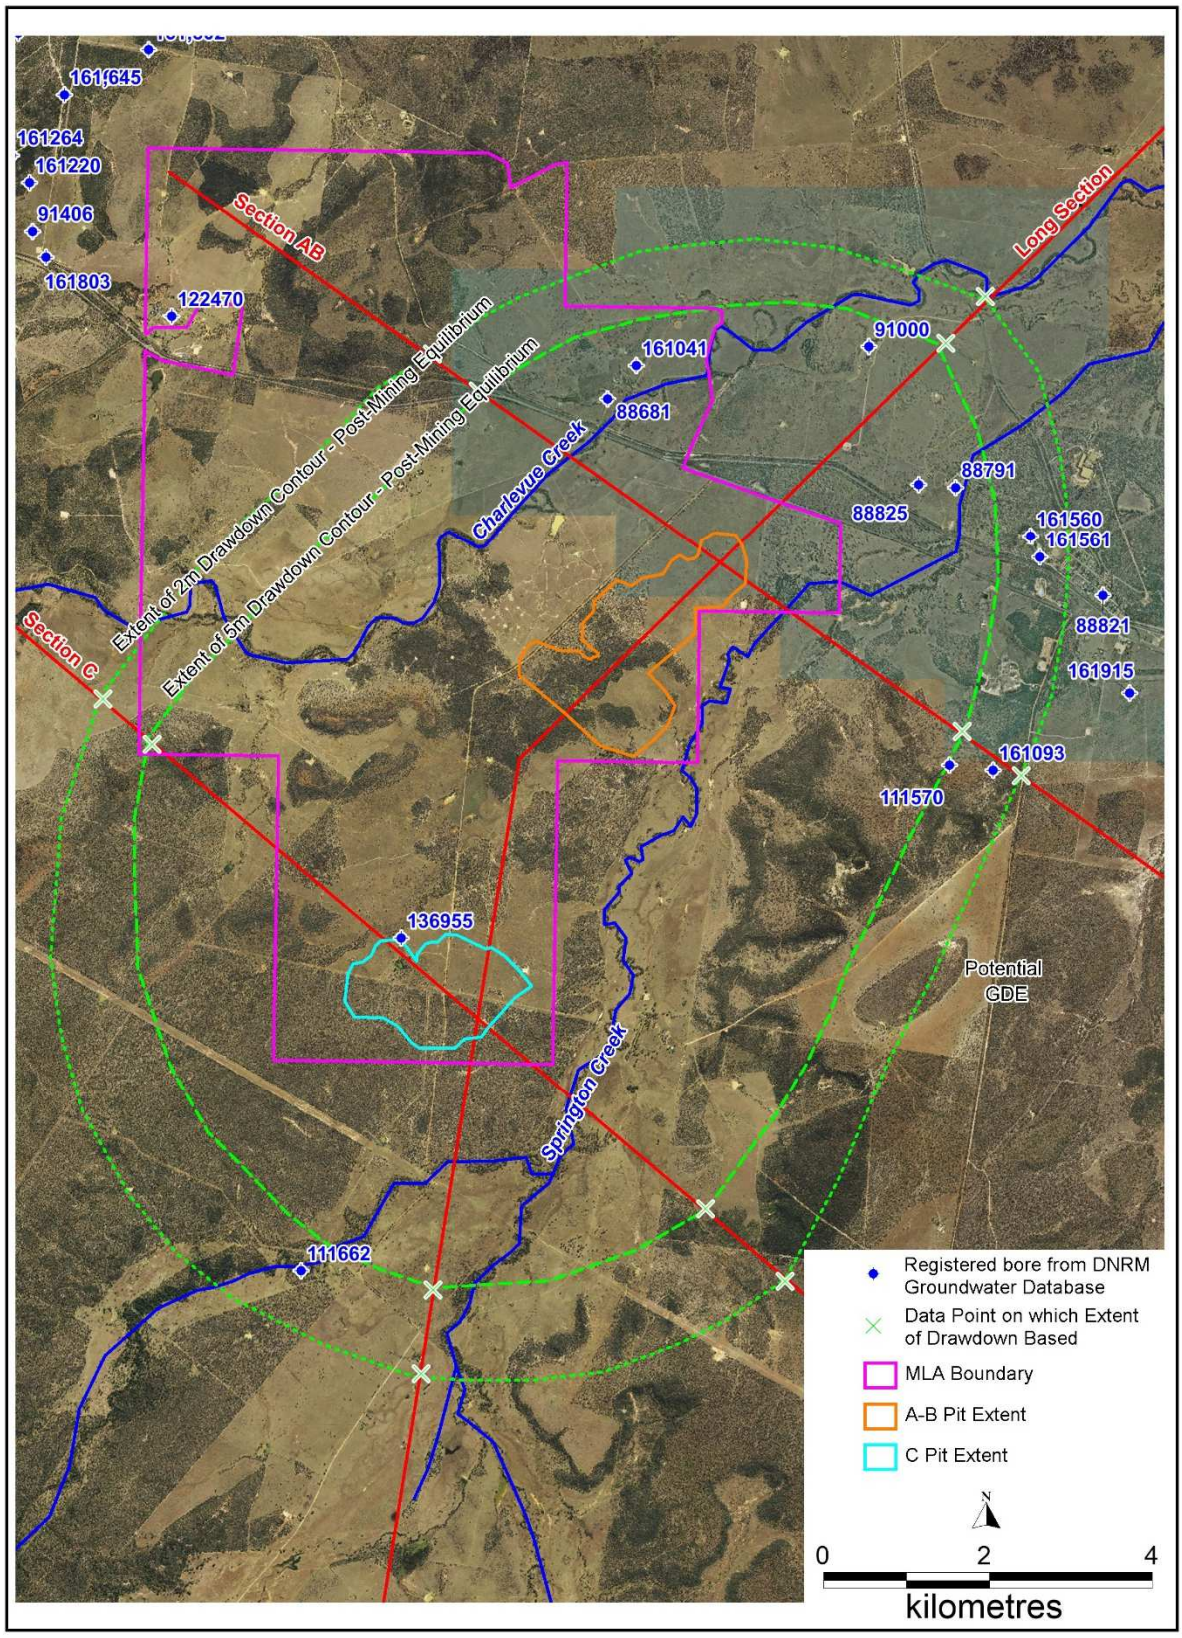

Figure 6-8: Extent of 2 m and 5 m Water Level Drawdown – Post-Mining Equilibrium

6.6.2 Groundwater inflow to the Mined Voids

The rate of groundwater inflow to the mined voids during the operational period of mining has been calculated via the following methodology:

- The seepage rate through the pit walls and floor was calculated within the Seep/W models from the two cross section models (AB Pit Section and C Pit Section) and the long section model for both the AB Pit and C Pit.
- The seepage rate was calculated as the mine development progressed and included the rate of seepage to the mining operation from the backfilled spoil
- The seepage rate, which was calculated on a per-metre basis in the models, was multiplied over the length of pit, using data from the model that was appropriate to each area;
- The modelled inflow rates for each mining year and for each pit are shown below in Table 7-1, in units of both litres per second (L/s) and cubic metres pe day (m^3/day);
- For the purpose of water balance modelling, the effects of evaporation on pit inflows was calculated to provide a value for inflow rates less evaporation (Table 7-1). The evaporation rate was applied using "Morton's estimate of wet environment areal evaporation over land" that was obtained for the project area from the SILO datadrill. This evaporation dataset was used for calculating evaporation from the pit walls and floor, based on advice from the project hydrologist WRM (M Batchelor pers. comm.). Evaporation was applied to the modelled inflow using a pan factor of 0.8 for the surface of the pit, decreasing linearly to a pan factor of 0.5 at the base of the pit (with the lower evaporation at the base of the pit due to shading etc.). The net inflow rate to each pit (modelled inflow less evaporation) is shown in Table 7-1.

Other observations/ notes with respect to the calculated inflow rates are as follows:

- The increase in the modelled and net inflow rate in years 11 and 12 of the AB pit is due to groundwater from the spoil reporting to the final void area. The spoil was modelled as being placed dry (fully-drained but with a residual water content); the groundwater level in the spoil increased over time due to inflow from the floor and walls of the mined area, as this inflow rate was not subject to evaporation. In addition, the rate of recharge to the spoil occurs at a rate that is higher than the natural ground, allowing a water table to develop within the spoil. By mining years 11 and 12 the water level within the spoil had developed to a level that allowed relatively significant rates of inflow to occur.
- For the purpose of future associated water reporting it is concluded that it would be more reasonable to assume the rate of inflow prior to development of the spoil aquifer (i.e. ~5.7 L/s or ~500 m^3/day) as the water that is developed from the spoil is derived mainly from rainfall recharge to the spoil and does not represent water from the natural formation.
- The modelled inflow rate and net inflow rate (less evaporation) reduces significantly in mining years 17 and 18 for the AB Pit and at mining year 18 for the C Pit. This is due to the partial backfilling of the final void area with spoil.
- For the post-mining years the net groundwater inflow rate is zero, as the rate of inflow from the pit walls above the backfilled area of spoil and the final void lake occurs at such a low rate that the rate of evaporation is significantly greater than the modelled rate of inflow.

Table 6-3: Calculated Rates of Inflow to the AB Pit and C Pit

Year	AB Pit				C Pit			
	Modelled Inflow Rate		Less Evaporation		Modelled Inflow Rate		Less Evaporation

6.7 Uncertainty Analysis

6.7.1 Introduction

A sensitivity analysis of the groundwater model developed for the Gemini Project has been undertaken with reference to the following documents:

- Barnett et al. (2012) *Australian Groundwater Modelling Guidelines*. Sinclair Knight Merz and National Centre for Groundwater Research and Training, Waterline Report Series No. 82, June 2012; and,
- Middlemis, H. & Peeters, L.J.M. (2018) *Explanatory Note, Uncertainty Analysis in Groundwater Modelling*. Report prepared for the Independent Expert Scientific Committee on Coal Seam Gas and Large Coal Mining Development through the Department of the Environment and Energy (Draft).
- Reilly, T.E. & Harbaugh, A.W. (2004) *Guidelines for Evaluation of Groundwater Flow Models.* United States Geological Survey, Scientific Investigations Report 2004-5038.

A groundwater model sensitivity analysis involves the evaluation of model input parameters to see how much they affect model outputs, which are heads and flows (Reilly & Harbaugh 2004). The process of sensitivity analysis can be conducted manually or automatically; in the manual approach, multiple model simulations are made in which ideally a single parameter is adjusted by an arbitrary amount (Reilly & Harbaugh 2004). The emphasis of sensitivity modelling is on determining how sensitive the model is to each parameter tested, using a non-technical interpretation of “sensitive” (Barnett et al. 2012).

The explanatory notes for uncertainty analysis that were prepared for the IESC (Middlemis & Peeters 2018) outline three general approaches to uncertainty analysis; these are, in order of increasing complexity:

1. Scenario analysis with subjective probability;
2. Deterministic modelling with linear probability quantification; and,
3. Stochastic modelling with Bayesian probability.

The first method (scenario analysis with subjective probability) has been applied to this modelling study. This methodology is judged to be appropriate to the analysis of a Seep/W model, which utilises a single set of parameters for each material type. A sensitivity analysis of the Gemini Project model was undertaken as follows:

- The base-case models were used to establish the extent of 5 m drawdown from the edge of the final voids to the north, south, east and west of the mining area. The location of the section models, as well as detail from the models pre and post-mining, are shown in Figures 3-1 and 3-2. The sections highlight the relationship between the various groundwater units, including the degree to which faulting and folding compartmentalises the units (as shown from Figures 6-1 to 6-6, which show detail of the cross section models in the area of mining);
- The base-case model was altered to make changes to specific parameters (discussed below) and to assess the impact that the change in parameters had on the location of the extent of the 5 m drawdown contour at the post-mining equilibrium.
- The parameters that were selected for the sensitivity analysis are summarised below in Table 6-4 and include:
    - Horizontal hydraulic conductivity (Kh;
    - Vertical hydraulic conductivity (Kz);
    - Specific yield (Sy) and coefficient of volume compressibility (*mv*) (which is related to the aquifer specific storage (Ss), as described in Section 6.3.2.2); and,
    - Recharge.

6.7.2 Results

The results of the sensitivity analysis are discussed below and are presented in Table 6-4 and on Figure 6-8, which shows the extent of the 5 m post-mining equilibrium drawdown contour for each uncertainty analysis parameter. Results are summarised as follows:

- The model is assessed to be most sensitive to changes in horizontal hydraulic conductivity (Kh) and recharge, with results as follows;
    - An increase in the Kh of the Permian coal measures (coal seams and interburden) by a factor of 10 results in an increase in the extent of the 5 m drawdown contour at post-mining equilibrium years post-mining of between 800 m (to the east of C Pit) and 2,000 m (to the south of C Pit), as shown on Figure 6-8. The variability in the extent of the 5 m drawdown contour is related to dominant rock type in each direction and the variability in faulting, folding and dip direction of the coal measures. The drawdown contours also extend further to the north/south than to the east/west. This is interpreted to be related to:
        - The more continuous extension of coal seams along geological strike, as the coal seams have a higher permeability than the interburden and are the main conduits for groundwater flow within the coal measures; and,

        - The steep dip of the coal seams to the east and west, as a component of the drawdown will be acting in a direction that includes a combination of the Kh and the lower hydraulic conductivity Kz of the unit.

    - An increase in the recharge by a factor of 10, from 0.1% of average annual rainfall to 1% of average annual rainfall, results in a reduction in the extent of drawdown of between -550 m (to the west of Pit C) and -1,300 m (to the east of Pit C). The variability in the impact of the change in recharge is interpreted to be related to factors such as the thickness of Tertiary sediments and the weathered Permian sediments, in conjunction with the factors such as folding and faulting that also impact the other parameters tested.

- The model is relatively sensitive to changes in vertical hydraulic conductivity (Kz); an increase in the Kz of the Permian coal measures (interburden and coal seams) by a factor of 10 results in an increase in the extent of 5 m drawdown of between approximately 100 m (to the west of C Pit) to 670 m (to the south of C Pit);
- An increase in the storage properties (specific yield (Sy) by a factor of 2 and coefficient of volume compressibility (*mv*) by a factor of 10) results in a decrease in the extent of the 5 m drawdown contour relative to the base case of between -330 m (to the north of AB Pit) and -1,200 m (to the east of C Pit).

  Because the specific yield component of storage only acts locally (i.e. close to the walls of the open cut), the main impact on drawdown is related to the change in the coefficient of volume compressibility (*mv*). A lower value for *mv* (and hence *Ss*) indicates a geotechnically stiffer (less compressible) aquifer; by contrast an increase in the aquifer *mv* (and hence *Ss*), as undertaken in the uncertainty analysis, will result in a more compressible aquifer, which in turn will act to decrease the extent of drawdown.

Table 6-4: Results of Uncertainty Analysis

Scenario	Description	Base Case	Sensitivity Model	Change (m) in extent of 5 m drawdown contour*	
Long Section Model through AB Pit and C Pits				**North of AB Pit**	**South of C Pit**
1	Increase Kh of Permian Interburden <80 mbgl x 10	0.01 m/day	0.1 m/day	1,800	2,000
	Increase Kh of Coal Seams < 80 mbgl x 10	0.37 m/day	3.7 m/day		
	Increase Kh of Permian Interburden >80 mbgl x 10	0.001 m/day	0.01 m/day		
	Increase Kh of Coal Seams >80 mbgl x 10	0.02 m/day	0.2 m/day		
2	Increase Kz of Permian Interburden <80 mbgl x 10	0.001 m/day	0.01 m/day	450	670
	Increase Kz of Coal Seams < 80 mbgl x 10	0.037 m/day	0.37 m/day		
	Increase Kz of Permian Interburden >80 mbgl x 10	0.0001 m/day	0.001 m/day		
	Increase Kz of Coal Seams >80 mbgl x 10	0.002 m/day	0.02 m/day		
3	Increase specific yield (*Sy*) of Permian Interburden x 2	0.02 (2%)	0.04 (4%)	-330	-430
	Increase specific yield (*Sy*) of coal seams x 2	0.01 (1%)	0.02 (2%)		
	Increase storage coefficient (*Ss*) of Permian coal seams and Interburden x 10	1×10^{-5}	1×10^{-4}		
4	Increase Recharge x 10	0.1% of rainfall	1% of rainfall	-650	-1200
AB Pit Cross Section Model				**West of AB Pit**	**East of AB Pit**
1	Increase Kh as described above	As above	As above	1,000	1,200
2	Increase Kz as described above	As above	As above	350	440
3	Increase Sy and Ss as described above	As above	As above	-930	-700
4	Increase recharge as described above	As above	As above	-1,400	-1,200
C Pit Cross Section Model				**West of C Pit**	**East of C Pit**
1	Increase Kh as described above	As above	As above	900	800
2	Increase Kz as described above	As above	As above	100	210
3	Increase Sy and Ss as described above	As above	As above	-800	-1200
4	Increase recharge as described above	As above	As above	-550	-1,300

* A positive value indicates an increase in the extent of drawdown, a negative value indicates a decrease in the extent of drawdown

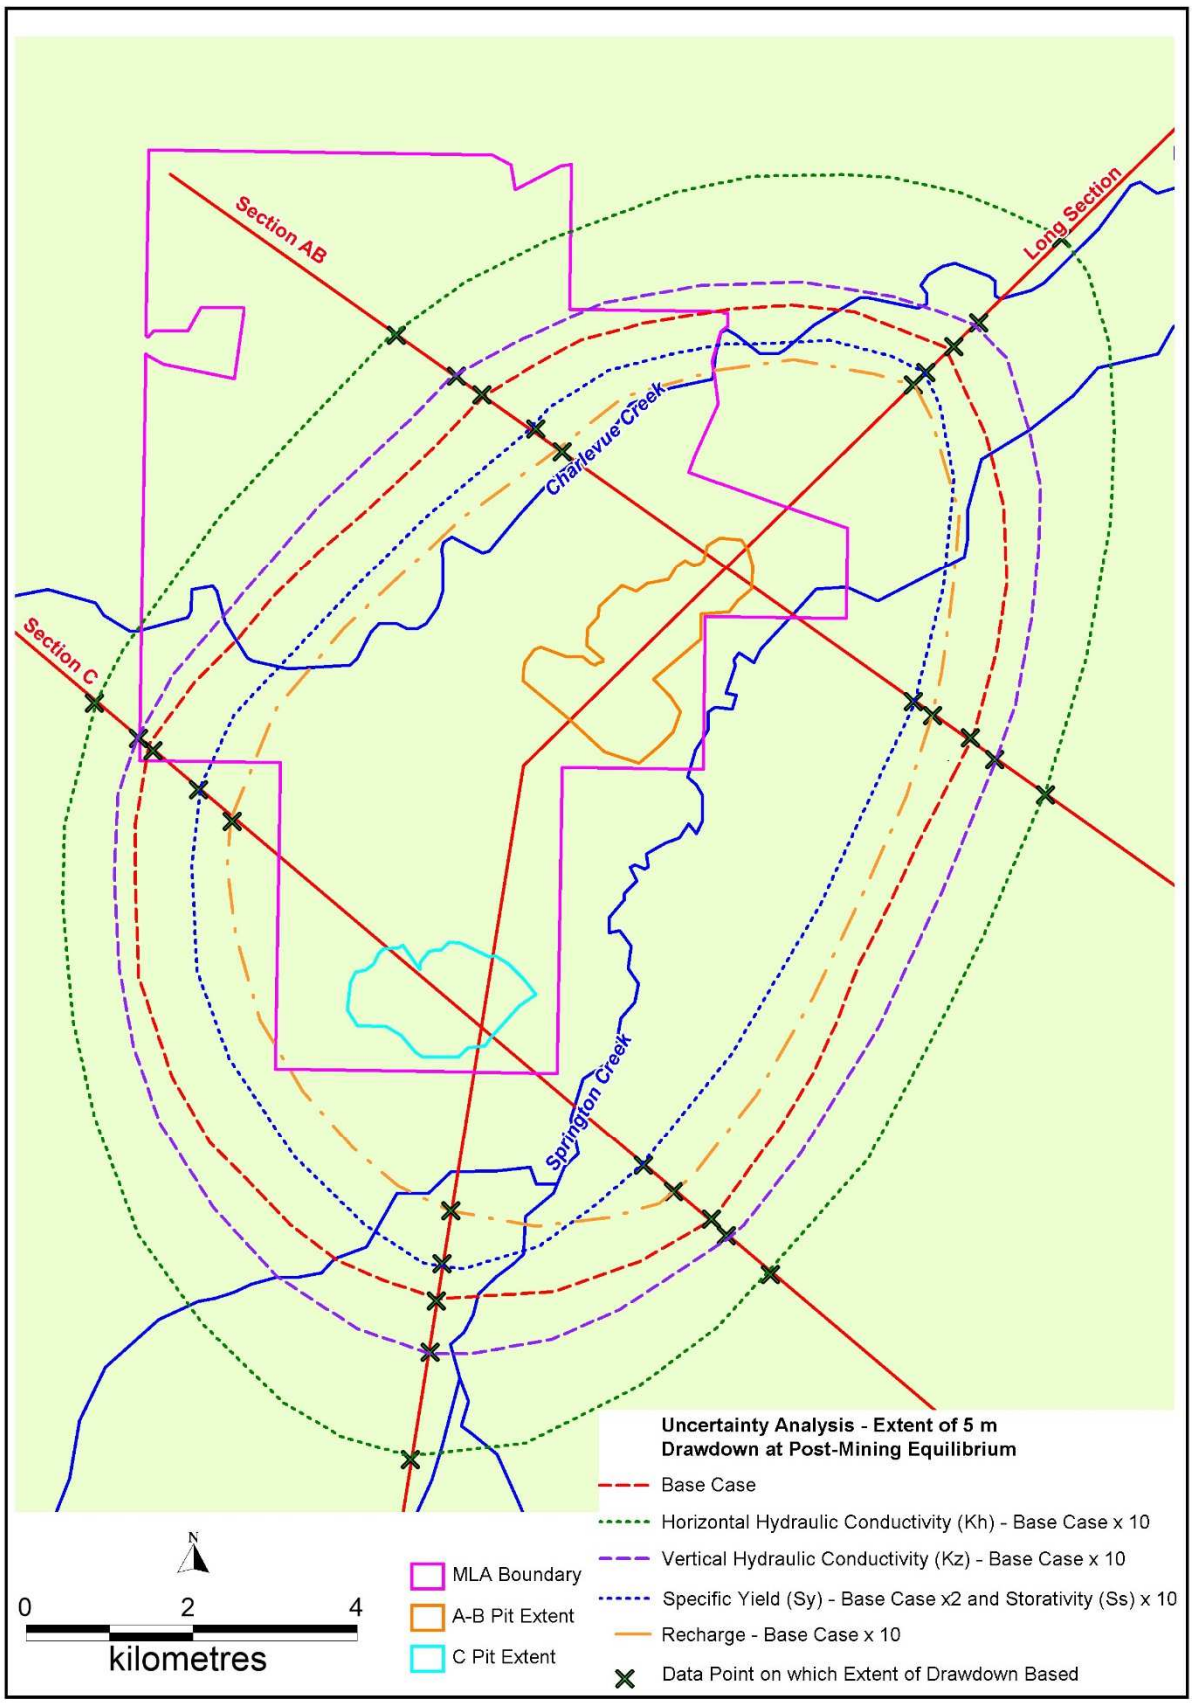

Figure 6-9: Uncertainty Analysis

7.0 GROUNDWATER IMPACTS FROM MINING

7.1 Impacts on Existing Groundwater Users

Figures 6-7 and 6-8 show the location of eleven (11) registered groundwater bores (bores from the DNRM groundwater database that are listed as being either existing or abandoned but useable) within the 2 m drawdown zone at end of mining (Figure 6-7) and/or at post-mining equilibrium (Figure 6-8). Summary data for the bores within this zone are shown below in Table 7-1. In summary:

- Bores 136955 and 11662 are located on land that is owned by Magnetic South (the proponent for the Gemini project);
- Two bores (161560 and 161561) appear to be monitoring bores for the Dingo Landfill;
- A number of bores record groundwater that is highly saline and assessed to be of no beneficial use (as discussed in Section 4.3, an EC of 6,000 µS/cm is assessed to be the upper limit of salinity tolerance for beef cattle, sheep, horses and pigs with no loss of production (ANZECC 2000), with a decline in animal health at progressively higher salinity values. Bores 88681, 88791 and 91000 record EC values of 10,000 µS/cm, 19,200 µS/cm and 14,660 µS/cm respectively, and on this basis are assessed to have little to no beneficial use);
- Bores that remain in the area of potential impact (i.e. that are not discussed in the above dot points) include:
    - Bores 88825 and 161041, which are sites with relatively little available data, but which are located within the zone of potential impact to the northeast and west-northwest of AB Pit respectively;
    - Bores 111570 and 161093 also record relatively fresh groundwater (<1,000 µS/cm) at shallow depth. While these bores are located within the extent of 2 m drawdown, these bores are also assessed to be isolated from the regional groundwater system (refer discussion in Section 7.2.1 below)

At sites including 111570 and 161093 it is noted that the sites are not located within the zone of potential impact at end of mining, but are within the zone of potential impact at post-mining equilibrium.

Notwithstanding the time that it may take for drawdown impacts to be observed at the private groundwater bores listed in Table 7-1, it is recommended that a bore survey be undertaken on the potentially impacted properties (as defined by the extent of 2 m drawdown contour on Figure 6-8).

It is further noted that make-good agreements may be required for groundwater bores within the zone of potential impact in the event that groundwater level drawdown affects the utility of the bores.

Table 7-1: Bores from DNRM Groundwater Database within 2m Drawdown Zone

RN	Aquifer	EC (µS/cm)	SWL (mbgl)	Original Bore Name	Comment
88681	Duaringa Formation	10000			Located within MLA - land owned by Magnetic South
88791	Duaringa Formation	19200	-20	New Bore	Extremely saline - no beneficial use based on water quality
88825	Unknown			Windmill	
91000	Duaringa Formation	14660	-20	Mackenzie OLO	Extremely saline - no beneficial use based on water quality
111570	Tertiary-Undefined	240	-16	Ward	Refer Section 7.2.1 for discussion
111662	Tertiary-Undefined	750	-17	Smith	Located within land owned by Magnetic South
136955	Tertiary-Undefined	10300	-21		Located within MLA - land owned by Magnetic South
161041	Duaringa Formation		-29		
161093	Tertiary Mafic Volcanics	710	-19.5		Refer Section 7.2.1 for discussion
161560	Unknown	28102		Dingo Landfill MW2	Assumed to be monitoring bore at Dingo Landfill
161561	Unknown			Dingo Landfill MW1	Assumed to be monitoring bore at Dingo Landfill

7.2 Groundwater Dependant Ecosystems

7.2.1 Area of Mapped Potential GDE to East of MLA

A potential groundwater dependant ecosystem (GDE) has been mapped to the east of the MLA and is shown below in Figure 7-1. The following observations and comments are made with respect to the potential GDE:

- The top plot on Figure 7-1 shows the potential GDE from an aerial photograph as an ovaloid feature with an area of approximately 82 ha that is located approximately 4 km east of the MLA boundary.
- The bottom plot on Figure 7-1 shows the potential GDE underlain by contours of surface topography and includes water level data from available groundwater bores. From this plot it is noted that:
  - The surface elevation of the eastern area of the MLA is in the range 125 to 135 mAHD, with the elevation of the Springton Creek floodplain dropping below 120 mAHD in the area between the MLA boundary and the potential GDE;
  - The potential GDE is located on an elevated ridgeline; the feature is located within a shallow depression on the ridgeline that is surrounded to the south, west and east by elevation contours at 170 mAHD, with the central of the depression falling below 165 mAHD. This area drains to the northeast via a narrow zone that is at a surface elevation of approximately 167 mAHD.
- The potential GDE is therefore located within a shallow depression on the ridgeline that is likely to be internally draining under average rainfall conditions and that only discharges to the northeast under high rainfall conditions. It is interpreted that, under average rainfall conditions and at the tail end of high rainfall conditions, surface runoff within the relatively small catchment that reports to this area will pond in the area of the shallow depression and provide localised recharge to an

underlying groundwater lens that is likely to be disconnected from the regional groundwater system (discussed further below).

- The bottom plot on Figure shows available groundwater level data from site monitoring bores (water levels from July/August 2019 – refer Table 4-1) as well as from two registered groundwater bores from the DNRM groundwater database). The date of the groundwater measurement for the two registered bores is likely to be from the time of drilling/construction; bore 111570 was constructed in November 2001 and bore 161093 was constructed in August 2014 (refer Table 4-5 of this report). From the water level data shown on Figure 7-1 it is observed that:
  - The depth to water for bores constructed within Tertiary sediments and Permian coal measures ranges from 26.25 to 32.37 mbgl in this area (Figure 7-1 shows data for the shallowest bore in this area; the Tertiary bore at the location of DW7105W2 is dry). Based on the elevation at these sites, this equates to a groundwater elevation of 108-110 mAHD for bores in topographically elevated areas (DW7093W1 and DW7225W1) to 89.59 mAHD at bore DW7282W1 (located in a topographically lower area of the MLA adjacent to Springton Creek).
  - The water level in alluvium bore DW7292W1 is 11.19 mbgl, which equates to an elevation of 102.39 mAHD;
  - The water level in the site monitoring bores, which are assessed to be representative of the regional groundwater level, are therefore considerably lower than the elevation of the base of the potential GDE, which is at an elevation approximately 165 mAHD;
- The water level in the two private bores to the north of the potential GDE (16 mbgl at 111570 and 19.5 mbgl at 161093) equates to a groundwater elevation of 132 to 144 mAHD at these sites.
- Based on the observations discussed above, it is concluded that:
  - The potential GDE is located on an elevated ridgeline, but within a shallow depression that is likely to drain internally under average rainfall conditions but drains to the northeast under high rainfall conditions;
  - The drainage of surface runoff to the shallow depression is likely to result in localised recharge to a perched lens of groundwater that is disconnected from the regional groundwater system;
  - It is probable that this perched groundwater lens provides water to vegetation within the depression during the dry season, but that the groundwater lens is an extremely localised system that relies on replenishment by seasonal rainfall rather than being maintained by the regional groundwater system
- It is noted the EC of site groundwater monitoring bores, which are interpreted to be within the regional groundwater system, is high (15,000 µS/cm to 29,000 µS/cm – refer Section 4.3). However it is also noted that the EC of the registered bores to the north of the potential GDE is very low, with bore 111570 recording an EC of 240 µS/cm and bore 161093 recording an EC of 710 µS/cm. This is interpreted to provide further evidence that the groundwater system in this area is perched above the regional groundwater system, with the flowline from the area of the potential GDE (where recharge is interpreted to occur) to the area where these bores are located being very short.
- From the groundwater modelling data presented in Section 6.7.2 and Figure 6-8, it is noted that the 2 m drawdown contour at post-mining equilibrium extends under the area where the potential GDE is located. It is interpreted that the risk posed by drawdown from the mining operation to the potential GDE is very low, as:
  - It is interpreted that the potential GDE exists in an area where the groundwater system is very localised and is perched above the regional groundwater system; and,

  - The groundwater lens that is interpreted to be located beneath the potential GDE is likely to be maintained by seasonal surface water runoff rather than the regional groundwater system.

- It is noted that, based on the evidence available to date, it cannot be conclusively stated that the groundwater system is not continuously saturated from the area below the potential GDE (at RL165 mAHD to the regional groundwater system (at an elevation of 110 to 89 mAHD). However, based on professional experience and judgement, it is considered that:
  - It is most probable that the ridgeline and the potential GDE is underlain by a perched groundwater system and,
- In any case it is interpreted that the potential GDE is maintained by localised runoff and shallow recharge and that a reduction in the regional groundwater level of approximately 2 m, at a vertical distance of approximately 50 to 60 m below the base of the potential GDE, has a very low risk of impacting groundwater levels beneath the potential GDE.

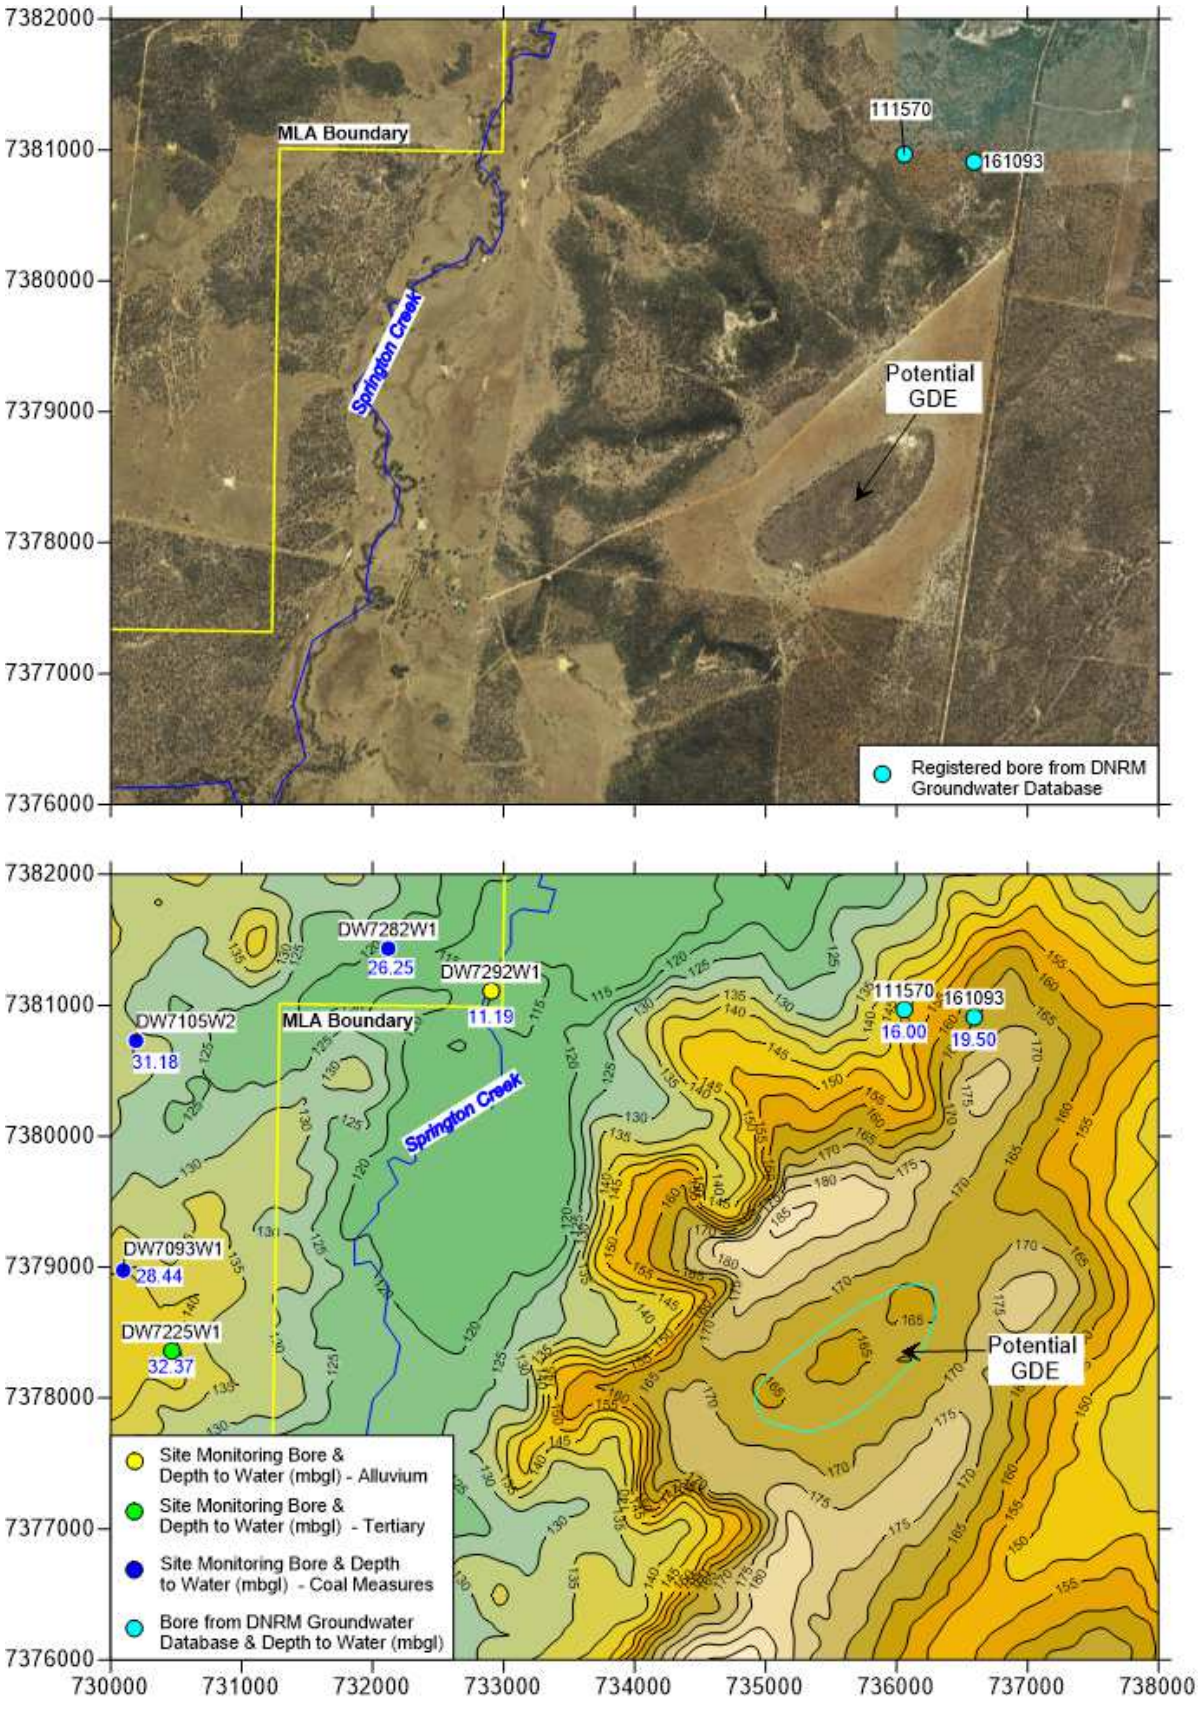

Figure 7-1: Assessment of Potential GDE to East of the Gemini Project MLA

7.2.2 GDE's Associated with Watercourses and Floodplains

A number of potential GDE's in the Project area are riverine-type wetlands that include riparian vegetation on watercourses and floodplains. It is understood from the ecological assessment (reference) that the riverine vegetation includes tree species such as blue gum (*Eucalyptus tereticornis*) and River oak (*Casuarina cunninghamiana*). With respect to the potential for the mining operation to impact this type of potential GDE the following observations are made:

- The water level drawdown associated with mining is predicted to be in excess of 5 m at some locations below both Charlevue Creek and Springton Creek (Section 6.6.1, Figures 6-7 and 6-8). It cannot be ruled out that drawdown from mining may affect water levels in the alluvium at some locations.
- This section therefore considers the potential for vegetation within the Project area to be currently dependent on groundwater, either totally or partially, which will then inform the risk to vegetation in the event that groundwater level drawdown from mining does impact groundwater levels within the alluvium.
- The assessment of current dependence of vegetation on groundwater considers both groundwater level and groundwater quality; these considerations are summarised as follows:
  - Groundwater level considerations:
    - It is understood from the ecological assessment (reference) that blue gum has a rooting depth of up to 10 m.
    - The measured depth to groundwater in the alluvium bores close to the creeks is between 8.77 m (DW7076W, adjacent to Charlevue Creek) and 11.19 m (bore DW7292W1, adjacent to Springton Creek). It is noted that the groundwater level is likely to be somewhat closer to ground surface at the invert (i.e. central line) of the creeks than in the bores, which are constructed outside the main creek channel.
    - Therefore, while the groundwater level is assessed as being close to the maximum depth that could be accessible by vegetation, it cannot be conclusively ruled out that the groundwater level is beyond the depth that is accessible to the root zone of some plants.
    - In addition, the seasonal range of water level within the alluvium is currently unknown. However, it is noted that bore DW7076W (adjacent to Charlevue Creek) is currently fitted with a datalogger (refer Section 4.2 and Figure 4-4) and that bore DW7292W1 (adjacent to Springton Creek) is programmed to be fitted with a datalogger; this data will allow assessment of the range of water level within the alluvium and the response of groundwater levels within the alluvium to rainfall recharge and stream flow events.
  - Groundwater quality considerations
    - As noted above, the riverine vegetation includes tree species such as blue gum (*Eucalyptus tereticornis*) and River oak (*Casuarina cunninghamiana*). With reference to available online information[1] it is noted that the species listed above are described as being tolerant of moderately saline conditions, which are defined[1] as being in the range of 4,000 to 8,000 µS/cm;
    - The measured EC of groundwater within the alluvium is relatively high, with a range from 15,200 µS/cm to 16,600 µS/cm for bore DW7076W (adjacent to Charlevue Creek) and a single field value for bore DW7292W1 of 5,948 µS/cm (adjacent to Springton Creek).

[1] http://www.plantstress.com/articles/salinity_m/salinity_m_files/salt%20tol%20australia.htm

- It is therefore assessed that, based on available EC data, the groundwater within the Charlevue Creek alluvium is too saline to be useable by the vegetation that occurs along the creek.
- The EC at bore DW7292W1 is within the range that is potentially useable by moderately salt-tolerant plants, but it is also noted that the depth to groundwater in that area (11.19 mbgl) is potentially beyond the depth that is accessible by vegetation.

Figure 7-2 (below) shows two photos that were taken at the time of airlift development of bore DW7076W, which is constructed within alluvium adjacent to Charlevue Creek. With reference to the photos in Figure 7-2 and the information outlined above, it is observed that:

- The photo on the left of Figure 7-2 shows bore DW7076W, with the trees in the background located within the or adjacent to the channel of Charlevue Creek;
- The photo on the right of Figure 7-2 shows vegetation within the channel of Charlevue Creek;
- Noting that the EC of groundwater in the Charlevue Creek alluvium at bore DW7076W is within the range of 15,200 µS/cm to 16,600 µS/cm, it is concluded that the groundwater at this site is too saline for use by the vegetation within the creek;
- However, the vegetation within and adjacent to Charlevue Creek appears healthy; on this basis it could be concluded that the vegetation is likely to subsist on water that becomes available following wet-season flow events in Charlevue Creek, and the soil moisture and/or perched groundwater that may exist for some time after flow events in the creek, rather than on the water table that exists at greater depth where the water is highly saline.

Figure 7-2: Alluvium Bore DW7076W and Charlevue Creek adjacent to Bore

On the basis of the above assessment, it is concluded that:

- Groundwater level drawdown from the proposed mining operation will extend beneath Charlevue Creek and Springton Creek and it cannot be ruled out that drawdown from mining may affect water levels in the alluvium at some locations.

- The riparian vegetation at site (within both Charlevue Creek and Springton Creek) is likely to subsist on water that becomes available following wet-season flow events in the creeks, and on the soil moisture and/or perched groundwater that may exist for some time after flow events in the creek, rather than on the water table that exists at greater depth (in the range of 9 to 11 m, based on available data) where the water is moderately to highly saline (and in the case of data for the Charlevue Creek alluvium, too saline to be tolerated by the vegetation species that line the creek);
- Therefore, even if mining does impact on groundwater levels within the alluvium, the risk of impacts to existing riparian vegetation is assessed to be very low, as it is assessed that it is unlikely that the vegetation is dependent on groundwater for survival.

Notwithstanding the above assessment, ongoing monitoring of groundwater levels is recommended, with a recommendation that bores within the alluvium are monitored via water level dataloggers to allow assessment of the range of seasonal water level variation at these sites. It is noted that a data logger is already fitted to bore DW7076W and that it is planned to install a logger in bore DW7292W1

7.3 Cumulative Impacts

There are no mining operations within the zone of predicted drawdown from mining at the Gemini Project site; it is therefore concluded that there are no cumulative impacts to assess.

7.4 Impacts on Groundwater Quality

Groundwater modelling (Section 6.0) predicts that a permanent cone of depression will develop that will direct groundwater flow towards the final voids; therefore, the risk of the project impacting on water quality (via outflow to the groundwater system) is assessed to be low.

It is, however, assessed that the Project could impact groundwater quality if the water within the final void were able to exit the void via unconsolidated sediments (i.e. the base of Tertiary) and flow via the groundwater system towards sensitive environmental receptors such as Springton Creek. For this reason, an assessment of the potential for water within the final voids to exit the void via the base of Tertiary sediments has been undertaken as follows:

- Contours for the base of Tertiary sediments was obtained for the area of the AB Pit and C Pit from the site geological model;
- The final void water level was obtained for each of the final voids from the WRM surface water assessment report (WRM 2019) and was assessed for:
  - The maximum final void water level for the Base Case; and,
  - The maximum final void water level for the High Inflow Case.
- The data for each mining area was assessed to establish whether any pathways existed for water to exit the final void via the base of Tertiary sediments, for the maximum Base Case and maximum High Inflow Case final void water levels.

The results of the assessment are summarised as follows:

- Assessment of the AB Pit:
  - Figure 7-3 shows the base of Tertiary contours for the area around the AB Pit and includes:
    - The limit of mining within the AB Pit;
    - The location of the final void;
    - The area of the final void that is within the area of inundation at the maximum water level for the High Inflow Case of 64.7 mAHD;

- The location of the closest environmental receptor (Springton Creek), which occurs to the east of the AB Pit.

- From the assessment it is concluded that:
  - The lowest level for the base of Tertiary adjacent to the AB Pit mining area and final void area is approximately 70.5 mAHD (as shown on Figure 7-3);
  - The base of Tertiary is therefore approximately 6 m higher than the maximum water level for the High Inflow Case;
  - There is no outlet for water within the final void of the AB Pit via the base of Tertiary sediments

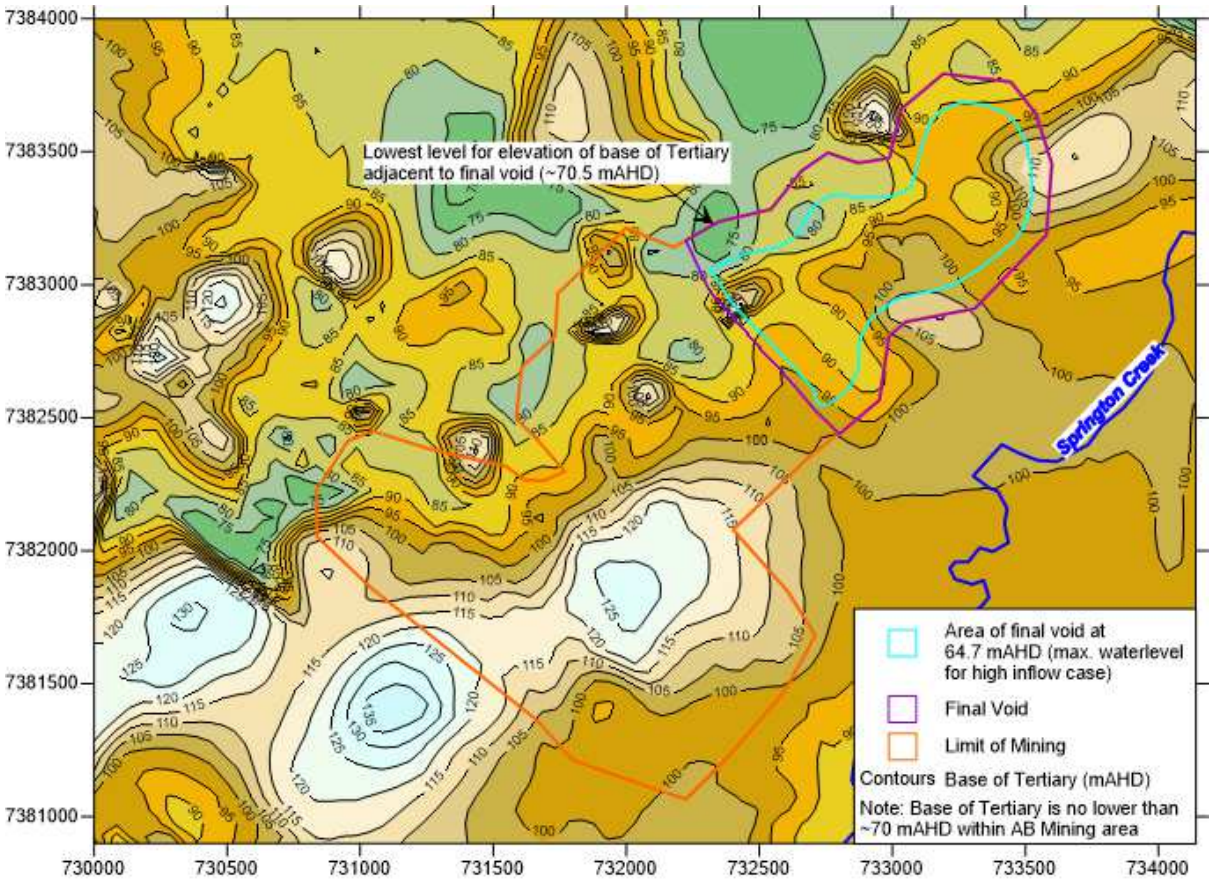

Figure 7-3: Base of Tertiary Contours and AB Pit Final Void Water Levels

- Assessment of the C Pit:
  - Figure 7-4 shows the base of Tertiary contours for the area around the C Pit and includes:
    - The limit of mining within the C Pit;
    - The location of the final void;
    - The area of the final void that is within the area of inundation at the maximum water level for the High Inflow Case of 80.0 mAHD;
    - The contour line for the base of Tertiary at the Base Case maximum water level of 73.6 mAHD;
    - The contour line for the base of Tertiary at the High Inflow Case maximum water level of 80.0 mAHD

- The location of the closest environmental receptor (Springton Creek), which occurs to the east of the C Pit.

- From the assessment it is concluded that:
  - The areas where the base of Tertiary is at or below the Base Case or High Inflow Case water levels in within the final void area, i.e. an area that will be removed by mining;
  - The lowest level for the base of Tertiary adjacent to the C Pit mining area and final void area is approximately 82.5 mAHD (as shown on Figure 7-4), which is approximately 2.5 m above the maximum water level for the High Inflow Case;
  - The elevation of the base of Tertiary increases away from the area described above to an elevation of approximately 88.5 mAHD, before the elevation of base of Tertiary reduces again towards Springton Creek
  - Therefore, there is no outlet for water within the final void of the C Pit via the base of Tertiary sediments

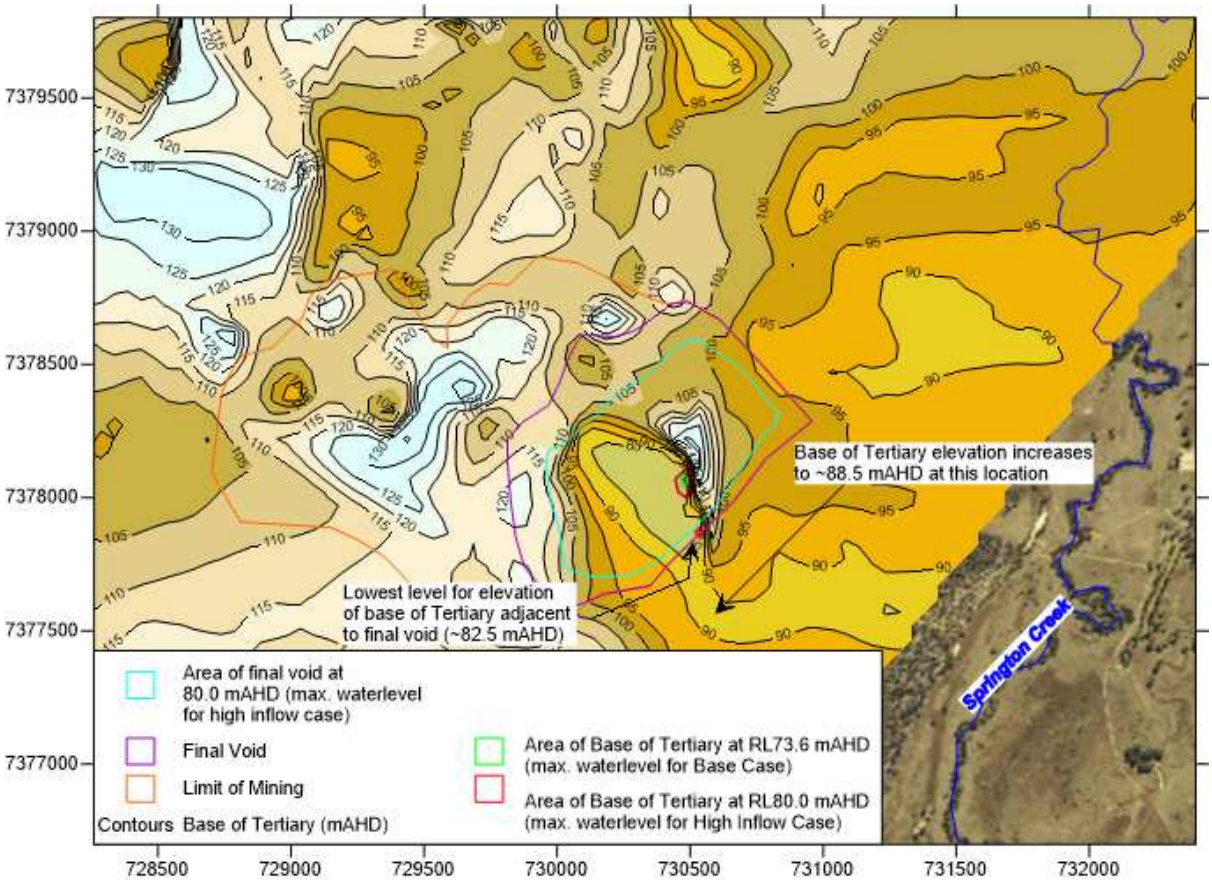

Figure 7-4: Base of Tertiary Contours and C Pit Final Void Water Levels

Based on the assessment undertaken above it is concluded that there is a very low risk of water within the final voids of the AB and C Pits impacting the surrounding groundwater system

.

8.0 SUMMARY AND CONCUSIONS

8.1 Review of Project and Site Data

- The Gemini Project proposes to mine coal from the Aries, Castor and Pollux coal seams of the Rangal Coal Measures, at depths of up to 185 mbgl;
- The mined voids will be progressively backfilled with waste rock (spoil) and the final voids will be backfilled with spoil to approximately 80 mbgl; this backfilling is being undertaken to reduce groundwater seepage to the final void and to limit the impact of mining on groundwater levels;
- Groundwater occurs within three main groundwater units at site, including:
  - Quaternary alluvium associated with Charlevue Creek and Springton Creek
  - Tertiary sediments of the Duaringa Formation; and,
  - The Permian Rangal Coal Measures, where groundwater occurs preferentially within the coal seams
- The site is heavily faulted and the faults may act to influence groundwater occurrence and movement as follows:
  - Shear zones associated with faulting may act as a store of water and as locally higher hydraulic conductivity zones. As discussed below, recharge to the groundwater system is assessed to be low; therefore the faults may provide initial relatively high inflow rates to the workings (in the order of several L/s), but the total storage within the faults is anticipated to be relatively low, with the initial rates of inflow not able to be sustained in the long-term; and,
  - Where the faults completely disrupt the coal seams, especially for cases where the coal seam terminates against lower-hydraulic conductivity interburden, the faults will act to disrupt groundwater flow.
- Available hydraulic conductivity and air-lift yield data indicates that there is notable reduction in hydraulic conductivity and bore yield for bores that are deeper than 80 mbgl compared to bores that are shallower than 80 mbgl.
- Groundwater level data at site are summarised as:
  - The water level within the alluvium ranges from 8.77 to 11.19 m below ground level for bores adjacent to the creek channels;
  - The water level with the Tertiary sediments ranges from dry (5 bores, ranging in depth from 14 to 23 m) to 15.38-44.74 mbgl (where water is present). The presence of water within the Tertiary sediments is related to the RL of the base of Tertiary and from review of available data it is assessed that it is probable that the Tertiary sediments are dry above 120 mAHD and likely dry above 110 mAHD; and,
  - The water level in the coal measures ranges from 16.91 to 46.62 mbgl for bore depths of between 38.4 and 136.7 m, with one bore dry at a depth of 31.59 m. The groundwater flow direction for groundwater within the coal measures is from southwest to northeast and from northwest to southeast, towards a depression that is centred on the area where the AB Pit is proposed to be developed.
- Groundwater quality data is summarised as:
  - All groundwater units at site record high EC groundwater, as follows:
    - Alluvial sediments – EC data is available from:

- A bore adjacent to Charlevue Creek (DW7076W), where the recorded EC range is from 15,200 µS/cm to 16,600 µS/cm; and,
- A bore adjacent to Springton Creek (DW7292W1) has recorded an EC value of 5,948 µS/cm from a single field value (sampling of the recently-drilled monitoring bores commenced in September 2019 with no laboratory data available to date);

▪ Tertiary sediments - the EC ranges from 20,200 µS/cm to 21,900 µS/cm;

▪ Coal seams - the EC ranges from 22,100 µS/cm to 28,500 µS/cm.

- Groundwater at site is above the ANZECC 2000 freshwater ecosystem protection trigger value (95% species protection) for boron (all samples), zinc (majority of samples) as well as aluminium, arsenic, copper, lead and nickel (a number of samples for each analyte).
- All groundwater samples collected to data are assessed to represent the background water quality for the site.
- The recharge rate to the groundwater units at site, which has been calculated via the chloride mass balance method, indicates an extremely low recharge rate of less than 1 mm/year for each groundwater unit. The low rate of calculated recharge is consistent with the observation of highly saline groundwater at site, which is present for even the shallow alluvial units.
- The observation of a low recharge rate for groundwater suggests that, even though relatively high rates of groundwater inflow may be observed from faults/shear zones as mining progresses, especially for the zone above 80 mbgl, the inflow rates are likely to be of short duration due to the relatively low volume that can be stored within fractures/faults and the very low rates of recharge observed at site (i.e. once the fault storage is depleted the faults are unlikely to be recharged).
- Because the faults may act as conduits for groundwater movement, the control of surface water around the site will be of particular importance (i.e. water that ponds at surface may recharge the underlying sediments and report as seepage to the pits via movement along faults/fractures). This mode of inflow would represent infiltrated surface water rather than groundwater from the formations.

8.2 Groundwater Modelling

- 2-dimensional groundwater models have been developed within the program Seep/W for three locations, including
  - A west-east cross section through the C Pit;
  - A west-east cross section through the AB Pit; and,
  - A long section that runs through the final void of both the C Pit and the AB Pit.
- The models take into account:
  - the mining schedule (progression of mining, depth of mining);
  - the progressive backfilling of the pits with waste rock (spoil); and,
  - The backfilling of the final voids to a dept that corresponds to approximately 80 mbgl.
- The models have been utilised to provide the following output:
  - Inflow rates over time to the mine throughout the mining period and to the final void, including inflow rates from the natural groundwater units (Permian coal measures, Tertiary sediments) as well as the spoil aquifer. Groundwater inflow rates to the final voids took into account the partial backfilling of the voids with spoil and the average level of the final void lakes.

- The predicted extent of drawdown (2 m and 5 m drawdown contours) at end of mining and post-mining equilibrium (i.e. steady-state)

- Observations with respect to the calculated inflow rates are as follows:
  - The highest inflow rates to the AB Pit occur in mining years 11 and 12 and are due to groundwater from the spoil reporting to the final void area;
  - For the purpose of future associated water licence reporting it is concluded that it would be more reasonable to assume the rate of inflow prior to development of the spoil aquifer (i.e. ~5.7 L/s or ~500 m^3/day) as the water that is developed from the spoil is derived mainly from rainfall recharge to the spoil and does not represent water from the natural formation;
  - The modelled inflow rates and net inflow rates (i.e. modelled inflow less evaporation) reduces significantly in mining years 17 and 18 for the AB Pit and at mining year 18 for the C Pit. This is due to the partial backfilling of the final void area with spoil; and,
  - For the post-mining years the net groundwater inflow rate is zero, as the rate of inflow from the pit walls above the backfilled area of spoil and the final void lake occurs at such a low rate that the rate of evaporation is significantly greater than the modelled rate of inflow.

8.3 Groundwater Impacts from Mining

Observations with respect to potential groundwater impacts from mining include:

- Impacts on existing groundwater users:
  - There are a total of eleven registered groundwater bores (listed from the DNRM groundwater database as either existing or abandoned but useable) within the zone of 2 m drawdown at post-mining equilibrium.
  - A number of sites are either located within land that is owned by Magnetic South (the project proponent) or record an EC >10,000 µS/cm, making the groundwater quality of little or no beneficial use.
  - Two bores that record an EC <1,000 µS/cm are assessed to be in an elevated area that is potentially disconnected from the regional groundwater system that the mining project is developed within. At these sites it is also noted that the sites are not located within the zone of potential impact at end of mining, but are within the zone of potential impact at post-mining equilibrium.
  - Notwithstanding the time that it may take for drawdown impacts to be observed at the private groundwater bores, it is recommended that a bore survey be undertaken on the potentially impacted properties (as defined by the extent of 2 m drawdown contour on Figure 6-8).
  - It is further noted that make-good agreements may be required for groundwater bores within the zone of potential impact, in the event that groundwater level drawdown affects the utility of the bores.
- Impacts on groundwater dependent ecosystems:
  - A potential groundwater dependant ecosystem (GDE) has been mapped to the east of the MLA and is discussed in Section 7.2.1. The potential GDE is located on an elevated ridgeline but in an area where surface water drainage is internal towards the potential GDE. It is therefore interpreted that the vegetation at this location may be groundwater dependent, but that the site is perched above the regional groundwater system and may be maintained in the dry season by a shallow groundwater lens that is seasonally replenished by surface flow and localised recharge. It is therefore interpreted that, although the site is located within the 2 m zone of

drawdown impacts from mining, there is a low risk of impact due to the perched nature of the system and the assessment that the site is likely to be disconnected from the regional groundwater system.

- A number of potential GDE's in the Project area are riverine-type wetlands that include riparian vegetation on watercourses and floodplains. With respect to the potential for the mining operation to impact this type of potential GDE, it is concluded that:
  - Groundwater level drawdown from the proposed mining operation will extend beneath Charlevue Creek and Springton Creek and it cannot be ruled out that drawdown from mining may affect water levels in the alluvium at some locations;
  - The riparian vegetation at site (within both Charlevue Creek and Springton Creek) is likely to subsist on water that becomes available following wet-season flow events in the creeks, and on the soil moisture and/or perched groundwater that may exist for some time after flow events in the creek, rather than on the water table that exists at greater depth (in the range of 9 to 11 m, based on available data) where the water is moderately to highly saline (and in the case of data for the Charlevue Creek alluvium, too saline to be tolerated by the vegetation species that line the creek); and,
  - Therefore, even if mining does impact on groundwater levels within the alluvium, the risk of impacts to existing riparian vegetation is assessed to be very low, as it is assessed that it is unlikely that the vegetation is dependent on groundwater for survival.
- Notwithstanding the above assessment, ongoing monitoring of groundwater levels is recommended, with a recommendation that bores within the alluvium are monitored via water level dataloggers to allow assessment of the range of seasonal water level variation at these sites. It is noted that a data logger is already fitted to bore DW7076W and that it is planned to install a logger in bore DW7292W1.

- Cumulative Impacts
  - There are no mining operations within the zone of predicted drawdown from mining at the Gemini Project site; it is therefore concluded that there are no cumulative impacts to assess.
- Impacts on Groundwater Quality
  - Groundwater modelling undertaken for this report predicts that a permanent cone of depression will develop that will direct groundwater flow towards the final voids; therefore, the risk of the project impacting on water quality (via outflow to the groundwater system) is assessed to be low.
  - It is, however, assessed that the Project could impact groundwater quality if the water within the final void were able to exit the void via unconsolidated sediments (i.e. the base of Tertiary) and flow via the groundwater system towards sensitive environmental receptors such as Springton Creek. For this reason, an assessment of the potential for water within the final voids to exit the void via the base of Tertiary sediments has been undertaken as follows:
    - Contours for the base of Tertiary sediments was obtained for the area of the AB Pit and C Pit from the site geological model;
    - The final void water level was obtained for each of the final voids from the WRM surface water assessment report (WRM 2019) and was assessed for:
      - The maximum final void water level for the Base Case; and,
      - The maximum final void water level for the High Inflow Case.

- The data for each mining area was assessed to establish whether any pathways existed for water to exit the final void via the base of Tertiary sediments, for the maximum Base Case and maximum High Inflow Case final void water levels.

- Based on the assessment described above it is concluded that there is no outlet via the base of Tertiary for water within the final void of either the AB Pit or the C Pit, for either the maximum Base Case water level or the maximum High Inflow Case water level.
- It is therefore concluded that there is a low risk of the Project impacting on groundwater quality.

APPENDIX C

SLUG TEST ANALYSIS SHEETS

WELL TEST ANALYSIS

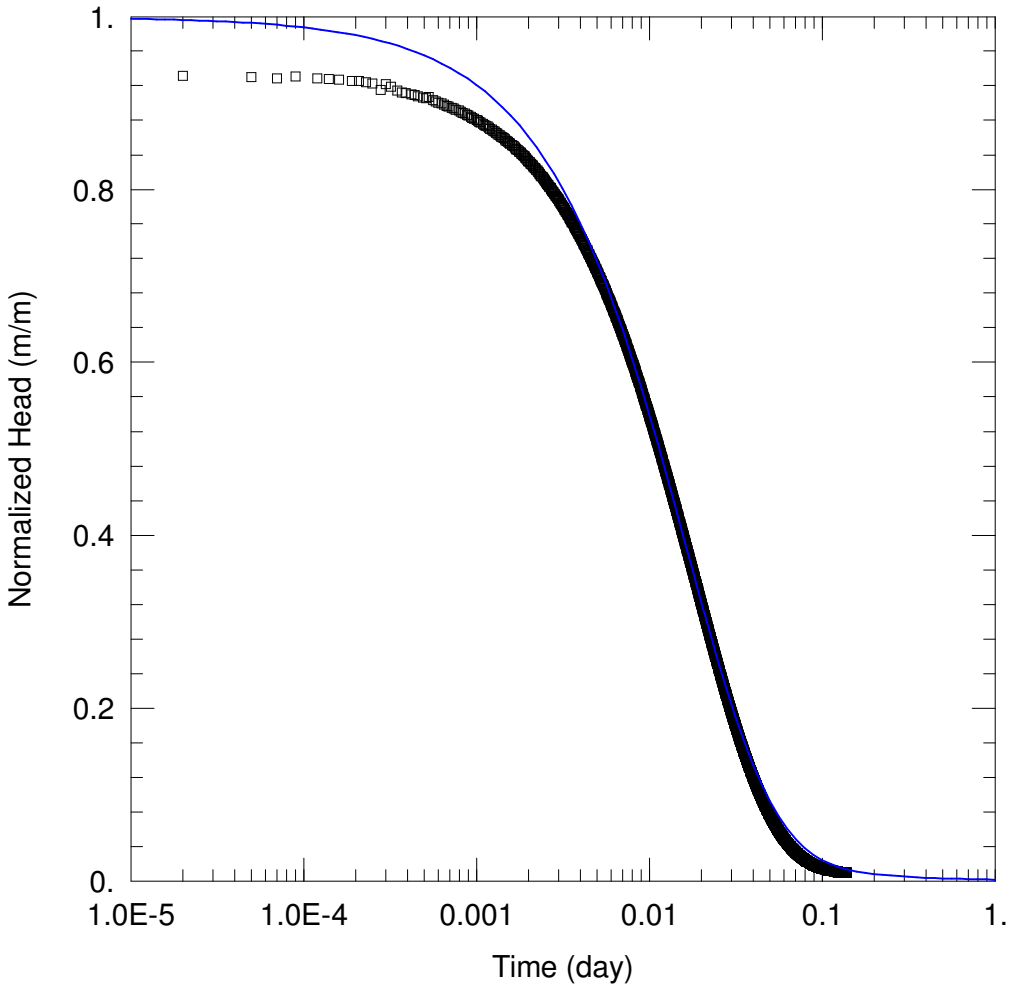
Data Set: D:\...\DW7033W1_KGS Model.aqt
Date: 09/07/19 Time: 15:12:19

PROJECT INFORMATION

Company: Gemini Project
Test Well: DW7033W1
Test Date: 17 July 2019

AQUIFER DATA

Saturated Thickness: 14.81 m



WELL DATA (DW7033W1)

Initial Displacement: 30.18 m
Total Well Penetration Depth: 14.81 m
Casing Radius: 0.025 m
Static Water Column Height: 14.81 m
Screen Length: 6. m
Well Radius: 0.025 m

SOLUTION

Aquifer Model: Unconfined
Solution Method: KGS Model

Kr = 0.7028 m/day
Kz/Kr = 0.1
Ss = 0.02476 m^{-1}

WELL TEST ANALYSIS

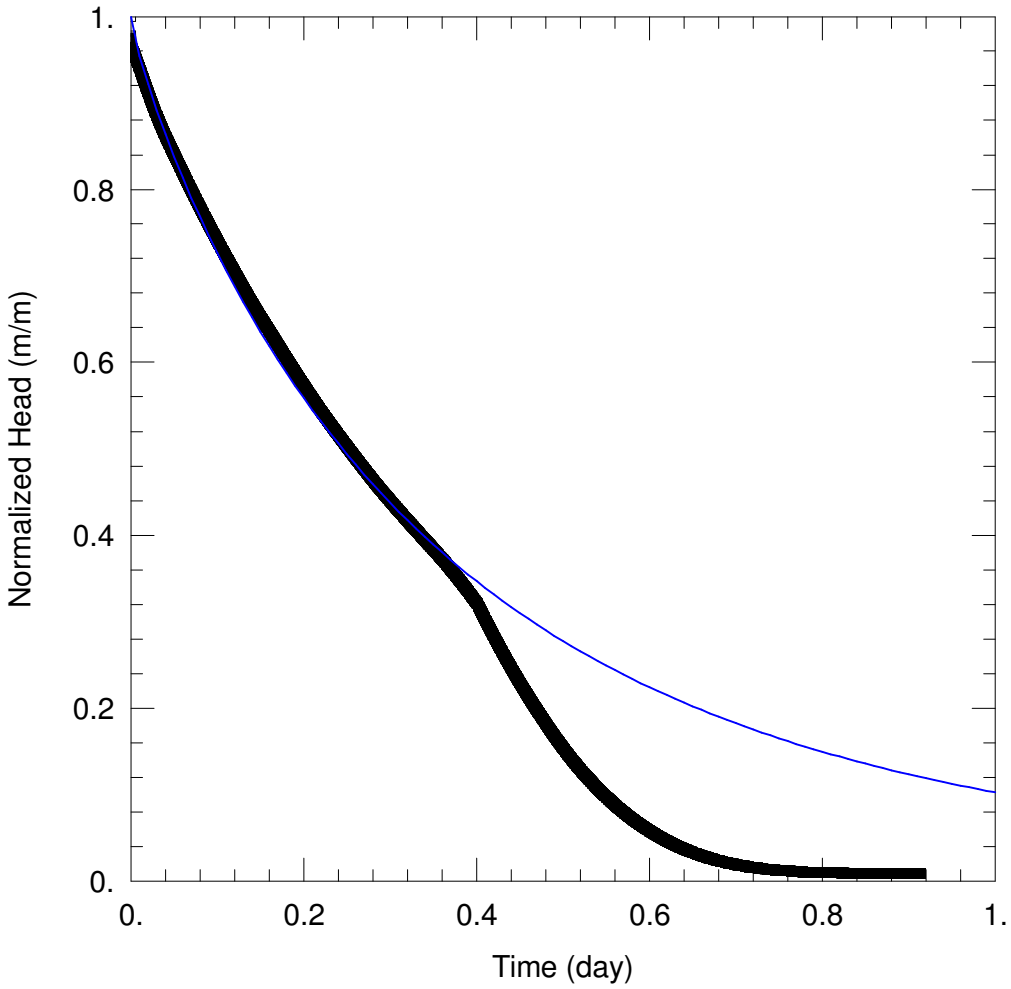
Data Set: D:\...\DW7033W2_KGS Model.aqt
Date: 09/07/19 Time: 15:14:31

PROJECT INFORMATION

Company: Gemini Project
Test Well: DW7033W2
Test Date: 17 July 2019

AQUIFER DATA

Saturated Thickness: 2. m



WELL DATA (DW7033W2)

Initial Displacement: 29.22 m
Total Well Penetration Depth: 45.28 m
Casing Radius: 0.025 m
Static Water Column Height: 45.28 m
Screen Length: 1.5 m
Well Radius: 0.025 m

SOLUTION

Aquifer Model: Confined
Solution Method: KGS Model

Kr = 0.06068 m/day
Kz/Kr = 1.
Ss = 0.0002924 m^{-1}

LEADERS IN MINING GEOCHEMISTRY

EXECUTIVE SUMMARY

ES1 Background

Magnetic South Pty Ltd (Magnetic South) is the project proponent and the applicant for Mining Lease (ML) and Environmental Authority (EA) to develop the Gemini Coal Project (the Project), a greenfield open cut mine to produce pulverised coal injection (PCI) coal and Coking Coal products for export for steel production. The Project term is anticipated to be 25 years from grant of the ML with this term including initial construction, mine operation and rehabilitation activities.

The Project is located on EPC 881 in the Bowen Basin, Central Queensland. Located 20 km east of Bluff and 6 km west of Dingo, the tenement straddles the Capricorn Highway and the Blackwater-Gladstone rail network (**Figure 1**, **Attachment A**).

The main activities associated with the Project that are related to mining waste geochemistry include:

- Exploration activities continuing in order to support mine planning.
- Construction and operation of a Coal Handling Preparation Plant (CHPP) and coal handling facilities adjacent to the MIA (including Run-of-Mine (ROM) coal, product stockpiles and reject stockpiles [coarse and fine rejects]).
- Development and mining of mine areas (open cut pits) and out-of-pit spoil emplacements.
- Progressive placement of spoil (overburden/interburden) in:
  - Emplacements, adjacent to and near the open cut voids.
  - Mine voids, behind the advancing open cut mining operations.
- Progressive rehabilitation of waste rock emplacement areas and mined voids.
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works). Material will be sourced from local quarries where required.
- Disposal of CHPP rejects (coarse and fine rejects) in out of pit waste rock emplacements, and in-pit behind the mining void.

Existing local and regional infrastructure, facilities and services will be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

The proposed mine will target the Rangal coal measures. Up to seven seams/plies are targeted, ranging in thickness from 0.5 m to 3.0 m. The seams are impacted by faulting and seam splitting and are typically overlain by overburden ranging in depth from 45 m to 60 m.

As the mine is planned to be an open cut mine, there will be spoil generated from removal of the overburden and interburden to access to the target coal seams. This spoil will report to the overburden emplacement facility and therefore needs to be geochemically characterised. Similarly, coal and coal reject (coarse reject and tailings) likely to be generated from washing of the target coal seams at the CHPP may also report to surface storage facilities and needs to be geochemically characterised, although the geochemical characterisation of coal reject materials is the subject of a separate report (RGS, 2019).

ES2 Scope of Work

As part of the technical studies being completed for input into the environmental approvals process for the Project, RGS Environmental Pty Ltd (RGS) was commissioned by Magnetic South to complete a geochemical assessment of mining waste (overburden and interburden) materials at the Project.

The objective of the scope of work was to complete a geochemical assessment of representative samples of mining waste materials in accordance with relevant legislation, guidelines and policies and with a level of rigour consistent with the Queensland EIS approvals process. The scope of work included:

- Review of available geochemical and geological data and drill hole database (including plans, drill hole logs and drill core photographs) associated with the Project;
- Design of a geochemical assessment program, including sampling for and testing of representative overburden and potential coal reject materials within the Project boundary. The program utilised exploration drill core/drill chip samples from drilling programs;
- Coordination of the material sampling and geochemical characterisation programs;
- Geochemical characterisation of overburden from the proposed open pit area and potential coal reject material from strata in and around the target seams;
- Development of any necessary environmental management measures related to overburden and potential coal reject emplacement and rehabilitation; and
- Preparation of a Geochemical Assessment Report based on existing information, sample analyses and discussion regarding any acid and metalliferous drainage (AMD) potential or other salinity and sodicity issues related to the Project.

The outcome of completion of the above scope of work is this stand-alone technical report (suitable for inclusion as an appendix to the regulatory approvals documentation), which provides an overview of the proposed Project; a description of the sampling and geochemical testing methodology; presentation and discussion of the results and findings; and develops conclusions and recommendations.

ES3 Methodology

The sampling strategy and subsequent geochemical characterisation strategy for mining waste materials from the proposed Project was guided by Australian (DME, 1995, DEHP, 2013; and COA, 2016) and international (INAP, 2009) technical guidelines for the geochemical assessment of mining wastes. The more recent guidelines favour a risk-based approach to determine the sampling frequency at a proposed mining operation. The sampling strategy at the Project identified representative (fresh drill core/drill chip) samples of mining waste materials from the exploration drilling program.

The results of the sampling and geochemical testing program provided important information to assist with the planning and management of operational and mine closure issues. In particular, the characterisation of mine waste materials potentially intended for use in mine rehabilitation activities was completed so that the geochemical characteristics of these materials were sufficiently well understood to ensure performance according to operational and mine closure planning expectations.

A total of 70 mining waste samples were collected from three drill holes at the proposed Project. The samples represented the main overburden, interburden and potential coal reject materials likely to be encountered during development at the proposed Project from surface down through the stratigraphic profile (including economic and uneconomic coal seams) to the base of the open pit.

The number of samples was selected to provide a good statistical representation of the amount and types of mining waste materials expected to be generated at the Project, whilst accounting for the risk profile indicated from the geology at the Project and a working knowledge of the Rangal Coal Measures.

A range of static and kinetic geochemical tests were completed on the samples. The geochemical tests were used to assess the presence and degree of risk from oxidation of reactive sulfides, potential for acid generation, and leaching of soluble metals/metalloids and salts. The assessment also included some characterisation of chemical parameters related to sodicity and material stability.

ES4 Conclusions

The main findings of the geochemical assessment are as follows:

- All of the mining waste samples tested are Non-Acid Forming (NAF), have excess Acid Neutralising Capacity (ANC) and typically have low sulfur content. The sulfur content of coal and carbonaceous siltstone can be elevated compared to typical background concentrations, but is mainly present in a non-sulfidic form, which does not contribute to acid generation. Overall, these materials have a low risk of acid generation and a high factor of safety with respect to potential for AMD.
- Initial and ongoing surface runoff and seepage from mining waste materials is expected to be moderately alkaline and have a moderate level of salinity.
- Kinetic leach column (KLC) test results indicate that mining waste materials are unlikely to generate acid conditions and are more likely to generate pH neutral to alkaline conditions.
- Metal/metalloid enrichment in mining wastes, compared to median crustal abundance in unmineralised soils, is limited to cobalt in a single carbonaceous siltstone sample. The nature of a coal deposit means some metals/metalloids are expected to be slightly elevated in some materials.
- Most metals/metalloids are sparingly soluble at the neutral to alkaline pH of leachate expected from bulk mining waste materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk mining waste materials are therefore expected to be low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities.
- Mining waste materials should be amenable to revegetation as part of rehabilitation activities, although, gypsum and fertiliser addition may need to be considered for sodic materials to limit dispersion and erosion and to provide a reasonable growth medium for revegetation and rehabilitation.
- As most mining materials appear to be susceptible to dispersion and erosion, additional testing including field trials, may be needed when the mine is operational and bulk materials are being generated. Such tests would help to determine the most appropriate management option for progressive rehabilitation of these materials during operations at mine closure.

ES5 Recommendations

As a result of the geochemical assessment work completed on mining waste materials at the Project, a number of recommendations are provided for these materials to minimise the risk of any significant environmental harm to the immediate and downstream environment.

- Placement of any carbonaceous mining waste material encountered during mining at the surface and outer batters of spoil emplacement areas should be avoided.
- Additional overburden/interburden testing and rehabilitation field trials should be completed during operations when bulk materials become available to confirm the most appropriate management option for progressive rehabilitation of these materials during operations and at mine closure.
- Surface water and seepage from the proposed mining and mining waste storage areas should be monitored to ensure that key water quality parameters remain within appropriate criteria. Water quality monitoring parameters should include pH, EC, total suspended solids (TSS) on a quarterly basis and the suite of water quality analyses described in **Table B4** (**Attachment B**) of this report opportunistically and at least on an annual basis.

Attachment D: KLC Test Results and Trends
Attachment E: ALS Laboratory Results

GLOSSARY OF TERMS AND ACRONYMS

Acidity	A measure of hydrogen ion (H+) concentration; generally expressed as pH.
Acid Base Account	Evaluation of the balance between acid generation and acid neutralisation processes. Generally determines the maximum potential acidity (MPA) and the inherent acid neutralising capacity (ANC), as defined below.
AMD	Acid and metalliferous drainage caused by exposure of sulfide minerals in mining waste materials to oxygen and water. Typically characterised by low pH and elevated concentrations of salts, sulfate and metals.
ANC	Acid neutralising capacity of a sample as kg H_2SO_4 per tonne of sample.
ANC:MPA Ratio	Ratio of the acid neutralising capacity and maximum potential acidity of a sample. Used to assess the risk of a sample generating acid conditions.
pH	Measure of the hydrogen ion (H+) activity in a sample solution, expressed in pH units.
EC	Electrical Conductivity, expressed as µS/cm.
eCEC	Effective cation exchange capacity provides a measure of the amount of exchangeable cations (Ca, Mg, Na and K) in a sample.
ESP	Exchangeable sodium percentage provides a measure of the sodicity of a materials and propensity to erode.
KLC test	Kinetic leach column tests are procedures used to measure the geochemical/ weathering behaviour of a sample of mine material over time.
MPA	Maximum Potential Acidity calculated by multiplying the total sulfur content of a sample by 30.6 (stoichiometric factor) and expressed as kg H_2SO_4 per tonne.
NAF	Non-acid forming. Geochemical classification criterion for a sample that will not generate acid conditions.
NAG test	Net acid generation test. Hydrogen peroxide solution is used to oxidise sulfides in a sample, then any acid generated through oxidation may be consumed by neutralising components in the sample. Any remaining acidity is expressed as kg H_2SO_4 per tonne.
NAPP	Net acid producing potential expressed as kg H_2SO_4 per tonne. Calculated by subtracting the ANC from the MPA.
Overburden	Material that overlays a coal resource and must be removed to mine the coal.
PAF	Potentially acid forming. Geochemical classification criterion for a sample that has the potential to generate acid conditions.
Static test	Procedure for characterising the geochemical nature of a sample at one point in time. Static tests may include measurements of mineral and chemical composition of a sample and the Acid Base Account.
Total Sulfur	Total sulfur content of a sample generally measured using a 'Leco' analyser expressed as % S.
Uncertain	Geochemical classification criterion for a sample where the potential to generate acid conditions remains uncertain and may require further analysis.

1.0 INTRODUCTION

1.1 Project Description

Magnetic South Pty Ltd (Magnetic South) is the project proponent and the applicant for Mining Lease (ML) and Environmental Authority (EA) to develop the Gemini Project (the Project), a greenfield open cut mine to produce pulverised coal injection (PCI) coal and Coking Coal products for export for steel production. The Project term is anticipated to be 25 years from grant of the ML with this term including initial construction, mine operation and rehabilitation activities.

The Project is located on EPC 881 in the Bowen Basin, Central Queensland. Located 20 km east of Bluff and 6 km west of Dingo, the tenement straddles the Capricorn Highway and the Blackwater-Gladstone rail network (**Figure 1**, **Attachment A**).

The main activities associated with the Project include:

- Exploration activities continuing in order to support mine planning.
- Development of a Mine Infrastructure Area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, explosives magazine and sewage, effluent and liquid waste storage.
- Construction and operation of a Coal Handling Preparation Plant (CHPP) and coal handling facilities adjacent to the MIA (including Run-of-Mine (ROM) coal, product stockpiles and reject stockpiles [coarse and fine rejects]).
- Construction and operation of a surface conveyor from the product stockpiles to a Train Load Out (TLO) facility and rail loop connecting to the Blackwater-Gladstone Branch Rail to transport product coal to coal terminals at Gladstone for export.
- Construction of access roads from the Capricorn Highway to the MIA, and to the TLO facility.
- Installation of a raw water supply pipeline to connect to the Blackwater Pipeline network.
- Construction of a 66 kV transmission line and switching/substation to connect to the existing regional network.
- Other associated minor infrastructure, plant, equipment and activities.
- Development of mine areas (open cut pits) and out-of-pit waste rock emplacements.
- Drilling and blasting of competent waste material.
- Mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers).
- Mining up to 1.9 Mtpa ROM Coal – average 1.8 Mtpa for an operational mine life of approximately 20 years.
- Progressive placement of waste rock (overburden/interburden) in:
  - Emplacements, adjacent to and near the open cut voids.
  - Mine voids, behind the advancing open cut mining operations.
- Progressive rehabilitation of waste rock emplacement areas and mined voids.
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works). Material will be sourced from local quarries where required.

- Disposal of CHPP rejects (coarse and fine rejects) in out of pit waste rock emplacements, and in-pit behind the mining void.
- Progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access.
- Development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, diversions and drains.

Existing local and regional infrastructure, facilities and services will be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

The proposed mine will target the Rangal coal measures. Up to seven seams/plies are targeted, ranging in thickness from 0.5 m to 3.0 m. The seams are impacted by faulting and seam splitting and are typically overlain by overburden ranging in depth from 45 m to 60 m.

As the mine is planned to be an open cut mine, there will be spoil generated from removal of the overburden and interburden to access to the target coal seams. This spoil will report to the overburden emplacement facility and therefore needs to be geochemically characterised. Similarly, coal and coal reject (coarse reject and tailings) likely to be generated from washing of the target coal seams at the CHPP may also report to surface storage facilities and needs to be geochemically characterised, although the geochemical characteristics of coal reject materials are the subject of a separate report (RGS, 2019).

1.2 Scope of Work

As part of the technical studies being completed for input into the environmental approvals process for the Project, RGS Environmental Pty Ltd (RGS) was commissioned by Magnetic South to complete a geochemical assessment of mining waste (overburden and interburden) materials at the Project.

The scope of work is based upon that described in RGS Proposal No. 2017002, dated 17th January, 2017 (RGS, 2017a). The objective of the scope of work was to complete a geochemical assessment of representative samples of mining waste materials in accordance with relevant legislation, guidelines and policies and with a level of rigour consistent with the Queensland EIS approvals process.

The scope of work included:

- Review of available geochemical and geological data and drill hole database (including plans, drill hole logs and drill core photographs) associated with the Project;
- Design of a geochemical assessment program, including sampling for and testing of representative overburden and potential coal reject materials within the Project boundary. The program utilised exploration drill core/drill chip samples from drilling programs;
- Coordination of the material sampling and geochemical characterisation programs;
- Geochemical characterisation of overburden from the proposed open pit area and potential coal reject material from strata in and around the target seams;
- Development of any necessary environmental management measures related to overburden and potential coal reject emplacement and rehabilitation; and
- Preparation of a Geochemical Assessment Report based on existing information, sample analyses and discussion regarding any acid and metalliferous drainage (AMD) potential or other salinity and sodicity issues related to the Project.

The outcome of completion of the scope of work is this stand-alone technical report (suitable for inclusion as an appendix to the regulatory approvals documentation), which provides an overview of the proposed

Project; a description of the sampling and geochemical testing methodology; presentation and discussion of the results and findings; and develops conclusions and recommendations.

The focus of this report is the acquisition and interpretation of the results of a static geochemical testing program of mining waste materials and the report also evaluates the results of a subsequent six-month kinetic geochemical testing program.

2.0 REGIONAL AND LOCAL GEOLOGY

2.1 Resource Description

The Project is located in one of the principal geological structural units of the Bowen Basin, the Dawson Fold Zone, which overlays part of the western extent of the Taroom Trough. The area comprises sediments from the Rewan, Rangal, Burngrove and Fairhill Formations, and is bound in the west by the Yarrabee Fault.

The Project contains the Aries, Castor, Pollux, Orion and Pisces Seams of the Rangal Coal Measures. A representation of the typical stratigraphic profile in the Project area is provided in **Figure A2** (**Attachment A**). The Rangal Coal Measures conformably overlie the Burngrove Formation and consist primarily of siltstones, sandstones and coal seams. The sediments are consistent with a deltaic depositional environment.

The Rangal coal seams form the dominant resource across several areas of the central Bowen Basin. The Aries, Castor and Pollux seams are minable entities at most of the local mines in the Blackwater area and commonly coalesce and split from each other. These relationships are controlled structurally by differential subsidence in different areas during deposition.

Recoverable coal will come from the Rangal coal seams but may also target the Upper Burngrove formation. The Burngrove Formation contains several coal seams and is generally considered of lesser importance due to moderate to high ash levels. It is possible that some seams may have potential to produce domestic or export thermal products, depending on wash plant density cut points and acceptable yields.

The relatively shallow depth of the targeted seams and the cumulative thickness of 3.5 to 4.5 m from the Pollux and overlying seams make the Gemini area suitable for open cut mining.

3.0 METHODOLOGY

3.1 Material Sampling

The sampling strategy and subsequent geochemical characterisation strategy for overburden and potential coal reject materials from the proposed Project was guided by Australian (DME, 1995, DEHP, 2013; and COA, 2016) and international (INAP, 2009) technical guidelines for the geochemical assessment of mining wastes. The more recent guidelines favour a risk-based approach to determine the sampling frequency at a proposed mining operation. The sampling strategy at the Gemini Project identified and collected representative (fresh drill core/drill chip) samples of overburden and potential coal reject materials from the exploration drilling program.

The results of the sampling and geochemical testing program provided important information to assist with the planning and management of operational and mine closure issues. In particular, characterisation of overburden materials potentially intended for use in mine rehabilitation activities was completed so that the geochemical characteristics of these materials were sufficiently well understood to ensure performance according to operational and mine closure planning expectations.

A total of 70 waste rock samples were collected from three drill holes at the proposed Project (DW7002, DW7003 and DW7012). The location of the drill holes used for drill core/drill chip sampling and geochemical testing with respect to the proposed open pit areas is provided in **Figure A3 (Attachment A).**

The samples represented the main overburden, interburden, potential coal reject materials likely to be encountered during development at the proposed Project from surface down through the stratigraphic profile (including economic and uneconomic coal seams) to the base of the open pit. The number of samples was selected to provide a good statistical representation of the amount and types of mining waste materials expected to be generated at the Project, whilst accounting for the risk profile indicated from the geology at the Project and a working knowledge of the Rangal Coal Measures. The samples were collected by JC Irvine Pty Ltd geological personnel (with some guidance from RGS), who also dispatched the samples to ALS Environmental Brisbane laboratory (ALS Brisbane) for geochemical characterisation.

The maximum drill hole depth and number of samples at each hole is provided at **Table 3-1**. The samples were selected for the geochemical assessment program to reflect the occurrence and distribution of the overburden and interburden materials that occur within the open pit.

Table 3-1: Drill Hole Maximum Sample Depth and Number of Samples

Drill Hole ID	Total Depth (m)	Number of Samples
DW7002	158.00	22
DW7003	120.00	22
DW7012	148.00	26
	TOTAL	**70**

3.2 Geochemical Characterisation

All geochemical test work completed in this project was based on industry recognised procedures for the geochemical characterisation and assessment of mine materials (Parker and Robertson, 1999; AMIRA, 2002; INAP, 2009 and COA, 2016). A summary of those parameters involved in completing a static and kinetic geochemical characterisation and assessment of mine materials is provided in **Attachment C**.

3.2.1 Static Tests

Static geochemical tests provide a 'snapshot' of the characteristics of a sample material at a single point in time. These tests were completed to screen all samples before selecting individual samples for more detailed static test and kinetic geochemical tests.

All 70 samples received by ALS were crushed, sub-sampled and pulverised before being subjected to a series of static geochemical tests on the pulverised (<75 µm) sample fractions. The geochemical test program was coordinated by RGS personnel and designed to assess the degree of risk from potential oxidation of sulfides, acid generation, and the presence of (and leaching of) soluble metals/metalloids and salts. Each solid sample underwent static geochemical testing for:

- pH (1:5 w:v);
- Electrical conductivity (EC) (1:5 w:v);
- Total sulfur [Leco method]; and
- Acid neutralising capacity (ANC) [AMIRA, 2002];

Selected samples (19 samples) were also tested for:

- Sulfide (chromium reducible sulfur – Scr) [AS 4969.7-2008 method].

From the total sulfur (or Scr where available) and ANC results, maximum potential acidity (MPA) and net acid producing potential (NAPP) values were calculated. Where available, the MPA and NAPP of these samples were calculated using the Scr data instead of total sulfur data. The use of Scr data (for fresh samples) provides a more accurate representation of the MPA that could theoretically be generated, as acid generation primarily occurs from reactive sulfide, whereas total sulfur can include other sulfur forms such as elemental sulfur, sulfate and organic sulfur.

After the results of the initial static geochemical tests were received and reviewed, 10 samples of mining waste materials were selected, prepared and subjected to whole rock multi-element tests. The samples were tested for:

- Total metals/metalloids (Al, As, B, Cd, Cr, Co, Cu, Fe, P, Pb, Mn, Ni, Sb, Se and Zn) in solids [HCl and HNO_3 acid digest followed by ICP-AES/MS];
- Total cations (Ca, Mg, Na and K) [HCl and HNO_3 acid digest followed by ICP-AES];
- Soluble metals/metalloids (Al, As, B, Cd, Cr, Co, Cu, Fe, P, Pb, Mn, Mo, Ni, Sb, Se, Si, V and Zn) [ICP-AES/MS (1:5 w:v water extracts)];
- Major cations (Ca, Mg, Na and K) [ICP-AES/MS (1:5 w:v water extracts)];
- Major anions (Cl, F, and SO_4) [ICP-AES/MS and PC Titrator (1:5 w:v water extracts)];

Ten (10) individual mining waste samples were also tested for:

- Exchangeable cations [ICP-AES].

The results were then used to calculate:

- Cation Exchange Capacity (eCEC); and
- Exchangeable Sodium Percentage (ESP).

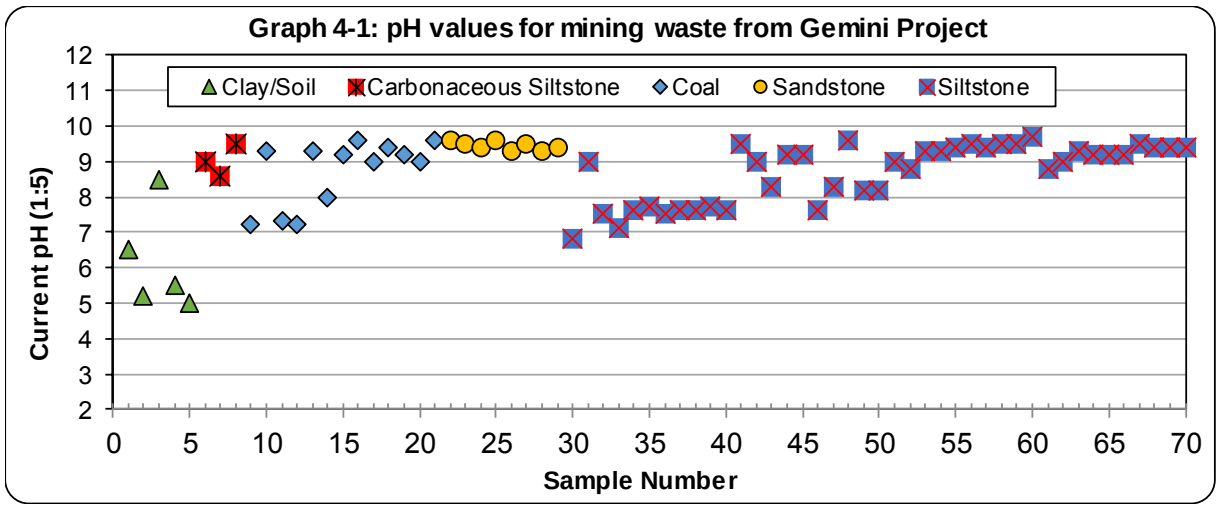
A copy of the static geochemical results received from ALS is provided in **Attachment E**.

3.2.2 Kinetic Tests

Following receipt and interpretation of the static geochemical test results, six Kinetic Leach Column (KLC) tests were set up at the RGS in-house laboratory using crushed samples (passing a 10mm sieve size). The KLC tests comprised composite mining samples representing the main lithological rock types likely to be generated at the proposed open pit as well as some carbonaceous material and uneconomic coal. The KLC tests were completed over a period of six months from July 2017 to January 2018, under a monthly watering and leaching cycle.

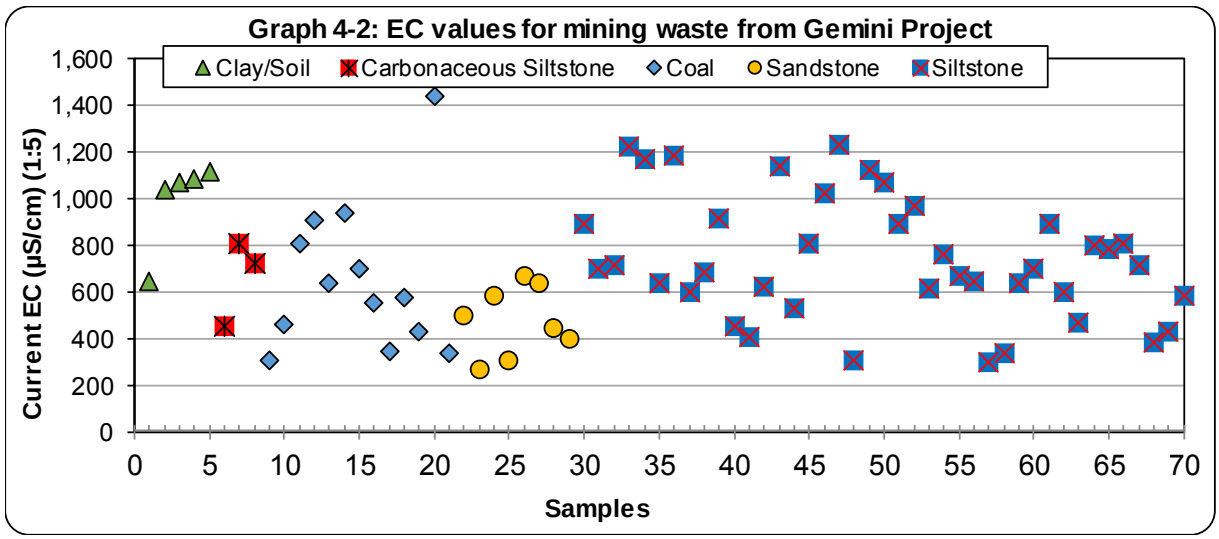
1.5 kg of each selected sample was accurately weighed and used in the KLC tests. Heat lamps were used on a daily basis to simulate sunshine and ensure that the KLC test materials were unsaturated and subject to oxidising conditions, between leaching events (essentially an assumed 'worst case' scenario for sulfide oxidation and potential acid/salt generation). Further details and a schematic of the KLC test arrangement are provided in **Attachment D**.

All leachate samples collected from the KLC tests were tested at ALS Brisbane for:



- pH and EC;
- Acidity and alkalinity [Automatic titrator];
- Dissolved metals/metalloids (Al, As, B, Cd, Cr, Co, Cu, F, Fe, Pb, Mn, Mo, Ni, Sb, Se, Si, V and Zn) [ICP-AES];
- Dissolved major cations (Ca, Mg, Na and K) [ICP-AES]; and
- Dissolved major anions (Cl, SO_4) [ICP-AES].

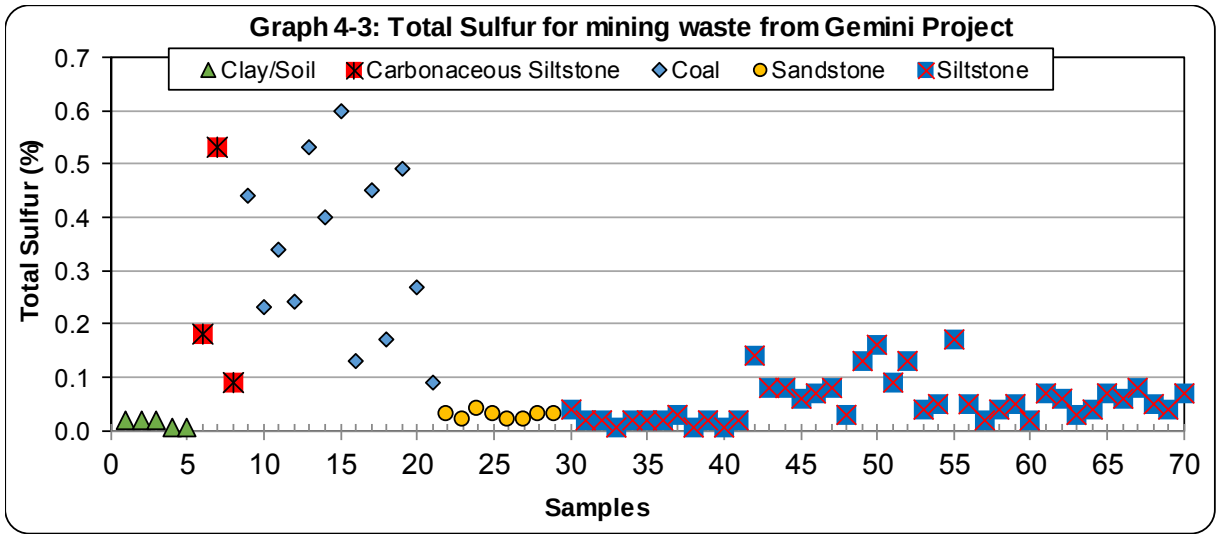
4.0 GEOCHEMICAL TEST RESULTS



4.1 Acid Base Account

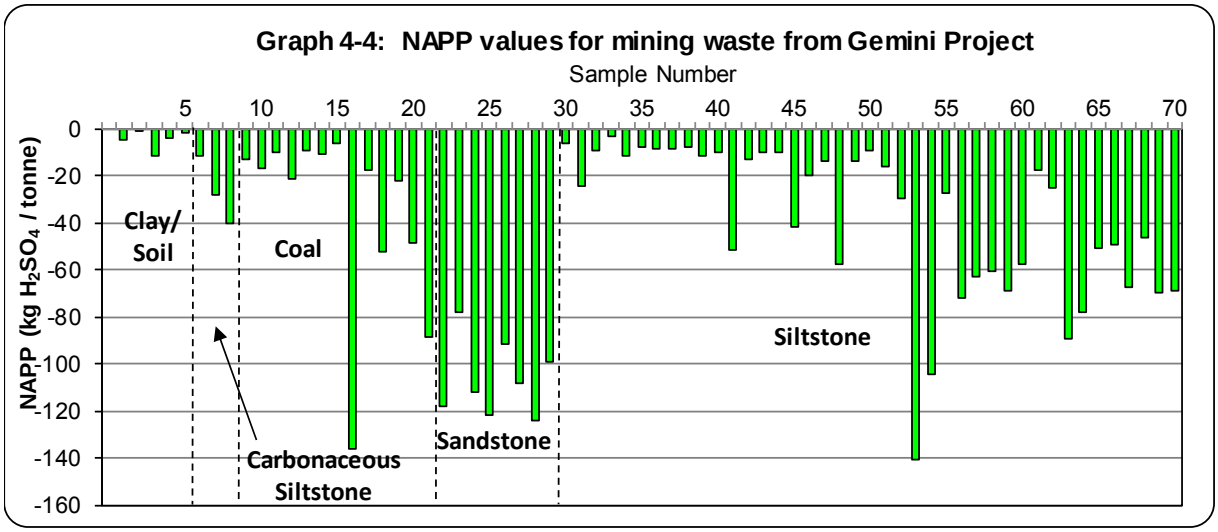
Acid Base Account results for the 70 mining waste samples from the Project are presented in **Table B1** (**Attachment B**) and summarised below. Results are shown by lithology to facilitate interpretation.

- **pH**: The $pH_{(1:5)}$ of the 70 samples across all sample types ranges from 5.0 to 9.7 and has a median value of 9.2 (**Graph 4-1**). The typical range of the deionised water used in these tests ranges from pH 5 to 6.5. The samples with the lowest pH values (pH 5.0 to 5.5) represent clay and soil material.

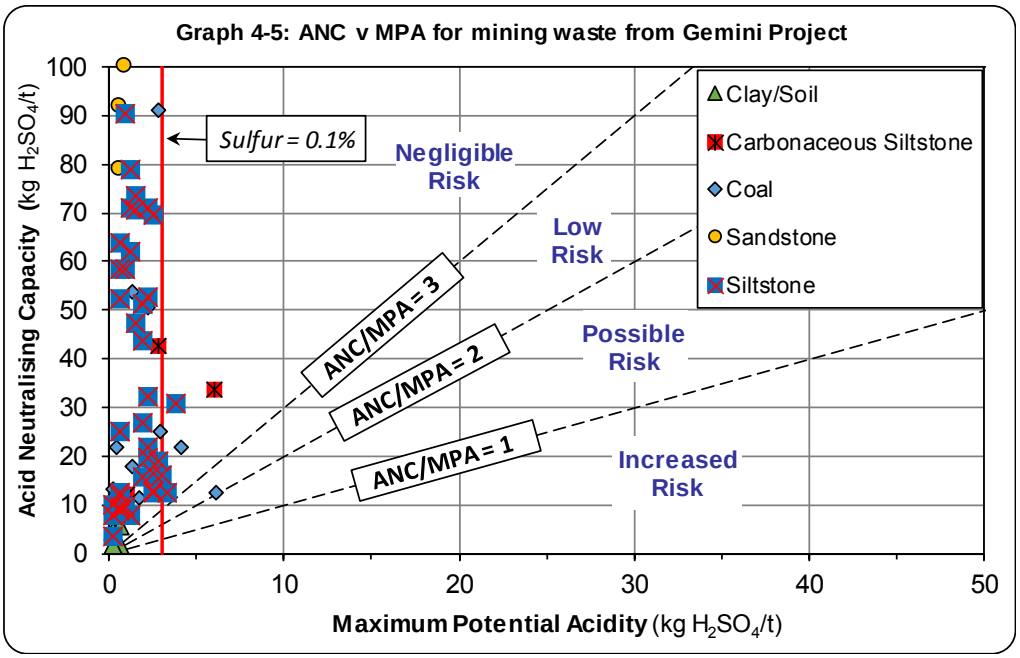


- **EC**: The current $EC_{(1:5)}$ for the 70 samples ranges from 270 to 1,440 µS/cm (**Graph 4-2**) and is typically moderate (median 646 µS/cm). The weathered material tends to have a higher EC value than the fresh material.

The pH and EC tests were completed on pulverised samples (≤ 75 µm) with a large surface area in contact with the leaching solution, thereby providing greater potential for dissolution and reaction, and represent an assumed 'worst case' scenario. It is also expected that the salinity of leachate from these low sulfur mining waste materials will diminish with time as salts are flushed from the rock matrix and a state of equilibrium develops. At that point, the salinity of seepage/runoff should stabilise at a lower asymptotic concentration relative to the weathering/erosion of the materials.



- **Sulfur**: The total sulfur content of the samples ranges from <0.01% to 0.60% (median 0.06 %S) (**Graph 4-3**). Compared to the median crustal abundance of sulfur (0.07%) (INAP, 2009) the median values of the mining waste materials is relatively low. Materials with a total sulfur content less than or equal to 0.1 % are essentially barren of sulfur, generally represent background concentrations, and have negligible capacity to generate acidity[1]. The sulfur content of carbonaceous siltstone and coal are both higher than natural background values and both lithologies show greater variation in sulfur content than the weathered material, sandstone and siltstone.



- **Sulfide Sulfur:** The sulfide sulfur content of 19 selected samples with total sulfur content greater than 0.1 %S was also tested (as measured in the Scr test). The results indicate that in the selected samples, an average of two-thirds of the sulfur content is present as non-sulfide sulfur, which is typically associated with non-acid generating forms of sulfur, such as organic sulfur, sulfate or secondary mineral sulfates such as gypsum. On average, one-third of the total sulfur content is present in the selected samples as sulfide sulfur (probably pyrite or marcasite) and has the potential to generate a small amount of acidity.
- **MPA**: Based on the total sulfur content (and sulfide sulfur content where available), the maximum potential acidity (MPA) that could be generated by the mining waste samples ranges from < 0.3 (below laboratory limit of reporting - LoR) to 6.0 kg H_2SO_4/t and has a low median value of 1.2 kg H_2SO_4/t.
- **ANC**: The ANC for the mining waste samples ranges from 1.6 to 142.0 kg H_2SO_4/t and has a moderate median value of 25.9 kg H_2SO_4/t. The fresh samples typically have higher ANC values compared to the weathered material.
- **ANC:MPA ratio**: The ANC:MPA ratio for the samples ranges from 2.1 to 178.0 and has a high median value of 23.6. Simplistically, this means that the samples have excess ANC over MPA.

[1] The median crustal abundance of sulfur (0.07 %S) has been rounded up to 0.1 % (INAP, 2009).

- **NAPP**: The calculated NAPP value for the mining waste samples is calculated by subtracting the ANC from the MPA and ranges from -140.8 to -1.0 kg H_2SO_4/t and has a median value of -24.6 kg H_2SO_4/t. **Graph 4-4** illustrates that all samples have a negative NAPP value, which is typically more negative for fresh materials compared to weathered materials.

Graph 4-5 shows a plot of ANC versus MPA for the 70 mining waste samples tested (by lithology). ANC/MPA ratio lines have been plotted on the graph to illustrate the factor of safety associated with the samples. Generally, those samples with an ANC:MPA ratio greater than 2 (or with a total or sulfide sulfur content ≤ 0.1 %) are considered to have a low to negligible risk of acid generation and a high factor of safety in terms of potential for AMD (INAP, 2009[2]; COA, 2016).

[2] INAP considers that mine materials with an ANC/MPA ratio greater than 2 are likely to be NAF unless significant preferential exposure of sulfides along fracture planes occurs in combination with insufficiently reactive ANC.

The results indicate that all of the mining waste samples tested plot in the low to negligible risk domains shown in the graph and represent materials with a very low risk of acid generation and a high factor of safety with respect to potential AMD.

Table 4-1 provides a summary of the geochemical classification criteria used by RGS to classify the acid forming nature of the 70 mining waste samples at the Project, and a breakdown of the number of samples in each classification category by lithology.

Table 4-1: Geochemical Classification Criteria for Mining Waste Materials

Geochemical Classification	Total Sulfur[1] (%)	ANC: MPA Ratio	NAPP (kg H_2SO_4/t)	Soil/Clay (n=5)	Carb. Siltstone (n=3)	Coal (n=13)	Sandstone (n=8)	Siltstone (n=41)
Non-Acid Forming (Barren)	≤ 0.1	-	-	5	2	9	8	39
Non-Acid Forming	> 0.1	> 2	≤ 0	0	1	4	0	2
Uncertain[2]	> 0.1	< 2	> -5 and ≤ +5	0	0	0	0	0
Potentially Acid Forming (Low Capacity)	> 0.1	< 2	≤ 5	0	0	0	0	0
Potentially Acid Forming	> 0.1	< 2	> 5	0	0	0	0	0

Notes:
1. Sulfide sulfur (using the Scr test) has been measured for selected waste rock samples and where available, sulfide sulfur has been used in place of total sulfur for sample classification and to calculate MPA.
2. Samples that fall outside the stated NAF/PAF classifications based on the criteria provided are classified as Uncertain.

The ABA test data presented in **Table B1 (Attachment B)** and discussed in this section have been used to classify the acid forming nature of the 70 mining waste samples from the Project. The results indicate that of the 70 samples tested, 90 % are classified as Non-Acid Forming (Barren) and 10 % are classified as Non-Acid Forming (NAF). No samples are classified as Uncertain or Potentially Acid Forming (PAF).

Overall, the ABA results confirm that the overwhelming majority of the mining waste materials have low sulfur content, excess ANC, a high factor of safety and a low risk of generating acidic drainage. Some of the carbonaceous siltstone and uneconomic coal samples have slightly elevated sulfide sulfur content compared to typical median crustal abundance, however these materials also have excess ANC and a low risk of generating acidic drainage.

4.2 Multi-Element Concentration in Solids

Multi-element scans were carried out on 10 selected samples to identify any elements (particularly metals/metalloids) present in the Project mining waste materials at concentrations that may be of environmental concern with respect to revegetation and surface water/groundwater quality. The total metals/metalloids concentration for individual elements in mine materials can be relevant for revegetation activities and/or where the potential exists for human contact (*eg*. if the material was to be used off-site).

The results from multi-element testing (total metals/metalloids) of the selected mining waste samples are presented in **Table B2 (Attachment B)**.

4.3 Geochemical Abundance Index

Total metal/metalloid concentrations in mining waste materials can be compared to the median crustal abundance for unmineralised soils (Bowen, 1979, INAP, 2009). The extent of enrichment is reported as the Geochemical Abundance Index (GAI), which relates the actual concentration in a sample with the median (or average) crustal abundance on a $\log_{10}$ scale. The GAI is expressed in integer increments from 0 to 6, where a GAI value of 0 indicates that the element is present at a concentration less than, or similar to, the median crustal abundance; and a GAI value of 6 indicates approximately a 100-fold enrichment above median crustal abundance **(Table 4-2)**.

Table 4-2: Geochemical Abundance Index (GAI) values and Enrichment Factors

GAI	Enrichment Factor	GAI	Enrichment Factor
-	Less than 3-fold enrichment	**4**	24 – 48 fold enrichment
1	3 – 6 fold enrichment	**5**	48 – 96 fold enrichment
2	6 – 12 fold enrichment	**6**	Greater than 96 fold enrichment
3	12 – 24 fold enrichment		

As a general rule, a GAI of 3 or greater signifies enrichment that may warrant further examination. This is particularly the case with some environmentally important 'trace' elements, such as As, Cr, Cd, Cu, Pb, Se and Zn, more so than with major rock-forming elements, such as Al, Ca, Fe, Mg and Na.

Elements identified as enriched may not necessarily be a concern for revegetation, drainage water quality or public health, but their significance should still be evaluated. The GAI provides an indication of metals/metalloids that may be enriched relative to the global median crustal abundance, however the following points should also be considered:

- The median crustal abundance varies between different literature sources, therefore affecting the calculated GAI values.
- If a sample is shown to be enriched relative to the median crustal abundance, there is no direct correlation that that particular sample will also leach metals/metalloids at elevated concentrations. The mobility of metals/metalloids is dependent on mineralogy, adsorption/desorption and the environment in which it occurs.
- Whilst some element concentrations can be elevated relative to the median crustal abundance, the nature of an ore deposit means the background levels are generally expected to be elevated.

Similarly, because an element is not enriched does not mean it will never be a concern, because under some conditions (eg. low pH) the solubility of common environmentally important elements such as Al, Cu, Cd, Fe and Zn increases significantly.

Table B2 (Attachment B) provides total metal/metalloid concentrations for the 10 selected mining waste samples described in **Section 4.2.** The relative enrichment of metals/metalloids in these samples compared to median crustal abundance (the Geochemical Abundance Index - GAI) is presented in **Table B3 (Attachment B)**.

The GAI results indicate that of the metals/metalloids measured, only one of the 10 selected samples was enriched compared to median crustal abundance with cobalt. While the concentration of cobalt is elevated relative to median crustal abundance, the nature of a coal deposit means some metals/metalloids are expected to be slightly elevated in mining waste materials.

The potential solubility of cobalt and other metals/metalloids was investigated further using water extract and KLC tests as presented in **Section 4.5** and **Section 4.6**, respectively.

4.4 Cation Exchange Capacity and Sodicity

The effective cation exchange capacity (eCEC) and exchangeable sodium percentage (ESP) results for 10 selected mining waste samples are presented in **Table B2 (Attachment B).** These samples were selected for testing as they will report to the spoil emplacement areas and could also be used in other site infrastructure and rehabilitation works.

The effective eCEC results show that the eCEC of the selected mining waste samples ranges from 4.2 to 18.0 meq/100g, and is typically low (mean = 10.0 meq/100g) (**Table 4-3**). For mining waste materials with low eCEC value, some fertiliser addition may be required to provide a reasonable growth medium for vegetation roots.

Table 4-3: Ratings for Effective Cation Exchange Capacity

eCEC Rating	CEC meq/100g
Very Low	<6
Low	6-12
Moderate	12-25
High	25-40
Very High	>40

The ESP results for the mining waste samples range from low (4.5%) to very high (31.5%) and are typically elevated (median = 19.3%), indicating that some of the sample materials are likely to be sodic. Generally, samples with ESP values less than 6 are considered non-sodic, whereas greater than 6 are considered moderately sodic, and greater than 14 are considered strongly sodic and may be susceptible to dispersion and erosion (Isbell, 2002; and Northcote and Skene, 1972).

Overall, the results of the eCEC and ESP tests on the selected mining waste samples indicate that most of the materials represented by these samples are likely to have elevated sodicity levels and may be susceptible to dispersion and erosion, although these characteristics may be improved to some extent by the addition of gypsum. In addition, fertiliser addition will need to be considered for some mining waste materials to provide a reasonable growth medium for revegetation and rehabilitation.

4.5 Water Quality Static Tests

There are no specific regulatory criteria for metal/metalloid concentrations in leachate from mining waste materials on mine sites in Queensland. As such, RGS has compared the multi-element results in water extracts from the 10 mining waste samples described in **Sections 4.2** and **4.3**, with Australian guidelines for livestock drinking water and aquatic freshwater ecosystems (ANZECC & ARMCANZ, 2000) guideline values. These guidelines are provided for context only and are not intended to be interpreted as "maximum permissible levels" for site water storage or discharge.

It should also be recognised that direct comparison of geochemical data with guideline values can be misleading. For the purpose of this study, guideline values are only provided for broad context and should not be interpreted as arbitrary 'maximum' values or 'trigger' values. Using sample pulps (ground to passing 75 µm) provides a very high surface area to solution ratio, which encourages mineral reaction and dissolution of the solid phase. Therefore, the results of screening tests on water extract solutions are assumed to represent an assumed 'worst case' scenario for initial surface runoff and seepage from mining waste materials.

The results from multi-element testing of water extracts (1:5 sample:water) from the 10 selected mining waste samples are presented in **Table B4 (Attachment B)**.

The pH of the water extracts ranges from 7.1 to 9.6 (median 9.2) and six samples have a pH value that is slightly greater than the upper limit of the pH range (pH 6 to 9) for 95 % species protection in freshwater aquatic ecosystems (ANZECC & ARMCANZ, 2000).

The water extracts have low to moderate EC values ranging from 270 to 1,220 µS/cm (median 710 µS/cm) indicating low to moderate salinity (and low to moderate concentrations of dissolved solids).

The current total alkalinity in the water extracts ranges from 244 to 3,620 mg $CaCO_3$/L) and has a median value of 720 mg $CaCO_3$/L. The alkalinity is mainly present as bicarbonate (HCO_3) in the samples. Most water extracts have a relatively low acidity value ranging from <1 to 101 mg $CaCO_3$/L, and excess alkalinity, leading to a positive net alkalinity value.

The total concentration of major ions in the water extracts is variable, with the dominant major ion typically being bicarbonate, accompanied by lower concentrations of sodium and chloride. Calcium magnesium, potassium and sulfate are also present in the water extracts in comparatively minor amounts. The concentration of dissolved sulfate in the water extracts ranges from 8 to 64 mg/L (median 24 mg/L) and therefore all the samples have a sulfate concentration more than an order of magnitude below the applied (ANZECC & ARMCANZ, 2000) water quality guideline criterion (1,000 mg/L) for livestock drinking water for this anion.

The concentration of trace metals/metalloids tested in the water extracts is typically low and predominantly below the laboratory LoR. Most metal/metalloid concentrations tested in the water extracts are below the applied water quality guideline criteria. The concentrations of arsenic (2 samples) and selenium (4 samples) are above the applied aquatic freshwater ecosystem water quality guideline concentrations for 95 % species protection (ANZECC & ARMCANZ, 2000). One of the water extracts samples has a selenium concentration (0.04 mg/L) higher than the applied livestock drinking watyer guideline value (0.02 mg/L). All other water extract samples have trace metal/metalloid concentrations at or below the applied livestock drinking water guidelines.

On the basis of these results, it is expected that the risk of potential impact on the quality of surface and groundwater water from water in contact with mining waste materials at the Project should be low.

The dynamic quality of mining waste contact water and any potential risk of to water resources at the site is investigated further using KLC tests in **Section 4.6.**

4.6 Water Quality Kinetic Tests

KLC testing has been completed on six composite samples of mining waste materials (using the methodology described in **Section 3.2.2** and **Attachment C**. The samples used in the KLC tests are listed in **Table B5** (**Attachment B**). The KLC tests were completed for a period of six months from July 2017 to January 2018 under a monthly watering and leaching cycle. The KLC tests were operated following mining industry guidelines for such tests (AMIRA, 2002; COA, 2016).

The leachate results from the KLC test program are presented alongside Australian water quality guideline values for livestock drinking water quality (ANZECC & ARCANZ, 2000). These guidelines are provided for context only and are not intended to be interpreted as “maximum permissible levels” for site water storage or discharge. It should be noted that the KLC samples were crushed to pass a 10 mm sieve size and therefore have a high surface area for potential geochemical reaction. The ratio of sample to water in the KLC tests was approximately 2:1 (w/v) (ie. concentrated), whereas the ratio of sample to water generally used in tests where results can (arbitrarily) be compared against guideline concentrations to provide relevant context is an order of magnitude more dilute at 1:5 (w/v). Whilst arbitrary comparisons against guideline concentrations can be helpful in some situations to provide relevant context, such comparisons cannot be directly extrapolated to the field situation at the Project.

The monthly KLC leach test results for the six composite mining waste samples are presented in **Attachment D**. Tables **KLC1** to **KLC6** provide the KLC test data for seven leach events (over six

months), selected components of which are also shown graphically. The KLC test results obtained to date indicate that:

- Leachate from the six KLC tests typically remains in the pH range 6 to 9 throughout the test period. The leachate pH from the sandstone sample (KLC3) was marginally above this pH range on one occasion.
- The acidity concentration in leachate from the six KLC tests is typically very low and ≤ 3 mg/L (as $CaCO_3$). In contrast, the alkalinity concentration in leachate for the six KLC tests is elevated and varies between 4 and 77 mg/L (as $CaCO_3$). These sample characteristics lead to positive net alkalinity values for all leachate samples.
- Apart from the carbonaceous siltstone and coal sample (KLC6), leachate from all KLC tests has an EC value less than 800 µs/cm. The EC value generally shows a steady or decreasing EC trend throughout the test period and at the end of six months the EC value is less than 203 µs/cm in leachate from all samples. The elevated EC value in the initial 'first flush' from KLC6 is probably at least partly due to the increased solubility of minerals through crushing the sample material before loading into the KLC test column.
- The major ion concentrations in leachate from the KLC tests are dominated by sodium and chloride (and bicarbonate) with lesser concentrations of sulfate in the siltstone samples KLC1 and KLC 2.
- The sulfate concentration in KLC leachate from all mining waste samples remains well below the applied ANZECC & ARMCANZ stock water quality guideline criterion (1,000 mg/L) over the test period.
- The KLC test samples retain at least ~95 % of their inherent total sulfur content after six months of exposure to idealised oxidising conditions, which reflects the slow rate of sulfide oxidation for these materials.
- The KLC test samples retain at least 99 % of their inherent ANC value after six months of exposure to idealised oxidising conditions.
- The sulfate generation rate results obtained for the six KLC tests on the mining waste samples have been used to determine the rate of sulfide oxidation in these materials. Most sulfate salts generated from sulfide reaction involving materials with a relatively low sulfide sulfur concentration are highly soluble, and therefore will be collected in column leachate. The dissolved sulfate (and calcium) concentrations in the KLC leachate are typically less than the solubility limit of gypsum ($CaSO_4$), for example, which indicates that sulfate generation is not controlled by gypsum dissolution in the KLC test materials. Therefore, the sulfate concentrations and oxidation rate calculations provide reasonable estimates of these parameters and the results align well with existing static and dynamic geochemical data derived from a wide range of mining waste materials (AMIRA, 1995). The sulfate generation rate and associated sulfide oxidation rate for the six KLC tests are shown in **Table 4-4**.
- The sulfate generation rate from the KLC samples ranges from 0.34 to 4.47 mg/kg/week indicating that the rate of sulfide oxidation is low in these materials (equivalent to an oxidation rate ranging from 1.40×10^{-10} to 1.91×10^{-9} kg $O_2/m^3/s$). Mining waste materials with an oxidation rate in the low range (ie. less than 1×10^{-8} kg $O_2/m^3/s$) and a moderate ANC level have an increased factor of safety, and are likely to generate leachate that is pH neutral and/or has low levels of acidity (AMIRA, 1995; Bennett *et al*., 2000). Hence, all of the KLC samples tested fall into this category. Overall, the KLC results reflect the range of material characteristics predicted from the static geochemical test results presented in **Section 4.1**.

Table 4-4: Sulfate Generation and Sulfide Oxidation Rates for KLC Tests on Mining Waste

KLC Sample Number	Sample Description	Sulfate Generation Rate (mg/kg/week)	Oxidation Rate (kg $O_2/m^3/s$)
KLC1	Siltstone	0.65	2.69×10^{-10}
KLC2	Siltstone	0.34	1.40×10^{-10}
KLC3	Sandstone	2.00	8.20×10^{-10}
KLC4	Coal	2.45	1.00×10^{-9}
KLC5	Weathered Coal	1.41	5.77×10^{-10}
KLC6	Carbonaceous Siltstone & Coal	4.47	1.91×10^{-9}

- The concentration of trace metals/metalloids in leachate from the KLC samples is low and typically below the laboratory limit of reporting (LoR). This suggests that most trace metals/metalloids are sparingly soluble at the current pH of the KLC leachate. All measured leached metals/metalloids have concentrations below the applied water quality guideline values (ANZECC & ARMCANZ, 2000). The only exception is the concentration of selenium in initial leachate from KLC 6 (carbonaceous siltstone and coal), although the selenium concentration reduces to below the laboratory LoR for all subsequent leaching events.

Potential implications of these results with respect to the management of mining waste materials at the Project are discussed further in **Section 5.0.**

5.0 DISCUSSION

5.1 AMD Potential and Management

The results of the ABA tests presented in **Section 4** indicate that the AMD potential of the mining waste samples low. The overwhelming majority of the mining waste samples are classified as NAF, have excess ANC, and have very low sulfur content. Whilst the sulfur content of coal and carbonaceous siltstone can be elevated compared to typical background concentrations, it is mainly present in the non-sulfidic form, which does not contribute to acid generation. Overall, these samples represent materials with a very low risk of acid generation and a high factor of safety with respect to potential AMD.

Operational sampling and geochemical testing of mining waste materials should be used strategically throughout the mine life to verify these findings. The focus of the testing should be on potential coal reject (coal seam roof and floor samples from drill core) and actual coal rejects (coarse rejects and tailings from the coal quality laboratory or CHPP when the mine is operational).

Whilst no actual coal reject samples were available to be included in this geochemical assessment, representative sample of these materials are the subject of a separate geochemical assessment program (RGS, 2019). In the test program described herein, geochemical results for carbonaceous siltstone and coal materials suggest that inherent sulfur is mainly present in a NAF (non-sulfide) form. Coal materials will only remain stockpiled at the Run-of-Mine (ROM) area for a relatively short period of time, and management of these materials should for this reason, involve regular collection and monitoring of surface runoff and seepage from the ROM area.

Representative samples of coal reject materials likely to be generated from the Project have already been subjected to a program of both static and kinetic geochemical tests to verify the static and dynamic geochemical nature of these materials (RGS, 2019). It is expected that a relatively small amount of PAF coal reject materials will be encountered at the Project, and this material will be encapsulated within a much larger volume of NAF overburden materials with excess neutralising capacity at spoil dumps, with little risk of any adverse environmental outcome. This strategy is successfully employed at several coal mines in the Bowen Basin (eg. Middlemount Coal Mine).

5.2 Multi-Element Composition and Water Quality

5.2.1 Multi-element Composition and Enrichment

The multi-element concentrations of metal/metalloids in mining waste materials are presented in **Section 4.2**, along with a comparison with median crustal abundance in soils. The results indicate that most of the mining waste materials are not significantly enriched with metals/metalloids compared to median crustal abundance for non-mineralised areas. Whilst one of the siltstone samples was enriched with cobalt compared to median crustal abundance, the nature of a coal deposit means some metals/metalloids are expected to be slightly elevated in some mining waste materials.

5.2.2 Water Quality

Static and kinetic geochemical test results indicate that initial surface run-off and seepage from the NAF mining waste materials is likely to be pH neutral to alkaline and have a moderate salinity value. Weathered mining waste materials tends to have a higher salinity value than fresh materials. Surface runoff and seepage from bulk mining waste materials is likely to be in the range (pH 6 to 9) required for 95 % species protection in freshwater aquatic ecosystems (ANZECC & ARMCANZ, 2000).

The major ion concentrations in leachate from NAF mining waste materials are relatively low and dominated by bicarbonate, sodium, chloride and to a lesser extent sulfate. The sulfate concentration in leachate from all mining waste samples tested is well below the applied ANZECC & ARMCANZ livestock water quality guideline criterion (1,000 mg/L).

The initial concentration of most trace metals/metalloids tested for water in contact with most mining waste materials is typically low and predominantly below the laboratory LoR and applied water quality guideline criteria. The static water extract results suggest that whilst the concentrations of arsenic and selenium can be above applied aquatic freshwater ecosystem water quality guideline concentrations for 95 % species protection (ANZECC & ARMCANZ, 2000) in a few individual samples. However, the concentration of these metals/metalloids in surface runoff and seepage from bulk mining waste materials is likely to be much lower and within the applied guideline concentrations described above. Whilst one carbonaceous siltstone water extract sample had a selenium concentration marginally above the applied livestock drinking water guideline value, all other water extract samples have trace metal/metalloid concentrations at or below the applied livestock drinking water guideline values.

Direct comparison of dynamic KLC test leachate concentration values against the applied livestock water quality guideline criteria is not strictly valid due to a number of factors including scale-up effects, the high sample:water ratio (2:1), the high sample surface area used in the KLC tests, and the highly oxidising (cyclical wet and dry) assumed "worst case" conditions. However, it does highlight those elements, which may have the potential to be mobile under fully oxidising conditions.

The KLC leachate results from the NAF mining waste materials indicate that most metals/ metalloids are sparingly soluble under the current water extract and KLC leachate pH conditions, when compared against applied Australian water quality guideline values (ANZECC & ARMCANZ, 2000). The only minor exception is selenium in the initial leachate from one carbonaceous siltstone/coal sample. It should be noted that this metalloid is commonly indicated as elevated in KLC test programs for mining waste materials from coal mines in the Bowen Basin, but is not commonly detected in surface and groundwater monitoring programs in the field.

On the basis of the water extract and KLC test results described above, it is expected that the risk of potential impact on the quality of surface and groundwater water from water in contact with mining waste materials at the Project should be low.

5.3 Revegetation and Rehabilitation

From a soil chemistry viewpoint, bulk mining waste materials are likely to be pH neutral to alkaline. Most of these materials may also have some risk of being susceptible to dispersion and erosion, although these material characteristics could be improved to some extent by the addition of gypsum. In addition, fertiliser addition may also need to be considered for these materials to provide a reasonable growth medium for revegetation and rehabilitation.

Additional testing, including field trials, may be needed when the mine is operational and bulk mining waste materials become available, to determine the best management option for progressive rehabilitation of these materials during operations and at mine closure.

6.0 CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusions

RGS has completed a geochemical assessment of mining waste materials at the Gemini Coal Project. The scope of work completed by RGS is described in **Section 1.2**. The main findings of the geochemical assessment are as follows:

- All of the mining waste samples are classified as NAF, have excess ANC and typically have low sulfur. Whilst the sulfur content of coal and carbonaceous siltstone can be elevated compared to typical background concentrations, it is mainly present in the non-sulfidic form, which does not contribute to acid generation. Overall, these samples represent materials with a very low risk of acid generation and a high factor of safety with respect to potential for AMD.
- Initial and ongoing surface runoff and seepage from mining waste materials is expected to be moderately alkaline and have a moderate level of salinity.
- Kinetic leach column (KLC) test results indicate that mining waste materials are unlikely to generate acid conditions and are more likely to generate pH neutral to alkaline conditions.
- Metal/metalloid enrichment in mining waste materials, compared to median crustal abundance in non-mineralised soils, is limited to cobalt in a single carbonaceous siltstone sample. However, the nature of a coal deposit means some metals/metalloids are expected to be slightly elevated in some materials.
- Most metals/metalloids are sparingly soluble at the neutral to alkaline pH of leachate expected from bulk mining waste materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk mining waste materials are therefore expected to be low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities.
- Mining waste materials should be amenable to revegetation as part of rehabilitation activities, although, gypsum and fertiliser addition may need to be considered for sodic materials to limit dispersion and erosion and to provide a reasonable growth medium for revegetation and rehabilitation.
- As most mining materials appear to be susceptible to dispersion and erosion, additional testing including field trials, may be needed when the mine is operational and bulk materials are being generated. Such tests would help to determine the most appropriate management option for progressive rehabilitation of these materials during operations at mine closure.

6.2 Recommendations

As a result of the geochemical assessment work completed on mining waste materials at the Project, a number of recommendations are provided for these materials to minimise the risk of any significant environmental harm to the immediate and downstream environment.

- Placement of any carbonaceous mining waste material encountered during mining at the surface and outer batters of spoil emplacement areas should be avoided.
- Additional overburden/interburden testing and rehabilitation field trials should be completed during operations when bulk materials become available to confirm the most appropriate management option for progressive rehabilitation of these materials during operations and at mine closure.
- Surface water and seepage from the proposed mining and mining waste storage areas should be monitored to ensure that key water quality parameters remain within appropriate criteria. Water quality monitoring parameters should include pH, EC, total suspended solids (TSS) on a quarterly basis and the suite of water quality analyses described in **Table B4** (**Attachment B**) of this report opportunistically and at least on an annual basis.

Notes

1. Current pH, EC, Alkalinity and Acidity provided for 1:5 sample:water extracts
2. Scr = Chromium Reducible Sulfur; MPA = Maximum Potential Acidity; ANC = Acid Neutralising Capacity; and NAPP = Net Acid Producing Potential.
3. Sample classification criteria detail provided in report text.

* Where total sulfur or ANC results are less than the laboratory Limit of Reporting (LoR) a value of half of the LoR is used .

Geochemical Assessment of Mining Waste Materials

ATTACHMENT C

GEOCHEMICAL ASSESSMENT OF MINING WASTE MATERIALS

ACID GENERATION AND PREDICTION

Acid generation is caused by the exposure of sulfide minerals, most commonly pyrite (FeS_2), to atmospheric oxygen and water. Sulfur assay results are used to calculate the maximum acid that could be generated by the sample by either directly determining the pyritic S content or assuming that all sulfur not present as sulfate occurs as pyrite. Pyrite reacts under oxidising conditions to generate acid according to the following overall reaction:

$$FeS_2 + 15/4\ O_2 + 7/2\ H_2O \rightarrow Fe(OH)_3 + 2\ H_2SO_4$$

According to this reaction, the maximum potential acidity (MPA) of a sample containing 1%S as pyrite would be 30.6 kg H_2SO_4/t. The chemical components of the acid generation process consist of the above sulfide oxidation reaction and acid neutralization, which is mainly provided by inherent carbonates and to a lesser extent silicate materials. The amount and rate of acid generation is determined by the interaction and overall balance of the acid generation and neutralisation components.

Net Acid Producing Potential

The net acid producing potential (NAPP) is used as an indicator of materials that may be of concern with respect to acid generation. The NAPP calculation represents the balance between the maximum potential acidity (MPA) of a sample, which is derived from the sulfide sulfur content, and the acid neutralising capacity (ANC) of the material, which is determined experimentally. By convention, the NAPP result is expressed in units of kg H_2SO_4/t sample. If the capacity of the solids to neutralise acid (ANC) exceeds their capacity to generate acid (MPA), then the NAPP of the material is negative. Conversely, if the MPA exceeds the ANC, the NAPP of the material is positive. A NAPP assessment involves a series of analytical tests that include:

Determination of pH and EC

pH and EC measured on 1:5 w/w water extract. This gives an indication of the inherent acidity and salinity of the waste material when initially exposed in a waste emplacement area.

Total sulfur content and Maximum Potential Acidity (MPA)

Total sulfur content is determined by the Leco high temperature combustion method. The total sulfur content is then used to calculate the MPA, which is based on the assumption that the entire sulfur content is present as reactive pyrite. Direct determination of the pyritic sulfur content can provide a more accurate estimate of the MPA.

Acid neutralising capacity (ANC)

By addition of acid to a known weight of sample, then titration with NaOH to determine the amount of residual acid. The ANC measures the capacity of a sample to react with and neutralise acid. The ANC can be further evaluated by slow acid titration to a set end-point in the Acid Buffering Characteristic Curve (ABCC) test through calculation of the amount of acid consumed and evaluation of the resultant titration curve.

Net acid producing potential (NAPP)

Calculated from the MPA and ANC results. The NAPP represents the balance between a sample's inherent capacities to generate and neutralise acid. If the MPA is greater than the ANC then the NAPP is positive. If the MPA is less than the ANC then the NAPP is negative.

Net Acid Generation (NAG)

The net acid generation (NAG) test involves the addition of hydrogen peroxide to a sample of mine rock or process residue to oxidise reactive sulfide, then measurement of pH and titration of any net acidity produced by the acid generation and neutralisation reactions occurring in the sample. A significant NAG result (*i.e.* final $NAG_{pH} < 4.5$) indicates that the sample is potentially acid forming (PAF) and the test provides a direct measure of the net amount of acid remaining in the sample after all acid generating and acid neutralising reactions have taken place. A $NAG_{pH} > 4.5$ indicates that the sample is non-acid forming (NAF). The NAG test provides a direct assessment of the potential for a material to produce acid after a period of exposure and weathering and is used to refine the results of the theoretical NAPP predictions. The NAG test can be used as a stand-alone test, but is recommended that this only be considered after site specific calibration work is carried out. RGS generally avoids use the NAG test at coal mining projects as the high organic content of some materials can cause erroneous results.

ASSESSMENT OF ELEMENT ENRICHMENT AND SOLUBILITY

In mineralised areas it is common to find a suite of enriched elements that have resulted from natural geological processes. Multi-element scans are carried out to identify any elements that are present in a material (or readily leachable from a material) at concentrations that may be of environmental concern with respect to surface water quality, revegetation and public health. The samples are generally analysed for the following elements:

Major elements	Al, Ca, Fe, K, Mg, Na and S.
Minor elements	As, B, Cd, Co, Cr, Cu, F, Hg, Mn, Mo, Ni, Pb, Sb, Se and Zn.

The concentration of these elements in samples can be directly compared with relevant state or national environmental and health based concentration guideline criteria to determine the level of significance. Water extracts are used to determine the immediate element solubilities under the existing sample pH conditions of the sample. The following tests are normally carried out:

Multi-element composition of solids.

Multi-element composition of solid samples determined using a combination of ICP-mass spectroscopy (ICP-MS), ICP-optical emission spectroscopy (OES), and atomic absorption spectrometry (AAS).

Multi-element composition of water extracts (1:5 sample:deionised water).

Multi-element composition of water extracts from solid samples determined using a combination of ICP-mass spectroscopy (ICP-MS), ICP-optical emission spectroscopy (OES), and atomic absorption spectrometry (AAS).

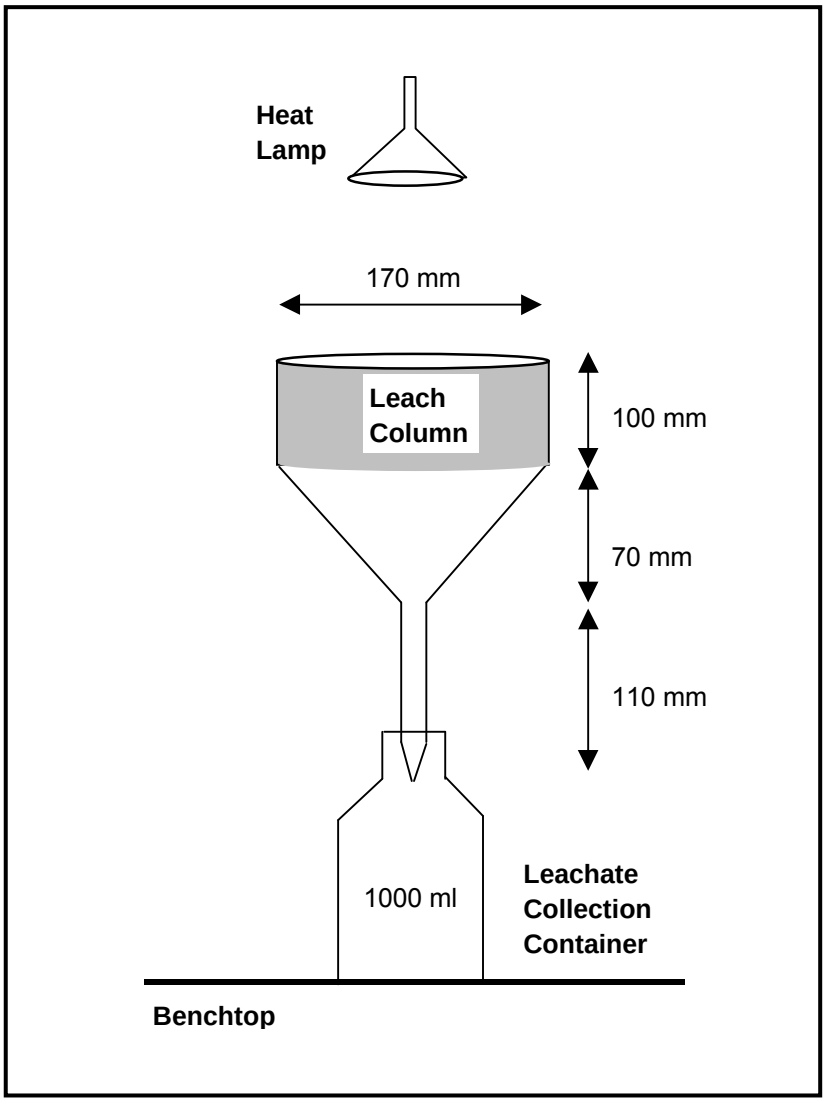
Under some conditions (*e.g.* low pH) the solubility and mobility of common environmentally important elements can increase significantly. If element mobility under initial pH conditions is deemed likely and/or subsequent low pH conditions may occur, kinetic leach column test work may be completed on representative samples.

KINETIC LEACH COLUMN TESTS

Kinetic leach column (KLC) tests can be used to provide information on the reaction kinetics of mining waste materials. The major objectives of kinetics tests are to:

- Provide time-dependent data on the kinetics and rate of acid generation and acid neutralising reactions under laboratory controlled (or onsite conditions);
- Investigate metal release and drainage/seepage quality; and
- Assess treatment options such as addition of alkaline materials.

The KLC tests simulate the weathering process that leads to acid and base generation and reaction under laboratory controlled or site conditions. The kinetic tests allow an assessment of the acid forming characteristics and indicate the rate of acid generation, over what period it will occur, and what management controls may be required.



In KLC tests, water is added to a sample and the mixture allowed to leach products and by-products of acid producing and consuming reactions. Samples of leachate are then collected and analysed. Intermittent water application is applied to simulate rainfall and heat lamps are used to simulate sunshine. These tests provide real-time information and may have to continue for months or years. Monitoring includes trends in pH, sulfate, acidity or alkalinity, and metals, for example. The pH of the collected leachate simulates the acid drainage process, acidity or alkalinity levels indicate the rate of acid production and acid neutralisation, and sulfate production can be related to the rate of sulfide oxidation. Metal concentration data provides an assessment of metal solubility and leaching behaviour.

Figure C1 shows the kinetic leach column set up used by RGS adapted from *AMIRA, 2002*. The columns are placed under heat lamps to allow the sample to dry between water additions to ensure adequate oxygen ingress into the sample material.

Approximately 2 kg of sample is accurately weighed and used in the leach columns and depending on the physical nature of the material and particle size can be used on an as-received basis (*i.e.* no crushing as with process residues) or crushed to nominal 5-10 mm particle size (as with waste rock). The sample in the column is initially leached with deionised water at a rate of about 400 ml/kg of sample and the initial leachate from the columns collected and analysed. Subsequent column leaching is carried out at a rate of about 400 ml/kg per month and again collected and analysed. The leaching rate can be varied to better simulate expected site conditions or satisfy test program data requirements. The column must be exposed to drying conditions in between watering events. The residual water content and air void content in the column can be determined by comparing the wet and dry column weights. A heat lamp is generally used above the sample during daylight hours to maintain the leach column surface temperature at about 30^{o}C.

CERTIFICATE OF ANALYSIS

Work Order	: **EB1711745**	Page	: 1 of 17
Client	: **RGS ENVIRONMENTAL PTY LTD**	Laboratory	: Environmental Division Brisbane
Contact	: MR ALAN ROBERTSON	Contact	: Customer Services EB
Address	: PO Box 3091 SUNNYBANK SOUTH QLD, AUSTRALIA 4109	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: +61 07 3344 1222	Telephone	: +61-7-3243 7222
Project	: Dingo West Coal Project	Date Samples Received	: 07-Jun-2017 15:30
Order number	: ----	Date Analysis Commenced	: 10-Jun-2017
C-O-C number	: ----	Issue Date	: 23-Jun-2017 07:35
Sampler	: ----		
Site	: ----		
Quote number	: BNBQ/218/16		
No. of samples received	: 71		
No. of samples analysed	: 71		

ilac-MRA NATA
Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Ben Felgendrejeris		Brisbane Acid Sulphate Soils, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Satishkumar Trivedi	Acid Sulfate Soils Supervisor	Brisbane Acid Sulphate Soils, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- ASS: EA013 (ANC) Fizz Rating: 0- None; 1- Slight; 2- Moderate; 3- Strong; 4- Very Strong; 5- Lime.

CERTIFICATE OF ANALYSIS

Work Order	: **EB1713010**	Page	: 1 of 16
Client	: **RGS ENVIRONMENTAL PTY LTD**	Laboratory	: Environmental Division Brisbane
Contact	: MR ALAN ROBERTSON	Contact	: Customer Services EB
Address	: PO Box 3091 SUNNYBANK SOUTH QLD, AUSTRALIA 4109	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: +61 07 3344 1222	Telephone	: +61-7-3243 7222
Project	: 2017002 Dingo west	Date Samples Received	: 26-Jun-2017 09:32
Order number	: ----	Date Analysis Commenced	: 29-Jun-2017
C-O-C number	: ----	Issue Date	: 04-Jul-2017 14:39
Sampler	: ----		
Site	: ----		
Quote number	: BNBQ/218/16		
No. of samples received	: 39		
No. of samples analysed	: 28		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Andrew Epps	Senior Inorganic Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Andrew Epps	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Ben Felgendrejeris		Brisbane Acid Sulphate Soils, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- **The samples in this work order have been re-batched from EB1711745.**
- ED037 (Alkalinity): NATA accreditation does not cover the performance of this service.
- ED038 (Acidity): NATA accreditation does not cover the performance of this service.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EG020-F (Dissolved Metals): Sample EB1716488-002 shows poor matrix spike recovery due to matrix interference. Confirmed by re-extraction re-analysis.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When no sampling time is provided, the sampling time will default 00:00 on the date of sampling. If no sampling date is provided, the sampling date will be assumed by the laboratory and displayed in brackets without a time component.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EG020-F (Dissolved Metals): Sample EB1718212-002 (KLC 2) has poor spike recovery due to matrix interference. Confirmed by re-analysis.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EG020-F (Dissolved Metals): Sample EB1723252-002 has poor spike recovery due to matrix interference. Confirmed by re-analysis.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- Ionic Balance out of acceptable limits due to analytes not quantified in this report.

ilac-MRA NATA
Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Greg Vogel	Laboratory Manager	Brisbane Inorganics, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- Ionic Balance out of acceptable limits due to analytes not quantified in this report.

1 Introduction

1.1 Background

Magnetic South Pty Ltd (Magnetic South) is the project proponent and the applicant for the Mining Lease (ML) and Environmental Authority (EA) to develop the Gemini Project (the Project), a greenfield open cut mine to produce pulverised coal injection (PCI) coal and Coking Coal products for export for steel production. The Project term is anticipated to be 25 years from grant of the ML with this term including initial construction, mine operation and rehabilitation activities.

The Project is located on EPC 881 in the Bowen Basin, Central Queensland. Located 20 km east of Bluff and 6 km west of Dingo, the tenement straddles the Capricorn Highway and the Blackwater-Gladstone rail network (**Figure A1**, **Attachment A**).

The main activities associated with the Project include:

- Exploration activities continuing in order to support mine planning.
- Development of a Mine Infrastructure Area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, explosives magazine and sewage, effluent and liquid waste storage.
- Construction and operation of a Coal Handling Preparation Plant (CHPP) and coal handling facilities adjacent to the MIA (including Run-of-Mine (ROM) coal, product stockpiles and reject stockpiles [coarse and fine rejects]).
- Construction and operation of a surface conveyor from the product stockpiles to a Train Load Out (TLO) facility and rail loop connecting to the Blackwater-Gladstone Branch Rail to transport product coal to coal terminals at Gladstone for export.
- Construction of access roads from the Capricorn Highway to the MIA, and to the TLO facility.
- Installation of a raw water supply pipeline to connect to the Blackwater Pipeline network.
- Construction of a 66 kV transmission line and switching/substation to connect to the existing regional network.
- Other associated minor infrastructure, plant, equipment and activities.
- Development of mine areas (open cut pits) and out-of-pit waste rock emplacements.
- Drilling and blasting of competent waste material.
- Mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers).
- Mining up to 1.9 Mtpa ROM Coal – average 1.8 Mtpa for an operational mine life of approximately 20 years.
- Progressive placement of waste rock (overburden/interburden) in:
  - Emplacements, adjacent to and near the open cut voids.
  - Mine voids, behind the advancing open cut mining operations.
- Progressive rehabilitation of waste rock emplacement areas and mined voids.
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works). Material will be sourced from local quarries where required.
- Disposal of CHPP rejects (coarse and fine rejects) in out of pit waste rock emplacements, and in-pit behind the mining void.

- Progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access.
- Development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, diversions and drains.

Existing local and regional infrastructure, facilities and services will be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway, and Gladstone export coal terminals.

The proposed mine will target the Rangal coal measures. Up to seven seams/plies are targeted, ranging in thickness from 0.5 m to 3.0 m. The seams are impacted by faulting and seam splitting and are typically overlain by overburden ranging in depth from 45 m to 60 m.

As part of the technical studies being completed for input into the environmental approvals process, RGS Environmental Pty Ltd (RGS) was commissioned by Magnetic South to complete a geochemical assessment of potential coal reject material at the Project.

1.2 Previous Studies

RGS previously completed a geochemical assessment of representative samples of mining waste materials at the Project focussing on overburden and interburden materials (RGS, 2018). The assessment found that the mining waste materials were non-acid forming (NAF), with excess acid neutralising capacity (ANC), and typically low sulfur content. Where higher sulfur was present in coal and carbonaceous siltstones, it was mainly present as non-sulfidic sulfide, and unlikely to contribute to acid generation. Overall, the mining waste materials were found to have a high factor of safety and a very low risk of acid generation. Overall, initial and ongoing surface runoff and seepage from mining waste materials represented by the samples tested was expected to be moderately alkaline and have a moderate level of salinity.

The mining waste materials contained low concentration of total metals/metalloids compared to median crustal abundance in non-mineralised soils, and most metals/metalloids were expected to be sparingly soluble at the neutral to alkaline pH of leachate from bulk mining waste materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk mining waste materials were predicted to be low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities.

Mining waste materials were found to be amenable to revegetation as part of rehabilitation activities, although, it was suggested that sodic materials could require gypsum and fertiliser amendment to limit dispersion and erosion and to provide a reasonable growth medium for revegetation and rehabilitation. Rehabilitation field trials on bulk materials were recommended to be completed during the operational phase of the mine to determine the most appropriate management option for progressive rehabilitation and at mine closure.

1.3 Scope of work

The objective of the work program was to complete a geochemical assessment of representative samples of potential coal reject materials as part of the mine assessment and approvals process. The scope of work was developed by RGS based upon information provided to RGS by Magnetic South as well as previous site experience (RGS, 2018) and included:

- Selection of samples to best represent the coal reject materials;
- Coordination of the geochemical analysis program;
- Geochemical characterisation of the samples utilising both static and kinetic testing methods; and
- Preparation of a report to discuss the sample analysis results.

The work program was completed in accordance with relevant industry guidelines (DME, 1995, DEHP, 2013; COA, 2016a,b,c; and INAP, 2009).

1.4 Local geology

The project is located within the Dawson Fold Zone of the Bowen Basin. The project is focussed on the Rangal Coal Measures – Permian aged sediments consisting of siltstones, sandstone and coal seams. Up to seven seams/plies are planned to be targeted, ranging in thickness from 0.5 to 3.0 m. Typically, overburden in the project area ranges in depth from 45 m to 60 m, with varying interburden thicknesses between the seams. A representative stratigraphic column of the project area is shown in **Figure A2 (Attachment A)**.

Seams within the Rangal Coal Measures Seams (particularly the Aries, Castor and Pollux seams) commonly coalesce and split. The coal quality across the deposit is variable, but it generally described as low-volatile bituminous coal with moderate ash, sulfur and phosphorous. The geochemical assessment completed by RGS (RGS, 2018) on the overburden and interburden present at the proposed project indicated that the carbonaceous siltstone and coal material present at the site had elevated sulfur, mainly in the form of non-sulfide sulfur (ie., non-acid generating). The clay, sandstone and siltstone present showed sulfur concentrations below natural background concentration (ie., less than 0.1 %S).

2 Methodology

RGS personnel worked (Dr. Alan Robertson) worked closely with Magnetic South personnel and related coal quality consultants to facilitate the development of an appropriate sampling and geochemical testing plan for representative samples of coal reject materials from the Project.

2.1 Sample selection and preparation

The sampling methodology used to obtain representative samples of coal reject materials from the proposed Project area was undertaken in accordance with relevant guideline documents. Whilst there are no specific regulatory requirements regarding the number of samples required, existing risk-based technical guidelines for the geochemical assessment of mine rock in Australia (AMIRA, 2002; COA, 2016c) and worldwide (INAP, 2009) were used by RGS as a framework for the sampling program.

The sampling strategy was based on:

- Existing knowledge of the geology/stratigraphy and geochemistry of the site and expected low potential for any significant environmental or health impacts;
- Size of operation;
- Sample representation requirements;
- Material volumes;
- Level of confidence in predictive ability; and
- Cost.

A total of 80 coal reject samples from coal quality washability tests were provided to RGS from 14 different drill holes, which consisted of 52 coarse reject and 28 fine reject samples. The location of the drill holes in relation to the site is shown in **Figure A3** (**Attachment A**). The samples were combined into 22 composite samples by reject type and coal seam/ply (14 coarse reject samples and 8 fine reject samples). **Table 2.1** provides the number of combined samples generated for each coal seam.

Table 2.1: Composite coal reject samples generated

Coal Seam	Reject Type	Number of samples
AR2	Coarse	1
	Fine	1
AR3	Coarse	2
	Fine	1
CAS	Coarse	4
	Fine	2
PLU1	Coarse	5
	Fine	2
PLU2	Coarse	2
	Fine	2
Total		**22**

Samples were sent to Australian Laboratory Services (ALS) in Stafford Queensland. Once received, samples were prepared by crushing (where required) and pulverising to less than 75 µm size. This method of sample preparation results in a homogenous sample, but also generates a large sample surface area in contact with the resultant assay solution. This provides a greater potential for dissolution and reaction and represents an assumed initial 'worst case' scenario for these materials.

2.2 Geochemical test program

A series of geochemical tests were completed on the samples. The test program was designed to assess the degree of risk from the presence and potential oxidation of sulfides, and generation and the presence/leaching of soluble metals/metalloids and salts. A detailed summary of the parameters involved in completing a static and kinetic geochemical characterisation and assessment of mine materials is provided in **Attachment B**.

2.2.1 Static tests

Static geochemical tests provide a 'snapshot' of the characteristics of a sample material at a single point in time. These tests were staged to screen individual samples before selecting either individual and/or composite samples for more detailed static test work.

The Acid Base Account (ABA) was used as a screening procedure whereby the acid-neutralising and acid-generating characteristics of the samples were assessed. All 22 composite samples were screened using ABA. The ABA screening included static geochemical testing for the following parameters:

- pH (1:5 w:v, sample:deionised water);
- Electrical conductivity (EC) (1:5 w:v, sample:deionised water);
- Total sulfur [Leco method]; and
- Acid neutralising capacity (ANC) [AMIRA, 2002 method].

The results of the ABA tests are discussed in **Section 3.1**. After the results of the ABA screening test were received and interpreted, a total of 13 samples were also tested for sulfide sulfur as chromium reducible sulfur (Scr) using the Australian Standard (AS 4969.7, 2008) method. The remaining 9 samples did not have sufficient sample mass remaining for Scr analysis to be carried out.

From the total sulfur (or Scr where available) and ANC results, maximum potential acidity (MPA) and net acid producing potential (NAPP) values were calculated. Where available, the MPA and NAPP of these samples were calculated using the Scr data instead of total sulfur data. The use of Scr data (for fresh samples) provides a more accurate representation of the MPA that could theoretically be generated, as acid generation primarily occurs from reactive sulfide, whereas total sulfur can include other sulfur forms such as elemental sulfur, sulfate and organic sulfur.

After the results of the initial static geochemical tests were received and reviewed, all 22 samples were used to create three composite samples – one representing coarse reject material from the Castor (CAS) and Aries (AR) seams; one representing coarse reject material from the Pollox (PLU1 and PLU2) seams; and one representing fine reject material. All the composite samples were subjected to multi-element testing at ALS. The samples were tested for:

- pH and EC (1:5 w:v, sample:deionised water);
- Major Cations (Ca, Mg, K, Na) [HCl and HNO_3 acid digest followed by ICP-AES/MS];
- Major Anions (Cl, SO_4, F) [ICP-AES/MS and PC Titrator (1:5 w:v water extracts)].
- Acidity and Alkalinity as $CaCO_3$ mg/L [PC Titrator (1:5 w:v water extracts)];
- Total metals/metalloids in solids (Al, As, B, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Hg, K, Mg, Mn, Mo, Na, Ni, Pb, Sb, Se, Si, Th, U, V, Zn) [HCl and HNO_3 acid digest followed by FIMS and/or ICP-AES/MS]; and
- Soluble metals/metalloids (Al, As, B, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Hg, K, Mg, Mn, Mo, Na, Ni, Pb, Sb, Se, Si, Th, U, V, Zn) [ICP-AES/MS and FIMS (1:5 w:v water extracts)];

The ALS test results for the static geochemical test program are provided in **Attachment E**, and summary results tables provided in **Attachment C**. The static test results are discussed in **Sections 3.1** to **3.4**.

2.2.2 Kinetic tests

Following receipt and interpretation of the static geochemical test results, two kinetic leach column (KLC) tests were set up at the RGS 'in house' laboratory. One KLC was set up using material from the coarse reject samples, while the second KLC was set up using material from the fine coal reject samples. The KLC tests began in May 2019 on a monthly watering and leaching cycle and were operated for a period of six months until November 2019. A description of the material represented by each KLC is shown below in **Table 2.2**.

Table 2.2: KLC material description

KLC Sample #	Description
KLC1	Coarse reject
KLC2	Fine reject

Approximately 1.5 kg of each composite sample was accurately weighed and used in each of the KLC tests. Heat lamps were used daily to simulate sunshine and ensure that the KLC materials were unsaturated and subject to oxidising conditions between leaching events (this is essentially an assumed "worst case" scenario for sulfide oxidation and potential acid/salt generation). Further details and a schematic of the KLC test arrangement are provided in **Attachment B**.

All leachate samples collected from the KLC tests were assayed at ALS Brisbane for:

- pH and EC
- Acidity and alkalinity [PC Titrator]
- Dissolved metals/metalloids (Al, As, B, Cd, Co, Cr, Cu, Fe, Mn, Mo, Ni, Pb, Sb, Se, V and Zn) [ICP-AES/MS];
- Dissolved major cations (Ca, Mg, Na and K) [ICP-AES/MS]; and
- Dissolved major anions (Cl, SO_4) and F [ICP-AES/MS].

The ALS test results for the kinetic geochemical test program are provided in **Attachment E**, and summary results tables and trends provided in **Attachment D**. The kinetic test results are discussed in **Section 3.5**.

3 Results

3.1 ABA results

ABA test results for the 22 composite coal reject samples from the Project are presented in **Table C1** (**Attachment C**) and summarised below. The results are shown by reject type to facilitate interpretation.

3.1.1 pH and EC

The natural pH of the deionised water used in the pH tests is typically in the pH range of 5.0 to 6.5. The $pH_{(1:5)}$ of the 22 samples ranges from 5.1 to 8.3 (**Figure 3.1**) and has a median pH value of 7.4. The pH results indicate that the coal reject materials are typically in the pH neutral range. There does not appear to be any significant correlation between pH and reject type or coal seam/ply.

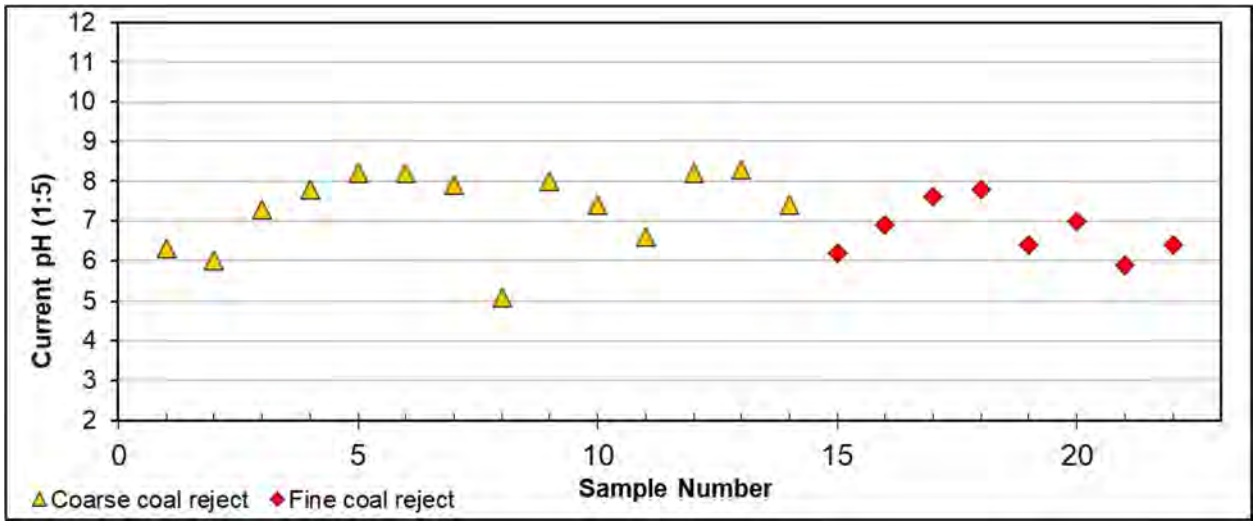

Figure 3.1: pH results for coal reject

The current $EC_{(1:5)}$ of the samples ranges from 398 to 1,620 µS/cm (median 774 µS/cm) (**Figure 3.2)**. There appears to be no significant correlation between EC and reject type or coal seam/ply.

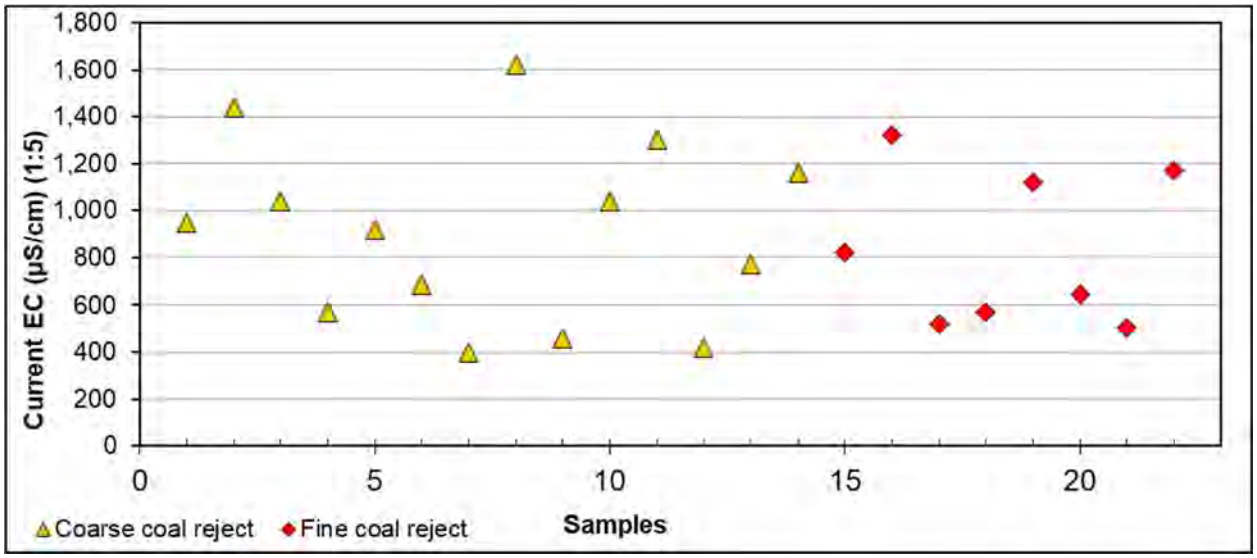

Figure 3.2: Electrical conductivity results for coal reject

To provide additional context, the $EC_{(1:5)}$ and $pH_{(1:5)}$ results are classified against pH and salinity criteria for mining waste materials, as defined by the Queensland DME (1995) technical guidelines for the environmental management of exploration and mining in Queensland (see **Table 3.1** below).

Table 3.1: Salinity and pH criteria for assessment of coal reject

	Very Low	Low	Medium	High	Very High
$pH_{1:5}$	**< 4.5**	**4.5 – 5.5**	**5.5 – 7.0**	**7.0 – 9.0** (Median – 7.4)	**> 9.0**
$EC_{1:5}$ (µS/cm)	**< 150**	**150 – 450**	**450 – 900** (Median – 774)	**900 – 2,000**	**> 2,000**

Note: Adapted from DME, 1995. Highlighted cells show the category corresponding to the median pH and EC values (orange shading) for the coal reject samples.

Based on the median pH and EC values, the coal reject samples tested are generally regarded as having 'high' soil pH and 'medium' salinity values.

The pH and EC tests were obtained from pulverised samples (≤ 75 µm) with a large surface area in contact with the leaching solution. This provides a greater potential for dissolution and reaction and represents an assumed initial 'worst case' scenario. It is also expected that the salinity of leachate from coal reject materials will diminish with time as salts are flushed from the sample matrix and a state of equilibrium develops. At that point, the salinity of seepage/runoff should stabilise at a lower asymptotic concentration relative to the oxidation/weathering/erosion of the materials.

3.1.2 Total sulfur

The total sulfur content of the samples ranges from 0.23 to 4.20 %S and has a median value of 1.03 %S, compared with the median crustal abundance value of 0.07 %S in unmineralised soils (Bowen, 1979; INAP, 2009). Materials containing greater than 0.1 %S are considered to potentially have some capacity to generate acidity. **Figure 3.3** provides the sulfur content of the sample materials and shows that most coal reject samples have a total sulfur concentration above median crustal abundance.

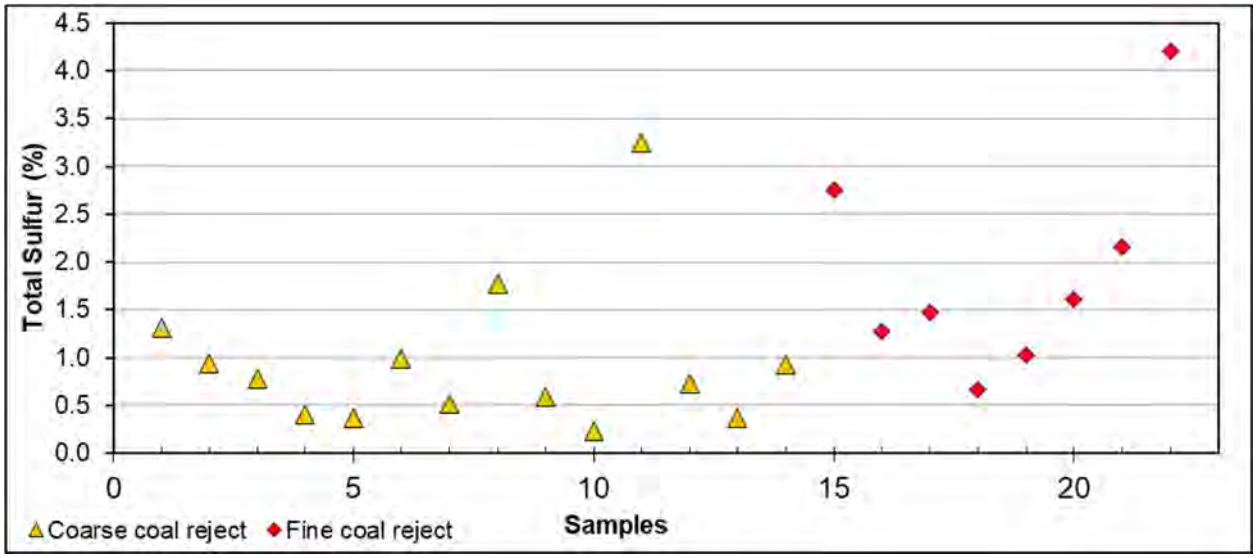

Figure 3.3: Total sulfur results for coal reject

3.1.3 Sulfide sulfur

The sulfide sulfur content for the 13 samples tested using the Scr method is illustrated in **Figure 3.4** . Sample 1 (coarse reject) and Samples 15 to 22 (fine reject) were not tested due to a lack of available sample material. The test results show a sulfide content ranging from 0.12 to 3.22 %S. The results indicate that, on average, more than half of the total sulfur content is present as sulfide sulfur (most likely pyrite/marcasite) and may have some potential to generate acidity.

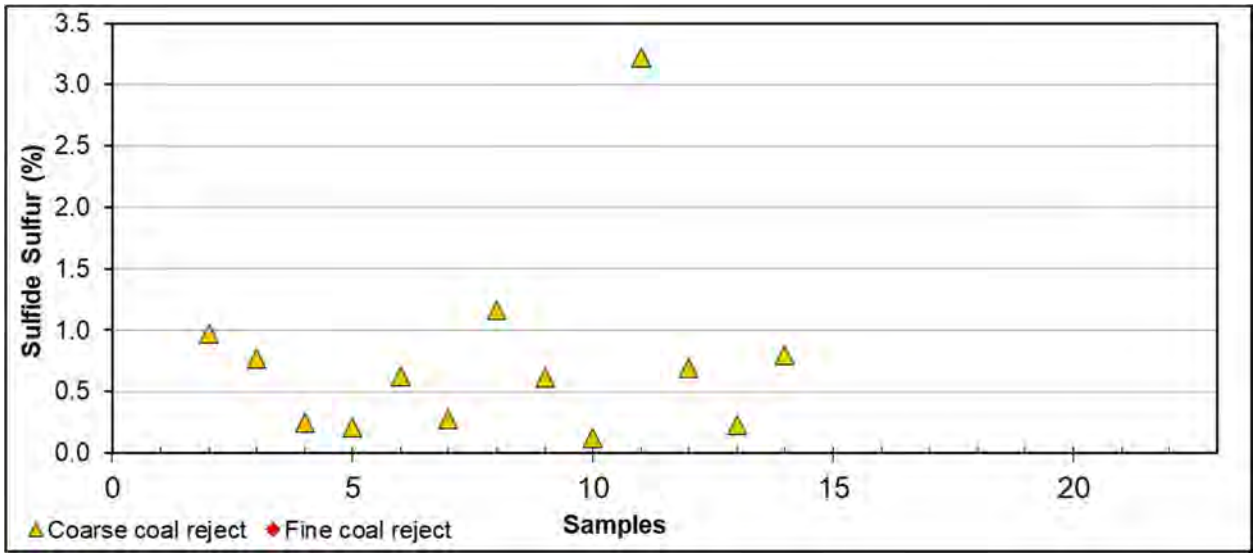

Figure 3.4: Sulfide sulfur results for coal reject

3.1.4 Maximum potential acidity

The Maximum Potential Acidity (MPA) for the reject samples ranges from 3.7 to 128.6 kg H_2SO_4/t, and has a median value of 31.5 kg H_2SO_4/t.

3.1.5 Acid neutralising capacity

The Acid Neutralising Capacity (ANC) for the reject samples ranges from 11.5 to 396.0 kg H_2SO_4/t and has a median value of 68.5 kg H_2SO_4/t (approximately double the median MPA).

3.1.6 Net acid producing potential

The Net Acid Producing Potential (NAPP) is the capacity of a sample to generate acidity (MPA) minus its capacity to neutralise acidity (ANC). The NAPP values for the reject samples range from -351.0 to 72.7 kg H_2SO_4/t, with a negative median value of -33.4 kg H_2SO_4/t (**Figure 3.5**). Sixteen (16) of the 22 coal reject samples have a negative NAPP value and six coal reject samples have a positive NAPP value.

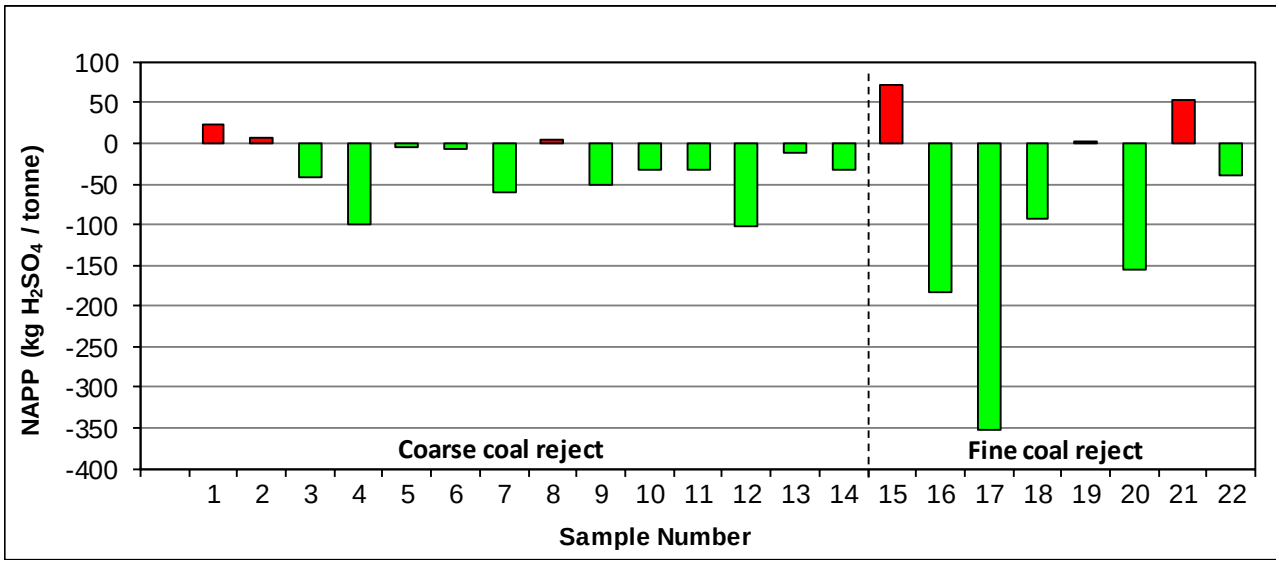

Figure 3.5: NAPP results for coal reject

3.1.7 ANC:MPA ratio

The ANC:MPA ratio of the samples ranges from 0.1 to 9.8, with a median value of 2.7. **Figure 3.6** shows a plot of the ANC versus MPA values for the samples. ANC:MPA ratio lines have been plotted on the graph to illustrate the factor of safety associated with the samples in terms of potential for generation of acid and metalliferous drainage (AMD). Generally, samples with an ANC:MPA ratio of greater than 2 are considered to represent material with a low to negligible risk of acid generation and a high factor of safety in terms of potential for AMD (COA, 2016c; INAP, 2009).

A total of 12 samples fall in the low to negligible risk categories, whilst 5 samples fall in the possible risk category, and 5 samples fall in the increased risk category.

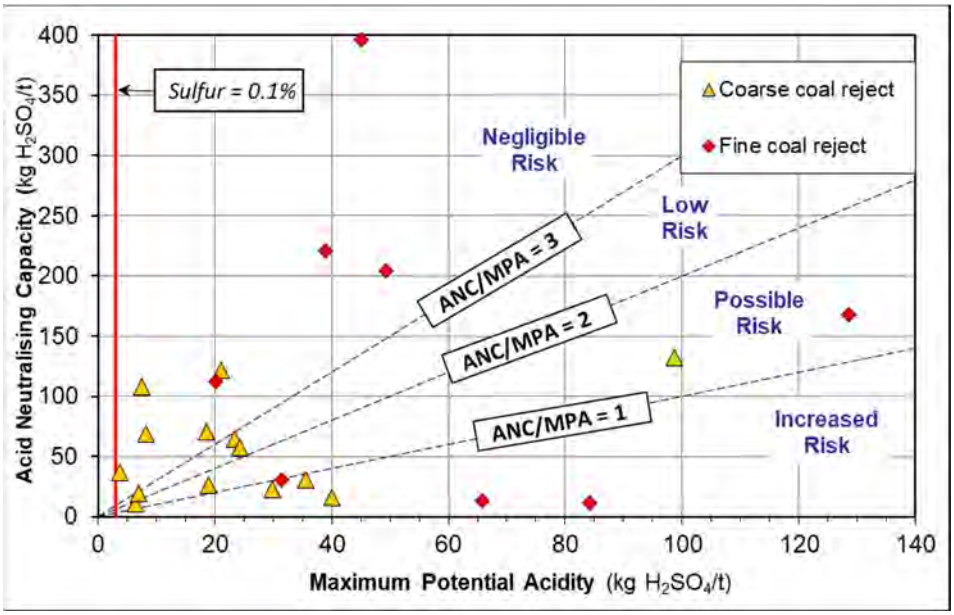

Figure 3.6: ANC vs MPA for coal reject

3.1.8 Geochemical classification

The results of the ABA testing have been used to classify the acid forming nature of the 22 coal reject samples. The classification criteria reflect Australian (COA, 2016c) and international (INAP, 2009) guidelines for the classification of mine waste materials. **Table 3.2** summarises the criteria used by RGS and gives a breakdown of the number of samples in each category.

Table 3.2: Geochemical classification criteria for coal reject

Geochemical Classification	Total Sulfur[1] (%)	NAPP (kg H_2SO_4/t)	ANC:MPA Ratio	No. Samples (n = 22)
Non-Acid Forming	> 0.1	≤ -5	≥ 2	15
Uncertain	> 0.1	> -5 and ≤ +5	≥ 1	2
Potentially Acid Forming (Low Capacity)	> 0.1	> +5 and ≤ +10	< 1	2
Potentially Acid Forming	> 0.1	> +10	< 1	3

The data presented in **Table 3.2** illustrate that 15 of the 22 samples tested (68 %) are classified as non-acid forming (NAF) as a result of the excess ANC present in these samples. Two samples are classified as Uncertain and have a low NAPP value that is negative or close to zero. Two samples are classified as potentially acid forming (low capacity) (PAF-LC) and have a positive NAPP value between 5 and 10 kg H_2SO_4/t. Three samples are classified as PAF and have a positive NAPP value greater than 10 kg H_2SO_4/t .

Whilst there is no strong correlation between the reject material type or coal seam/ply source, two of the three samples classified as PAF were sourced from the AR2 seam/ply and one was sources from the PLU2 seam/ply. Whilst AR seam/plys were included in this assessment, the AR seam coal reject materials make up a small fraction of the overall total coal reject materials likely to be generated at the Project. In addition, two of the three samples classified as PAF represent fine coal reject material which again makes up a relatively small fraction of the total coal reject materials, compared to coarse coal reject materials.

It is expected that blending of the coal reject materials during co-disposal at the Project will result in a bulk coal reject material that is classified as NAF. Most coal reject materials represented by the samples tested have excess ANC and is likely to provide a significant source of buffering to any acidity generated from the small proportion of PAF materials.

3.2 Multi-element concentration in solids

Multi-element assays were carried out on the three composite coal reject samples described in **Section 2.2.1** to identify any elements (metals/metalloids) present in these materials at concentrations that may be of environmental concern with respect to revegetation and surface water/groundwater quality. The total metals/metalloids concentration for individual elements in these materials can be relevant for revegetation activities and/or where the potential exists for human contact (eg. if the material was to be used off-site).

The results from the multi-element tests (total metals/metalloids) are shown in **Table C2** (**Attachment C**). For comparison, guideline values from the National Environmental Protection Measure (NEPM) (NEPC, 2013) are shown for some elements. Where no guideline values are listed, none are specified in the NEPM. All major, minor and trace elements tested returned values below those listed in the NEPM for Health-Based Investigation Level – HIL (C); public open spaces - recreational land use.

3.3 Geochemical abundance index

Total metal/metalloid concentrations in mining waste materials can be compared to the median crustal abundance for un-mineralised soils (Bowen, 1979, COA, 2016c and INAP, 2009). The extent of enrichment is reported as the Geochemical Abundance Index (GAI), which relates the actual concentration in a sample with the median (or average) crustal abundance on a $\log_{10}$ scale. The GAI is expressed in integer increments from 0 to 6, where a GAI value of 0 indicates that the element is present at a concentration less than, or similar to, the median crustal abundance; and a GAI value of 6 indicates approximately a 100-fold enrichment above median crustal abundance (see **Table 3.3**).

Table 3.3: Geochemical Abundance Index values and Enrichment Factors

GAI	Enrichment Factor	GAI	Enrichment Factor
-	Less than 3-fold enrichment	**4**	24 – 48 fold enrichment
1	3 – 6 fold enrichment	**5**	48 – 96 fold enrichment
2	6 – 12 fold enrichment	**6**	Greater than 96 fold enrichment
3	12 – 24 fold enrichment		

As a general rule, a GAI of 3 or greater signifies enrichment that may warrant further examination. This is particularly the case with some environmentally important 'trace' elements, such as arsenic, chromium, cadmium, copper, lead, selenium and zinc, more so than with major rock-forming elements, such as aluminium, calcium, iron, manganese and sodium.

Elements identified as enriched may not necessarily be a concern for revegetation, drainage water quality or public health, but their significance should still be evaluated. While the GAI provides an indication of metals/metalloids that may be enriched relative to the global median crustal abundance, the following points should also be considered:

- The median crustal abundance varies between different literature sources, therefore affecting the calculated GAI values.
- If a sample is shown to be enriched relative to the median crustal abundance, there is no direct correlation that that sample will also leach metals/metalloids at elevated concentrations. The mobility of metals/metalloids is dependent on mineralogy, adsorption/desorption and the environment in which it occurs.
- Whilst some element concentrations can be elevated relative to the median crustal abundance, the nature of an ore deposit means the background levels are generally expected to be elevated.

Similarly, because an element is not enriched does not mean it will never be a concern, because under some conditions (eg. low pH) the solubilities of common environmentally important elements such as aluminium, copper, cadmium, iron and zinc increase significantly.

Table C3 (**Attachment C**) provides total metal/metalloid concentrations for the three composited samples described in **Section 2.2**, and is compared to median crustal abundance (GAI). The GAI results indicate that of the metals/metalloids measured, none are significantly enriched compared to median crustal abundance. Hence, further examination is not considered necessary.

The potential solubility and mobility of any metals/metalloids in the materials was investigated further through water extract tests and the results are presented in **Section 3.4**.

3.4 Water quality static tests

There are no specific regulatory criteria for metal/metalloid concentrations in leachate from mining waste material on mine sites in Queensland. As such, RGS has compared the multi-element results in water extracts from the selected composite samples with the Australian guideline values for livestock drinking water and aquatic freshwater eco-systems (ANZECC and ARMCANZ, 2000). These guidelines are provided for context only and are not intended to be interpreted as "maximum permissible levels" for site water storage or discharge.

It should also be recognized that direct comparison of geochemical data with guideline values can be misleading. For the purpose of this study, guideline values are only provided for broad context and should not be interpreted as arbitrary "maximum" or "trigger" values. Using sample pulps (ground to passing 75 µm) provides a high surface area to solution ratio, which encourages mineral reaction and dissolution of the solid phase. The results on screening tests on water extract solutions is assumed to represent a "worst case" scenario for initial surface runoff and seepage from mining waste materials.

The results from multi-element testing of water extracts (1:5 solid:water) from the samples are presented in **Table C4** (**Attachment C**). The pH of the water extracts ranges from pH 8.0 to 8.5 (median 8.0) and is considered to be slightly alkaline and within the range for 95 % species protection in freshwater aquatic ecosystems as set out in ANZECC and ARMCANZ (2000).

The alkalinity value in the water extract samples is dominated by bicarbonate and significantly exceeds any acidity value, such that the net alkalinity value is strongly positive. This results confirms that bulk coal reject materials represented by the samples tested have excess ANC and should provide a significant source of buffering to any acidity generated from any PAF materials.

The EC in the water extracts ranges from 593 to 1,040 µS/cm (median 865 µS/cm) and is typically moderate. The results confirm that these materials exhibit medium salinity and moderate concentrations of dissolved solids when in contact with water.

The range in concentrations for the major ions in solution in the water extracts are provided in **Table 3.4**. The concentrations for all major ions were well below the water quality guidelines for livestock drinking water.

Table 3.4: Major ion concentrations in solution

Ion	Minimum (mg/L)	Maximum (mg/L)	Median (mg/L)
Calcium (Ca)	10	70	64
Magnesium (Mg)	10	38	34
Potassium (K)	10	16	12
Sodium (Na)	52	108	92
Chloride (Cl)	22	44	38
Fluoride (F)	0.2	0.6	0.4
Sulfate (SO_4)	140	398	286

The concentration of the dissolved trace metals/metalloids tested in the water extracts is generally at or below the laboratory limit of reporting (LoR) for most samples. The exceptions are barium, manganese, molybdenum and silica, although the concentrations are below the applied water quality guideline values (ANZECC & ARMCANZ, 2000), where these exist.

Overall, the results indicate that dissolved metal/metalloid concentrations in initial surface runoff and seepage from the sample materials are unlikely to significantly impact upon the quality of surface and groundwater resources.

3.5 Water quality kinetic tests

As described in **Section 2.2.2** and **Attachment B**, a KLC test program was completed on composite samples representing coarse reject (KLC1) and fine reject (KLC2) materials from the Project. The KLC tests were operated following mining industry guidelines for such tests (AMIRA, 2002; COA, 2016c). The KLC tests commenced in May 2019 and were operated monthly for a period of six months until November 2019.

The KLC test results and trends are presented in **Attachment D** and summarised in this section. The leachate results from the KLC test program are presented alongside the Australian water quality guideline values for livestock drinking water quality (ANZECC & ARMCANZ, 2000). These guidelines are provided for context only and are not intended to be interpreted as "maximum permissible values" for site water storage or discharge. It should be noted that the KLC samples were used as received and have a high surface area for potential geochemical reactions. The ratio of sample to water in the KLC leach tests was approximately 3:1 (w:v); which is more concentrated then that used in the static tests (ie 1:5 w/v). Whilst arbitrary comparisons against water quality guideline concentrations can be useful in some situations and help to provide relevant context, such comparisons cannot be directly extrapolated to the field situation at the Project.

3.5.1 Leachate chemistry

The available KLC test results to date indicate that:

- Leachate from the KLC tests has a pH value in the range 4.90 to 7.22 over the test period. It should be noted that the pH of the deionised water used in the KLC tests over this period has a pH value ranging from 5.45 to 6.01. Apart from the first two leach events for the fine coal reject sample (KLC2) and the final leach event for both samples, the pH of the collected KLC leachate is greater than the pH of the deionised water used in the KLC tests. These results indicate that pH values within bulk co-disposed coal reject materials are likely to be in the pH neutral range, and towards the lower end of the pH range of 6 to 9 for 95 % species protection in freshwater aquatic ecosystems (ANZECC and ARMCANZ, 2000).
- Leachate from the KLC tests has an EC value in the range 1,100 to 3,001 µS/cm, which is fairly consistent throughout the test period. The EC values are generally higher in the fine reject materials (KLC2) compared to the coarse reject material (KLC1).
- The acidity value in leachate from the KLC tests over the test period is low for the coarse reject material (KLC1) and initially higher for the fine reject material (KLC 2). The alkalinity value in leachate from both the coarse and fine reject materials is generally low and results in a variable net alkalinity value over the test period.
- The concentration of major ions in leachate from the KLC tests is dominated by calcium, magnesium sodium, chloride and sulfate (and bicarbonate). The calcium, magnesium and sulfate concentrations typically show a moderately increasing trend over the test period, whereas the sodium and chloride concentrations generally show a reducing trend.
- The sulfate release rate from the KLC samples was relatively steady over the test period, apart from the fifth leachate sample from the fine reject (KLC5), which showed a temporary spike in sulfate release rate before returning to normal levels. The sulfate concentration in leachate from the KLC tests is generally greater than, and less than, the applied guideline value of 1,000 mg/L (ANZECC & ARMCANZ, 2000) for the fine reject material and coarse reject materials, respectively.
- The reject samples used in the KLC tests retain at least ~92.2 % of their inherent total sulfur content after six months of exposure to idealised oxidising conditions, which reflects the relatively slow rate of sulfide oxidation (and low risk of potential acid generation) for these materials.
- The KLC test samples retain at least 97.3 % of their inherent ANC value after six months of exposure to idealised oxidising conditions, which reflects the slow release of alkalinity from these materials.

- The concentrations of trace metals/metalloids in the leachate from the KLC tests is generally low and typically below the laboratory LoR. Most trace metals/metalloids are sparingly soluble at the current pH of the KLC leachate. Exceptions are aluminium, cadmium, copper, manganese selenium and zinc, which can have concentrations in KLC leachate greater than the applied water quality guideline trigger values for aquatic freshwater ecosystems (95 % species protection level) (ANZECC & ARMCANZ, 2000). However, all of the metals/metalloid concentrations are less than the applied livestock drinking water guideline trigger values.

3.5.2 Sulfide oxidation and sulfate generation rates

The sulfate generation rate results obtained for the coal reject samples used in the KLC tests have been used to determine the rate of sulfide oxidation in these materials. Most sulfate salts generated from sulfide reaction involving materials with a relatively low sulfide sulfur concentration are highly soluble, and therefore will be collected in column leachate. The dissolved sulfate (and calcium) concentrations in the KLC leachate are typically much less than the solubility limit of gypsum ($CaSO_4$), for example, which indicates that sulfate generation is not controlled by gypsum dissolution in the KLC test materials. Therefore, the sulfate concentrations and oxidation rate calculations provide reasonable estimates of these parameters and the results align well with existing static and dynamic geochemical data derived from a wide range of mine waste materials (AMIRA, 1995). The sulfate generation rate and associated sulfide oxidation rate for the two KLC tests are shown in **Table 3.5**.

Table 3.5: Sulfate Generation and Sulfide Oxidation Rates for KLC tests on coal reject

KLC Sample Number	Sample Description	Sulfate Generation Rate (mg/kg/week)	Oxidation Rate (kg $O_2/m^3/s$)
KLC1	Coarse Coal Reject	74.5	3.09×10^{-8}
KLC2	Fine Coal Reject	93.6	3.89×10^{-8}

The sulfate generation rate from the KLC samples ranges from 74.5 to 93.6 mg/kg/week indicating that the rate of sulfide oxidation is relatively low in these materials (equivalent to a sulfide oxidation rate ranging from 3.09 to 3.89 x 10^{-8} kg $O_2/m^3/s$). Mining waste materials with an oxidation rate in the low range (ie., less than 5 x 10^{-8} kg $O_2/m^3/s$) and a moderate ANC level have an increased factor of safety and are likely to generate leachate that is pH neutral and/or has a low level of acidity (AMIRA, 1995; Bennett *et al*., 2000). Hence, both the coarse and fine reject samples tested fall into this category. Overall, the KLC results reflect the range of material characteristics predicted from the static geochemical test results presented in **Section 3.1**.

Potential implications of these results with respect to the management of coal reject materials at the Project are discussed further in **Section 4.**

4 Discussion

4.1 AMD potential and management

The results of the ABA tests presented in **Section 3.1** indicate that the AMD potential of the coal reject materials is variable. As a bulk material, the coal reject materials are expected to be NAF with excess ANC, that should provide long term buffering to any acid generated. Overall, most coal reject materials have a relatively low risk of acid generation and an increased factor of safety with respect to potential AMD.

If left exposed to oxidising conditions, some of the coal reject materials with elevated total sulfur content may have the potential to generate moderately saline leachate containing an elevated concentration of sulfate. It is therefore recommended that coal reject materials are managed in a way that reduces the risk of connectivity with surface and groundwater resources. In existing Bowen Basin coal mines, this outcome is generally achieved by disposing of these materials either a dedicated co-disposal storage facility or through encapsulation within spoil storage areas, well away from the outside surface of the final rehabilitated landforms. The utilisation of spoil storage areas for coal reject disposal takes advantage of a much larger volume of NAF spoil material with excess ANC. If coal reject materials are left exposed to oxidising conditions for an extended period of time prior to encapsulation, dosing with agricultural limestone (ie. fine limestone) could also be considered as a contingency measure, if warranted.

Notwithstanding the method selected for management of coal reject material, it is recommended that regular collection and monitoring of surface runoff and seepage from storage areas be completed. The potential for connectivity between coal reject materials and any surface water or groundwater resources should also be evaluated.

It is recommended that some representative samples of coal reject materials be generated and subjected to both static and kinetic geochemical testing in the future when bulk materials become available, to verify the expected geochemical nature of these materials. It is likely that the relatively small amount of coal reject material generated at the Project can be safely encapsulated within a much larger volume of NAF spoil material with excess ANC, with little risk of any adverse environmental outcomes. This strategy has successfully been employed at several coal mines within the Bowen Basin.

4.2 Multi-element composition and water quality

4.2.1 Multi-element composition and enrichment

The multi-element concentration of the metals/metalloids present in the coal reject materials are presented in **Sections 3.2** and **3.3**. The results indicate that the sample materials typically have low total metal and metalloid concentrations in solids, mostly below the laboratory limit of reporting (LoR) and all below the applied NEPC (HIL(C)) guideline for soils.

Comparison with median crustal abundance values in un-mineralised soils indicates that the coal reject materials are not significantly enriched with metals/metalloids.

4.2.2 Water quality

The static and kinetic geochemical test results indicate that surface runoff and seepage from coal reject materials is likely to be pH neutral and have a moderate salinity value. The pH of surface runoff and seepage from these materials is likely to be towards the lower end of the pH range (6 to 9) for 95 % species protection in freshwater aquatic ecosystems as set out in ANZECC and ARMCANZ (2000).

The major ion concentrations in surface runoff and seepage from coal reject materials are dominated by calcium, magnesium, sodium, sulfate, chloride (and bicarbonate). The sulfate concentration has the potential to be above the applied livestock drinking water quality guideline criterion of 1,000 mg/L.

The concentration of most trace metals/metalloids tested for water in contact with coal reject materials is generally low, typically below the laboratory LoR, and below the applied water quality guideline criteria. Most

trace metals/metalloids are sparingly soluble at the current pH of coal reject materials. Exceptions are the concentrations of aluminium, cadmium, copper, manganese selenium and zinc which can be greater than the applied water quality guideline criteria for aquatic freshwater ecosystems (95 % species protection level) (ANZECC & ARMCANZ, 2000). However, all of the metals/metalloid concentrations are less than the applied livestock drinking water guideline trigger values.

Overall, the static and kinetic geochemical test results indicate that dissolved metal/metalloid concentrations in initial surface runoff and seepage from coal reject materials are unlikely to significantly impact upon the quality of surface and groundwater resources. However, some coal reject materials, if left exposed to oxidising conditions, may have the potential to generate brackish leachate containing elevated concentrations of sulfate and some metals/metalloids compared to applied water quality guideline values. Therefore, coal reject materials should be encapsulated within spoil storage areas, well away from the outside surface of the final rehabilitated landforms. If coal reject materials are left exposed to oxidising conditions for an extended period of time prior to encapsulation, dosing with agricultural limestone (ie. fine limestone) could also be considered as a contingency measure, if warranted.

5 Conclusions and Recommendations

5.1 Conclusions

RGS has completed a geochemical assessment of the coal reject material at the Project. The main findings of the geochemical assessment are:

- The coal reject samples represent materials with a variety of geochemical characteristics ranging from NAF to PAF. As a bulk material, coal reject is expected to be NAF with excess ANC. Overall, most coal reject materials have a relatively low risk of acid generation and an increased factor of safety with respect to potential for AMD.
- Initial and ongoing surface runoff and seepage from coal reject materials is expected to be pH neutral and have a moderate level of salinity. The salinity of leachate from higher sulfur coal reject materials could increase over time if exposed to atmospheric conditions, due to release of sulfate through sulfide oxidation.
- Comparison with guideline values and median crustal abundance in un-mineralised soils indicates that the coal reject materials are not significantly enriched with metals/metalloids.
- Most metals/metalloids are sparingly soluble at the current pH of the leachate from coal reject materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk coal reject materials are expected to be relatively low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities.

5.2 Recommendations

As a result of the geochemical assessment work completed on coal reject materials at the Project, several recommendations are provided to minimise the risk of any significant environmental harm to the immediate and downstream environment.

- Operational sampling and geochemical testing of representative samples of coal reject material should be used as required when the mine is operational to verify the findings of this report.
- Coal reject materials should be encapsulated in spoil storage areas well away from the outside surface of the final rehabilitated landforms, where there is a low risk of connectivity to surface water or groundwater resources.
- If coal reject materials are left exposed to oxidising conditions for an extended period of time prior to encapsulation, dosing with agricultural limestone (ie. fine limestone) could also be considered as a contingency measure, if warranted.
- Surface water and seepage from the coal reject storage areas should be monitored to ensure that key water quality parameters remain within appropriate criteria. Water quality monitoring parameters should include pH, EC and total suspended solids (TSS) on a quarterly basis and the suite of water quality analyses described in **Table C4** (**Attachment C**) of this report opportunistically and at least on an annual basis.

Attachment B Geochemical assessment methods for mining waste materials

ACID GENERATION AND PREDICTION

Acid generation is caused by the exposure of sulfide minerals, most commonly pyrite (FeS_2), to atmospheric oxygen and water. Sulfur assay results are used to calculate the maximum acid that could be generated by the sample by either directly determining the pyritic S content or assuming that all sulfur not present as sulfate occurs as pyrite. Pyrite reacts under oxidising conditions to generate acid according to the following overall reaction:

$$FeS_2 + 15/4\ O_2 + 7/2\ H_2O \rightarrow Fe(OH)_3 + 2\ H_2SO_4$$

According to this reaction, the maximum potential acidity (MPA) of a sample containing 1%S as pyrite would be 30.6 kg H_2SO_4/t. The chemical components of the acid generation process consist of the above sulfide oxidation reaction and acid neutralization, which is mainly provided by inherent carbonates and to a lesser extent silicate materials. The amount and rate of acid generation is determined by the interaction and overall balance of the acid generation and neutralisation components.

Net Acid Producing Potential

The net acid producing potential (NAPP) is used as an indicator of materials that may be of concern with respect to acid generation. The NAPP calculation represents the balance between the maximum potential acidity (MPA) of a sample, which is derived from the sulfide sulfur content, and the acid neutralising capacity (ANC) of the material, which is determined experimentally. By convention, the NAPP result is expressed in units of kg H_2SO_4/t sample. If the capacity of the solids to neutralise acid (ANC) exceeds their capacity to generate acid (MPA), then the NAPP of the material is negative. Conversely, if the MPA exceeds the ANC, the NAPP of the material is positive. A NAPP assessment involves a series of analytical tests that include:

Determination of pH and EC

pH and EC measured on 1:5 w/w water extract. This gives an indication of the inherent acidity and salinity of the waste material when initially exposed in a waste emplacement area.

Total sulfur content and Maximum Potential Acidity (MPA)

Total sulfur content is determined by the Leco high temperature combustion method. The total sulfur content is then used to calculate the MPA, which assumes that the entire sulfur content is present as reactive pyrite. Direct determination of the pyritic sulfur content can provide a more accurate estimate of the MPA.

Acid neutralising capacity (ANC)

By addition of acid to a known weight of sample, then titration with NaOH to determine the amount of residual acid. The ANC measures the capacity of a sample to react with and neutralise acid. The ANC can be further evaluated by slow acid titration to a set end-point in the Acid Buffering Characteristic Curve (ABCC) test through calculation of the amount of acid consumed and evaluation of the resultant titration curve.

Net Acid Generation (NAG)

The net acid generation (NAG) test involves the addition of hydrogen peroxide to a sample of mine rock or process residue to oxidise reactive sulfide, then measurement of pH and titration of any net acidity produced by the acid generation and neutralisation reactions occurring in the sample. A significant NAG result (*i.e.* final $NAG_{pH} < 4.5$) indicates that the sample is potentially acid forming (PAF) and the test provides a direct measure of the net amount of acid remaining in the sample after all acid generating and acid neutralising reactions have taken place. A $NAG_{pH} > 4.5$ indicates that the sample is non-acid forming (NAF). The NAG test provides a direct assessment of the potential for a material to produce acid after a period of exposure and weathering and is used to refine the results of the theoretical NAPP predictions. The NAG test can be used as a stand-alone test but is recommended that this only be considered after site specific calibration work is carried out. RGS generally avoids use the NAG test at coal mining projects as the high organic content of some materials can cause erroneous results.

ASSESSMENT OF ELEMENT ENRICHMENT AND SOLUBILITY

In mineralised areas it is common to find a suite of enriched elements that have resulted from natural geological processes. Multi-element scans are carried out to identify any elements that are present in a material (or readily leachable from a material) at concentrations that may be of environmental concern with respect to surface water quality, revegetation and public health. The samples are generally analysed for the following elements:

Major elements	Al, Ca, Fe, K, Mg, Na and S.
Minor elements	As, B, Cd, Co, Cr, Cu, F, Hg, Mn, Mo, Ni, Pb, Sb, Se and Zn.

The concentration of these elements in samples can be directly compared with relevant state or national environmental and health based concentration guideline criteria to determine the level of significance. Water extracts are used to determine the immediate element solubilities under the existing sample pH conditions of the sample. The following tests are normally carried out:

Multi-element composition of solids.

Multi-element composition of solid samples determined using a combination of ICP-mass spectroscopy (ICP-MS), ICP-optical emission spectroscopy (OES), and atomic absorption spectrometry (AAS).

Multi-element composition of water extracts (1:5 sample:deionised water).

Multi-element composition of water extracts from solid samples determined using a combination of ICP-mass spectroscopy (ICP-MS), ICP-optical emission spectroscopy (OES), and atomic absorption spectrometry (AAS).

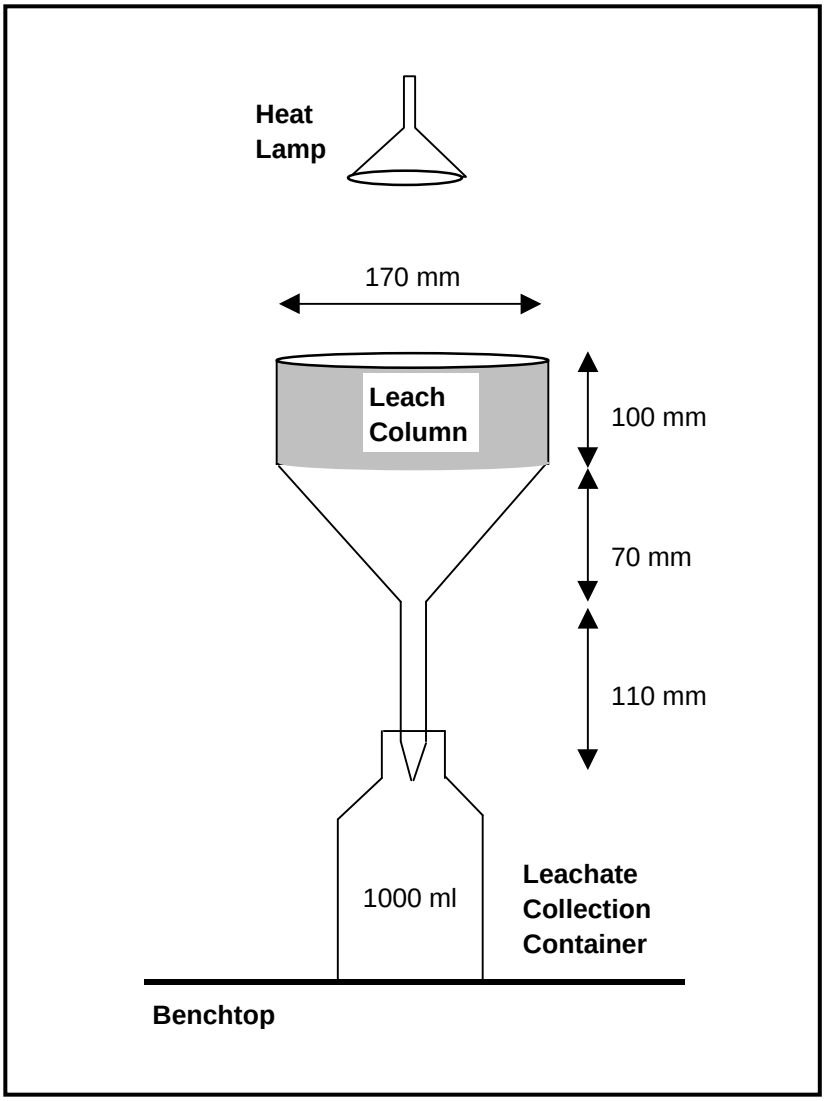
Under some conditions (*eg*. low pH) the solubility and mobility of common environmentally important elements can increase significantly. If element mobility under initial pH conditions is deemed likely and/or subsequent low pH conditions may occur, kinetic leach column test work may be completed on representative samples.

KINETIC LEACH COLUMN TESTS

Kinetic leach column (KLC) tests can be used to provide information on the reaction kinetics of mining waste materials. The major objectives of kinetics tests are to:

- Provide time-dependent data on the kinetics and rate of acid generation and acid neutralising reactions under laboratory controlled (or onsite conditions);
- Investigate metal release and drainage/seepage quality; and
- Assess treatment options such as addition of alkaline materials.

The KLC tests simulate the weathering process that leads to acid and base generation and reaction under laboratory controlled or site conditions. The kinetic tests allow an assessment of the acid forming characteristics and indicate the rate of acid generation, over what period it will occur, and what management controls may be required.



In KLC tests, water is added to a sample and the mixture allowed to leach products and by-products of acid producing and consuming reactions. Samples of leachate are then collected and analysed. Intermittent water application is applied to simulate rainfall and heat lamps are used to simulate sunshine. These tests provide real-time information and may have to continue for months or years. Monitoring includes trends in pH, sulfate, acidity or alkalinity, and metals, for example. The pH of the collected leachate simulates the acid drainage process, acidity or alkalinity levels indicate the rate of acid production and acid neutralisation, and sulfate production can be related to the rate of sulfide oxidation. Metal concentration data provides an assessment of metal solubility and leaching behaviour.

Figure B1 shows the kinetic leach column set up used by RGS adapted from *AMIRA, 2002*. The columns are placed under heat lamps to allow the sample to dry between water additions to ensure adequate oxygen ingress into the sample material.

Approximately 2 kg of sample is accurately weighed and used in the leach columns and depending on the physical nature of the material and particle size can be used on an as-received basis (*i.e.* no crushing as with process residues) or crushed to nominal 5-10 mm particle size (as with waste rock). The sample in the column is initially leached with deionised water at a rate of about 400 ml/kg of sample and the initial leachate from the columns collected and analysed. Subsequent column leaching is carried out at a rate of about 400 ml/kg per month and again collected and analysed. The leaching rate can be varied to better simulate expected site conditions or satisfy test program data requirements. The column must be exposed to drying conditions in between watering events. The residual water content and air void content in the column can be determined by comparing the wet and dry column weights. A heat lamp is generally used above the sample during daylight hours to maintain the leach column surface temperature at about 30^{o}C.

Notes: < indicates concentration less than the detection limit. Shaded cells exceed applied guideline values.

1. ANZECC & ARMCANZ (2000). Trigger values for aquatic ecosystems (95% species protection level)

2. ANZECC & ARMCANZ (2000). Recommended guideline limits for Livestock Drinking Water.

* Cr (VI) = hexavalent. ** 0.013 mg/Lfor pentavalent Arsenic (V).

for still water bodies only, moving rivers at low flow rates should not exceed 2,200µS/cm

^ calculated based on total dissolved solids (TDS) conversion rate of 0.67% of EC. TDS is an approximate measure of inorganic dissolved salts and should not exceed 2,400mg/L for livestock drinking water.

No. of samples received	: 23		
No. of samples analysed	: 23		

ilac-MRA NATA
Accreditation No. 825
Accredited for compliance with ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Kim McCabe	Senior Inorganic Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Satishkumar Trivedi	Senior Acid Sulfate Soil Chemist	Brisbane Acid Sulphate Soils, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EA031 (Saturated Paste pH): NATA accreditation does not cover the performance of this service.
- EA032 (Saturated Paste EC): NATA accreditation does not cover the performance of this service.
- ASS: EA013 (ANC) Fizz Rating: 0- None; 1- Slight; 2- Moderate; 3- Strong; 4- Very Strong; 5- Lime.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.

Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.

Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- Sodium Adsorption Ratio (where reported): Where results for Na, Ca or Mg are <LOR, a concentration at half the reported LOR is incorporated into the SAR calculation. This represents a conservative approach for Na relative to the assumption that <LOR = zero concentration and a conservative approach for Ca & Mg relative to the assumption that <LOR is equivalent to the LOR concentration.

1 Introduction

1.1 BACKGROUND

Magnetic South Pty Ltd proposes to develop the Gemini Project (the Project), a coal mine and associated infrastructure, located within the Fitzroy Basin. The proposed mine development site is located approximately 7.6 km west from the township of Dingo and 19.4 km southeast of Bluff (Figure 1.1).

WRM was commissioned by Magnetic South Pty Ltd to undertake a surface water impact assessment for the Project. This report presents the following:

- An overview of the regulatory framework which applies to the Project;
- A description of the existing surface water environment surrounding the Project, and the associated environmental values;
- A detailed description of the proposed water management strategy in and around the Project and details of the expected performance of the proposed water management system;
- A discussion of the potential impacts of the Project.

1.2 PROJECT DESCRIPTION

The Gemini Project is a greenfield open cut mine to produce Pulverised Coal Injection (PCI) coal and Coking Coal products for export for steel production. The Project term is anticipated to be 25 years from grant of the ML, with this term including initial construction, mine operation and rehabilitation activities. The main activities associated with the Project include:

- Exploration activities continuing in order to support mine planning;
- Development of a Mine Infrastructure Area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, explosives magazine and sewage, effluent and liquid waste storage;
- Construction and operation of a Coal Handling Preparation Plant (CHPP) and coal handling facilities adjacent to the MIA (including Run-of-Mine (ROM) coal, product stockpiles and reject stockpiles [coarse and fine rejects]);
- Construction and operation of a surface conveyor from the product stockpiles to a Train Load Out (TLO) facility and rail loop connecting to the Blackwater-Gladstone Branch Rail to transport product coal to coal terminals at Gladstone for export;
- Construction of access roads from the Capricorn Highway to the MIA, and to the TLO facility;
- Installation of a raw water supply pipeline to connect to the Blackwater Pipeline network;
- Construction of a 66 kV transmission line and switching/substation to connect to the existing regional network;
- Other associated minor infrastructure, plant, equipment and activities;
- Development of mine areas (open cut pits) and out-of-pit waste rock emplacements;
- Drilling and blasting of competent waste material.
- Mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers);

- Mining up to 1.9 Mtpa ROM Coal – average 1.8 Mtpa for an operational mine life of approximately 20 years;
- Progressive placement of waste rock in:
    - Emplacements, adjacent to and near the open cut voids;
    - Mine voids, behind the advancing open cut mining operations.
- Progressive rehabilitation of waste rock emplacement areas and mined voids;
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works). Material will be sourced from local quarries where required;
- Disposal of CHPP rejects (coarse and fine rejects) in out-of-pit spoil dumps, and in-pit behind the mining void;
- Progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access;
- Development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, diversions and drains.

Figure 1.2 shows the layout of key project features, in particular the two proposed mine pits, associated out-of-pit spoil dumps, haul roads and CHPP, MIA and TLO.

Figure 1.1 – Locality Plan

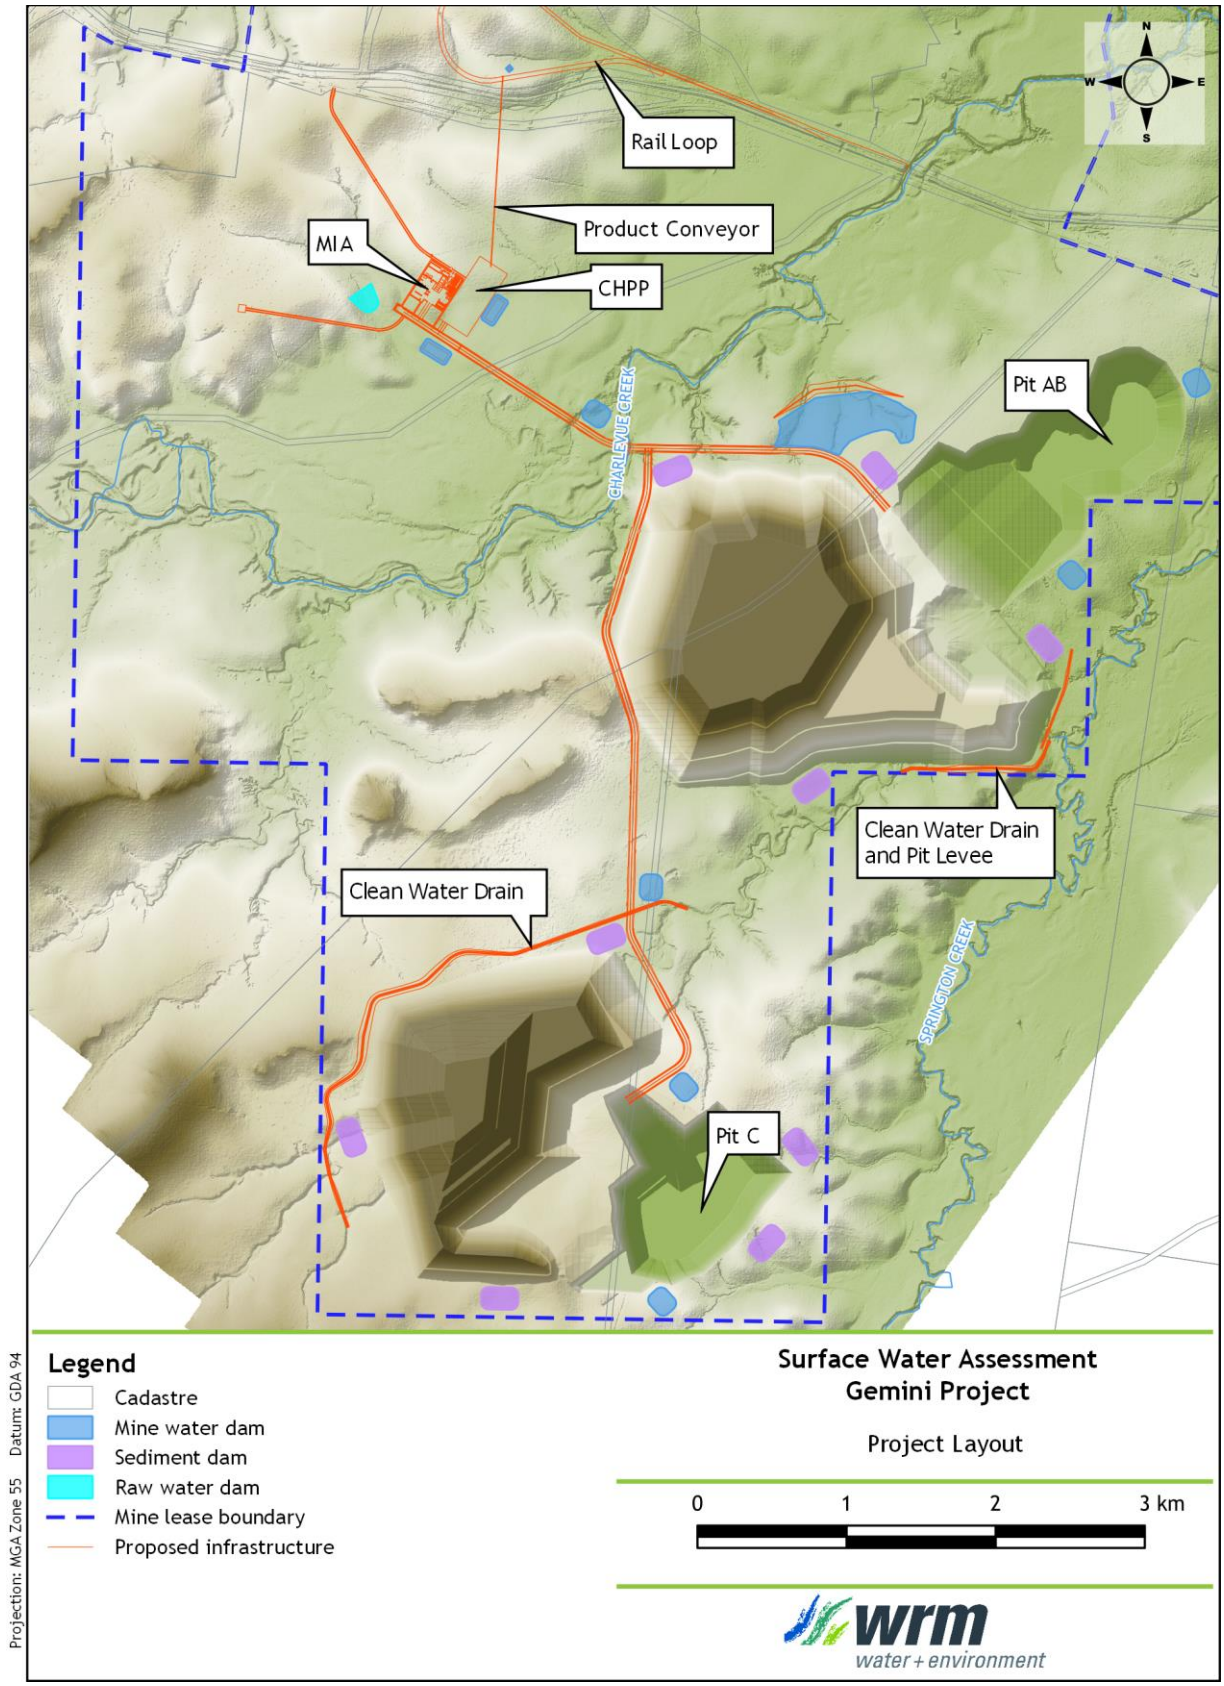

Figure 1.2 - Project layout

2 Regulatory framework

This section describes the regulatory framework (legislation, policies and standards) at Commonwealth and State level that would apply to surface water management for the Project.

2.1 COMMONWEALTH

2.1.1 EPBC Act

Under the Commonwealth Environmental Protection and Biodiversity Conservation Act 1999 (EPBC Act), an action requires approval from the Federal Environment Minister if the action has, will have, or is likely to have a significant impact on a Matter of National Environmental Significance (MNES).

An EPBC Referral (2010/5775) for the project lodged in 2010, was declared 'Not a Controlled Action if undertaken in a Particular Manner' in July 2011.

The Particular Manner Decision (EPBC 2010/5775) required the following measures to be taken to avoid significant impacts on the Fitzroy River turtle:

- To prevent downstream impacts to the Fitzroy River Turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate pits in a manner that prevents surface water from entering the pit during a 1:1,000 year flood event.
- To prevent downstream impacts to the Fitzroy River Turtle (Rheodytes leukops) the person taking the action must appropriately bund or locate dams in a manner that prevents surface water from entering or damaging the dams during a during a 1:1,000 year flood event.

The currently proposed Gemini Project is consistent with the original EPBC referral in that:

- It is unlikely to have a significant impact on a MNES; and
- The same measures will be taken for the Gemini Project to avoid significant impacts on the Fitzroy River Turtle.

2.1.2 Independent Expert Scientific Committee

The Independent Expert Scientific Committee (IESC) on Coal Seam Gas and Large Coal Mining Developments provides scientific advice to decision makers on the impact that coal seam gas and large coal mining development may have on Australia's water resources.

The IESC provides independent, expert scientific advice on coal seam gas and large coal mining proposals as requested by the federal and state government regulators. The IESC assesses the proposals against the Information Guidelines for Independent Expert Scientific Committee and provides advice (IESC, 2018) on coal seam gas and large coal mining development proposals where there is a significant impact on water resources. The core purpose of the guideline is to determine whether a coal seam gas (CSG) or large coal mining development has or is likely to have a significant impact on a water resource. The requirements of the guideline have been considered in preparation of this surface water assessment.

2.2 QUEENSLAND

2.2.1 EP Act 1994

Resource activities are defined as environmentally relevant activities (ERAs) under the Queensland Environmental Protection Act 1994 (EP Act) and as such, the development and operation of the Project is regulated by the EP Act. The objective of the EP Act is to:

> *Protect Queensland's environment while allowing for development that improves the total quality of life, both now and in the future, in a way that maintains the ecological processes on which life depends (ecologically sustainable development).*

2.2.1.1 Environmental Authority

An environmental authority (EA) is granted in accordance with the EP Act and details the prescribed conditions that govern the ERA. In the context of surface water management, the EA sets out conditions that will be relevant to the Project, including:

- Management of contained water including release;
- Water management plan requirements;
- Regulation of water structures including dams and levees;
- Saline drainage management;
- Acid rock drainage management; and
- Storm water and sediment laden runoff management.

Model Mining Conditions

New mining project EA applications should apply the model mining conditions as outlined in Model Mining Conditions (DEHP, 2017). The purpose of the model mining conditions is to provide a consistent set of conditions to meet the general environmental protection commitments given for EAs for mining activities administered under the EP Act. The model conditions may be used as a basis for proposing environmental protection commitments in application documents (such as an EIS). Model conditions can be modified to suit the specific circumstances of a mining project, subject to the assessment criteria outlined in the EP Act.

Schedule F – Water (Fitzroy model conditions) form the basis of the requirements for the Project Water Management System design.

2.2.1.2 Environmental Protection (Water) Policy 2009

The Environmental Protection (Water) Policy 2009 (EPP Water) is the primary instrument for surface water management under the EP Act. The EPP Water governs discharge to land, surface water and groundwater, aims to protect environmental values (EVs) and sets water quality guidelines and objectives.

The processes to identify Environmental Values (EVs) and to determine Water Quality Guidelines (WQGs) and Water Quality Objectives (WQOs) in Queensland waters are based on the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ guidelines).

2.2.1.3 Mackenzie River Sub-basin Environmental Values and Water Quality Objectives 2011

The relevant document, pursuant to the EPP Water, for the Project is the Mackenzie River Sub-basin Environmental Values and Water Quality Objectives Basin No. 130 (part), including all waters of the Mackenzie River Sub-basin (DEHP, 2011). The document is made pursuant to the provisions of the EPP Water. It contains Environmental Values (EVs) and Water Quality Objectives (WQOs) for waters in the Mackenzie River Sub-basin, and they are listed under Schedule 1 of EPP Water. Refer to Section 3 for further details.

2.2.1.4 Manual for Assessing Consequence Categories and Hydraulic Performance of Structures

The Manual for Assessing Consequence Categories and Hydraulic Performance of Structures (the Manual) (DES, 2016) defines the methodology and assessment criteria to determine if a structure associated with an ERA should be regulated under the EP Act. The Manual details the hydraulic design requirements for regulated structures and has been used as a reference in the preliminary design of the water management system and preliminary sizing of dams associated with the Project.

2.2.1.5 Guideline - Application Requirements for Activities with Impacts to Water

This guideline focuses on the types of impacts that environmentally relevant activities (ERAs) can have on water and outlines the information to be provided to the department as part of the ERA application process.

Section 4 of the guideline requires the applicant to provides details on a number of surface water-related issues, including:

- Discharges and releases;
- Unplanned and uncontrolled releases;
- Water infrastructure;
- Wetlands;
- Hydrology of receiving waters; and
- Mixing zones.

The guideline also refers to the department's technical guideline "Wastewater releases to Queensland waters", which is discussed in Section 2.2.1.6.

2.2.1.6 Technical Guideline - Wastewater Release to Queensland Waters

This guideline is provided to support a risk-based assessment approach to licensing releases of wastewater to surface water and applies the philosophy of the ANZECC & ARMCANZ (2000) Water Quality Guidelines and the intent of the Environmental Protection (Water) Policy 2009.

The information requirements identified in this guideline are as follows:

- Describe the proposed activity.
- Describe the receiving environment.
- Predict outcomes or impacts of the proposed wastewater release.
- Set circumstances, limits and monitoring conditions.

The Project's accommodation village will comprise a small sewage treatment plant. Waste sludge is expected to be removed for disposal by a regulated waste contractor. Treated effluent will be irrigated to a designated area in accordance with accepted conditions.

2.2.2 Water Act 2000

In Queensland, the Water Act 2000 (Water Act) is the primary statutory document that establishes a framework for the planning, allocation and use of non-tidal water. The Water Act is primarily administered by the Department of Natural Resources, Mines and Energy (DNRME) and the Department of Energy and Water Supply (DEWS).

The main purpose of the Water Act is to provide a framework for the following:

- The sustainable management of Queensland's water resources and quarry material by establishing a system for:
    - The planning, allocation and use of water; and
    - The allocation of quarry material and riverine protection.
- The sustainable and secure water supply for the south-east Queensland region and other designated regions;
- The management of impacts on underground water caused by the exercise of underground water rights by the resource sector; and
- The effective operation of water authorities.

A watercourse is defined by the Water Act as a river, creek or stream in which water flows permanently or intermittently and includes the bed and banks and any other element of a river, creek or stream confining or containing water.

The diversion of drainage features does not require authorisation under the Water Act.

2.2.2.1 Water Plan (Fitzroy Basin) 2011

The Water Plan (Fitzroy Basin) 2011, which replaces the Water Resource (Fitzroy Basin) Plan 2011, is subordinate legislation to the Water Act. The plan is developed and administered by DNRME. The purpose of the plan is:

- To define the availability of water in the Fitzroy Basin;
- To provide a framework for sustainably managing water and the taking of water;
- To identify priorities and mechanisms for dealing with future water requirements;
- To provide a framework for establishing water allocations;
- To provide a framework for reversing, where practicable, degradation in natural ecosystems;
- To regulate the taking of overland flow water; and
- To regulate the taking of groundwater.

The Project is located in the area managed by the Water Plan (Fitzroy Basin) 2011 that manages overland flow. Works on drainage features that capture overland flow must meet the requirements of the plan and may require authorisation under the Water Act.

2.2.2.2 Water Regulation 2016

Water Regulation 2016 is subordinate legislation to the Water Act and provides details, protocol and instruction for the following:

- Water rights and planning;
- Statutory authorisations to take or interfere with water;
- Matters relating to water licenses;
- Water allocations;

2.2.3 Water Supply (Safety & Reliability) Act 2008

The Water Supply (Safety and Reliability) Act 2008 provides for the safety and reliability of water supply in Queensland. The purpose is achieved primarily by:

- Providing a regulatory framework for providing water and sewerage services in the State;
- Providing a regulatory framework for providing recycled water and drinking water quality, primarily for protecting public health;
- The regulation of referable dams; and
- Stating flood mitigation responsibilities.

3 Environmental Values

The Project is located within the Mackenzie Southern Tributaries (refer section 2.2.1.3) of the Mackenzie River sub-basin shown in Figure 3.1. The following EVs have been nominated broadly to the mapped areas for protection of zone:

- Aquatic ecosystems;
- Farm supply/use;
- Stock Water;
- Human consumption;
- Primary recreation;
- Secondary recreation;
- Visual recreation;
- Drinking water;
- Industrial use;
- Cultural and spiritual values.

The following WQOs for the above EVs are provided in Table 3.1. Where different EVs have different WQOs the lowest value has been adopted. WQOs are displayed for physio-chemical parameters only.

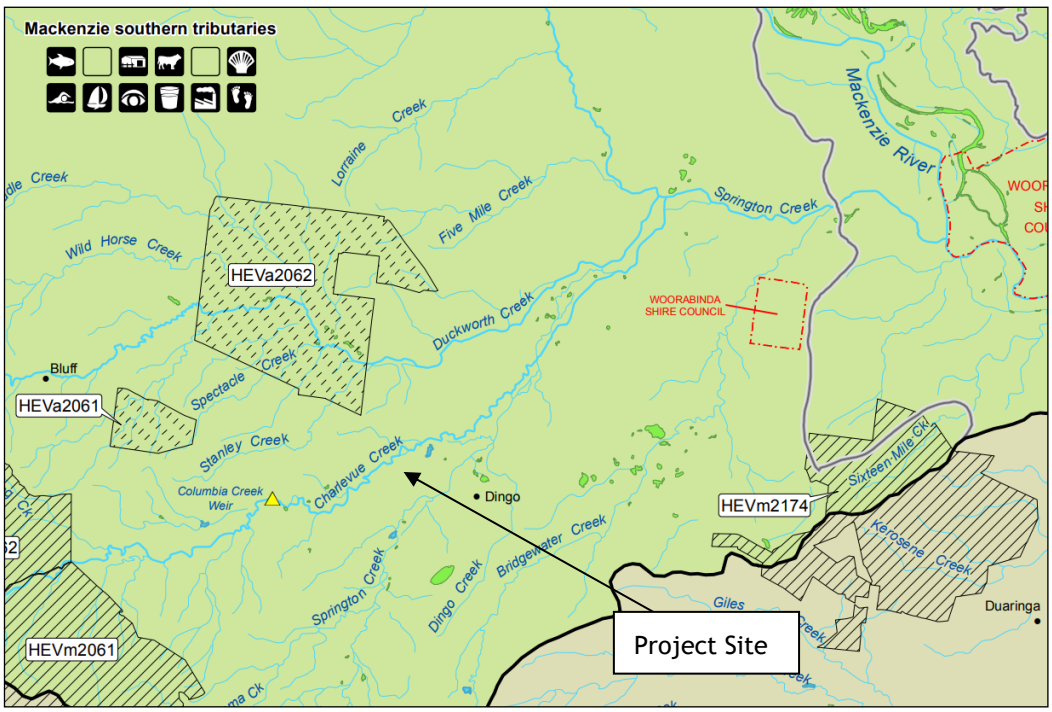

Figure 3.1 – Mackenzie River Sub-basin EVs

Table 3.1 – Water Quality Objectives for the Mackenzie River sub-basin

Parameter	WQO	Relevant EV
Ammonia N	< 20 µg/L	Aquatic ecosystem
Oxidised N	< 60 µg/L	Aquatic ecosystem
Organic N	< 420 µg/L	Aquatic ecosystem

Selenium	< 0.02 mg/L < 0.005 mg/L	Stock watering, Aquatic ecosystem
Uranium	< 0.1 mg/L	Irrigation
Vanadium	< 0.5 mg/L	Irrigation
Zinc	< 5 mg/L < 0.008 mg/L	Irrigation Aquatic ecosystem

3.1 AQUATIC ECOSYSTEM ENVIRONMENTAL VALUES

3.1.1 Fitzroy Basin Aquatic Ecosystem Health

The Fitzroy Partnership for River Health is a collaboration between Government, industry, research organisations and community to facilitate improved water quality monitoring, collate and assess data, and publicly report on waterway health and sustainable use.

The Partnership compiles water quality, biological and ecological health data for all waterways in the Fitzroy Basin and assigns them one of the following grades:

a. **Excellent**. All water quality and biological health indicators meet desired levels.
b. **Good**. Most water quality and biological health indicators meet desired levels.
c. **Fair**. There is a mix of good and poor levels of water quality and biological health indicators.
d. **Poor**. Some or few water quality and biological health indicators meet desired levels.
e. **Fail**. Very few or no water quality and biological health indicators meet desired levels.

In 2017-18 the Fitzroy Basin (including the Mackenzie River tributaries covering the Project area) received a C grade for aquatic ecosystem health. The Mackenzie Basin was graded C overall. It was graded B for physical/chemical and nutrients, C for toxicants and D for ecology. It was graded B for stock use and A for cropping use.

3.1.2 Aquatic ecology assessment of the Project area

Baseline aquatic ecology surveys for the Project were undertaken by AARC, and details of the results are provided in a separate report. The following extract from that report summarises the aquatic values of the Project area.

Extensive clearing for agricultural purposes has been undertaken across much of the study area including the removal of riparian vegetation. The removal of riparian vegetation and direct stock access to the waterways has resulted in bank instability, erosion and occurrence of weeds.

Stream sediments were found to contain a high proportion of sand particles with some sites containing a mixture of silt and clay. Metal concentrations in stream sediment were generally low, except for nickel levels at site DWR6.

Macroinvertebrate diversity, abundance and PET richness were generally low. SIGNAL scores were correspondingly low and consistent with the expected results for ephemeral streams in an agricultural setting. The AusRivAS predictive modelling assessed the aquatic environments at the sample sites as significantly impaired to highly degraded. While impaired habitats are common in ephemeral creeks, the extent and severity of the impairment indicates low waterway health.

The diversity and abundance of fish and crustaceans was found to be low.

4 Existing surface water environment

4.1 LOCAL CLIMATE - RAINFALL AND EVAPORATION DATA

Figure 4.3 shows locations of Bureau of Meteorology (BOM) and DNRME rainfall and evaporation recording stations with a significant period of record near the Project. Table 4.1 shows summary details of these stations.

Table 4.2 shows the variability in monthly rainfall at Dingo Post Office, which is the nearest rainfall station.

Table 4.1 – Rainfall stations in the vicinity of the Project

Long term daily rainfall and evaporation data for the area from January 1889 to August 2019 (130 years) was obtained from the SILO (https://www.longpaddock.qld.gov.au/silo/). This data set is corrected for accumulated daily rainfall totals and missing data and is well suited to use in water balance modelling. Annual rainfall is presented in Figure 4.1. Monthly average rainfall and evaporation are shown in Figure 4.2. Average annual rainfall is 692 mm/a and average annual (pan) evaporation is 2,053 mm/a.

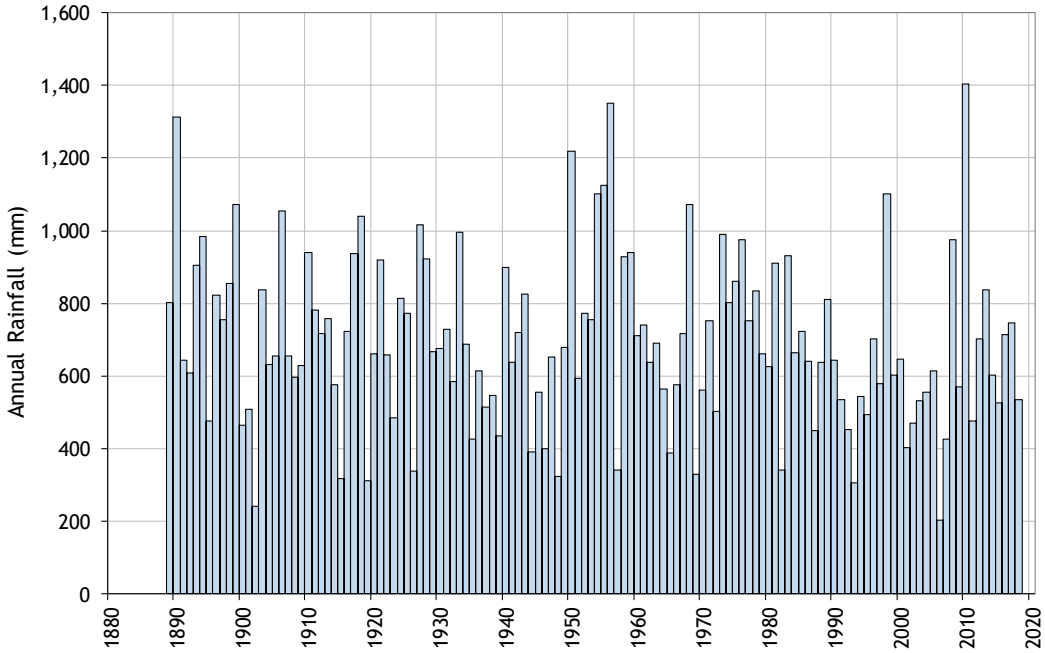

Figure 4.1 - Annual rainfall at Dingo Post Office - 1889 to 2019 (SILO)

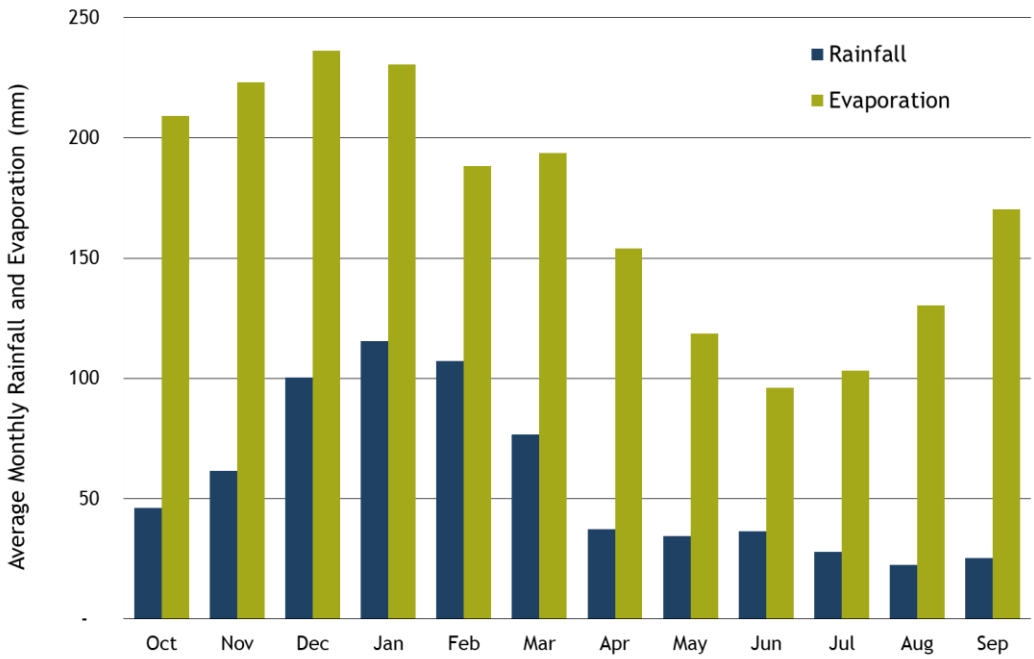

Figure 4.2 - Average monthly rainfall and pan evaporation at Dingo Post Office

4.2 CATCHMENT CONTEXT

As shown in Figure 4.3, the Project area is in the upper Mackenzie River catchment – part of the Fitzroy River Basin.

The Project area is in the catchment of Springton and Charlevue Creeks. Springton Creek joins the Mackenzie River approximately 47 km downstream of the Project. The upstream extent of the Fitzroy River is at the Dawson River/Mackenzie River. The Fitzroy River flows to the ocean east of the City of Rockhampton, approximately 400 km downstream of the Project area, and has a total catchment area of approximately 143,000 km^2. The total catchment area of the Mackenzie River sub-basin (including the catchments of the Nogoa and Comet Rivers) is 12,989 km^2.

As shown in Figure 4.4, the streams crossing the Project area (which include Charlevue Creek and Springton Creek) flow generally northeast, where Charlevue Creek joins Springton Creek approximately 3.6 km downstream of the Project, then later joins the Mackenzie River (Figure 4.4).

The Project mining lease application area is approximately 55.7 km^2. Charlevue Creek has a catchment area of approximately 343 km^2 to its confluence with the Springton Creek crossing the Project area and Springton Creek has a catchment area of 325 km^2 to the confluence with Charlevue Creek.

All waterways of the Project area are ephemeral and experience flow only after sustained or intense rainfall in the catchment. Stream flows are highly variable, with most channels drying out during winter to early spring when rainfall and runoff is historically low, although some pools hold water for extended periods. Therefore, physical attributes, water quality, and the composition of aquatic flora and fauna communities are also expected to be highly variable over time.

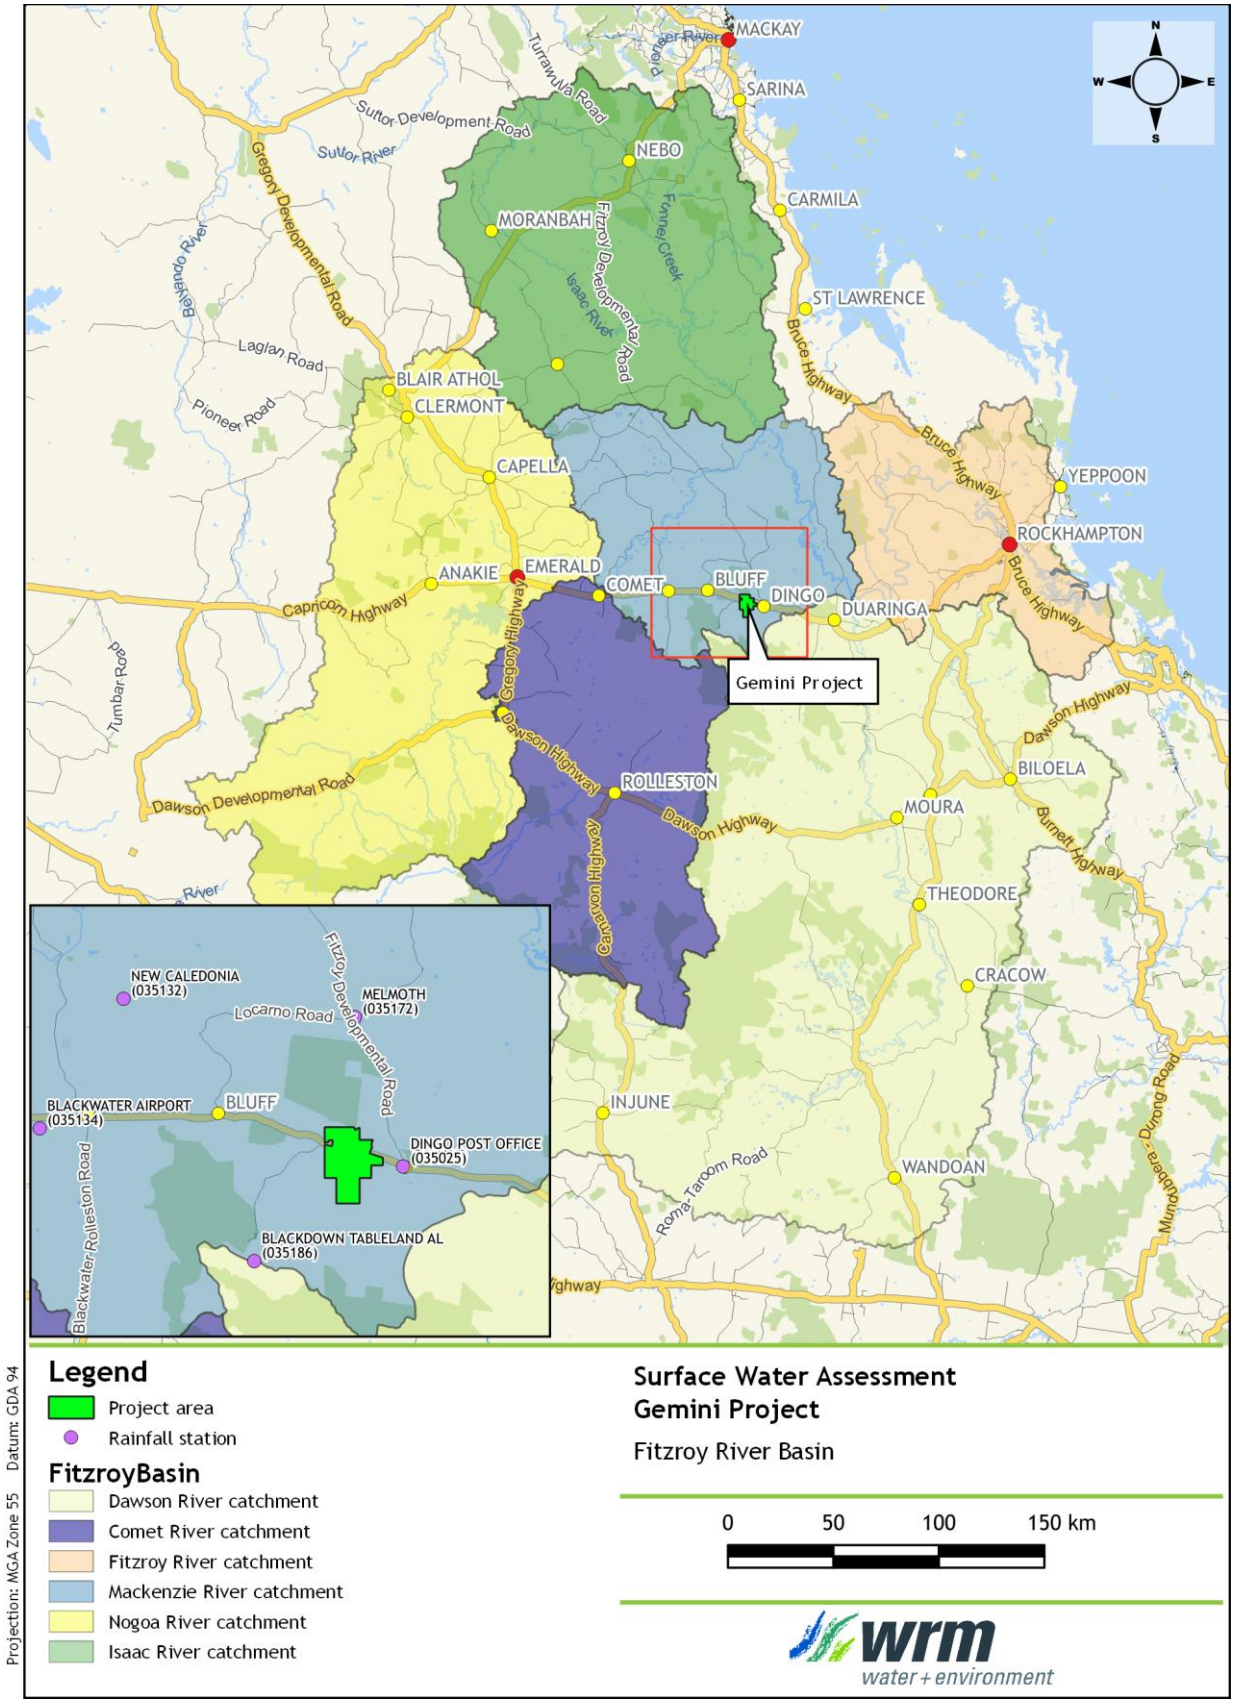

Figure 4.3 – Fitzroy River Basin

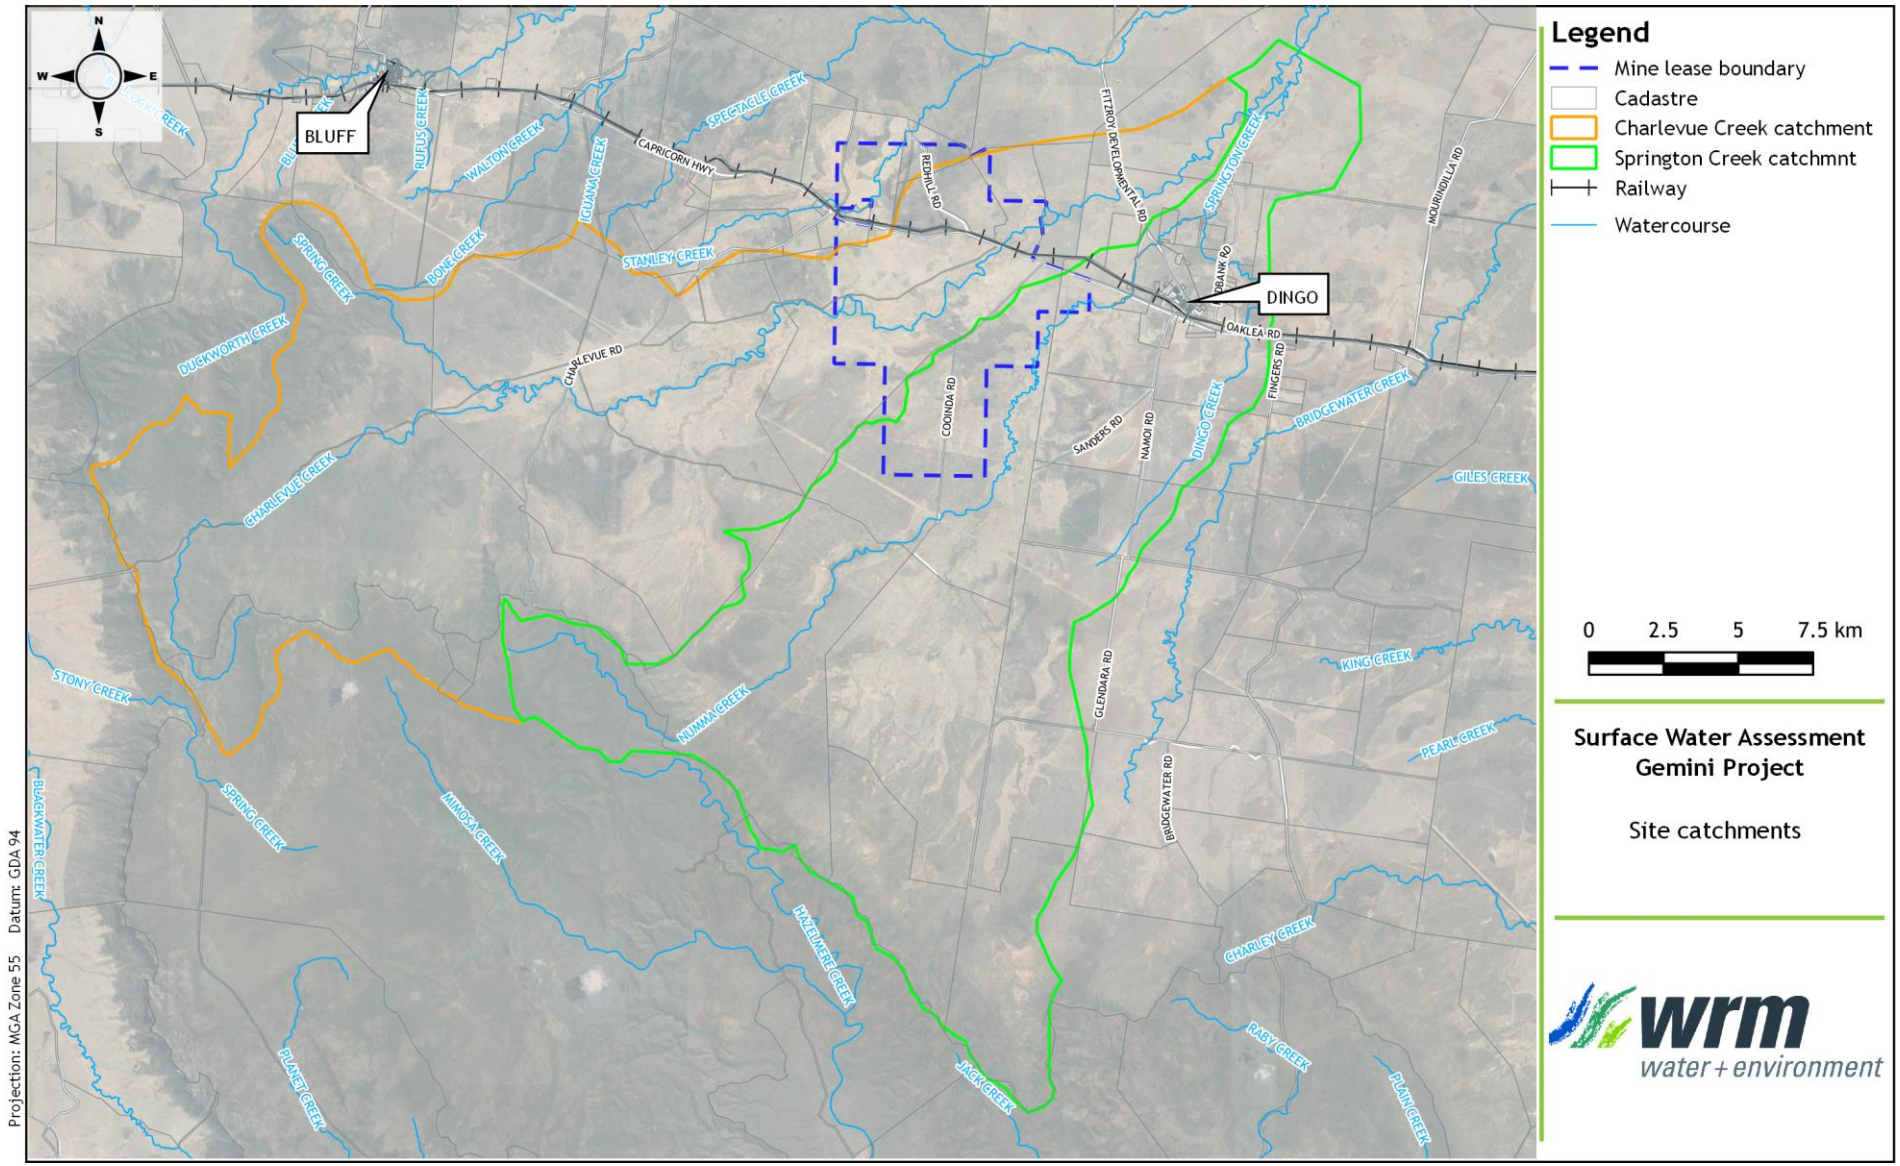

Figure 4.4 - Site catchments

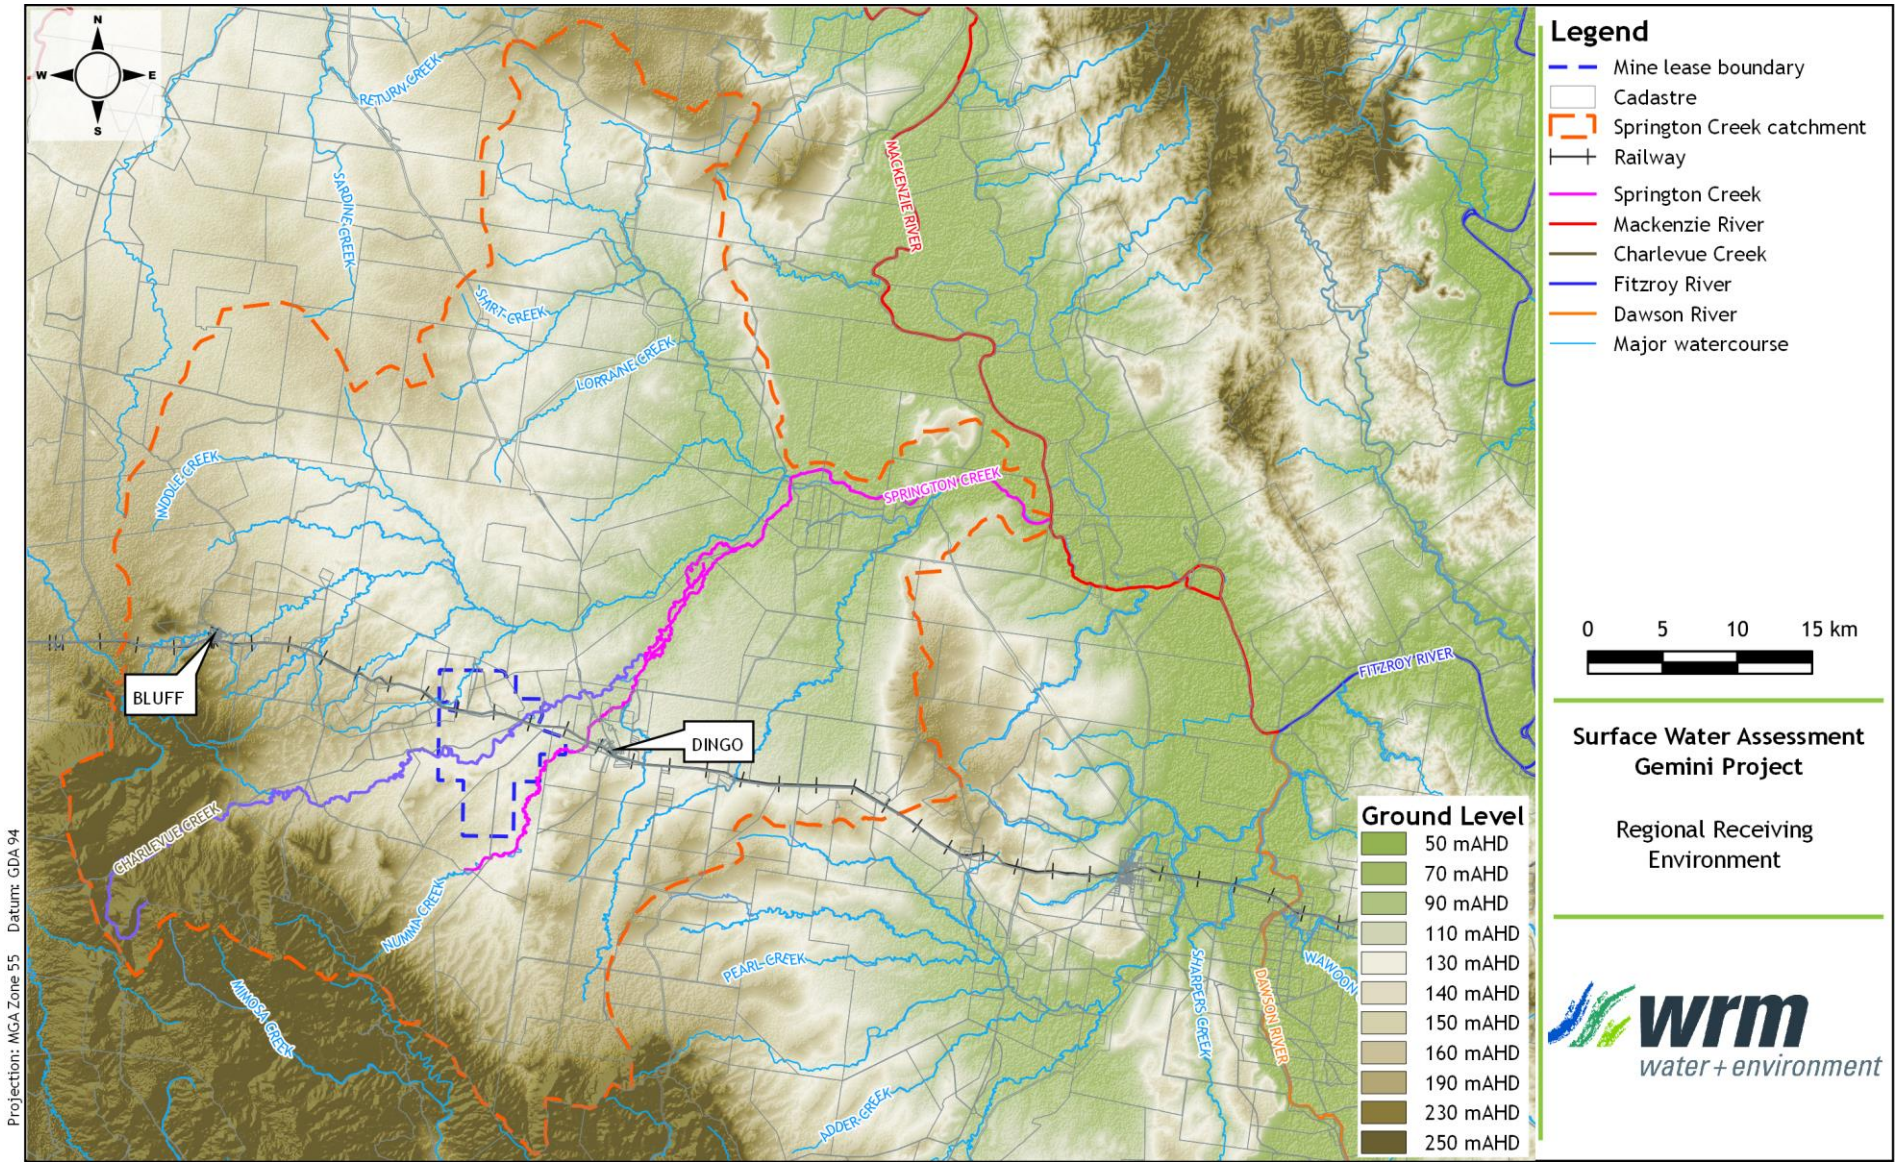

Figure 4.5 – Regional receiving environment

4.3 LOCAL STREAM MORPHOLOGY

The Project area is located within the Central Highlands region of the central Bowen Basin. The Bowen Basin is an early Permian to middle Triassic basin, extending through eastern Queensland from Collinsville in the north to Goondiwindi in the south.

The local stratigraphy typically comprises Permian coal measures overlain by Triassic and Tertiary sediments.

All nearby drainage features are ephemeral. In the Project area, Springton Creek and Charlevue Creek cross alluvial floodplains. The reaches of Springton Creek and Charlevue Creek in the proposed mining area have well-defined channels, typically with alluvial clay beds and well established in-channel vegetation.

4.4 STREAMFLOW

There are no streamflow gauges located in the local catchments in the vicinity of the Project. The local streams are ephemeral, and based on the observed behaviour of other streams in the region, streamflow mostly occurs shortly after rainfall between September and April.

4.5 FLOODING

A flood study has been undertaken for this assessment. The extent, depth and velocity of flooding across the MDL in the 1% AEP flood are shown in Figure 4.15 and Figure 4.16. The full details of the flood study are provided in Appendix A.

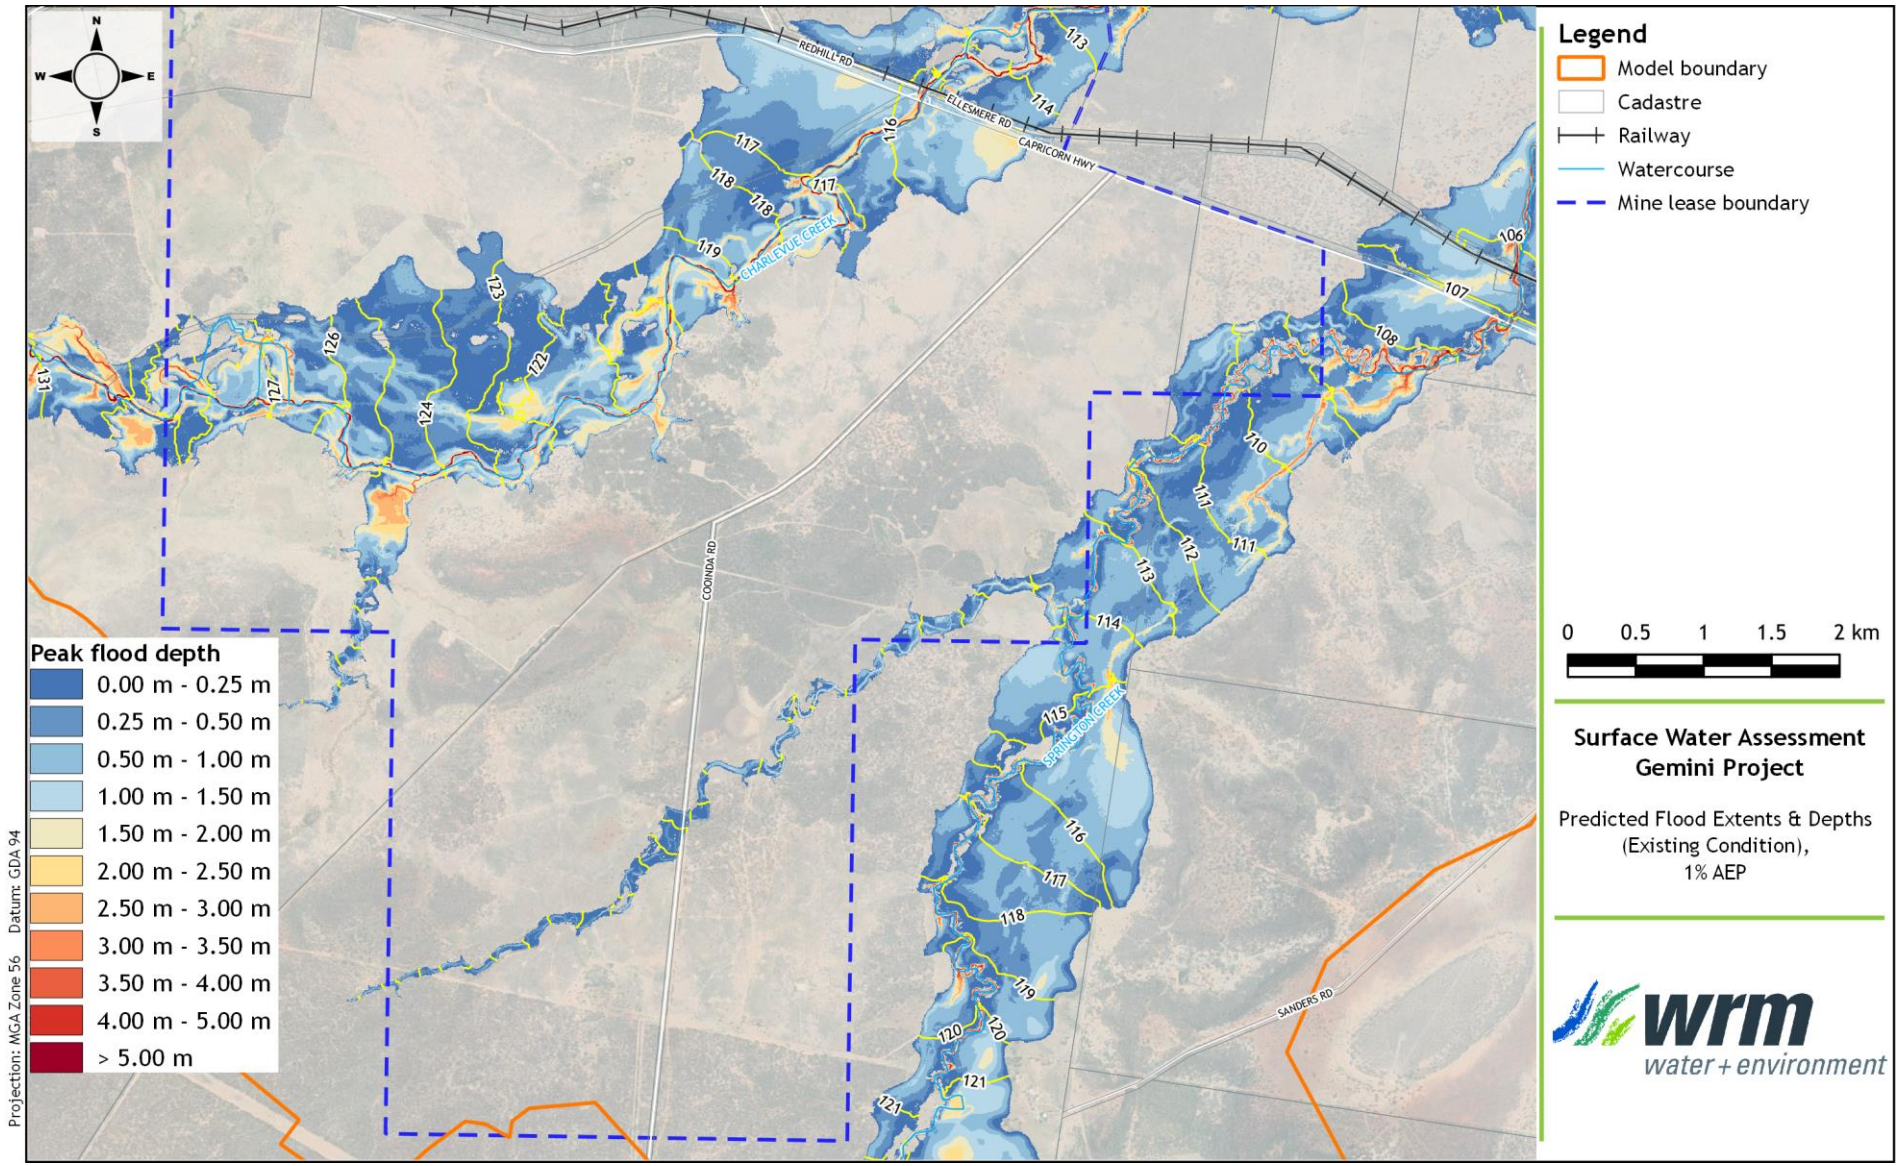

Figure 4.15 – Existing conditions 1% AEP flood depths and water level contours

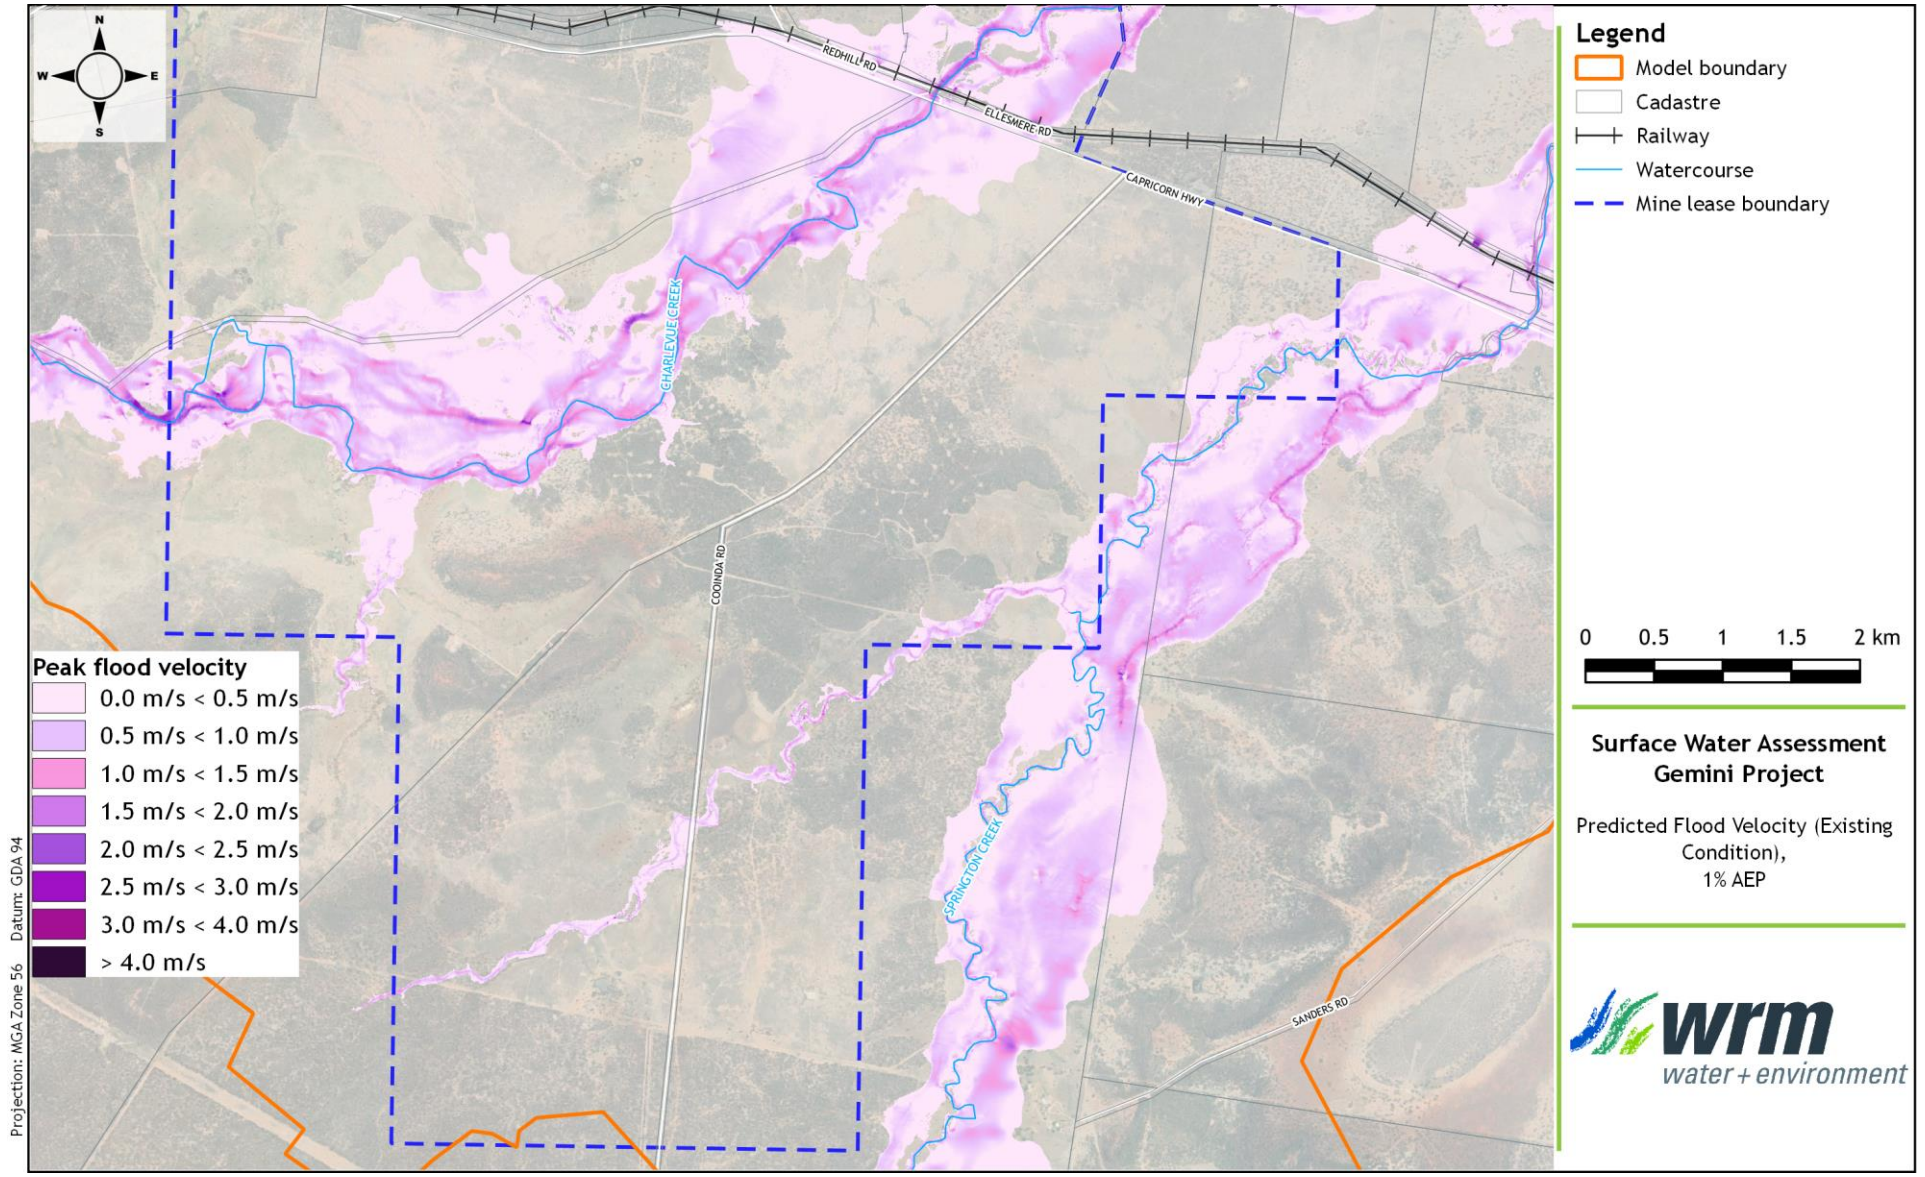

Figure 4.16 - Existing conditions 1% AEP flood velocities

4.6 WATER QUALITY

4.6.1 Baseline quality of receiving waters

Water quality of the region is variable and dependent on antecedent flow conditions and site-specific factors, such as adjacent land use and site disturbances.

A baseline water quality monitoring program has been implemented for the Project, and limited water quality data is available to characterise site water quality.

AARC (2019) provided the results of laboratory testing of field samples taken in Charlevue Creek and Springton Creek in late February 2018 and mid April 2019. The results for some key physico-chemical parameters can be summarised as follows:

- electrical conductivity (EC) within the WQO (i.e. 72 – 138 µS/cm);
- turbidity and suspended solids higher than the WQO (i.e. 422 – 5,630 NTU and 58 - 6,170 mg/L respectively);
- pH generally within but occasionally lower than the WQO (i.e. 6.1 – 7.3).

Surface water quality was found to be generally poor. Exceedances of the turbidity WQO were observed across all sites. Low DO levels were also recorded in stagnant pools along ephemeral the waterways. However, at the time of sampling there was no surface flow, and as such, these exceedances are not reliable indicators of long-term system health.

Petroleum hydrocarbon concentrations in Charlevue Creek and Springton Creek exceeded WQO values at downstream locations. These results may indicate an existing local source of petroleum hydrocarbons. Possible sources include crude oil, heavy fuel oils, lubricating oils, asphalt. The Capricorn Highway is a possible point source for the petroleum hydrocarbons observed at nearby locations.

There were no flow monitoring stations installed at the Project site prior to the surface water quality samples being taken. The results of the site water balance model have been used to estimate the relative magnitude of the flow events occurring in the days prior to the samples being taken.

As runoff was observed to have essentially ceased at the time of sampling, the modelled (using the AWBM) runoff for the 'undisturbed' catchment type over the 7 days prior to the sampling events on 23 February 2018 and 8 April 2019 was compared to the range of modelled weekly totals estimated over the period of climate record from 1889. The results are plotted in Figure 4.17 below, which shows that during both periods the modelled runoff would have been exceeded in the wettest 3% to 4% of weeks in the climate record (noting that runoff greater than 1 mm/week would only occur about 6% of the time).

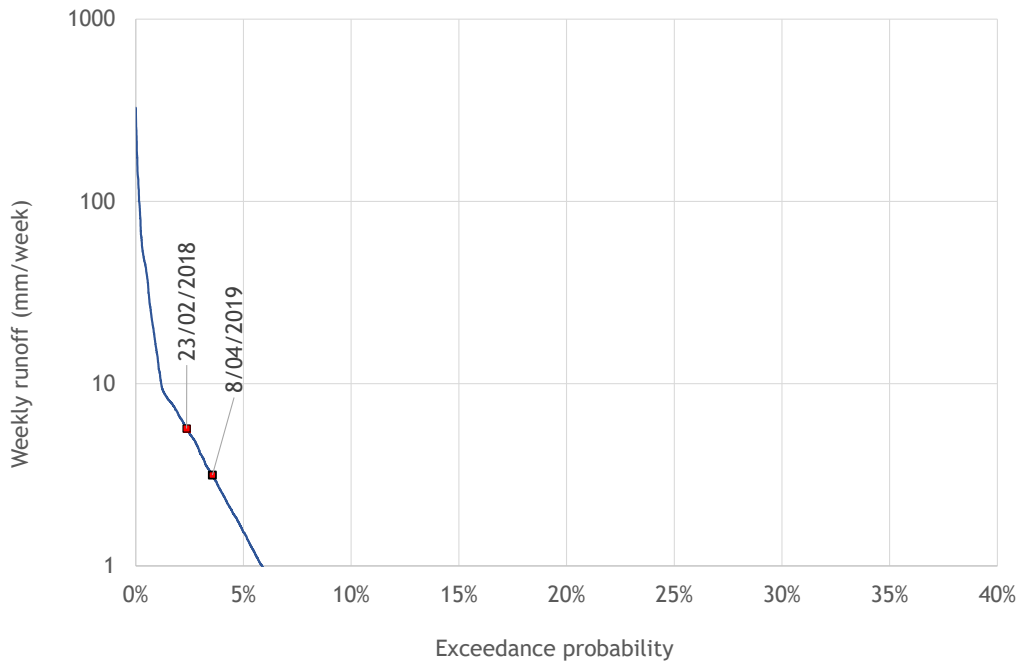

Figure 4.17 – Flow frequency curve based on rainfall runoff modelling of Springton Creek using the AWBM

4.6.2 Geochemical characterisation of overburden

RGS undertook a geochemical assessment (RGS, 2018) of representative samples of mining waste materials for the project. The samples represented the main overburden, interburden and potential coal reject materials likely to be encountered. The main findings of the assessment are as follows:

- Initial and ongoing surface runoff and seepage from mining waste materials is expected to be moderately alkaline and have a moderate level of salinity.
- Kinetic leach column (KLC) test results indicate that mining waste materials are unlikely to generate acid conditions and are more likely to generate pH neutral to alkaline conditions.
- Metal/metalloid enrichment was limited to cobalt in a single carbonaceous siltstone sample. However, the nature of a coal deposit means some metals/metalloids are expected to be slightly elevated in some materials.
- Most metals/metalloids are sparingly soluble at the neutral to alkaline pH of leachate expected from bulk mining waste materials. Dissolved metal/metalloid concentrations in surface runoff and leachate from bulk mining waste materials are therefore expected to be low and unlikely to pose a significant risk to the quality of surface and groundwater resources at relevant storage facilities.
- Most mining materials appear susceptible to dispersion and erosion, and appropriate management processes will need to be developed based on field trials for progressive rehabilitation of these materials during operations and at mine closure.
- Mining waste materials should be amenable to revegetation as part of rehabilitation activities, although, gypsum and fertiliser addition may need to be considered for sodic materials to limit dispersion and erosion and to provide a reasonable growth medium for revegetation and rehabilitation.

5 Proposed water management strategy

5.1 SITE WATER TYPES

Land disturbance associated with mining has the potential to adversely affect the quality of surface runoff in downstream receiving waters through increased sediment loads. In addition, runoff from active mining areas (including coal stockpiles, etc.) may have increased concentrations of salts and other pollutants when compared to natural runoff.

For the purpose of site water management, site water has been classified into the types shown in Table 5.1 on the basis of the likely water quality characteristics.

Table 5.1 – Site water types

Water Type	Definition
Mine affected water	In accordance with the DEHP Guideline Model Mining Conditions, mine affected water means the following types of water: i) pit water, tailings dam water, processing plant water; ii) water contaminated by a mining activity which would have been an environmentally relevant activity under Schedule 2 of the Environmental Protection Regulation 2008 if it had not formed part of the mining activity; iii) rainfall runoff which has been in contact with any areas disturbed by mining activities which have not yet been rehabilitated, excluding rainfall runoff discharging through release points associated with erosion and sediment control structures that have been installed in accordance with the standards and requirements of an Erosion and Sediment Control Plan to manage such runoff, provided that this water has not been mixed with pit water, tailings dam water, processing plant water or workshop water; iv) groundwater which has been in contact with any areas disturbed by mining activities which have not yet been rehabilitated; v) groundwater from the mine dewatering activities; vi) a mix of mine affected water (under any of paragraphs i to v) and other water.
Sediment water	Surface water runoff from areas that are disturbed by mining operations (including out-of-pit waste rock emplacements). This runoff does not come into contact with coal or other carbonaceous material and may contain high sediment loads but does not contain elevated level of other water quality parameters (e.g. electrical conductivity, pH, metals, metalloids, non-metals). This runoff must be managed to ensure adequate sediment removal prior to release to receiving waters. Note that prior to release through sediment control structures this water is considered mine affected water.
Clean catchment water	Surface runoff from areas unaffected by mining operations. Clean catchment water includes runoff from undisturbed areas and fully rehabilitated areas.
Raw water	Untreated water, generally from an external water supply, that has not been contaminated by mining activities.
Potable water	Treated water suitable for human consumption.

The proposed strategy for the management of surface water at the Project is based on the separation of water from different sources based on anticipated water quality.

On the basis of the expected runoff and groundwater inflow quality, the site water management system separates water into two segregated management systems:

- Mine affected water system - which will manage runoff and seepage from the mine pits, CHPP, coal stockpiles, and MIA. This is a closed system designed to prevent releases of mine affected water to the environment.
- Sediment water system - runoff from overburden dumps will be managed under an erosion and sediment control plan which is to be implemented throughout the Project, such that sediment generated and transported by runoff will be settled in a sediment dam. As overburden runoff quality is expected to be relatively benign, the sediment dams will potentially discharge directly into the environment (after the settlement of suspended sediment), and as such, will not affect the mine water balance. However, the water balance assessment has also assumed sediment dams will be pumped back to the CHPP for reuse.

Clean water from undisturbed areas is generally diverted around the areas of disturbance.

To facilitate the diversion of clean water from undisturbed area, the following drainage works are proposed:

- Minor drainage works and a pit levee are proposed to the south-east of Pit AB to ensure high flows from an unnamed second order tributary of Springton Creek do not access the pit.
- A drain is proposed to divert clean runoff from the upper reaches of an unnamed second order tributary of Springton Creek around the out-of-pit waste rock emplacement associated with Pit C.

These engineered drainage features will be required throughout operations at each mine pit and will become permanent features at mine closure.

A raw water supply pipeline is also proposed to supplement site water supplies, and will be delivered to a dedicated raw water dam, which will also intercept clean water from its local upstream catchment.

5.2 MINE DEVELOPMENT AND STAGING

Over the 18-year operating life of the Project, the operation will be staged as indicated in the following series of figures, which show the catchment areas to each mine water storage and the land use types comprising each catchment. These “snapshots” of mine operations have been adopted for the purpose of the site water balance modelling.

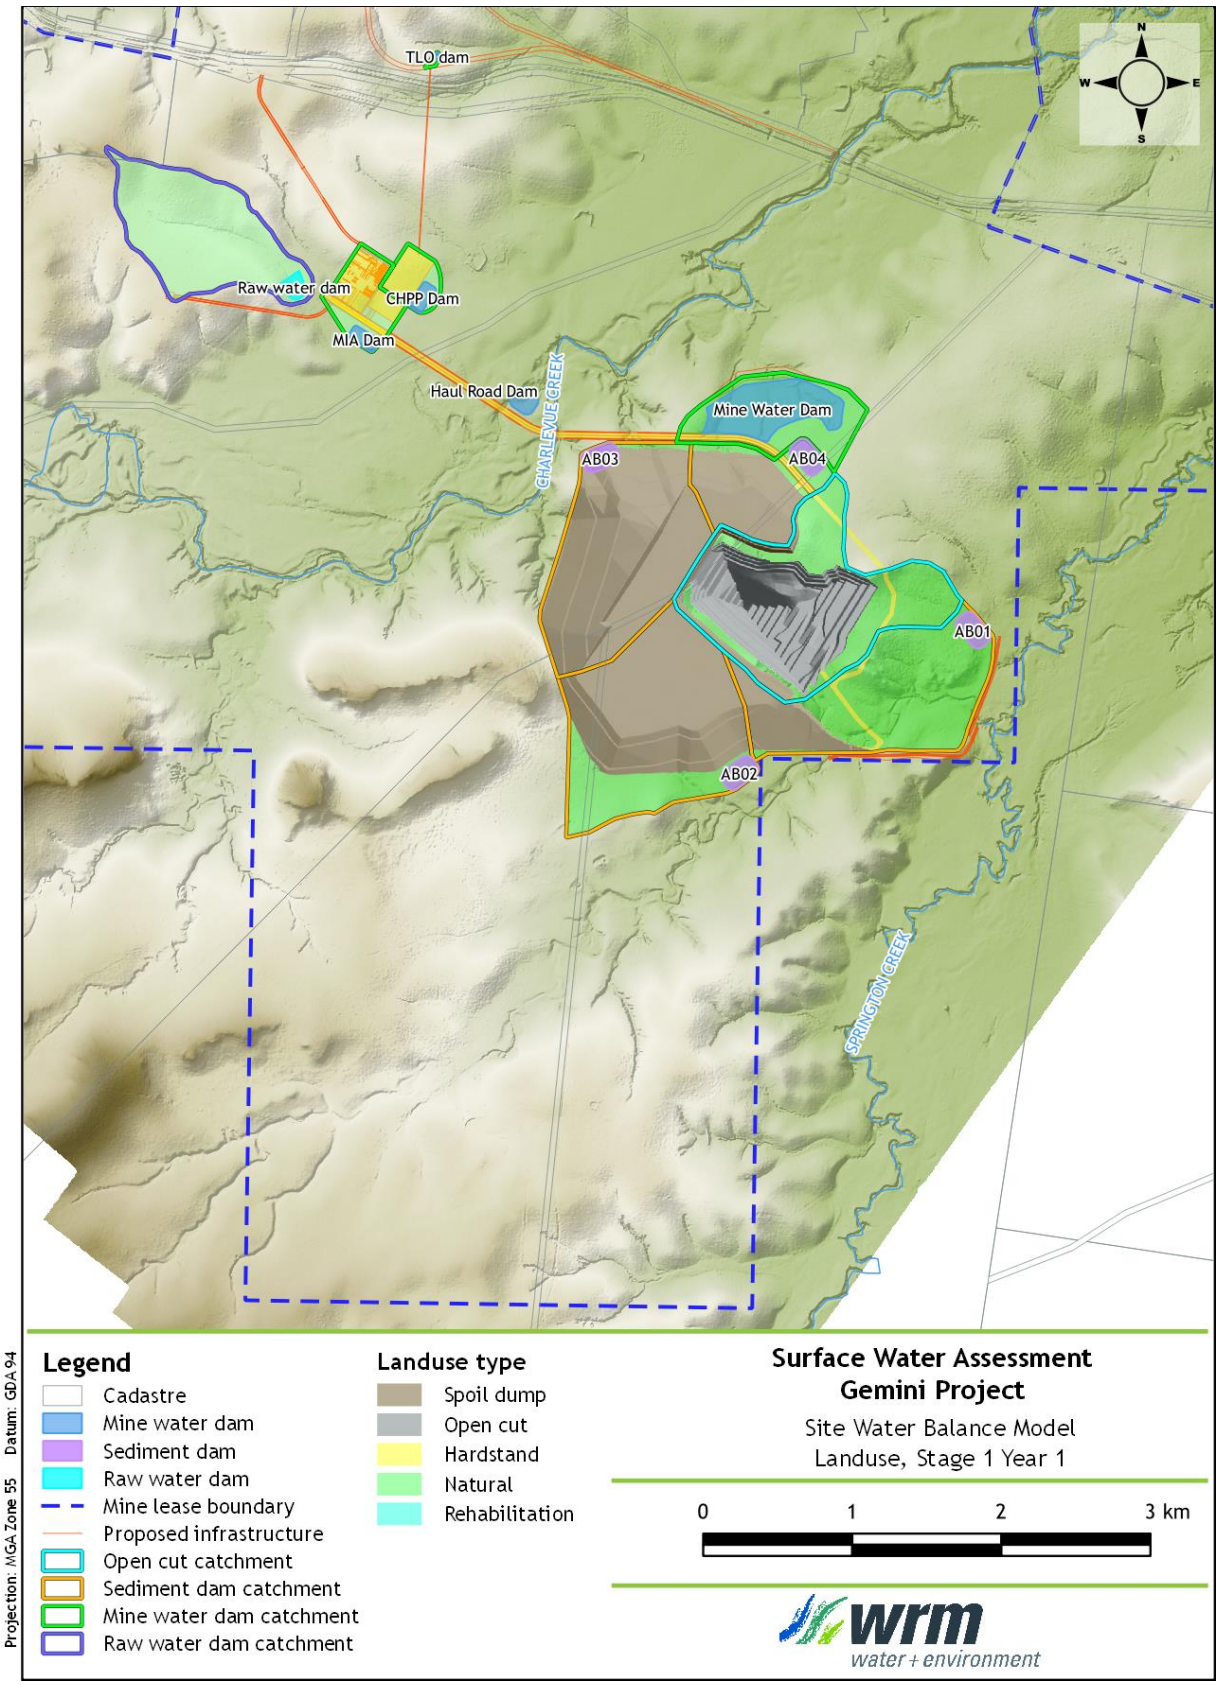

Figure 5.1 - Proposed water management system layout - Stage 1 (Year 1)

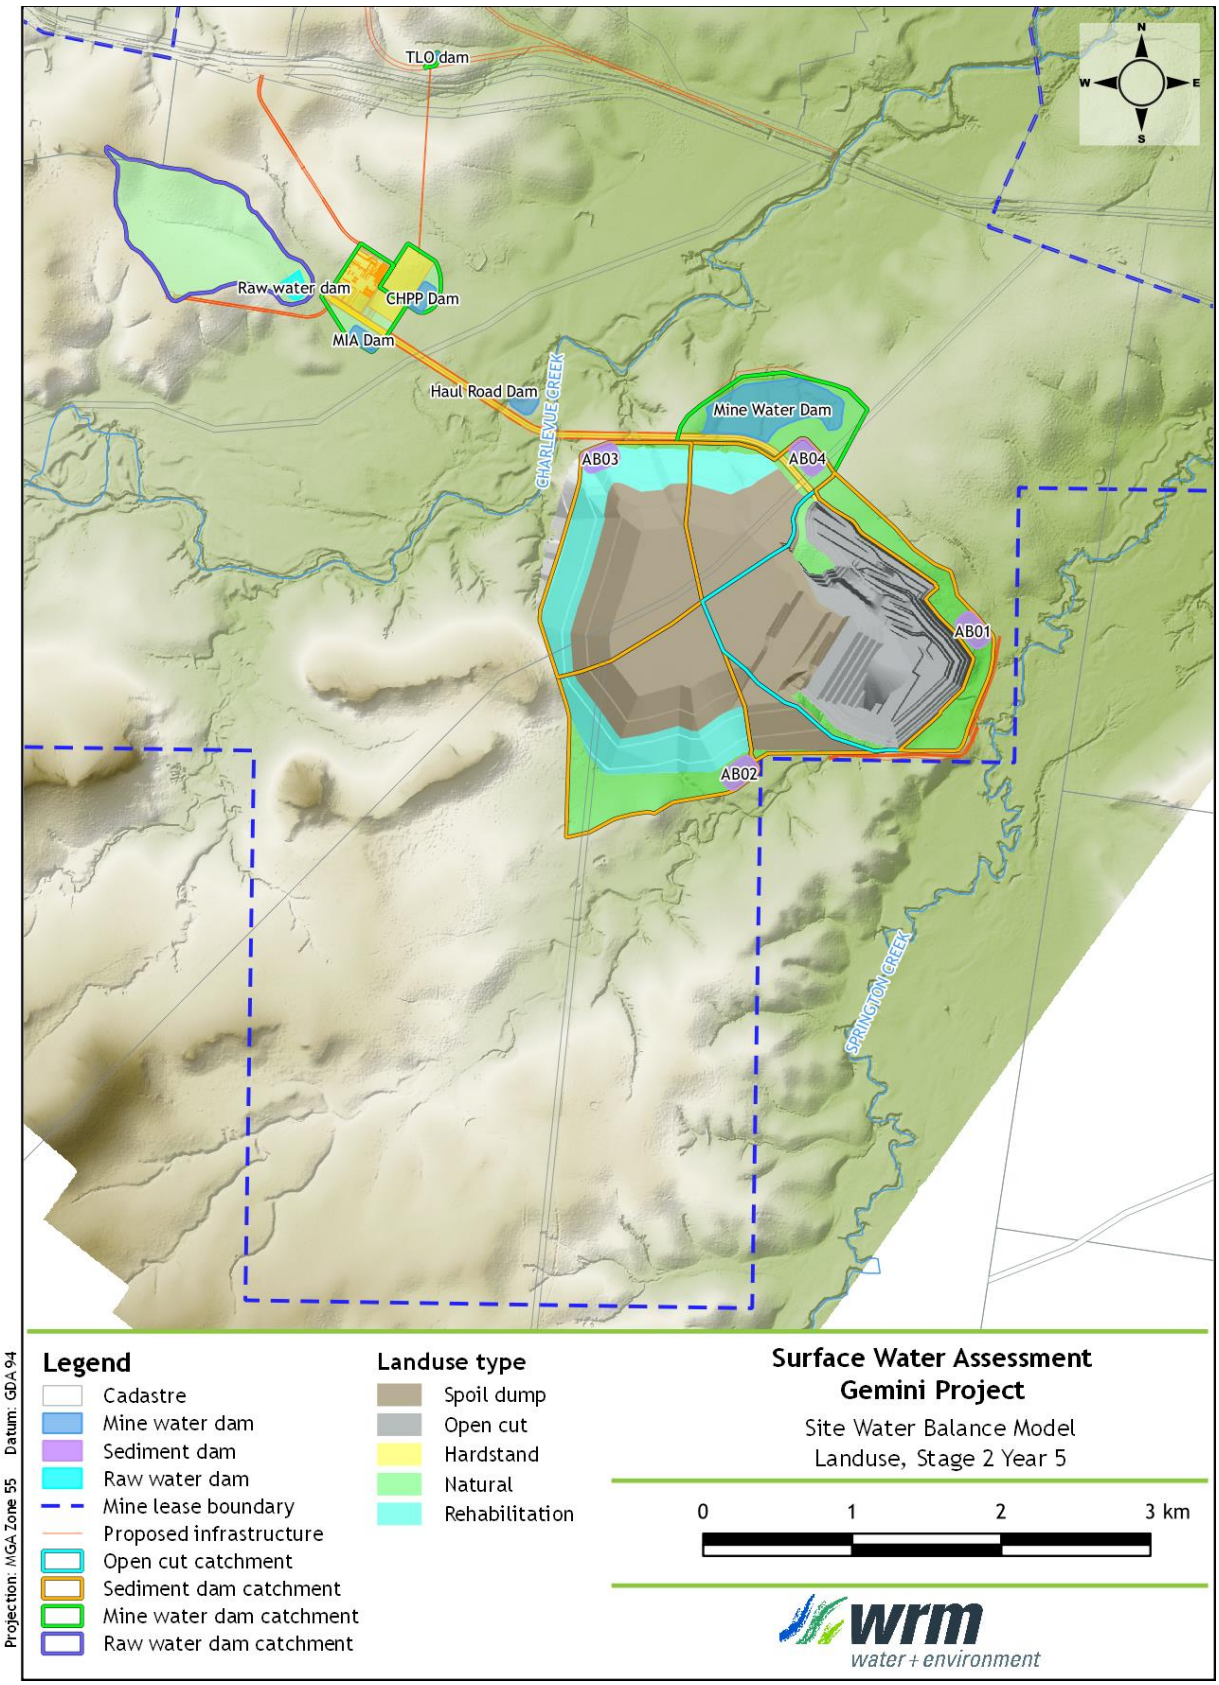

Figure 5.2 - Proposed water management system layout - Stage 2 (Year 5)

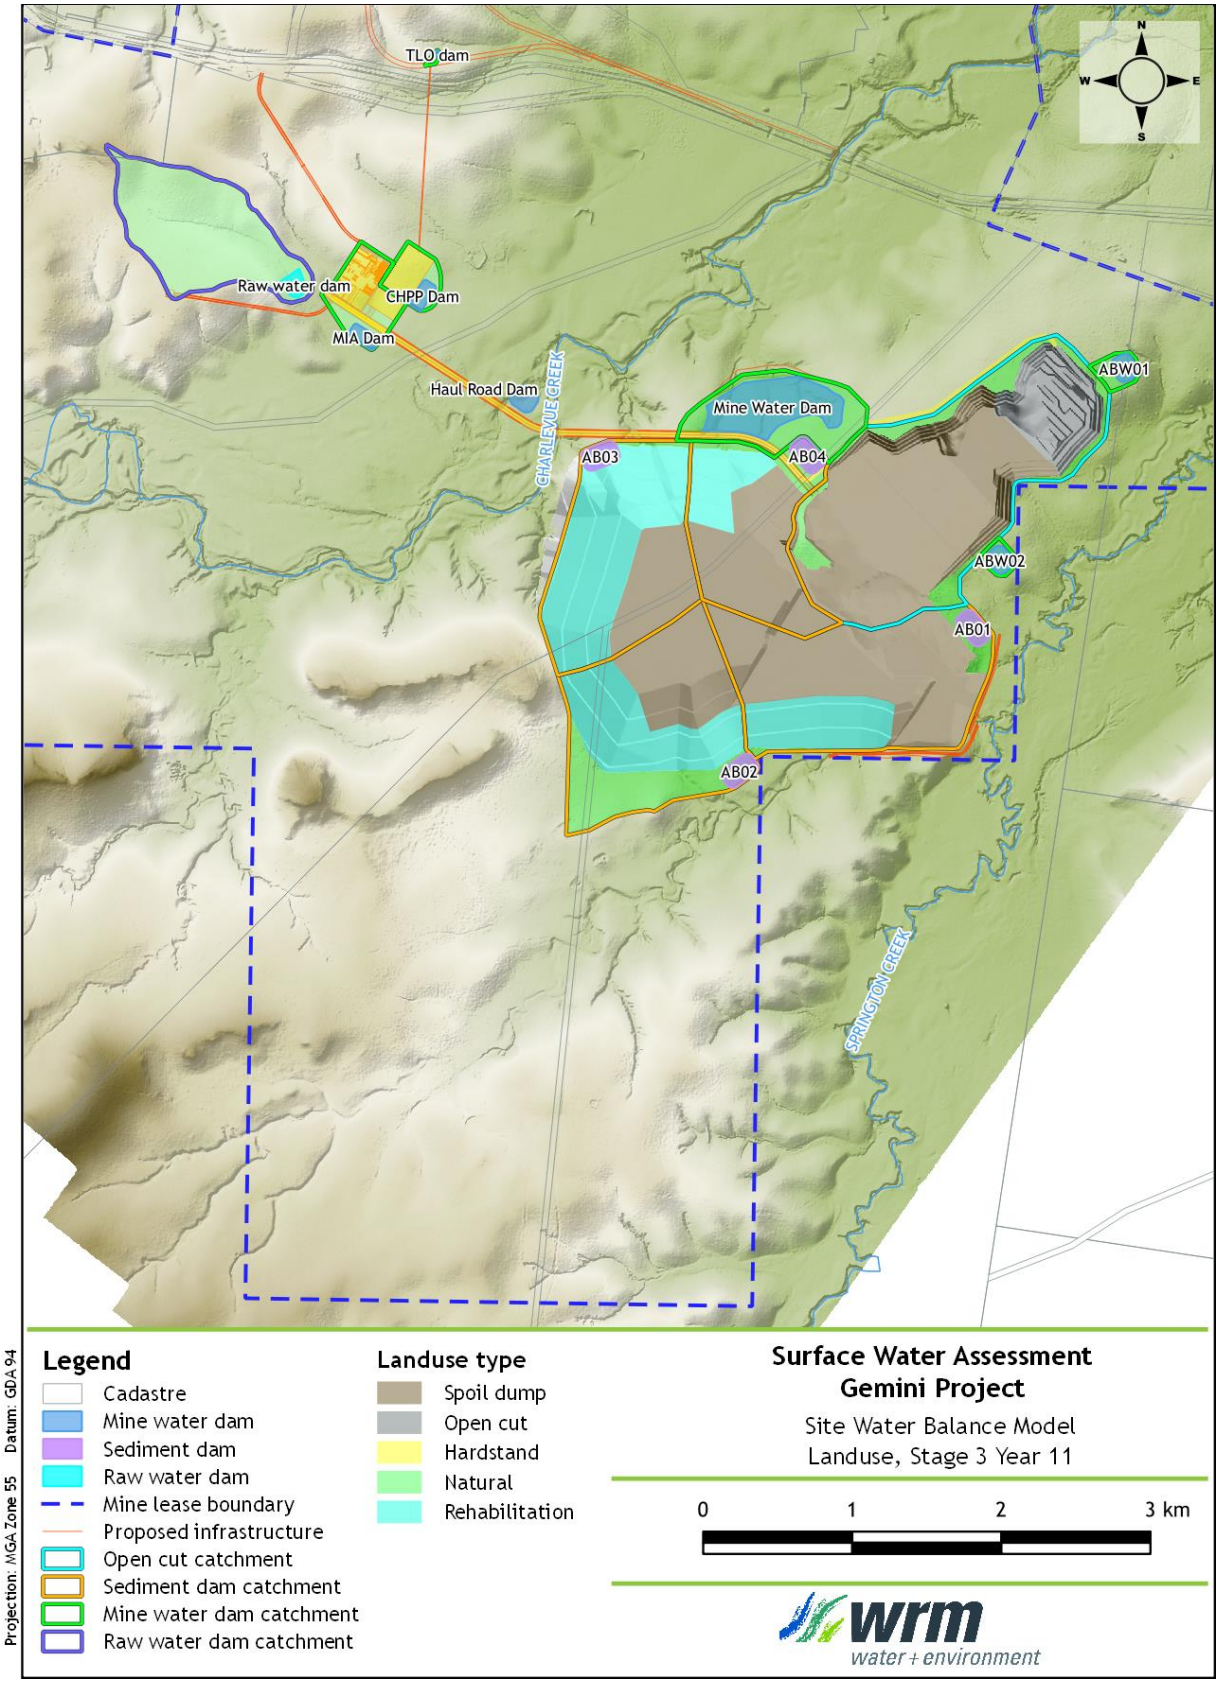

Figure 5.3 - Proposed water management system layout - Stage 3 (Year 11)

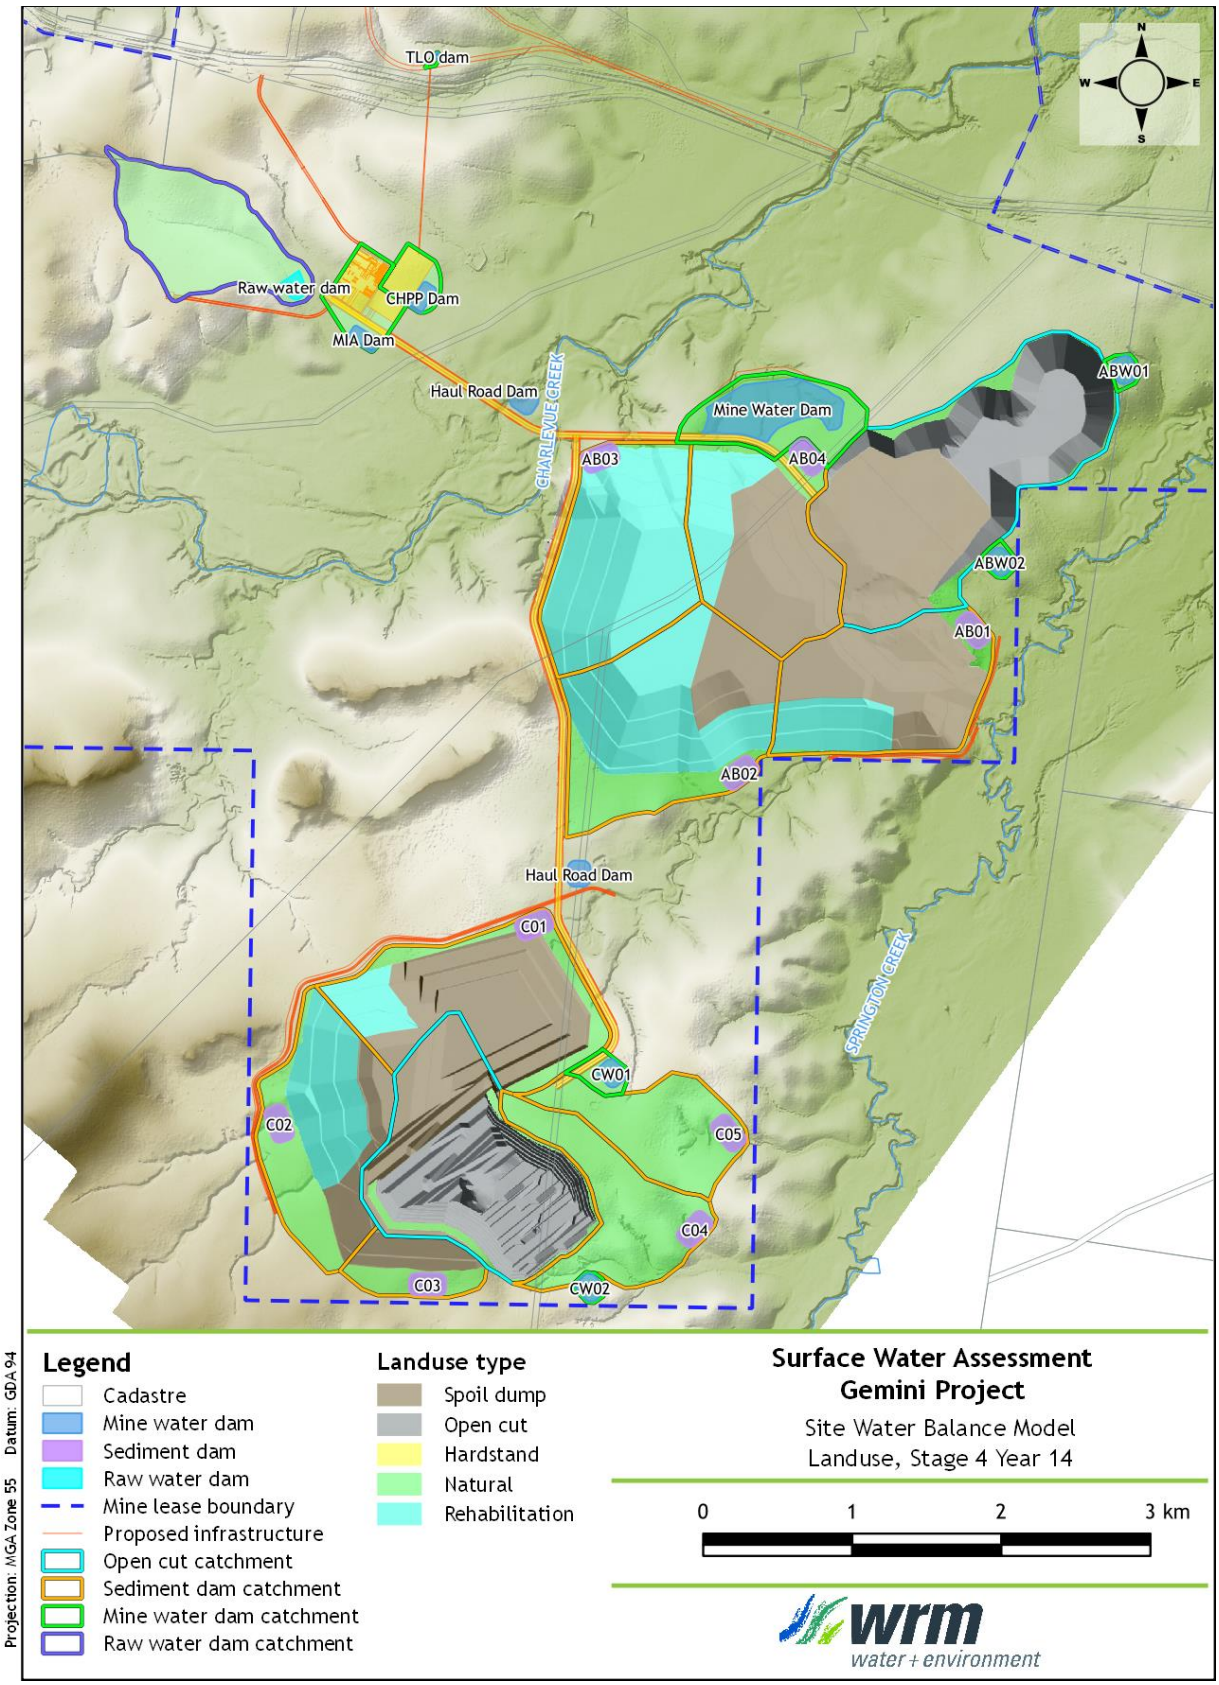

Figure 5.4 - Proposed water management system layout - Stage 4 (Year 14)

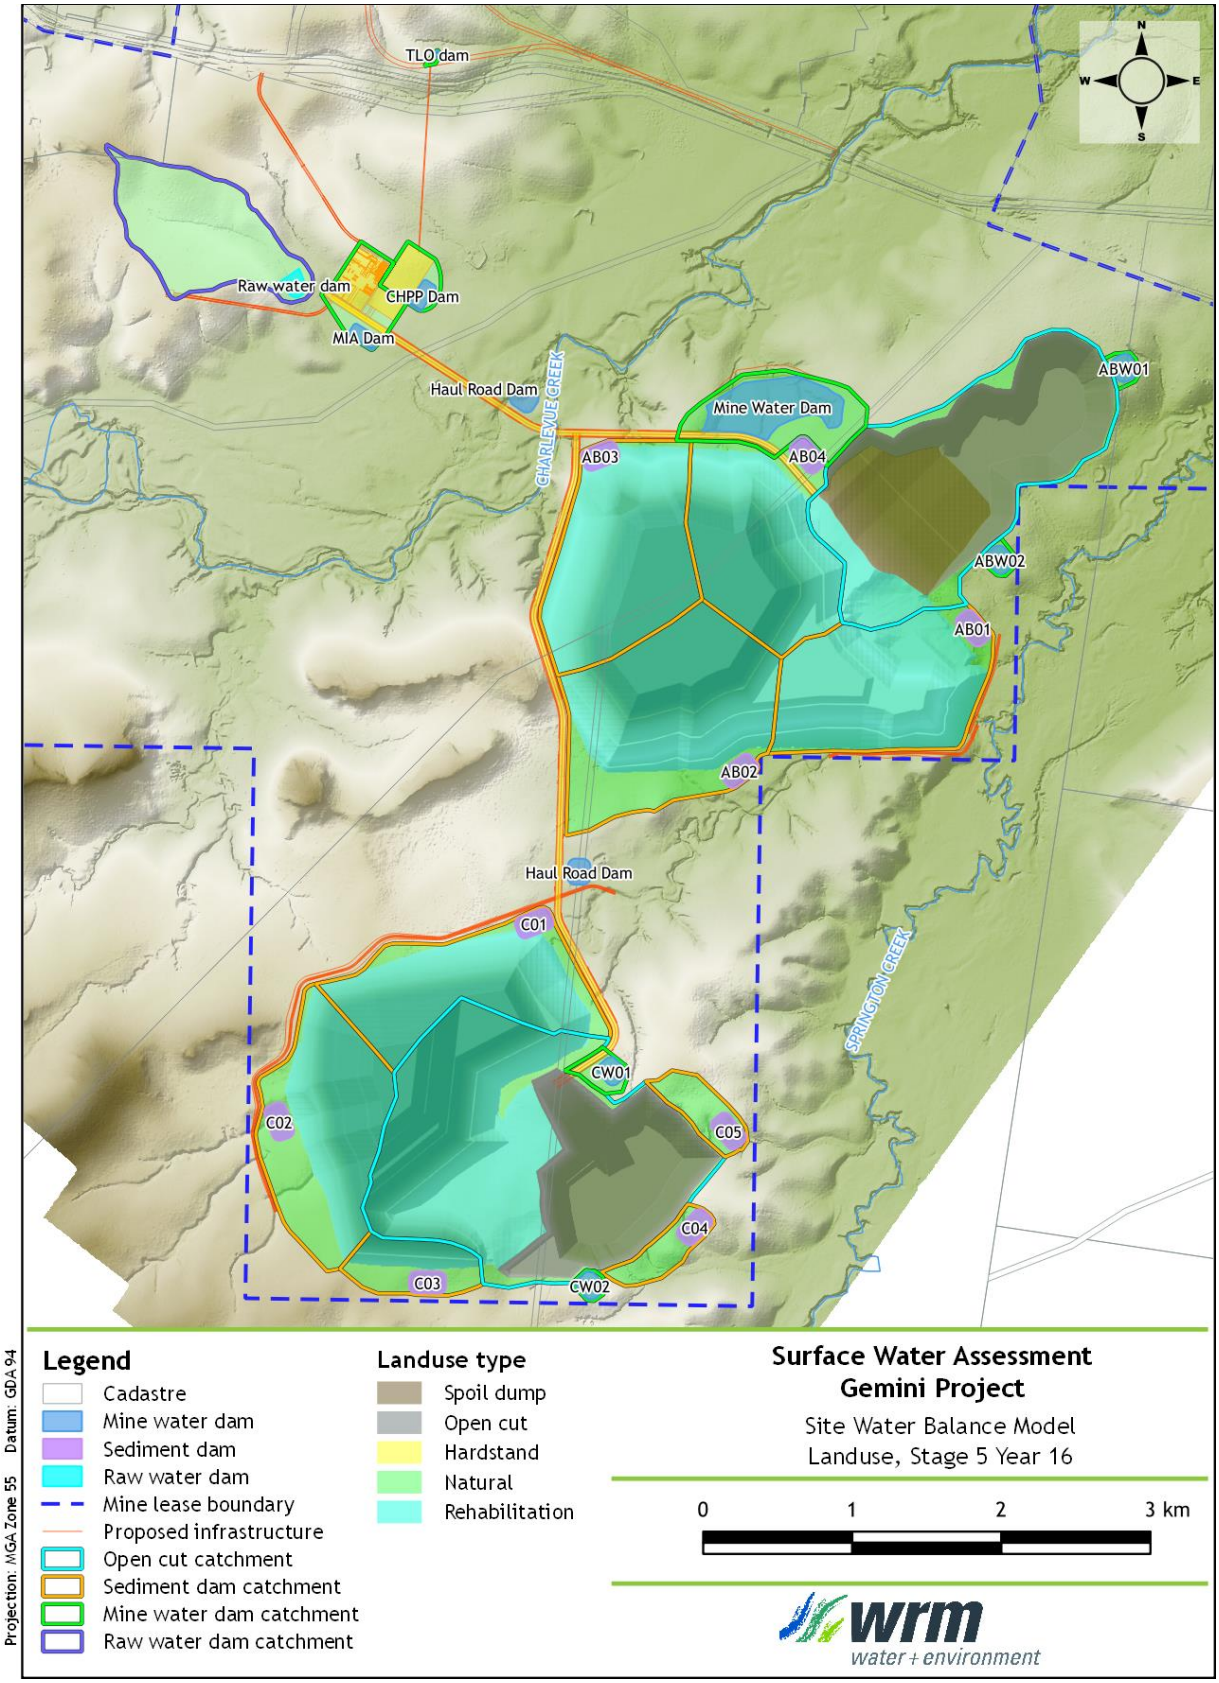

Figure 5.5 - Proposed water management system layout - Stage 5 (Year 16)

5.3 WATER MANAGEMENT SYSTEM COMPONENTS

5.3.1 Mine affected water dams

Several types of dams are proposed to hold mine affected runoff, including:

Mine Water Dam – receives pumped groundwater and surface runoff dewatered from AB Pit and C Pit (and potentially from the MIA and CHPP dams if required). Water will be transferred from the Mine Water Dam for reuse at the CHPP and for other uses as required. Offsite discharge of mine water will be avoided by operating below a maximum operating level and directing emergency overflows from the Mine Water Dam via a spillway to the mine pit. If stored water quality allows, controlled mine water releases may be made to Charlevue Creek in accordance with the Environmental Authority (these releases have been conservatively excluded from the site water balance model to ensure water can be contained on site without release under historical climate conditions).

AB Pit – will be used as a supplementary mine water storage after commencement of mining in C Pit.

Out-of-pit mine water dams – a number of small staging dams may be used to collect water pumped from the mine pits before transferring to the Mine Water Dam. These dams are small and have not been included in the site water balance model. Offsite discharge of mine water from these dams will be avoided by directing emergency overflows via spillways to the mine pit.

Haul Road Dams – two small dams will be used to manage runoff from disturbed catchments. One dam (between Pit AB and Pit C) will be used to contain runoff from the Pit C haul road, while the other dam will be used to collect runoff from the haul road on the western side of Charlevue Creek.

MIA Dam - will capture and contain runoff from the MIA and coal stockpiles. Oil/water separators are proposed for vehicle wash and workshop areas to treat hydrocarbon contaminated runoff prior to capture. Compared to runoff captured from other disturbed areas of the site, water captured in the MIA dam will be more likely to contain elevated contaminant concentrations. The dam will be sized and operated such that the risk of off-site release is very low. This would be achieved by providing a water storage capacity approximately equivalent to the runoff from the 1 in 20 AEP 4 month rainfall (4 ML/ha) – which is the hydrological design criteria for the 'failure to contain – overtopping' scenario in the Manual for assessing consequence categories and hydraulic performance of structures.

CHPP Dam - will capture and contain runoff from the CHPP. Compared to runoff captured from other disturbed areas of the site, water captured in the CHPP dam will be more likely to contain elevated contaminant concentrations. The dam will be sized and operated such that the risk of off-site release is very low. This would be achieved by providing a water storage capacity approximately equivalent to the runoff from the 1 in 20 AEP 4 month rainfall (4 ML/ha) – which is the hydrological design criteria for the 'failure to contain – overtopping' scenario in the Manual for assessing consequence categories and hydraulic performance of structures.

TLO Dam – A series of sediment traps and small drainage dams will be used to capture washdown and overflow from trains and sumps before it is directed to the TLO Dam. Water collected in this small dam will pumped to the Mine Water Dam. The dams will be sized and operated such that the risk of off-site release is very low.

Table 5.2 – Gemini Project mine affected water dam details

Storage	Catchment area (ha)	Storage capacity (ML)
Mine Water Dam	50.3	1,000
MIA Dam	22.4	96.5
CHPP Dam	11.9	101.7
Raw Water Dam	78.1	56.6
TLO Dam	0.5	0.5

5.3.2 Raw Water Dam

The raw water dam receives raw water imported via the offsite water supply pipeline described in Section 5.1. This dam will also capture clean surface runoff from its local undisturbed upslope catchment.

5.3.3 Sediment dams

Catchment runoff from overburden dumps at AB Pit and C Pit will be captured in sediment dams. Sediment dams will be designed and operated in accordance with the Department of Environment and Heritage Protection Guideline - *Stormwater and environmentally relevant activities (DEHP, 2017).*

This guideline states that"

"For events up to and including a 24 hour storm event with an ARI of 1 in 10 years, the following must be achieved:

i. a sediment basin must be designed, constructed and operated to retain the runoff at the site(s) approved as part of the ERA application;

ii. the release stormwater from these sediment basins must achieve a total suspended solids (TSS) concentration of no more than 50mg/L for events up to and including those mentioned above. For events larger than those stated above, all reasonable and practical measures must be taken to minimise the release of prescribed contaminants."

The sediment dams have therefore been sized as follows:

- Water storage capacity 1 in 10 AEP 24 hour storm event with and adopted volumetric event runoff coefficient for disturbed catchments of 0.5; and;
- total sediment basin volume = settling zone capacity + sediment storage volume. The sediment storage volume is the portion of the basin storage volume that progressively fills with sediment until the basin is de-silted;
- solids storage volume = 25% of water storage volume.

If required, water captured in sediment dams will be pumped back into the mine water system. Table 5.3 shows the required sediment dam volumes using this method.

Table 5.3 – Gemini Project sediment dam details

Storage	Catchment area (ha)	10year 24 hour water storage capacity (ML)	Solids storage volume (ML)	Total Storage capacity (ML)
AB01	146.1	105.9	26.5	132
AB02	155.5	112.7	28.2	141
AB03	121.8	88.3	22.1	110
AB04	114.9	83.3	20.8	104
C01	132.7	96.2	24.1	120
C02	106.8	77.4	19.4	97
C03	32.4	23.5	5.9	29
C04	76.0	55.1	13.8	69
C05	64.8	47.0	11.7	59

5.3.4 Engineered drainage features

5.3.4.1 Clean water drainage

Engineered drainage features are proposed at two locations to facilitate the diversion of clean water (Figure 1.2):

- Minor drainage works and a pit levee are proposed to the south-east of Pit AB to ensure high flows from an unnamed second order tributary of Springton Creek do not access the pit.
- A drain is proposed to divert clean runoff from the upper reaches of an unnamed second order tributary of Springton Creek around the out-of-pit waste rock emplacement associated with Pit C.

The engineered drainage features will be required throughout operations at each mine pit and will become permanent features at mine closure.

Runoff and seepage from the mine pits will be contained within the mine affected water (MAW) system. The mine pits and MAW dams are located such that it would not be possible for this MAW water to enter the engineered drainage features.

The overburden dumps will be initially placed within the levees, and (in accordance with the erosion and sediment control plan) sediment-laden runoff would be directed to sediment dams via drains designed to prevent overflow into the engineered drainage features.

As the final overburden dump profile is developed, a series of contour drains would direct runoff away from the engineered drainage structures and to sediment dams. Overflows to engineered drainage features would only occur after treatment in a sediment dam.

The preliminary channel designs of the clean water drains are provided in Section 7.

5.3.4.2 Levees

The purpose of the engineered drainage features is to ensure low flows are directed around the active mining area. Where a channel crosses a low-lying area or a gully adjacent to the active pit, a levee would be required to "*reduce the risk of ingress of clean floodwaters into operational areas where they may become contaminated with possible adverse impact on water management operations and containment performance.*"

The levees would therefore be 'regulated structures' and would be designed, constructed and decommissioned in accordance with the 'Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933)' and 'Structures which are dams or levees constructed as part of environmentally relevant activities (ESR/2016/1934)'.

These levee structures would be temporary, required only until the final overburden profile is achieved and the associated permanent drainage systems commissioned. However, they would likely become integral with the final rehabilitated overburden dump landform at decommissioning.

While the engineered drainage channels themselves would not necessarily be regulated structures, they will need to be designed to ensure they do not interfere with the functioning of the levees in the design flood event (for example by inducing scour which could affect the integrity of the levee).

5.4 CATCHMENT AREAS AND LAND USE

A summary of adopted catchment areas and land use types for each stage are provided in Table 5.4 to Table 5.8. The proposed disturbance footprints are shown in Figure 5.1, Figure 5.2, Figure 5.3, Figure 5.4, and Figure 5.5.

Table 5.4 – Catchment areas and land use breakdown summary – Stage 1 - Year 1

Dam	Contributing catchment (ha)

5.5 PRELIMINARY CONSEQUENCE CATEGORY ASSESSMENT

5.5.1 Consequence assessment - dams

A consequence assessment has been completed for the dams making up the proposed water management system, in accordance with the Manual for assessing consequence categories and hydraulic performance of structures (DES, 2016) (the Manual).

The Manual sets out the requirements of the administering authority, for consequence category assessment and certification of the design of 'regulated structures', constructed as part of environmentally relevant activities (ERAs) under the Environmental Protection Act 1994 (EP Act).

Each dam is assigned a Consequence Category of High, Significant or Low depending on its potential to cause harm. A structure categorised as a Significant or High consequence, is referred to as a regulated structure. Such structures must comply with hydraulic performance objectives set out in the Manual.

5.5.1.1 Assessment protocols

The manual requires an assessment of the potential for harm under the following failure event scenarios:

(a) ***'Failure to contain – seepage'*** – spills or releases to ground and/or groundwater via seepage from the floor and/or sides of the structure;

(b) **'Failure to contain – overtopping'** – spills or releases from the structure that result from loss of containment due to overtopping of the structure; and

(c) **'Dam break'** – collapse of the structure due to any possible cause.

5.5.1.2 Assessment criteria

For each failure event scenario, a consequence category is assigned depending on the potential to cause:

- Harm to Humans;
- General Economic Loss; or
- General Environmental Harm.

The potential for harm at the Gemini Project is described in general terms in the following section, and the adopted Consequence Categories are summarised in Table 5.9.

Harm to humans

Consumption of contaminated water

The nearest known surface town water supply systems are on the Mackenzie River and Fitzroy River, and would not be materially affected by discharge of the contents of any of the dams at the WCP (due to the total stored volume being less than 1000 ML, and the very large dilution potential).

Due to the ephemeral nature of the nearby streams, surface water is generally not used as a source of potable water in the region. All dams at the WCP are located such that human consumption of any contaminated waters is very unlikely, and would not meet the 'Significant' threshold of potentially affecting the health of 10 or more people.

Dam Break

For the purposes of the Manual, the assessment excludes site personnel engaged by the resource operation and located on the tenements. Due to the sparse population in the region, there are no workplaces or dwellings in the potential failure impact zone of the site water dams. All dams are located such that people are not routinely present in the potential failure path if an embankment was to fail.

General Economic Loss

There are no significant commercial operations in the immediate downstream reaches of Springton Creek or Charlevue Creek likely to be affected by contamination under any of the potential failure impact scenarios.

The potential damage caused by dam-break of the Mine Water Dam embankment is likely limited due to its limited height and storage capacity. However, damage to Aurizon's Blackwater rail line, a critical link for regional coal export, could result in significant economic loss to third parties.

Environmental Harm

Stored water quality in the Mine Water Dam, and MIA/CHPP Dam, are likely to be similar to mine water dams at other Central Queensland mine sites, with moderately elevated salinity, and pH, and some dissolved metals.

As there are no High Environmental Value (HEV) Zones identified in the downstream receiving environment, there is limited potential to cause harm to Significant Environmental Values.

Table 5.9 - Summary of consequence assessment - dams

	Main Water Dam	CHPP and MIA Dams	Raw Water Dam	Sediment Dams
Failure to contain - seepage				
Harm to humans	L	L	L	L
General environmental harm	S	L	L	L
General economic loss/damages	L	L	L	L
Failure to contain - overtopping				
Harm to humans	L	L	L	L
General environmental harm	S	L	L	L
General economic loss/damages	L	L	L	L
Dam break				
Harm to humans	L	L	L	L
General environmental harm	L	L	L	L
General economic loss/damages	S	L	L	L
OVERALL CCA RATING	S	L	L	L
Requires DSA/MRL	Y*	N	N	L
Requires engineered spillway	Y	Y	Y	Y
Requires lining (unless detailed groundwater investigation indicates risks are low)	Y	Y	N	N

L = Low consequence

S = Significant consequence

*DSA for Mine Water Dam – no DSA required if spills are directed to the Mine Pit via an appropriately robust overflow system (the Mine Pit provides the DSA)

5.5.1.3 Failure to Contain - Seepage

Localised impacts of seepage to the ecology of the on-site reaches of Springton and Charlevue Creek and its tributaries is possible, but any significant impact would be limited in extent. The Mine Water Dam and MIA/CHPP Dams have been therefore been assigned a Significant Consequence category, however, a detailed groundwater assessment should be carried out to further inform the detailed design of seepage management measures or reclassification of structures if appropriate.

5.5.1.4 Failure to Contain - Dam Break and Overtopping

The manual states that a dam is to have a Significant Consequence Category if it meets the following criteria:

> Would *be likely to be caused to Significant Values - and at least one of the following:*
>
> *i) loss or damage or remedial costs greater than $10,000,000 but less than $50,000,000; or*
>
> *ii) remediation of damage is likely to take more than 6 months but less than 3 years; or*
>
> *iii) significant alteration to existing ecosystems; or*
>
> *iv) the area of damage (including downstream effects) is likely to be at least 1 km^2 but less than 5 km^2*

Given the relatively small volume and concentrations of contaminants, it is unlikely that remedial measures would take more than three years. However, it is likely that remediation would take more than one year. Therefore, a Significant Consequence Category is justified for the Environmental Harm trigger for all mine affected water dams. The environmental dam is an excavated storage and therefore dambreak is not a likely failure mechanism for this dam.

5.5.2 Consequence assessment - levees

A consequence assessment has also been completed for the proposed levees protecting the mine pit from flood inundation. The Manual includes specific considerations for the assessment of levees.

5.5.2.1 Assessment protocols

Where a levee is designed to prevent ingress of mine-affected flood water into an operational area, and the pit would be encroached by a flood event with a probability more than or equal to 0.1% AEP, it is designated a regulated structure.

As the levees proposed for the project are required to protect the pit from flooding in the 0.1% AEP flood, they are regulated structures.

There is no requirement for a consequence assessment for the 'failure to contain – seepage' scenario to be conducted for levees.

5.5.2.2 Assessment criteria

For each failure event scenario, a consequence category is assigned depending on the potential to cause:

- Harm to Humans;
- General Economic Loss; or
- General Environmental Harm.

Third parties are unlikely to be impacted in terms of 'Harm to Humans' or 'General Economic Loss', and as a result, 'Low' Consequence Categories are applicable to these classes of 'Harm'.

Under the 'dam break' scenario, the failure of either structure could result in the release of significant quantities of sediment laden water to the downstream receiving environment (due to the subsequent erosion of overburden dumps and other disturbed areas). As a result, a significant consequence category is justified for both levees due to the potential for 'General Environmental harm'.

The potential for harm due to failure of levees at the WCP, and the adopted Consequence Categories are summarised in Table 5.10.

Table 5.10 - Summary of levee consequence assessment ('dam break' scenario)

	Springton Creek levees
Harm to humans	L
General environmental harm	S
General economic loss/damages	L
OVERALL CCA RATING	S

5.5.2.3 Hydraulic performance criteria for levees that are regulated structures

The hydraulic performance objectives for levees in relation to the 'dam break' scenario that relate to the levees at the Gemini Project are to be achieved by designing and maintaining each levee so that:

- it isolates and diverts the peak flow from a design storm of critical duration for the contributing catchment at an AEP of 0.1%; and
- in at least one place in the levee crest, there is a restricted length of low crest, limiting the freeboard at that point, such that a flood exceeding the design protection level of the levee will be directed to a planned area or areas within the zone to be protected.

6 Site water balance

6.1 WATER DEMANDS

6.1.1 Coal handling and preparation plant

The CHPP will comprise a dense medium cyclone / spirals / flotation plant. Flotation tailings, screen bowl effluent and concentrate, fines reject thickening cyclone overflow, fines reject screen undersize and belt press filter filtrate will be fed to a tailings thickener to separate solids. Solids from the tailings thickener will be processed with belt press filters to remove rejects from the flocculants.

The use of the belt press filters reduces the total water demand compared to traditional tailings disposal methods due to the low losses to waste moisture. The project description provides the following CHPP demand estimates throughout the project life, which includes allowance for coal crushing and conveyor dust suppression. Table 6.1 shows the details of forecast CHPP demands.

Table 6.1 - Forecast CHPP and TLO demands

Year	CHPP Demand (ML/a)	TLO Demand (ML/a)
1	162.0	0.72
2	162.0	0.73
3	162.0	0.73
4	162.0	0.73
5	162.0	0.73
6	162.0	0.72
7	162.0	0.72
8	162.0	0.71
9	162.0	0.72
10	162.0	0.72
11	162.0	0.70
12	162.0	0.74
13	162.0	0.74
14	162.0	0.74
15	162.0	0.74
16	162.0	0.72
17	162.0	0.74
18	143.4	0.65

6.1.2 Train loading operation (TLO)

TLO water demands for controlling dust generation for the TLO, rail loading and freight would be managed by:

- Shrouding and sprays on delivery/transfer to the loadout bin;
- During wagon loading;
- Telescopic chutes;
- Use of water sprays and surfactants;
- During freight - application of a veneer prior to departure;
- Removal of any wagon overload situations.

A 40L/wagon water demand is adopted, where a wagon contains 80 tonne of product coal. Table 6.1 shows the details of forecast CHPP demands.

6.1.3 Haul road dust suppression

The proposed mining schedule for the project includes starting mining at AB Pit and progressing to C Pit.

Mine affected water will be used as a priority for haul road dust suppression. Water for haul road dust suppression will be sourced from the Mine Water Dam which will be supplied with water from the operational pits and supplemented with sediment dam or raw water when required.

Haul Road water demand will be increasing throughout the project life where. Haul road dust suppression water demand is expected to commence at around 315 ML/a, and increases to approximately 512 ML/a at Stage 5.

6.1.4 Potable water demands

Potable water will be delivered to site by truck and stored in potable water tanks before distribution around the site using pressure pumps and small-bore poly pipes.

6.2 GROUNDWATER INFLOWS TO MINING PITS

Groundwater inflows were estimated by JBT Consulting Australia Pty Ltd (JBT, 2019). The estimates provided by JBT Consulting are net inflows to the pit after evaporation losses from the pit faces and the entrained moisture losses due to mining. The adopted net inflow rates are provided in Table 6.2.

Groundwater inflows are expected to increase over time and eventually the net inflow would exceed the total site water demand. Water is therefore expected to accumulate in the mine water dam over the long term. The relatively large capacity of the mine water dam has been provided specifically for this purpose.

Table 6.2 - Estimated net annual groundwater inflow to pits after losses

6.3 WATER BALANCE MODEL

A computer-based operational simulation model (OPSIM) was used to assess the dynamics of the mine water balance under conditions of varying rainfall and catchment conditions throughout the development of the Project. The OPSIM model dynamically simulates the operation of the water management system and keeps complete account of all site water volumes and representative water quality on a daily time step.

The model has been configured to simulate the operations of all major components of the water management system. The simulated inflows and outflows included in the model are given in Table 6.3.

Table 6.3 - Simulated inflows and outflows to the water management system

Inflows	Outflows
Direct rainfall on water surface of storages	Evaporation from water surface of storages
Catchment runoff	CHPP demand
Raw water supply	Haul road dust suppression demand
Groundwater inflows	TLO water demands
	Dam overflows

6.4 SIMULATION METHODOLOGY

6.4.1 Modelled staging of mine plans

The water balance model was run on a daily time step for an 18 year period, corresponding with the proposed mine life between Year 1 and Year 18. The model assumes that operations commence in January.

Catchment land use changes were assessed through the discrete stages, described in the previous section. These stages have been selected using the mining progression information, and provide a representative disturbance footprint for each stage.

6.5 CATCHMENT RUNOFF

6.5.1 Catchment runoff salinity

The OPSIM model includes a conservative salt balance with each catchment type assigned a fixed salinity.

Water samples taken from Springton and Charlevue Creeks had a median EC of 114 µS/cm (74 mg/L). For the purpose of the site salt balance, runoff from undisturbed (natural) catchments was assumed to have a salinity (EC) of 150 µS/cm.

Kinetic leach column (KLC) testing of the local overburden material (RGS, 2019) showed that leachate from all KLC samples (apart from the carbonaceous siltstone and coal) had initial EC values less than 800 µS/cm, and at the end of six months less than 203 µs/cm. Based on these results, for the purpose of the site salt balance, runoff from spoil was assumed to have a salinity of 600 µS/cm. Runoff from highwalls was assigned an EC of 8,000 µS/cm to account for potential contact with the coal seams, which would result in increased salinity, and hardstand areas were conservatively assigned an EC of 900 µS/cm.

6.5.2 Catchment runoff rates

The OPSIM model uses the Australian Water Balance Model (AWBM) (Boughton, 2003) to estimate runoff from rainfall. The AWBM is a saturated overland flow model which allows for variable source areas of surface runoff. The AWBM uses a group of connected conceptual storages (three surface water storages and one ground water storage) to represent a catchment. Water in the conceptual storages is replenished by rainfall and is reduced by evaporation (surface stores only). Simulated surface runoff occurs when the conceptual storages fill and overflow.

The model uses daily rainfalls and estimates of catchment evapotranspiration to calculate daily values of runoff using a daily water balance of soil moisture. The model has a baseflow component which simulates the recharge and discharge of a shallow subsurface store. Runoff depth calculated by the AWBM model is converted into runoff volume by multiplying the contributing catchment area.

The model parameters define the storage depths (C1, C2 and C3), the proportion of the catchment draining to each of the storages (A1, A2 and A3), and the rate of flux between them (Kb, Ks and BFI).

Catchments across the site water management system have been characterised into the following land use types:

- Natural/undisturbed, representing areas in their natural state;
- Roads, hardstand and mining pit floor areas;
- Spoil dump, representing uncompacted dumped overburden material;
- Open cut, representing pit area; and
- Rehabilitated, representing established rehabilitated spoil areas.

Adopted rainfall runoff parameters are summarised in Table 6.4. In the absence of site-specific parameters, parameters typical for coal mines in the Bowen Basin were adopted.

Specifically, the adopted parameters were selected so that the values of C_{avg} were less than those established for the corresponding catchments types by validation of the Isaac Plains Mine (IPM) water balance model against recorded site data (including water storage volumes) over the period from January to December 2018. The validation model was configured to reflect the site operations during this period, with appropriate transfer rates, system configuration and water inflows and outflows. Site rainfall and evaporation data was used for the calibration.

During 2018, the primary mine affected water storage at IPM was S3 Pit (a mined-out pit area), therefore the validation of the water balance model was undertaken against the recorded inventory in S3 Pit between January and December 2018.

The simulated S3 Pit storage inventory generally reproduced the observed overall mine observed water inventory fluctuations over the verification period between January and December 2018 with the exception of a few data points

Compacted catchments (mining pit, roads/hardstand and stockpile/industrial areas) are characterised by hard surfaces which inhibit water infiltration, resulting in much higher rates of surface runoff.

To represent compacted catchments, the depth of the model surface stores was substantially reduced and baseflow eliminated. The simulated volumetric runoff coefficient for disturbed catchments was 21%, about 4 times higher than natural catchments. This value is similar to typical values for urban catchments, which have similar characteristics.

The adopted model parameters for “rehabilitated spoil” assume lower opportunities for evapotranspiration than natural catchments and also that a significant component of runoff will seep through the spoil, discharging over several weeks rather than running off within a few hours of rainfall. The modelled runoff coefficient of 8.6% is around 1.5x that for natural catchments.

The model parameters for “spoil” represents the uncompacted dumped overburden material, both in-pit and out-of-pit. It has also been applied to areas available for rehabilitation. The runoff coefficient of 9.8 % is around double that of natural catchments.

Notwithstanding the above, an onsite water monitoring system will be used to validate system performance against the design assumptions (including adopted model parameters) in terms of water quality and water quantity, so that an adaptive management can be implemented to protect the surface water environment. The monitoring system would be used to ensure the performance of the water management system is not affected by any variance between adopted model parameters and actual parameters.

Table 6.4 – Adopted AWBM parameters

Parameter	Spoil Dump	Hardstand	Natural	Established Rehab	Open Cut
A1	0.134	0.134	0.134	0.134	0.134
A2	0.433	0.433	0.433	0.433	0.433
A3	0.433	0.433	0.433	0.433	0.433

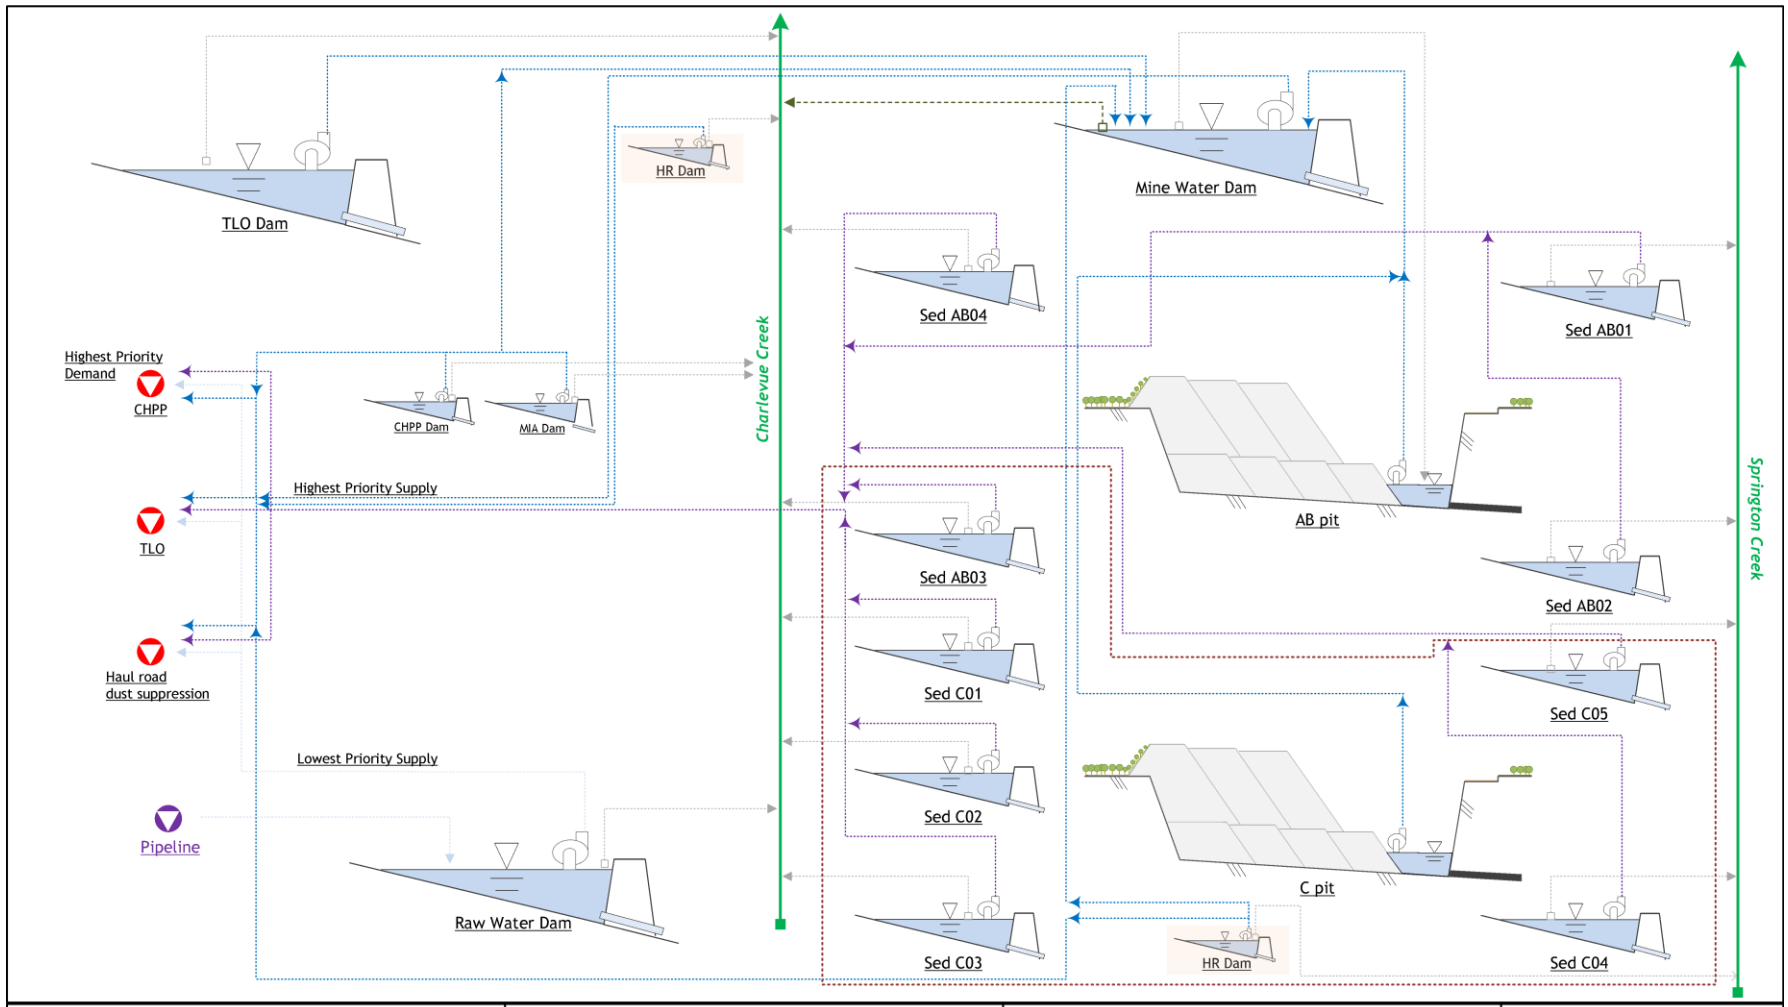
C2	50	20	100	60	20
C3	120	40	180	130	40
C_{avg}	74.9	26.7	124.6	83.7	26.7
BFI	0.35	0	0.2	0.35	0
K_{base}	0.6	0	0.82	0.6	0
K_{surf}	0.1	0.1	0.17	0.1	0.1
Rehab runoff/rainfall	9.8%	20.9%	5.1%	8.6%	20.9%
Runoff salinity (EC) µS/cm	600	900	150	150	8,000

Figure 5.1 to Figure 5.5 show how catchment landuse will change as the project develops.

A schematic of the integrated Gemini Project water management system configuration is shown in Figure 6.1. A summary of the proposed storages within the integrated WMS and their operating strategies are summarised in the following sections.



6.6 MODELLING OF WATER DEMAND

6.6.1 Haul road dust suppression

Haul road dust suppression watering rates were applied to haul road areas that vary as mining progresses. The following rules were used to determine the applied dust suppression rate on any given day of the historical rainfall record:

- The assessment used daily evaporation rates sourced from the SILO evaporation dataset;
- For a dry day (zero rainfall), the haul road watering rate is equal to the daily evaporation rate;
- For a rain day when rainfall is less than the daily evaporation rate, the watering rate is reduced and is only required to make up the remaining depth to the daily evaporation rate;
- For a rain day when rainfall exceeds the daily evaporation rate, no haul road watering is required; and
- It was assumed that 29 metres of the haul road width would be watered.

The estimated consumption rates for each phase are summarised in Table 6.5 (but note that the totals will vary with climate in the model).

Notes

Spill Flow Directions:
Good engineering practice is to include a stabilised spillway as a contingency for dam safety. This arrow does not indicate that these discharges (spills/overflows) are a part of the water management system or that spills will occur. The arrow is to show the direction of water flow (by gravity) should the dam water level exceed the dam spillway level.

6.8 OPERATING RULES

The operating rules to be applied to the links joining the various elements in the water balance model are summarised in Table 6.7 below.

Table 6.7 – Gemini Project water management system operating rules

Item	Node Name	Operating Rules
1.0	***External Water Supply***	
1.1	Pipeline	• Supplies the Raw Water Dam – which in turn supplies the haul road dust suppression, CHPP and TLO; • Yearly allocation assumed unlimited; • Capacity limited to 200L/s.
2.0	***Supply to Demands***	
2.1	CHPP	• Demands in priority, from the Mine Water Dam, Sediment Dams and Raw Water Dam respectively.
2.2	Haul road dust suppression	• Demands from the Mine Water Dam, Sediment Dam and Raw Water Dam; • Demands vary daily according to the loss model detailed in this report.
2.3	TLO	• Demands from the Mine Water Dam, Sediment Dams and Raw Water Dam; • Demands according to the coal production rate and usage rate (L/t ROM).
3.0	***Transfer of pit water***	
3.1	Mine Pit	• Pit dewatering directed to Mine Water Dam, at a nominal rate of 200 L/s. Pumping to cease when the maximum operating level reached.
4.0	***Operation of site dams***	
4.1	Mine Water Dam	• Receives pumped transfers from the Mine Pit up to the maximum operating level; • Receives pumped transfers from the MIA dam, CHPP dam and runoff dams; • Storage overflows to Pit; • Controlled releases in accordance with the EA conditions may be made to Charelevue Creek if required, but this has been conservatively excluded from the model.
4.4	Raw water Dam	• Receives pumped transfers from pipeline to a maximum operating level (to be determined); • Overflows to Charlevue Creek.
4.5	TLO Dam	• Pumping to Mine Water Dam; • Overflows to Charlevue Creek.
4.6	AB01	• Sediment dam, active from Year 1 onwards; • Overflows to Springton Creek.
4.7	AB02	• Sediment dam, active from Year 1 onwards; • Overflows to Springton Creek.
4.8	AB03	• Sediment dam, active from Year 1 onwards; • Overflows to Charlevue Creek.

Item	Node Name	Operating Rules
4.9	AB04	• Sediment dam, active from Year 1 onwards; • Overflows to Charlevue Creek.
4.10	C01	• Sediment dam, active from Year 14 onwards; • Overflows to Charlevue Creek.
4.11	C02	• Sediment dam, active from Year 14 onwards; • Overflows to Charlevue Creek.
4.12	C03	• Sediment dam, active from Year 14 onwards; • Overflows to Charlevue Creek.
4.13	C04	• Sediment dam, active from Year 14 onwards; • Overflows to Springton Creek.
4.14	C05	• Sediment dam, active from Year 14 onwards; • Overflows to Springton Creek.
4.15	MIA Dam	• Receive runoff from MIA area; • Pumping to Mine Water Dam.
4.16	CHPP Dam	• Receive runoff from CHPP area; • Pumping to Mine Water Dam.
4.17	Haul Road Dams*	• Receive runoff from haul road areas; • Pumping to Mine Water Dam.
5.0	***Receiving water***	
5.1	Springton Creek	• Receives uncontrolled overflows from the following sediment dams: ○ AB01; ○ AB02; ○ C04; ○ C05.
5.2	Charlevue Creek	• Receives uncontrolled overflows from the following sediment dams: ○ AB03; ○ AB04; ○ C01; ○ C02; ○ C03.
6.0		• All storages and pits receive local catchment runoff and lose water through evaporation

Note: * Storages have immaterial contribution to overall site water balance and therefore are not included in the site water balance model.

6.9 WATER BALANCE MODEL RESULTS

The results of the site water balance model are summarised in the following sections.

6.9.1 Mine water dam behaviour

The results of the water balance model presented in Figure 6.2 show that as pit catchments and groundwater inflows increase, the likelihood of needing to store large volumes of water in the mine water dam increases. By the end of Year 7, the median stored volume is at the Mine Water Dam's maximum operating volume.

As the mine water dam catchment is so small, fluctuations in water level due to rainfall and runoff are relatively small. The dam can therefore be maintained at an operating level relatively close to the spillway crest level with minimal risk of overflow. Notwithstanding, the mine water dam maximum operating level would include a freeboard to provide additional storage during rainfall events (i.e. the dam's maximum operating level is less than the dam capacity).

The mine water dam's maximum operating level has been chosen to manage the risk of overflows. The spillway directs overflows to AB Pit, so the likelihood of uncontrolled offsite discharge from the Mine Water Dam is negligible. Water would only be discharged from the system when there are significant flows in the receiving waters in accordance with the EA conditions.

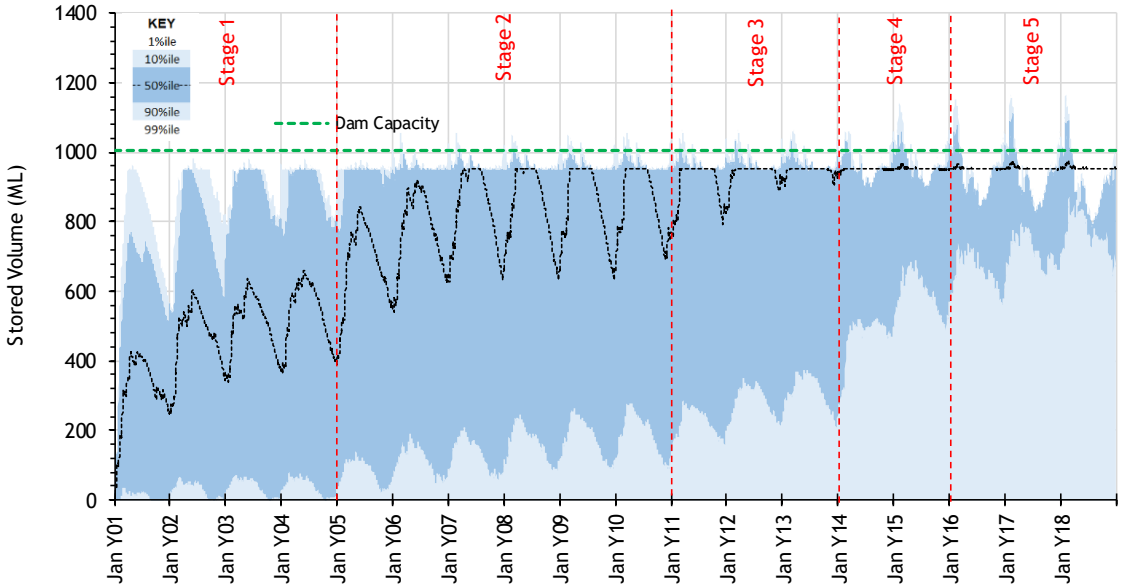

Figure 6.2 - Mine Water Dam - stored water volume behaviour

6.9.2 Likelihood of pit inundation

Figure 6.3 shows a plot of water volumes accumulating in AB pit and C pit over the project life. The plot shows the median stored volume is minimal on all days.

At AB Pit, stored water volumes can be maintained at relatively low volumes which would not interrupt mining operations. The 10th percentile In pit inventory is negligible prior to each wet season, prior to the end of AB Pit mining at the end of Year 13.

After Year 13, AB Pit can be used to stored excess water from C Pit in very wet periods. While the median stored water volume is negligible, up to 3,250ML of water could be stored in AB Pit at the 1% confidence level, which corresponds to a level just below the expected equilibrium final void lake water level.

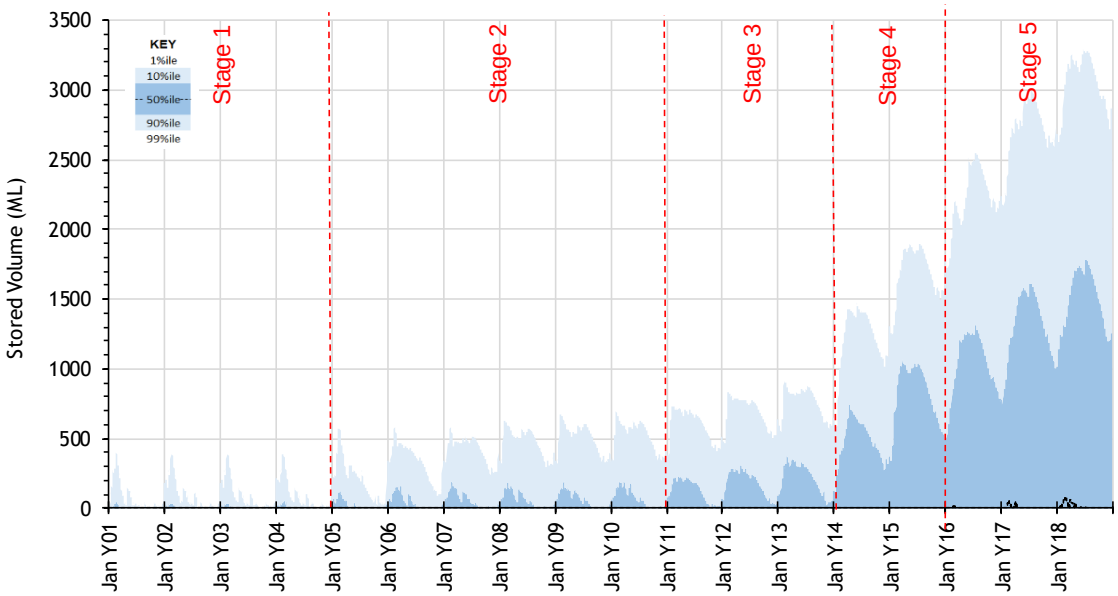

Figure 6.3 - AB pit - stored volume behaviour

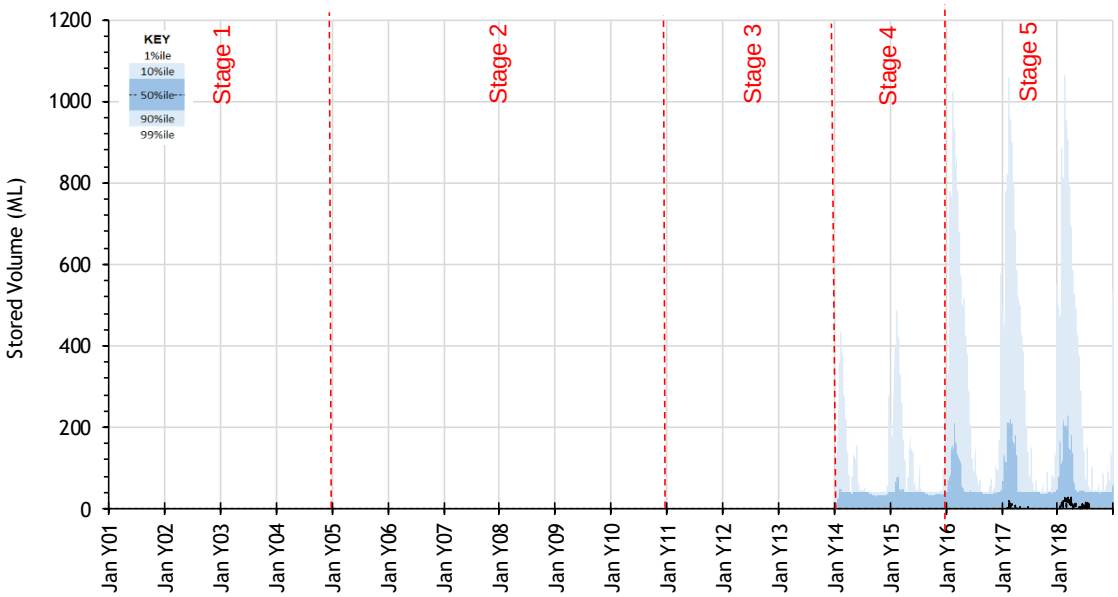

Figure 6.4 - C pit - stored volume behaviour

6.9.3 Water supply reliability

Figure 6.5 shows imported water requirements from the external pipeline are highest in the early project stages. Under very dry conditions, the demand could reach 500 ML/a, but median Year 1 demand is less than 100 ML/a. During later years, accumulated stored pit and sediment dam water is sufficient to supply demands in all but the driest years.

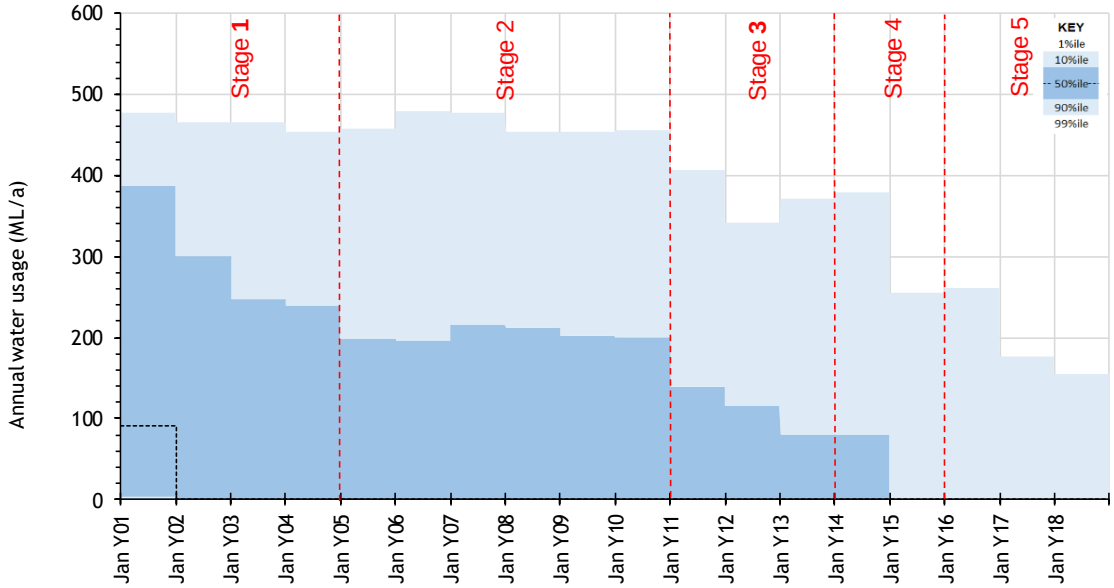

Figure 6.5 – Raw water pipeline usage

6.9.4 Sediment dam releases

Figure 6.6 and Figure 6.7 show that the likelihood of sediment dam discharges to Charlevue and Springton Creeks increases over the mine life. In the early years, the likelihood of discharge is low, as contributing catchments are relatively small, and captured water may be used to supplement site water demands. However, in later years the likelihood of discharges increases. Water captured in sediment dams is expected to have low salinity and coarse sediments will settle out, such that any impacts to downstream water quality are expected to be minor.

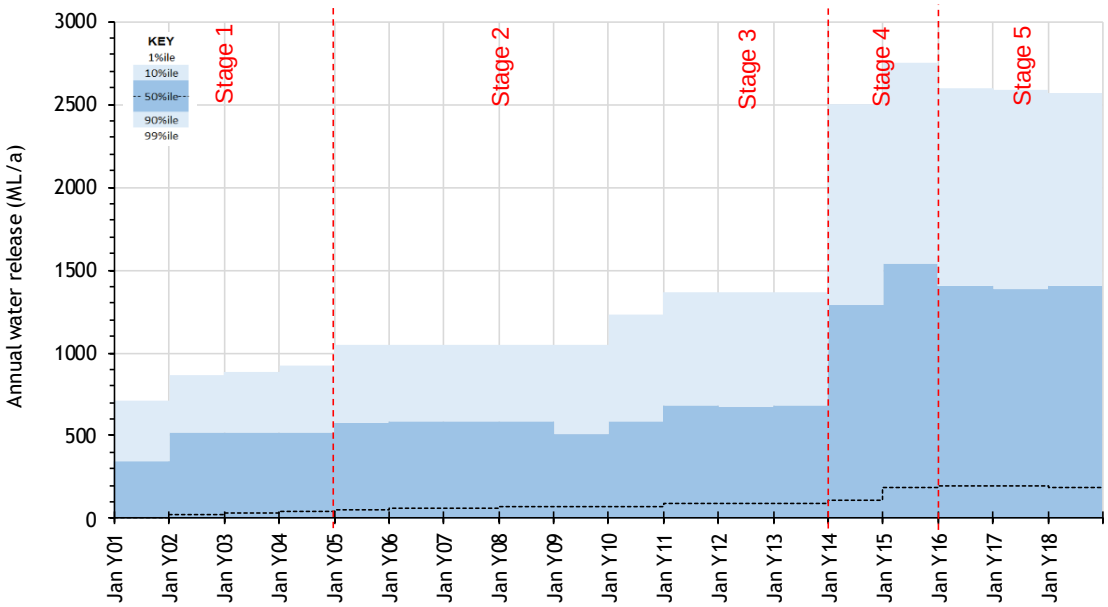

Figure 6.6 – Sediment dam spills to Charlevue Creek

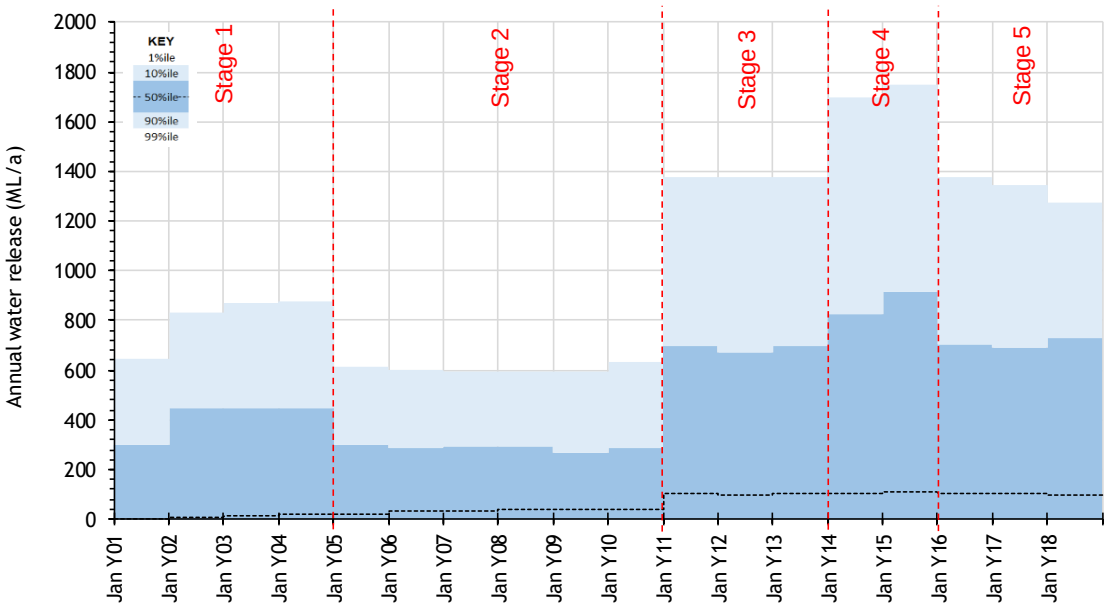

Figure 6.7 – Sediment dam spills to Springton Creek

6.9.5 Overall site water balance

The overall average annual site water balance is summarised in Table 6.8.

Table 6.8 – Average annual site water balance

Component	Process	Volume (ML/a)					
		Stage 1 Y1 - Y4 (4 years)	Stage 2 Y5 - Y10 (6 years)	Stage 3 Y11 - Y13 (3 years)	Stage 4 Y14 - Y15 (2 years)	Stage 5 Y16 - Y18 (3 years)	Total (18 years)
Inflows	Rainfall and runoff	973	1,052	1,215	2,148	2,214	7,602
	Net groundwater inflow	32	32	210	118	37	428
	External supply pipeline	89	51	29	17	11	196
	Total	1,093	1,135	1,454	2,283	2,261	8,226
Outflows	Evaporation	250	317	386	629	762	2,344
	Haul road dust suppression	315	336	405	469	515	2,040
	CHPP Usage	162	162	162	162	162	810
	Spill from Raw Water Dam	37	41	41	43	44	206
	Spill from Sediment Dams	223	245	398	669	652	2,187
	Spill from Mine Affected Water Dams	0	0	0	0	0	0
	Total	988	1,102	1,392	1,972	2,135	7,587
Change in Site Water Inventory		**102**	**29**	**59**	**308**	**122**	**619**

7 Flood mitigation and impacts

The proposed mine operations and associated infrastructure are largely located outside of the Charlevue Creek and Springton Creek flood inundation areas identified in Section 4.5. However, the potential for the following project features to interact with floodwater has been investigated as part of this assessment:

- The rail loop, which is located near the northern margin of the Charlevue Creek floodplain, in close proximity to the existing Capricorn Highway and Aurizon's Blackwater rail corridor.
- The CHPP/MIA fill pad which is located to the north of the Charlevue Creek floodplain.
- The haul road between AB Pit and the CHPP, which crosses Charlevue Creek;
- The AB Pit spoil dump, which encroaches towards the Charlevue Creek floodplain
- The AB Pit levee, which is required to prevent inundation of the AB Pit mine area from flooding at the downstream end of an unnamed second order tributary of Springton Creek, which is to be diverted around the proposed mine area.
- The C Pit overburden dump which will necessitate the construction of a drain to divert clean runoff in the upper reaches of the unnamed second order tributary of Springton Creek around the workings.

The locations of the mine infrastructure horizontal alignments of the drainage channels and associated levees are shown in Figure 7.1. The flood models were used to:

- Assess the impact of the Project on peak flood levels.
- Assess peak water levels and velocities along the levees and channels proposed to protect the proposed mine areas from flooding;

The preliminary channel designs included in the assessment have the following design features:

- Pit AB:
    - compound trapezoidal channel shape:
        - 1 m deep low flow channel with 5 m base width;
        - Base width of high flow channel 15 m;
        - side slopes 1V in 3H;
    - longitudinal slope: 0.4% (the existing channel has a slope of approximately 0.3%);
    - design 1 in 50 AEP depths are up to 3.7 m, and peak velocities range up to 2.5 m/s;
- Pit C:
    - compound trapezoidal channel shape:
        - 1m deep low flow channel with 4 m base width;
        - width of high flow channel 15 m;
        - side slopes 1V in 3H;
    - longitudinal slope varies between 0.25% and 0.4%; and
    - design 1 in 50 AEP depths are up to 1.3 m, and peak velocities range between 1.0 m/s and 2.0 m/s.

Figure 7.1 shows the Project will temporarily increase Charlevue flood levels immediately upstream of the proposed haul road crossing. In the 1% AEP flood, these impacts are contained within the mine lease area.

There will be no impact on flood levels in the Charlevue Creek or Springton Creek at the existing Capricorn Highway, Blackwater Rail corridor, or downstream of the Project area.

While the unnamed tributary of Springton Creek is not a watercourse as defined under the Water Act, the diversion channel will be designed taking into consideration the principles set out in the Guideline: "Works that interfere with water in a watercourse – watercourse diversions" (DNRM, September 2014). This document sets out key design principles and requirements for the functional designs of permanent diversions. It includes guidance on watercourse diversion design and operation including maintenance, monitoring and revegetation. Preliminary designs are shown in Figure 7.3 to Figure 7.8 which also show the post development flood conditions with diversions and levees in place.

The works at AB Pit will locally increase flood levels in Springton Creek by up to 0.22 m in the 1% AEP flood. These impacts would extend off the lease area onto land owned by Magnetic South Pty Ltd, and reduce with distance downstream of the boundary.

The full details of the methodology and results of flood modelling for a range of flood events are presented in Appendix A.

8 Final void behaviour

8.1 OVERVIEW

Water levels in the final voids will vary over time, depending on the prevailing climatic conditions, and the balance between evaporation losses and inflows from rainfall, surface runoff, and groundwater.

A GOLDSIM model (separate to the OPSIM model used for the operational modelling) was used to assess the likely long-term behaviour of the final void pit lakes. The historical rainfall and evaporation sequences were repeated 5 times to create a long-term climate record for use in the model.

The potential effects of climate change were assessed using climate-change adjusted SILO climate data developed as part of the Consistent Climate Scenarios (CCS) project by the Queensland Government's Department of Environment and Science (DES).

8.2 FINAL VOID CONFIGURATION

The final void configurations and contributing catchment areas are shown in Figure 8.1. The proposed final void catchments include the pits' plan areas, and immediate upslope catchments. Key details of the final voids are as follows:

- AB Pit final void will be approximately 72 m deep, with a floor level of 40 mAHD and an overflow level of approximately 112 mAHD.
- C Pit final void will be approximately 70 m deep, with a floor level of 58 mAHD and an overflow level of approximately 128 mAHD.

The final void will be located and designed such that it is not inundated by flooding in the probable maximum flood (refer Figure 8.2). Accordingly, no flood levee will be required to prevent inundation of the final void. The levee constructed to protect the operational pit would not be required post-mining, and would therefore be decommissioned or form part of the rehabilitated dump.

The landform would include a surface drain to direct runoff from the southern side of the final landform north-east towards Springton Creek, to prevent runoff from this area entering the final void.

The final landform surface drain channel would be designed in detail as part of design of the final dump landform. It would have a longitudinal slope similar to the slope of the existing minor Springton Creek tributaries in the area, and would be sized to ensure that it is a stable and self-sustaining component of the final landform.

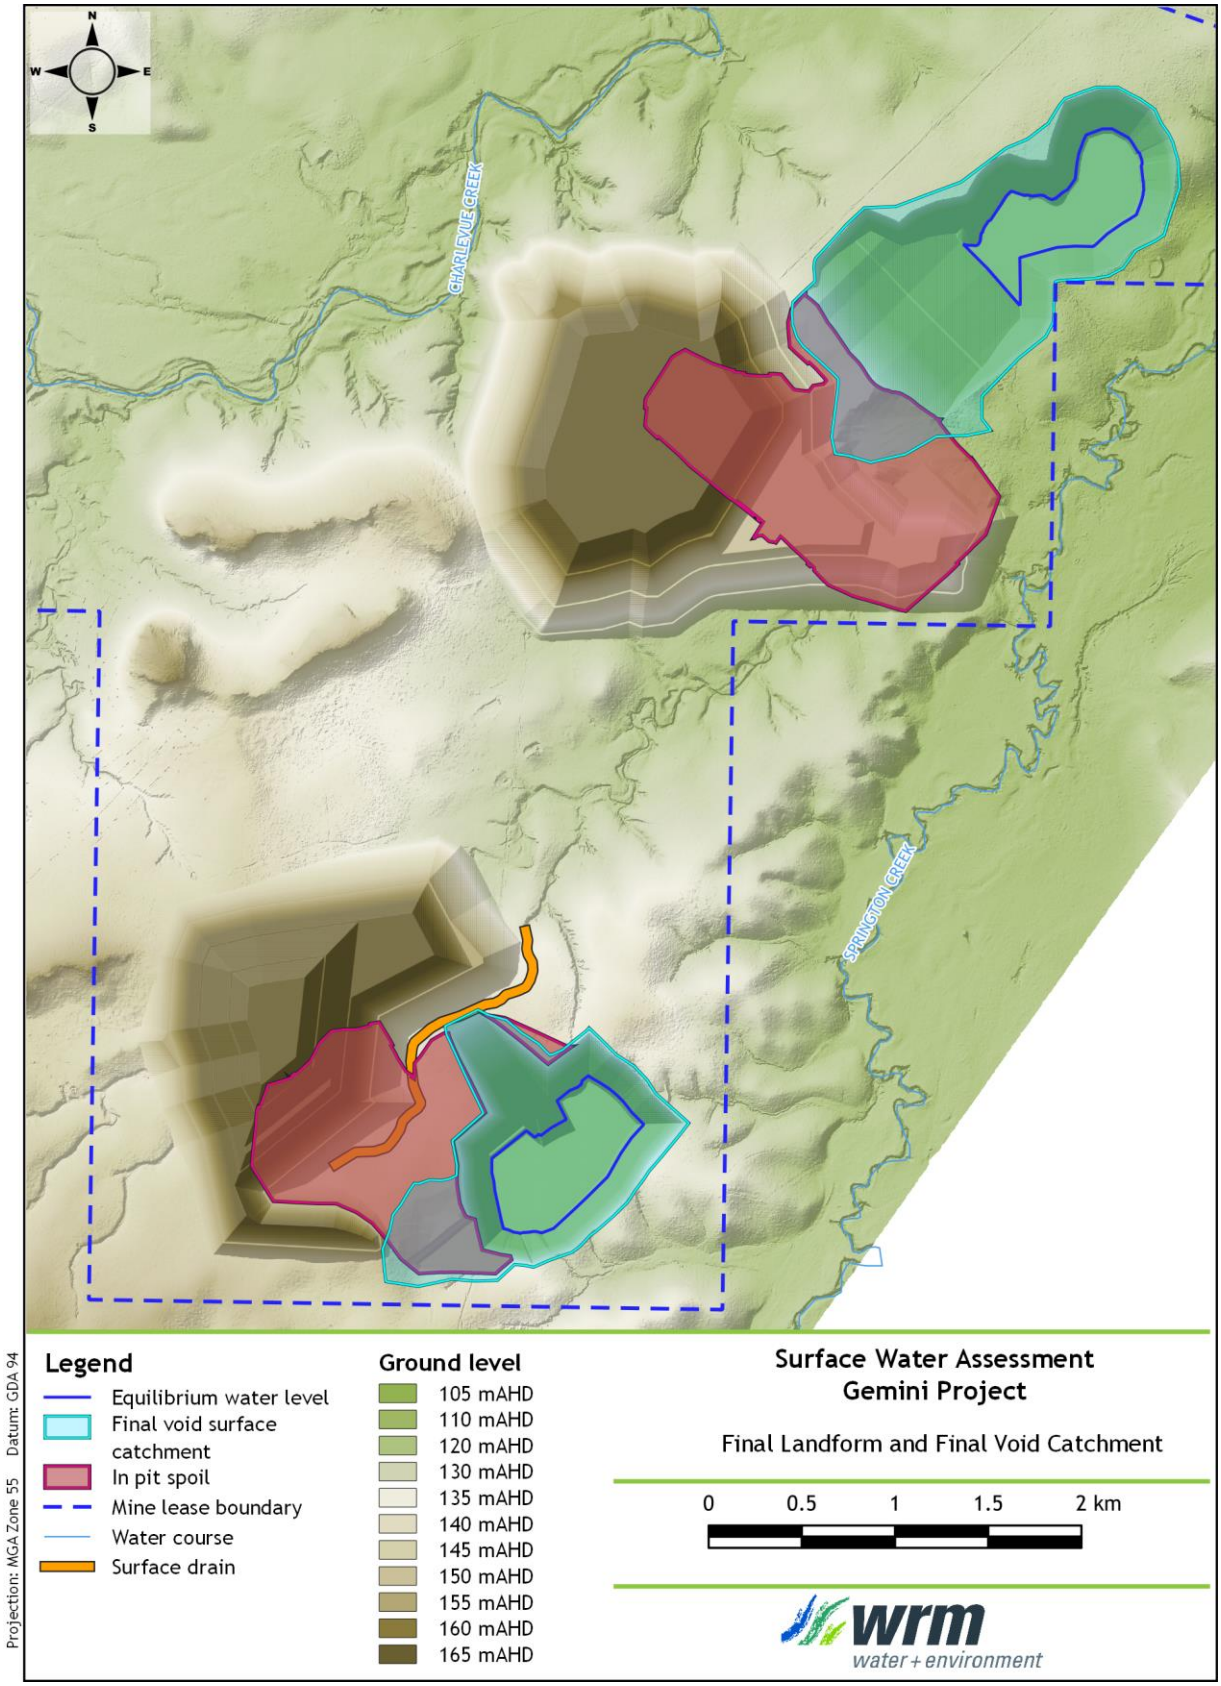

Figure 8.1 - Final landform and final void catchments

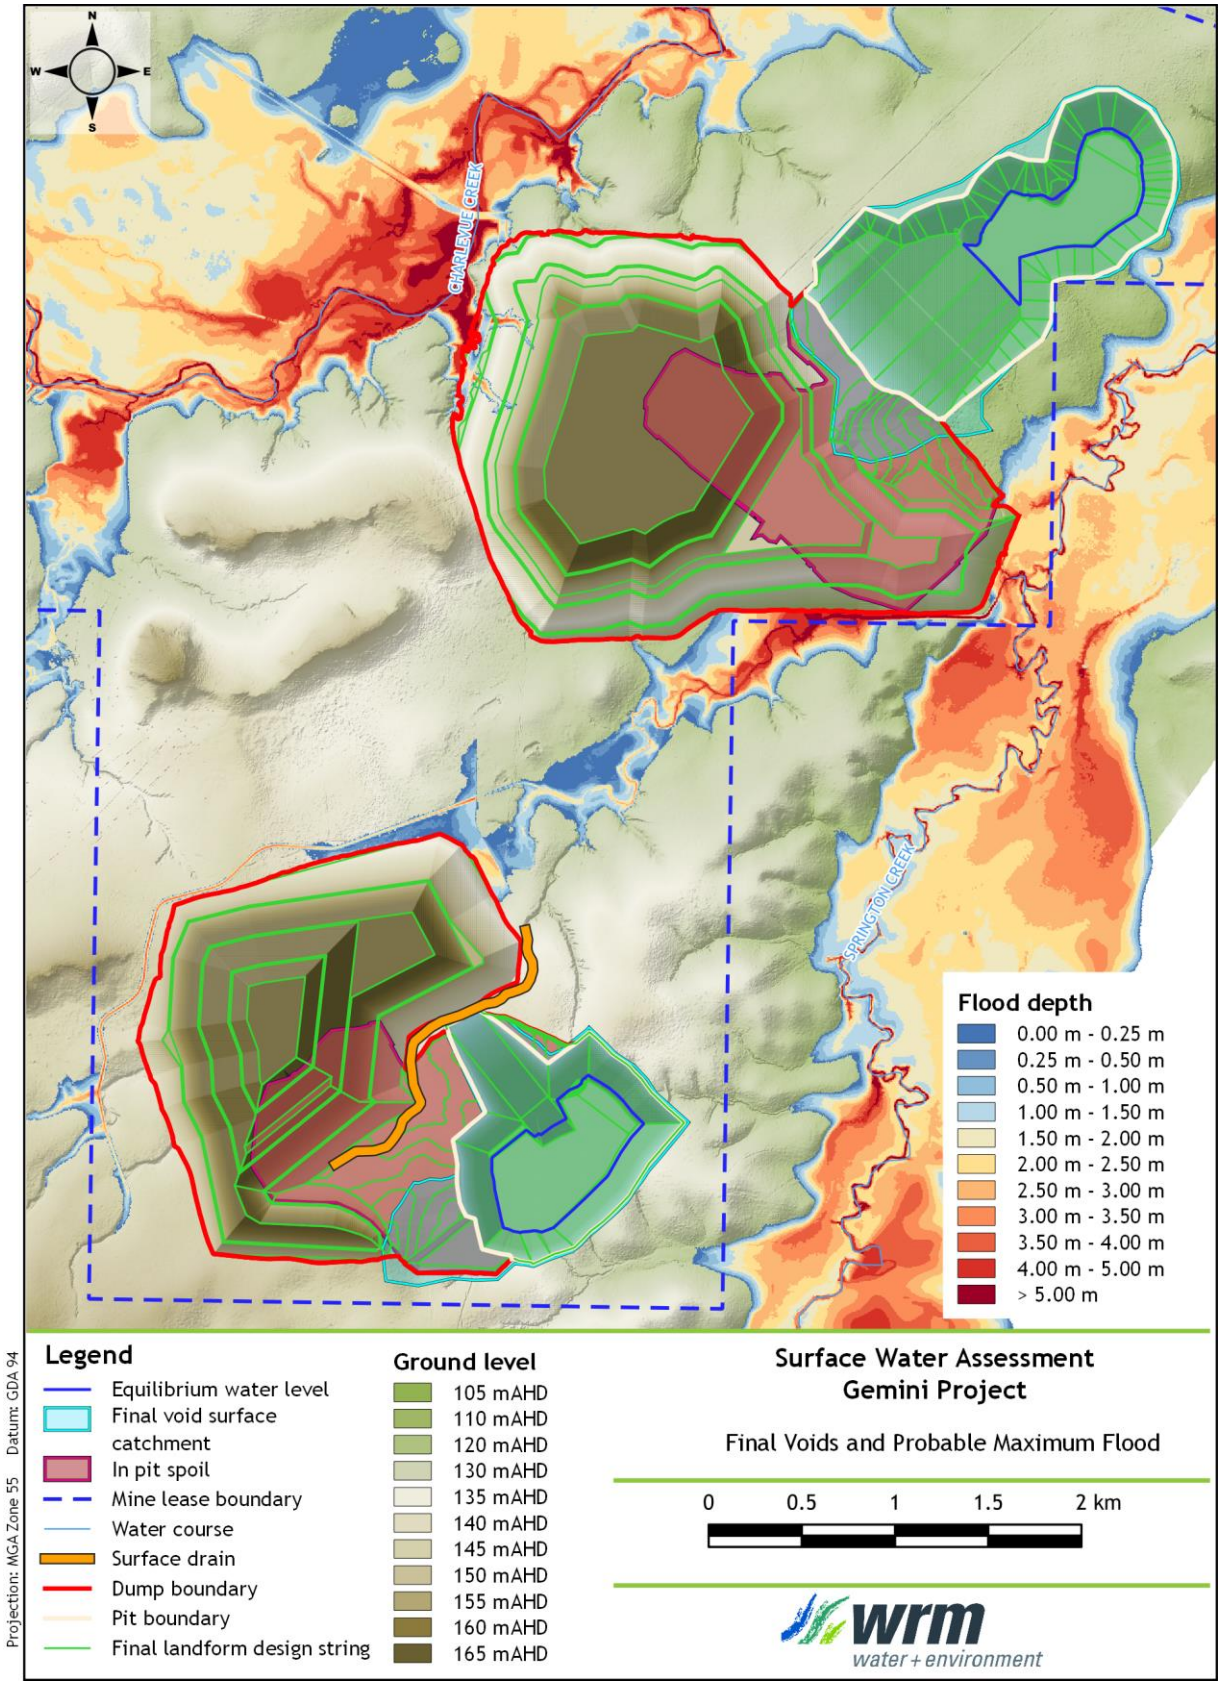

Figure 8.2 - Final landform and flood levels in Probable Maximum Flood

8.3 CONCEPTUAL MODEL

A representative schematisation of a conceptual final void water balance is presented in Figure 8.3.

The figure shows that key water inputs include rainfall on pit lake water surfaces, runoff from pit faces and rehabilitated upstream catchment areas, and groundwater interception. Depending on the configuration of the spoil dump, rainfall may also infiltrate through in-pit spoil.

Outflows are generally limited to evaporation. Under certain circumstances (i.e. if the final void water level exceeds the level of a neighbouring aquifer), outflows may also include seepage losses to surrounding aquifers. Water accumulating in the pit lake may also infiltrate into the adjacent overburden, creating additional water storage in this 'spoil aquifer'.

Sources of salt include salts dissolved in groundwater and catchment runoff. In the absence of any seepage or surface outflows to the environment, there is generally no removal of salt from the system, and thus, salts are expected to accumulate over time.

In principle, for an initially empty void, water is expected to accumulate until evaporative losses from the wetted surface area balance the combined influence of catchment runoff, rainfall and groundwater interception. Where catchment inflows are limited, over a sufficiently long time-scale, water levels are expected to reach a nominal steady state, with some variation about the steady state level during prolonged periods of wet or dry climate bias. This principle works in reverse for any voids that are filled (e.g. by pumping) above their steady state level prior to relinquishment; water levels will reduce due to evaporation until the wetted surface contracts to a point where evaporative losses balance inflows.

The Gemini Project voids are to be partially backfilled to prevent the interchange of water between the coal seams and the lakes – resulting in lower water levels and salinities than would otherwise be the case.

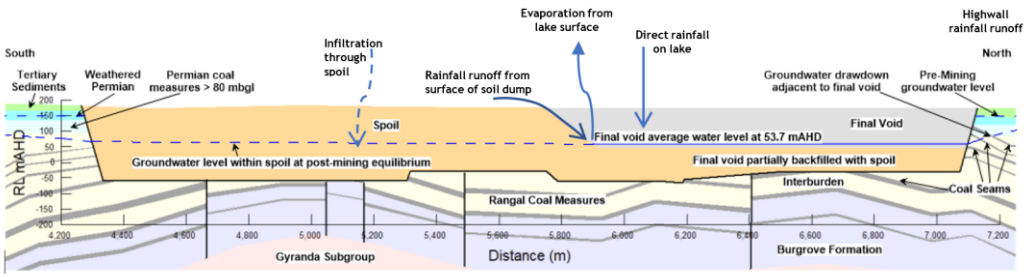

Figure 8.3 – Final landform and pit lake catchment

8.4 NUMERICAL MODELLING APPROACH

The GOLDSIM model simulates the generation, movement and loss of water on a daily time-step within each final void, over a 515-year period. The volume of water in the void is calculated at each time step as the sum of direct rainfall to the void surface, catchment runoff, and groundwater inflows, less evaporation losses.

The model tracks the quantity salt captured and stored within the system. Key components of the model are summarised in the following sub-sections, including descriptions of key model inputs, assumptions and sensitivity parameters.

8.5 STAGE-STORAGE CHARACTERISTICS

The stage-storage and stage-area curves for the voids were estimated from the final landform terrain model. The adopted relationships are shown in Figure 8.6.

8.6 CATCHMENT RUNOFF

Surface runoff catchment areas draining to the final voids were determined based on the adopted final landform. The following land use assumptions were adopted:

- All overburden dumps and cleared areas within the final void catchments will be rehabilitated and revegetated after cessation of mining;
- All rehabilitated catchment will naturally revert toward pre-disturbed conditions over time (as vegetation matures and top soil weathering and consolidation takes place). The long-term runoff properties will be somewhere between rehab and natural catchment.

The AWBM was used to model surface water runoff. The AWBM parameters adopted for rehabilitated areas in the operational water balance were also used for the final void analysis. The modelled surface catchments to each void are summarised in Table 8.1.

Table 8.1 – Final void surface catchments (ha)

Catchment type	AB Pit	C Pit
Natural	15.1	2.0
Pit	104.6	115.7
Rehab	98.0	20.3
Total	**217.7**	**138.0**

8.7 PIT SURFACE EVAPORATION

Evaporation from the void lake water surface was modelled using estimates of Morton's Lake evaporation. The reduced evaporation resulting from shading and wind shielding provided by the pit walls was modelled using an adjustment factor referred to herein as the 'pit factor'. A linearly varying depth-dependent storage evaporation factor has been applied to each void to simulate the change in evaporation as void water levels increase. The storage evaporation factors are as follows:

- Bottom of void – 0.5;
- Top of void – 0.8.

Pit factors are supported by the findings of ACARP Project No. C7007 (2001) which entailed development of a practical methodology for predicting the hydrology and water quality of final spoil-void systems. The study proposed adopting typical pit factors of 0.56 for near-empty pits and 0.78 for near-full pits based on modelling undertaken at several mines in Queensland and NSW.

8.8 GROUNDWATER

Ground water investigations by JBT Consulting indicate that due to partial backfilling of the voids, groundwater inflows to the final voids are expected to be negligible.

8.9 CLIMATE CHANGE IMPACTS

Climate-change adjusted SILO climate data are available from the Queensland Government Department of Environment and Science (DES), and were developed as part of the Consistent Climate Scenarios (CCS) project. The CCS project hosts data from 19 separate global climate models (GCMs), which explore four emissions scenarios, three timing horizons and three climate warming sensitivities. The nineteen separate models can be split into four Representative Future Climate (RFC) partitions, defined below:

- HI: a high level of global warming, where the Eastern Indian Ocean (EIO) warms faster than the Western Pacific Ocean (WPO);
- HP: a high level of global warming, where the WPO warms faster than the EIO;
- WI: a low level of global warming, where the EIO warms faster than the WPO; and
- WP: a low level of global warming, where the WPO warms faster than the EIO.

Figure 8.4 is an excerpt from the CCS project user guide (DSITIA, 2015) showing the four RFC quadrants, component models and indicative rainfall trends. The caption associated with the original version of this figure has been reproduced as a footnote[1].

Data based on the mean result of all models within each RFC quadrant is offered by the CCS for applications where considering the output of all 19 models is not feasible/practical. This approach has been followed for the purposes of assessing climate change sensitivity as part of current investigations. Table 8.2 and Table 8.3 list the percentage change in evaporation and rainfall respectively, based on mean output for the four RFC quadrants. Data is based on the most conservative carbon emission rate (RCP8.5) available in the CCS dataset, and expected climate as at 2070. Data has been listed for the low, medium and high sensitivities. Information is for the Gemini Project location.

The adjustments listed in Table 8.2 and Table 8.3 have been applied to the long-term SILO daily climate time-series, and passed through the AWBM rainfall runoff sub-model to produce daily estimates of runoff (rehabilitated land use AWBM parameter set used). Annual average runoff depths have been plotted against average annual net evaporation depths (evaporation minus rainfall) in Figure 8.5 to illustrate the potential to impact on long-term water levels in the Gemini Project pit lakes. Note the naming convention used in the figure, and henceforth in this document, is XX.Y where XX is the scenario (e.g. HI) and Y is the sensitivity (medium).

Figure 8.5 shows that all scenarios predict increases in net evaporation, and that all scenarios predict reductions in runoff. It is evident that all scenarios will result in lower final void water levels than the base case scenario. The sensitivity of final void water levels to changes in future climate change have been assessed by modelling all the above scenarios.

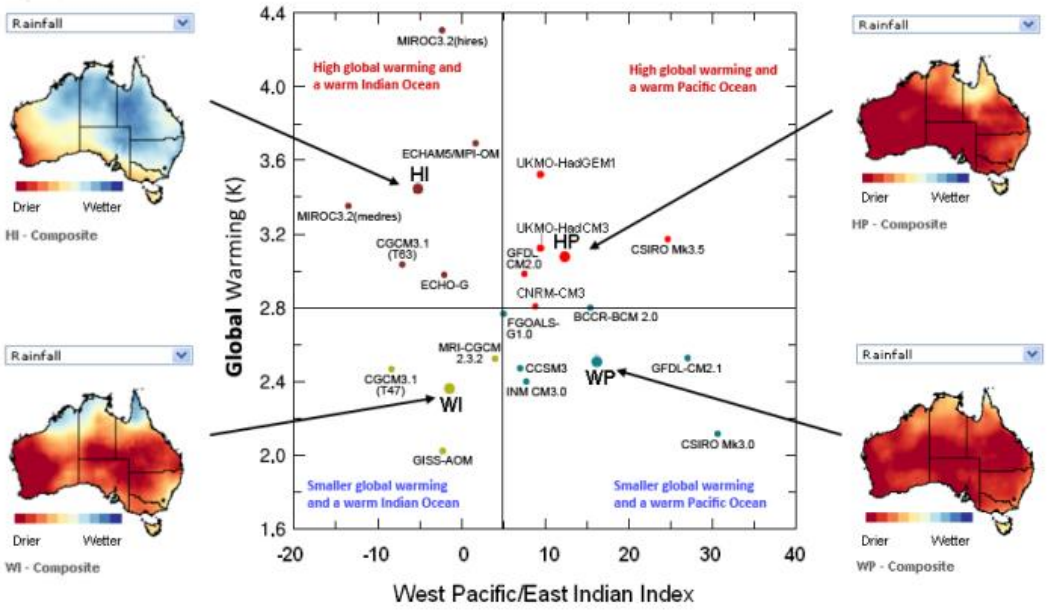

Figure 8.4 – A partition of Global Climate Models for future climate using global warming sensitivity and ocean warming indices (source: DSITIA, 2015)

[1] From DSITIA, 2015 – Figure 8.1 (verbatim): A partition of CMIP3 Global Climate Models (GCMs) for future climate using global warming sensitivity and ocean warming indices (adapted from Watterson, 2011). Values for nineteen individual GCMs (forced by the SRES A1B emissions scenario) are represented by the small dots and labelled by their GCM model code (Table 8.2). The central horizontal and vertical lines separate the four Representative Future Climate (RFC) partitions. The larger dots indicate the CCS composite means for GCMs within each of the four RFC responses: (HI) high global warming and a warmer Indian Ocean; (HP) high global warming and a warmer Pacific Ocean; (WP) lower global warming and a warmer Indian Ocean and (WP) lower global warming and a warmer Pacific Ocean. The maps show projected 21st Century changes in rainfall for the GCMs clustered in each of the four (HI, HP, WI and WP) RFC partitions.

8.10 LAKE SALINITY

As the void lake will not spill, and seepage into the local Permian material is expected to be minimal, salinity will rise over time as salts are transported from the local surface catchment and contained in the void. A simple conservative solute model was coupled with the lake water balance to estimate the potential lake salinity.

Water samples taken from Springton and Charlevue Creek had a median EC of 114 µS/cm, while kinetic leach column (KLC) testing of the local overburden material (RGS, 2019) showed that leachate from all KLC samples (apart from the carbonaceous siltstone and coal) had initial EC values less than 800 µS/cm, and at the end of six months less than 203 µs/cm.

While runoff salinity is therefore likely to gradually decline over time as salts are leached from the adjacent ground into runoff and seepage, for this final void assessment, runoff was conservatively assumed to have the following fixed salinities:

- Natural Runoff - 100 mg/L (equivalent to EC of approximately 150 µS/cm);
- Rehabilitation - 200 mg/L (equivalent to EC of approximately 308 µS/cm);
- Pit Runoff – 390 mg/L (equivalent to EC of approximately 600 µS/cm).

These assumptions will tend to result in the model overestimating long-term contribution of runoff to void lake salinity.

8.11 MODEL RESULTS

Figure 8.6 and Figure 8.7 show the simulated long-term water levels in the final voids. The results show the following:

For AB Pit:

- Under the existing (SILO) climate scenario - the modelled water level reaches equilibrium at around 52.9 mAHD within 50 years and generally remains at this level throughout the remainder of the simulation (fluctuating between 47.4 and 57.6 mAHD).
- The maximum modelled water level (57.6 mAHD) is around 54 m below the void overflow level of approximately 112 mAHD, and well below the potential level of groundwater seepage to the tertiary aquifer.
- Figure 8.6 shows that under the climate change scenarios, the equilibrium water level is lower than the existing climate scenario.

For C Pit:

- Under the existing (SILO) climate scenario - the water level reaches equilibrium at around 70.3 mAHD within 50 years and generally remains at this level throughout the remainder of the simulation (fluctuating between 66.0 and 73.5 mAHD).
- The maximum modelled water level is around 54.4 m below the void surface overflow level of approximately 128 mAHD, and well below the potential level of groundwater seepage to the tertiary aquifer.
- Figure 8.7 shows that under all climate change scenarios, the equilibrium water level is lower than the existing climate scenario.

Table 8.4 summarises the simulated long-term water balance for the base case scenario and the WP.M scenario, which is closest to the average of all modelled climate scenarios.

Table 8.5 shows the equilibrium levels for surface water in the final voids for the existing (SILO) climate scenario and the climate change scenario.

Figure 8.8 and Figure 8.9 show the results of the salt balance. Salt accumulates within both voids over time. Under the existing climate conditions scenario, the void lake salinity exceeds a TDS of 30,000 mg/L after approximately 500 years of simulation. During the first 200 years, apart from short periods when inflows are very low, and salt concentrations temporarily increase rapidly due to evaporation, lake salinities are predicted to be less than 10,000 mg/L.

8.12 SENSITIVITY ANALYSIS

The sensitivity of the equilibrium water level to uncertainty in the key input parameters was tested by reducing the AWBM USC values to half their original values – to increase runoff to the void.

Under these conditions, the equilibrium water level remained below:

- 63.9 mAHD at AB Pit, and
- 80.0 mAHD at C Pit.

Table 8.6 shows that under the high runoff scenario, total average inflows at equilibrium increase by approximately 26% compared to the base case, and the increase in lake water surface area results in a corresponding increase in evaporation.

Table 8.6 – Sensitivity analysis – high runoff - average annual final void water balance – at equilibrium

		C Pit	
		Sensitivity analysis	
		Base Case	High Runoff

9 Vulnerability to climate change during operations

The long-term effects of climate change on final void behaviour have been assessed in Section 8.

A number of potential adaptive measures have been considered to assist with resilience to climate change effects, most of which will be implemented in any case to cater for the high climatic variability experienced in the region:

- Contingency measures for directing excess inflows to the mine pit;
- Off-site water supplies of sufficient capacity to deliver the entire site water demand;
- Water efficient plant design;
- Overdesign of drainage and containment systems to cater for increased duration, frequency and intensity of rainfall due to climate change effects.

10 Potential surface water impacts and mitigation measures

10.1 OVERVIEW

The potential impacts of the Project on water resources identified in the preceding sections of the report, and proposed mitigation measures, are summarised in the following sections:

- the diversion of an unnamed tributary of Springton Creek, including changes to the channel and floodplain geometry – and resultant potential changes to stream morphology;
- impacts on the flooding regime in Charlevue Creek and Springton Creek;
- impacts on flood levels at the Capricorn Highway and the Blackwater Rail Corridor upstream of the proposed rail loop and train loadout;
- the creation of a final void lake at the completion of mining;
- short-term loss of catchment area – and subsequent reduction in streamflow in local streams due to the capture of runoff within on-site storages and the open cut pit;
- long-term reduction in streamflow in local streams due to residual loss of catchment to the final void;
- impacts on regional water availability due to the potential need to obtain water from external sources to meet construction and operational water requirements for the Project;
- adverse impacts on the quality of surface runoff draining from the disturbance areas to the various receiving waters surrounding the Project, during both construction and operation of the Project;
- adverse impacts on environmental values in the Mackenzie River catchment associated with releases from the sediment management system.

10.2 FLOODING IMPACTS

The outcomes of the flood impact assessment are as follows:

- The proposed rail loop will not impact Charlevue Creek or Springton Creek flooding.
- The Project will temporarily increase Charlevue Creek flood levels immediately upstream of the proposed haul road crossing. These impacts are contained within the mine lease area.
- There will be no impact on flood levels in the Springton Creek or Charlevue Creek at the existing Capricorn Highway, Blackwater Rail corridor, or downstream of the Project area.
- The works at AB Pit will locally increase flood levels in Springton Creek by up to 0.22 m in the 1% AEP flood. These impacts would extend off the lease area onto land owned by Magnetic South Pty Ltd, and reduce with distance downstream of the boundary.
- There will be localised off-lease impacts on flood levels in the unnamed tributary of Springton Creek immediately upstream of AB Pit and C Pit.
- There are four locations where (based on the flood model results) floodwaters could potentially come into contact with the overburden dumps:

- **Northeastern end of Pit C** – due to flow backing up to the west of the haul road crossing of the engineered drainage feature. Modelled flow velocities in this area are less than 0.4 m/s in the 0.1% AEP design flood, and would therefore not cause the migration of sediment from the final landform;
- **Western side of Pit AB** – due to water backing up a minor tributary of Charlevue Creek. Flow velocities in this area are expected to be less than 0.2 m/s, and therefore the likelihood of migration of sediment from these dumps is minimal;
- **Eastern side of Pit AB** – due to flow on the left (western) floodplain of Springton Creek. Flow velocities against the final landform are modelled to be less than 1.2 m/s in the 0.1% AEP flood, and therefore the likelihood of erosion of the dump toe is minimal; and
- **Southern side of Pit AB** – due to water overflowing from the unnamed tributary of Springton Creek upstream of the inlet to the engineered drainage feature. During operations, this section of the dump would be protected by a temporary levee, which would be incorporated into the final landform profile on closure. In events up to the 0.1% AEP design flood, modelled flow velocities are less than 1 m/s along most of the length of the proposed levee. Such flows would be non-erosive – and especially given the relatively short flow durations in this small catchment, the risk of migration of sediment in floodwaters would be minimal. During detailed design of the engineered drainage feature, provision will be made to ensure that flows will be non-erosive along the final landform post-closure.

10.3 FINAL VOID LAKES

At mine closure, final voids will remain at each mine pit.

The floor of the AB pit will be at an elevation of approximately 40 mAHD or 72 m below the natural surface elevation (112 mAHD). The floor of the C pit will be at an elevation of approximately 60 mAHD or approximately 68 m below the natural surface elevation (128 mAHD).

Over time, the voids will fill with surface water runoff to form a lake. Based on water balance modelling:

For AB Pit:

- Under the existing (SILO) climate scenario - the modelled water level reaches equilibrium at around 52.9 mAHD within 50 years and generally remains at this level throughout the remainder of the simulation (fluctuating between 47.4 and 57.6 mAHD).
- The maximum modelled water level (57.6 mAHD) is around 54 m below the void overflow level of approximately 112 mAHD, and well below the potential level of groundwater seepage to the tertiary aquifer.
- Under the climate change scenarios, the equilibrium water level is lower than the existing climate scenario.

For C Pit:

- Under the existing (SILO) climate scenario - the water level reaches equilibrium at around 70.3 mAHD within 50 years and generally remains at this level throughout the remainder of the simulation (fluctuating between 66.0 and 73.5 mAHD).
- The maximum modelled water level is around 54.4 m below the void surface overflow level of approximately 128 mAHD, and well below the potential level of groundwater seepage to the tertiary aquifer.

- Under all climate change scenarios, the equilibrium water level is lower than the existing climate scenario.

Salt will accumulate within both voids over time. The void lake salinity is expected to exceed a TDS of 30,000 mg/L after approximately 500 years. Final void modelling suggests that during the first 200 years after closure, apart from short periods when inflows are very low, and salt concentrations temporarily increase rapidly due to evaporation, lake salinities will be less than 10,000 mg/L.

10.4 GEOMORPHOLOGICAL IMPACTS

An unnamed tributary of Springton Creek will be diverted to allow mining of the resource at both pits. This stream is not defined as a watercourse under the Water Act. Nonetheless, it is proposed that where practicable, the diversion works will be constructed to comply with the design principles set out in the Guideline: "Works that interfere with water in a watercourse – watercourse diversions".

The proposed diversion channel would be designed to accommodate flood flows at velocities which would be non-erosive in the 1 in 100 AEP flood with appropriate channel lining.

10.5 IMPACTS ON DOWNSTREAM FLOW REGIME

During operations, the Project's water management system will intercept runoff from disturbed areas of the mine site.

The water management system has been designed to achieve a high level of containment of mine affected water, with any overflows from the Main Water Dam directed to the mine pit. As controlled releases are not part of the proposed water management strategy for the mine affected water management system, runoff currently flowing from these parts of the catchment to Charlevue Creek and Springton Creek will be temporarily stopped during project operations.

As overburden runoff quality is expected to be relatively benign, sediment dams will potentially discharge directly into the environment (after the settlement of suspended sediment), and as such, will not reduce downstream flows. However, sediment dams will be pumped back to the mine affected water system if water quality monitoring shows the water is unsuitable for release. As shown in Table 10.1, the maximum captured catchment areas represent:

- 1.0% of Charlevue Creek catchment upstream of the Springton Creek confluence;
- 3.6% of Springton Creek catchment upstream of the Charlevue Creek confluence; and
- 2.3% of Springton Creek catchment downstream of the Charlevue Creek confluence.

Table 10.1 – Catchment excised by site water management system at Year 18

Description	Charlevue Creek	Springton Creek	Total
Total Intercepted in MW System (ha)	336.9	1,174.9	
To confluence (U/S) (ha)	32,243	32,497	
	1.0%	3.6%	
Downstream of confluence (ha)		2.3%	64,740

After mine closure, the water management system will be decommissioned but there will be some residual impact on streamflow due to drainage to the final voids. As shown in Table 10.2, the maximum captured catchment areas represent:

- 0.03% of Charlevue Creek catchment upstream of the Springton Creek confluence;
- 1.1% of Springton Creek catchment upstream of the Charlevue Creek confluence; and
- 0.6% of Springton Creek catchment downstream of the Charlevue Creek confluence.

The resultant impact on environmental values would be expected to be negligible.

Table 10.2 - Catchment excised by site water management system at mine closure

Description	Charlevue Creek	Springton Creek	Total
Total Intercepted in Final Void (ha)	10.0	345.0	
To confluence (U/S) (ha)	32,243	32,497	
	0.03%	1.1%	
Downstream of confluence (ha)		0.6%	64,740

The results of rainfall runoff modelling (using the AWBM) was used to estimate the impact of this loss of catchment on the frequency of low flows (assuming the contiguous rainfall/runoff and baseflow characteristics across the catchment -i.e. by factoring the runoff duration curve by the pre and post-mine catchment areas).

The change in the frequency of flows would be expected to be negligible as illustrated in Figure 10.1.

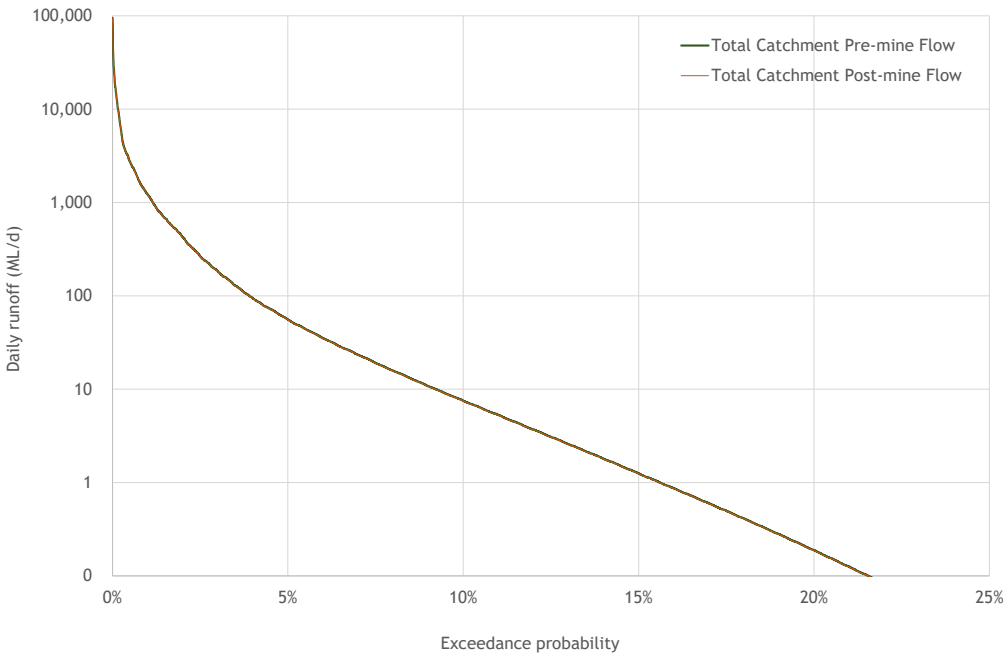

Figure 10.1 - Flow frequency curve based on rainfall runoff modelling of Springton Creek using the AWBM

10.6 IMPACTS ON RECEIVING WATER QUALITY

The potential impacts on receiving water quality will be managed by the site water management system.

To avoid significant downstream impacts, the system has been designed to achieve a high level of containment without the need for controlled releases, as the opportunities to release mine water are likely to be very limited. However, should water quality allow, water may be released to Charlevue Creek in accordance with Environmental Authority conditions consistent with the "*Model water conditions for coal mines in the Fitzroy basin*".

Any unplanned overflows from the Mine Water Dam, would overflow to the mine pit. The only potential mine water release points are the MIA Dam spillways. However, these dams will be operated in such a way that the risk of release is small.

Runoff from overburden dumps will be managed under an erosion and sediment control plan to reduce sediment loads to background levels before release. Water would be discharged either via sediment dam spillways or perforated riser pipes.

10.6.1 Seepage

There is some potential for seepage of water from the Mine Water Dam to Charlevue Creek. The dam will be designed with a floor and sides of material that will limit seepage to avoid environmental harm.

10.7 CUMULATIVE IMPACTS

The only known existing coal mine within the Springton Creek catchment is the recently commenced Bluff Coal Mine. The Walton Coal Project is also proposed within the catchment. These two projects are of relatively small scale and short life. The potential cumulative impacts of the two projects are discussed in the following sections.

10.7.1 Regional water availability

The water balance model shows that (due to the relatively low water requirements of the coal preparation plant) the mine site water requirements of the Gemini Project can largely be sourced from water collected within the site water management system.

Shortfalls in water supply for both the Walton Coal Mine and the Bluff Coal Mine are to be supplied with mine water from the Jellinbah Mine. As a result, the potential cumulative impacts of mine projects on water availability in the catchment of Springton Creek is limited to the effect of cumulative catchment excision by the two projects.

Based on catchment information presented in the Bluff Coal Mine EIS, the cumulative impact of the projects on flows in Springton Creek will be minimal.

10.7.2 Controlled releases

Mine affected water from the Project will be managed through a mine water management system which is designed to achieve full containment of mine water under historical conditions. The water management plans for the other project are similarly designed for the complete containment of mine water. Releases would only occur in accordance with Environmental Authority conditions consistent with the "*Model water conditions for coal mines in the Fitzroy basin*".

Releases from sediment dams are authorised under the EA if an ESCP is appropriately implemented. Water releases from both projects would only be allowed from the sediment water system if water quality meets the sediment dam release criteria to be set in the Environmental Authority.

If operated in accordance with the EA, the impact of releases from the projects on water quality in the regional catchment systems would be minimal.

11 Water monitoring

11.1 RECEVING WATER MONITORING

A Receiving Environment Monitoring Plan (REMP) will be developed for the Project in accordance with the model mining conditions. The REMP would be implemented to monitor, identify and describe any adverse impacts to surface water environmental values, quality and flows due to the authorised mining activity.

Water quality monitoring will be undertaken upstream and downstream of the project to detect downstream water quality impacts and to demonstrate compliance with the Environmental Authority release conditions. The proposed receiving water monitoring points are listed in Table 11.1 and shown in Figure 11.1. Locations have been chosen so that the sites are unaffected by the project operations but are accessible during wet weather.

Water quality will be monitored for the 'standard' suite water quality parameters included in the Model Water Conditions for coal mines in the Fitzroy basin - but not limited to, pH, EC, major anions (sulfate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS and a broad suite of soluble metals/ metalloids.

Water quality monitoring will be compliant with the National Water Quality Management Strategy. Samples will be collected monthly or during each flow event, where possible. Continuous water level, salinity, turbidity and pH monitoring equipment will be installed at the downstream stations.

Table 11.1 – Receiving water monitoring points

Description	Latitude (deg)	Longitude (deg)
Springton Creek US	-23.6976	149.2738
Springton Creek DS	-23.6434	149.3145
Charlevue Creek US	-23.6305	149.2715
Charlevue Creek DS	-23.6469	149.2104

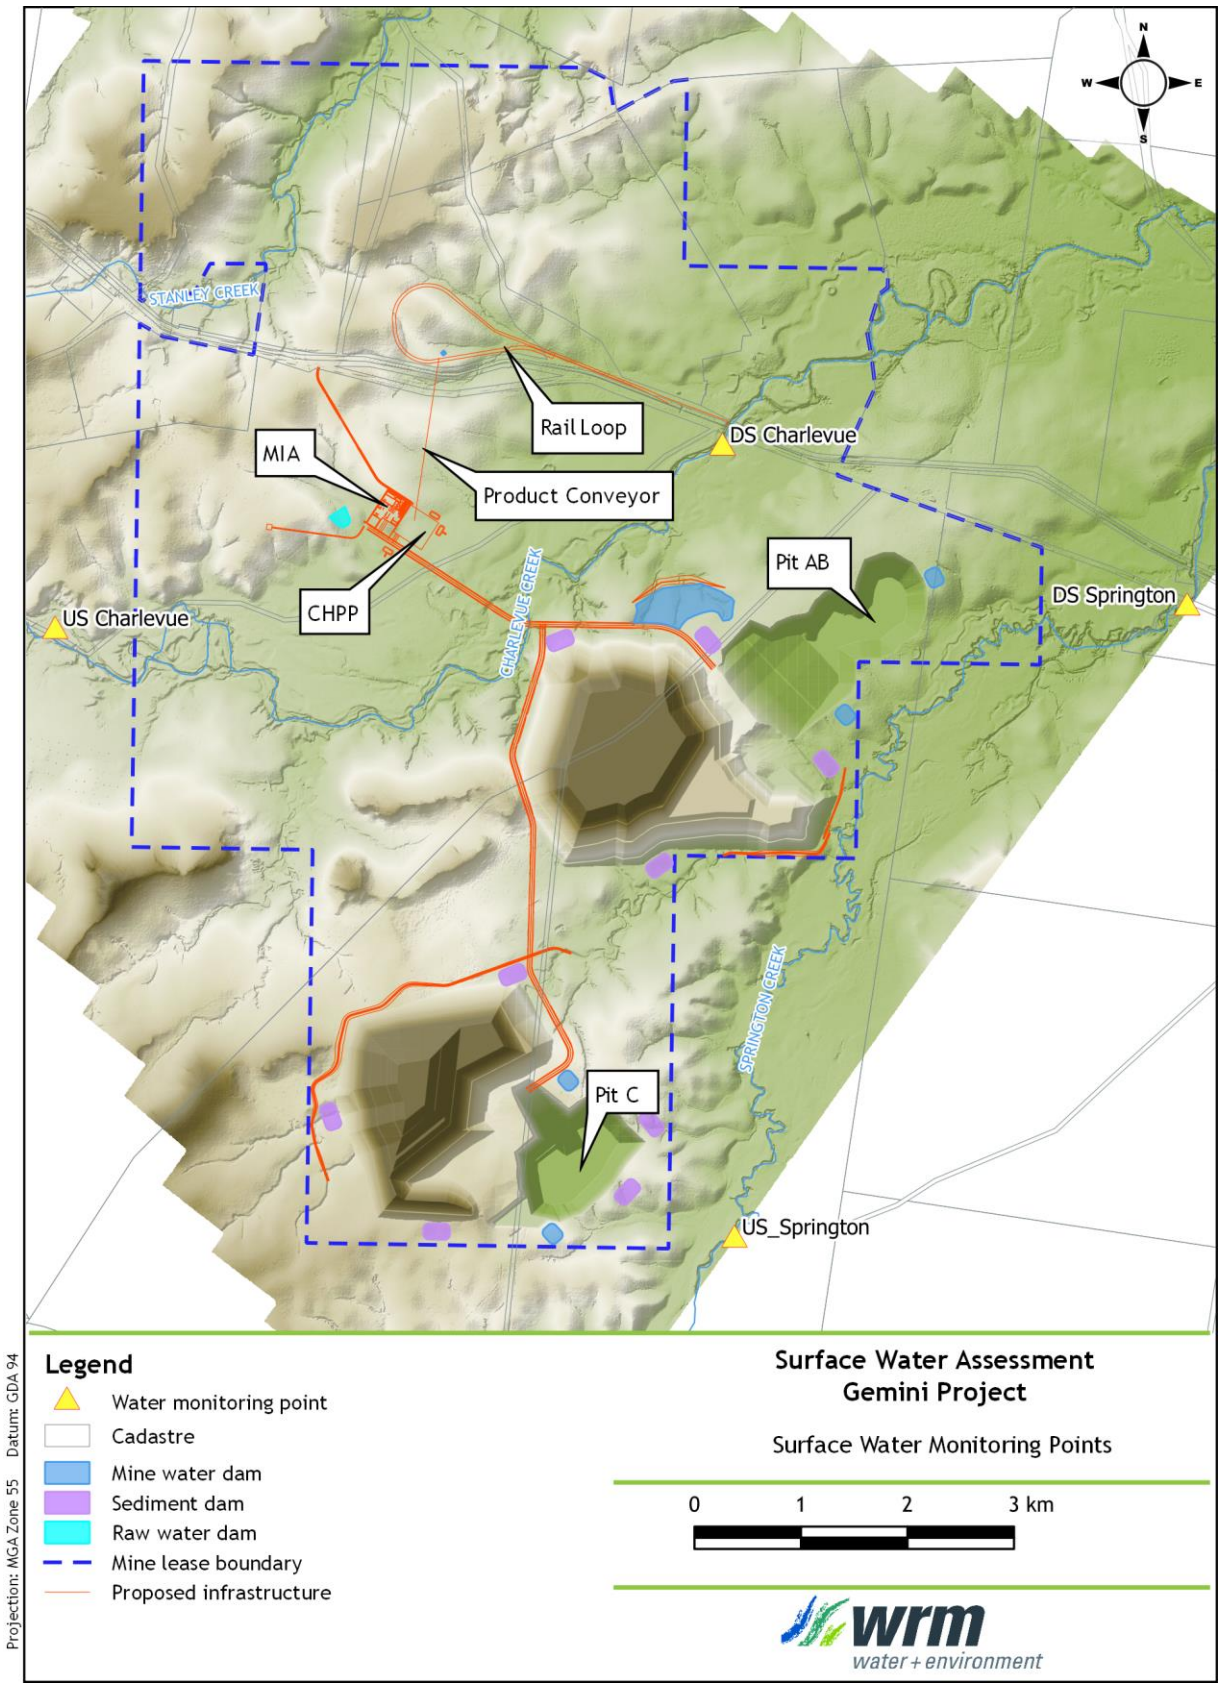

Figure 11.1 - Proposed upstream and downstream receiving water monitoring points

11.2 MINE WATER SYSTEM MONITORING

An onsite water monitoring system will also be used to validate system performance against the design assumptions in terms of water quality and water quantity, so that an adaptive management can be implemented to protect the surface water environment.

11.2.1 Mine affected water dam monitoring

Surface runoff and seepage water collected in the Mine Water Dam and Process Water Dam will be monitored for 'standard' water quality parameters including, but not limited to, pH, EC, major anions (sulphate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS and a broad suite of soluble metals/metalloids.

11.2.2 Spoil and sediment dam monitoring

Validation testwork will be undertaken on potential spoil materials as the Project develops to enable appropriate spoil management measures to be planned and implemented as required.

Some spoil materials may be sodic with potential for dispersion and erosion. Where highly sodic and/or dispersive spoil is identified, this material would not be placed in final landform surfaces and would not be used in construction activities. Regardless of the spoil type, especially where engineering or geotechnical stability is required, testing would be undertaken during construction to determine the propensity of such materials to erode.

Surface runoff and seepage from spoil piles, including any rehabilitated areas, would be monitored for 'standard' water quality parameters including, but not limited to, pH, EC, major anions (sulfate, chloride and alkalinity), major cations (sodium, calcium, magnesium and potassium), TDS and a broad suite of soluble metals/ metalloids.

The sediment dam monitoring would be used to validate the anticipated quality of water runoff reporting to sediment dams and haul road runoff dams. Initially, the sediment dam monitoring would occur on a regular (e.g. monthly) basis to demonstrate the water quality of stored waters is consistent with the relevant operating parameters to allow releases from sediment dams to occur when required. Subject to demonstrating the water quality objectives can be met, the frequency of monitoring and suite of parameters for the sediment dam monitoring would be reviewed and updated accordingly (e.g. to occur only when releases occur).

Appendix A Flood impact assessment

A1 Introduction

A1.1 PROJECT OVERVIEW

The Gemini Project is a proposed open cut coal mine in the Fitzroy Basin. The proposed mine development site is located approximately 7.6 km west from the town of Dingo and 19.4 km southeast of Bluff. The two main regional centres are Emerald, 110 km west of the site and Rockhampton, 134 km east of the Project area.

The mine development schedules are expected to include two open cut pits, AB Pit and C Pit (Figure A.3). AB Pit will disturb an area of 694 ha within the mining lease application areas and C Pit will have a 465 ha disturbance area. Additional disturbance areas include sediment and mine water dams, a mine industrial area (MIA), a coal handling processing plant (CHPP), a conveyor, a dedicated rail loop, train load out (TLO) and mine roads interconnecting this infrastructure.

The proposed mine lease area is crossed by two main drainage paths flowing in a northeasterly direction. The northern stream is Charlevue Creek and the southern stream is Springton Creek, where Charlevue Creek joins the Springton Creek 5.2 km northeast of Dingo.

A1.2 SCOPE OF THIS STUDY

A1.2.1 Study objectives

This report presents the methodology and results of hydrologic and hydraulic modelling undertaken to assess the impacts of the Gemini Project on flood behaviour in the reaches of Charlevue Creek and Springton Creek crossing the Project area. The modelling results define the existing flood conditions, as well as conditions during operation of the Project. The key outcomes of the study are to:

- Define existing flood conditions across the Project area for a range of design flood events, in terms of peak water levels and peak velocities;
- Assess peak water levels and velocities along the levees proposed to protect the proposed mine areas from flooding;
- Determine the impacts of the proposed Project during project operations;
- Assess the long-term flood conditions in events up to the probable maximum floodi and the residual impacts of the Project following mine closure.

As the flood investigations detailed in this report have been specifically undertaken for the purpose of impact assessment, the results presented herein should not be used for any other purpose without seeking advice from WRM regarding their applicability.

A2 Estimation of design discharges

A2.1 METHODOLOGY

The XP-RAFTS runoff-routing model (XP Software, Version 2018.1.2) was used to estimate design discharges for the Charlevue Creek and Springton Creek catchments. In the absence of suitable stream gauge data, the peak discharges estimated by the XP-RAFTS model were validated against the Rational Method and Regional Flood Frequency Estimation (RFFE) estimates.

The validated XP-RAFTS model was used to estimate design discharges based on design rainfall and temporal pattern data developed using AR&R 2016 methodology (Ball et al, 2016). Design discharge hydrographs were estimated for the 50%, 10%, 2%, 1% and 0.1% annual exceedance probability (AEP) design discharges as well as the probable maximum flood (PMF) design discharge.

A2.2 XP-RAFTS MODEL CONFIGURATION

A2.2.1 Spatial configuration

Figure A.1 shows the XP-RAFTS model configuration adopted in the vicinity of the Project area. The hydrologic model includes both Charlevue Creek catchment and Springton Creek catchment to 4 km downstream of the confluence of Charlevue Creek and Springton Creek. The combined catchment has a total area of 680.5 km^2, consisting of 43 sub-catchments.

A2.2.2 Sub-catchment parameters

The XP-RAFTS model uses a single sub-catchment approach to determine runoff hydrographs, based on the overall sub-catchment parameters (fraction impervious, roughness and slope). Sub-catchment fraction impervious and roughness (Manning's 'n') parameters were weighted based on the various land use types in each sub-catchment based on available topographic data and aerial photographs.

Table A.9 presents the adopted sub-catchment parameters including catchment area, percentage impervious, catchment slope and PERN 'n' catchment roughness coefficients.

Model parameters for each sub-catchment were determined as follows:

- A percentage impervious of zero was adopted for all sub-catchments;
- Catchment slopes were determined based on the available topographic data;
- A sub-catchment storage coefficient multiplication factor 'Bx' of 1.0 was adopted for all events;
- Sub-catchment PERN 'n' values were determined based on the density of vegetation in each sub-catchment. The adopted sub-catchment PERN 'n' value was 0.05 for sub-catchments with largely bushland areas; and
- Initial (IL) and continuing (CL) losses for the validation events were determined based on the recommended AR&R 2016 data hub parameter. The selection of initial and continuing losses for design events is described in Section A2.6.

A2.2.3 Routing parameters

Channel routing in the XP-RAFTS model was configured based on specifying a 'K' and 'X' value for each routing link. An 'X' value of 0.25 was adopted for all routing links. The 'K' values represent estimated flow travel times (in hours) and were calculated based on the flow path lengths and an assumed conservative flow velocity of 1 m/s.

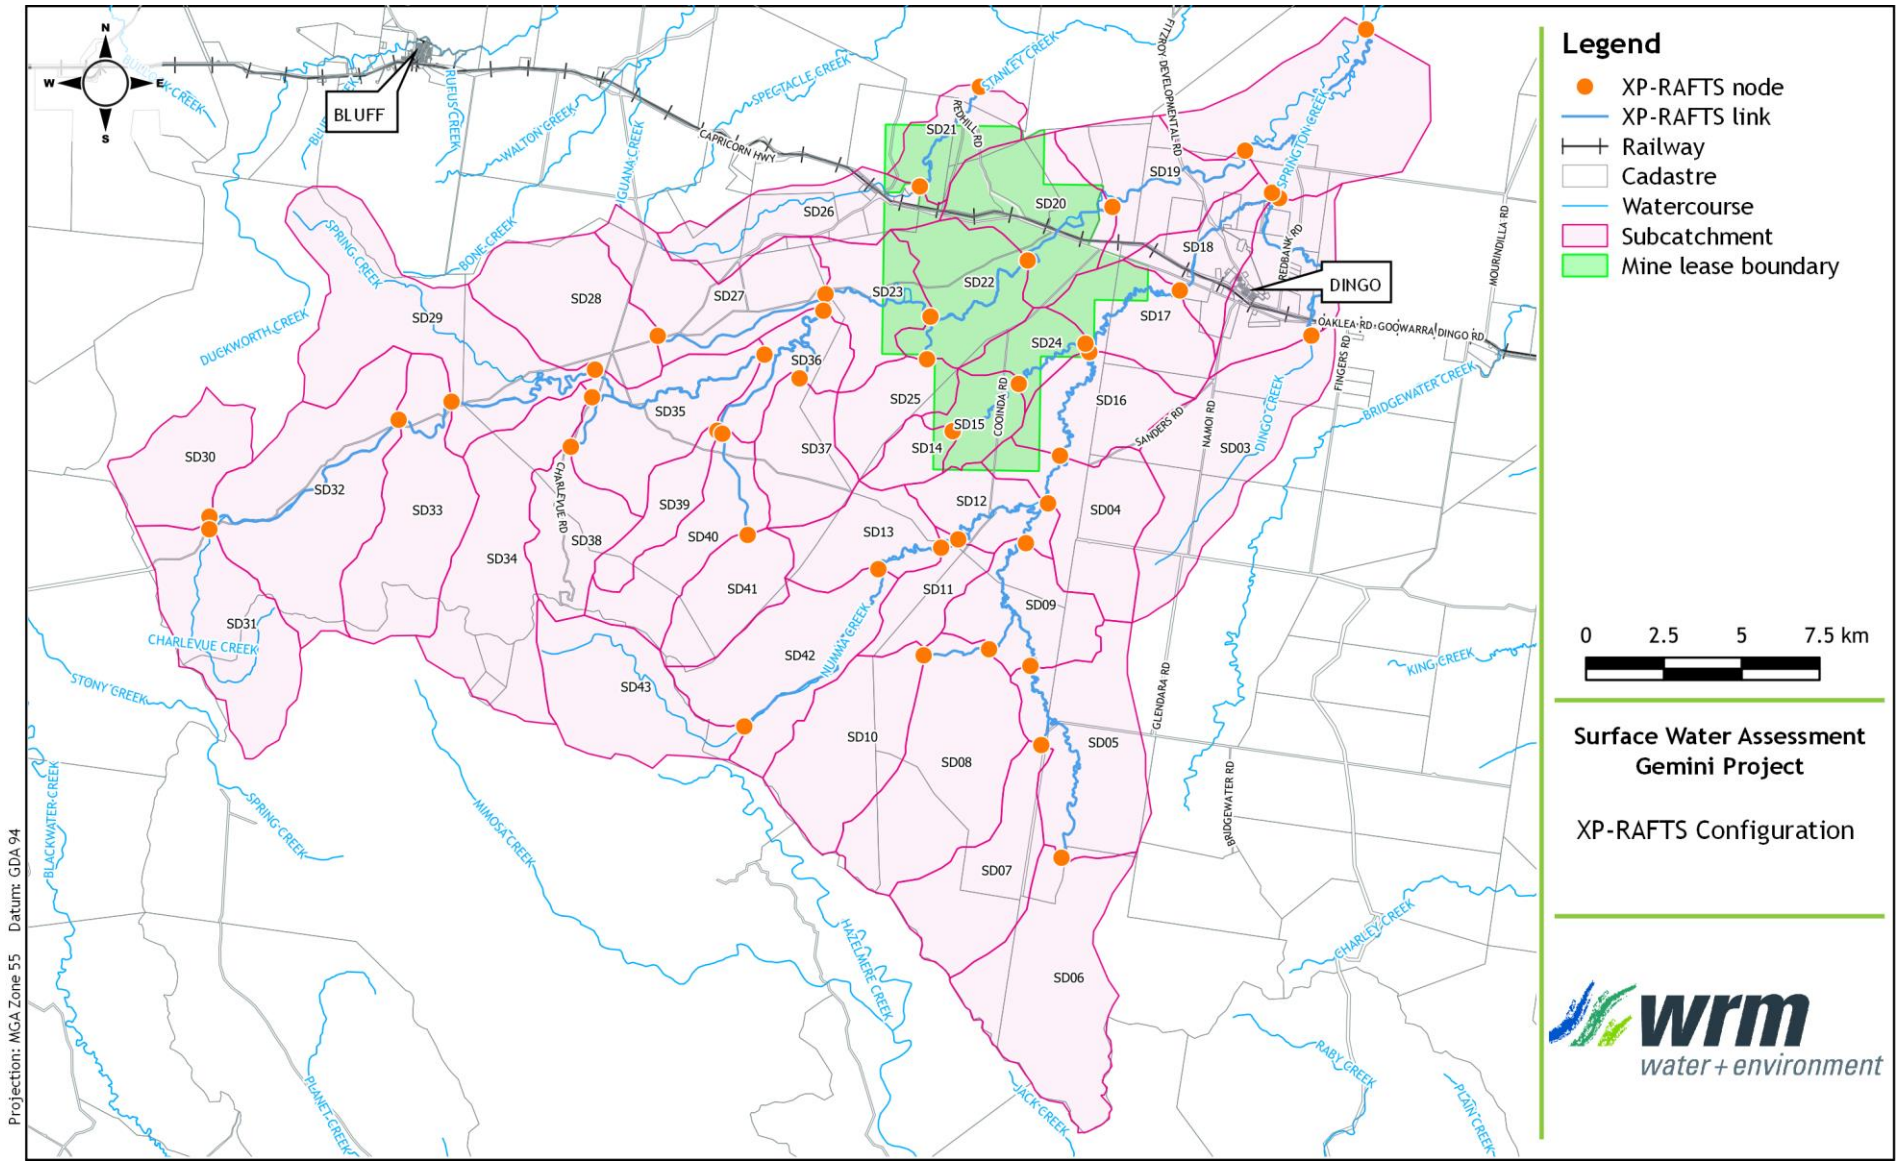

Figure A.1 – XP-RAFTS model configuration

A2.3 DESIGN RAINFALL DEPTH

A2.3.1 50% to 0.1% AEP design events

Design rainfall depths and intensities were derived using intensity-frequency duration (IFD) data obtained from the Bureau of Meteorology's (BoM's) 2016 Rainfall IFD Data System. Design rainfall IFDs were obtained based on the centroid point location at the combined Charlevue Creek and Springton Creek catchment.

A2.3.2 Probable maximum flood design event

PMP rainfall depths for durations up to 6 hours were estimated using the methodology given in *The Estimation of Probable Maximum Precipitation in Australia: Generalised Short Duration Method (GSDM)* (BoM, 2003).

PMF rainfall depths for durations longer than 6 hours were estimated using the standard methodology given in *The Estimation of Probable Maximum Precipitation: Generalised Tropical Storm Method Revised (GTSMR)* (BoM, 2006).

The followings parameters were adopted:

- For GSDM:
    - The terrain was assumed to be 100% rough, S = 0;
    - Elevation Adjustment Factor, EAF = 1;
    - Moisture Adjustment Factor, MAF = 0.85.
- For GTSMR:
    - Located in the coastal zone;
    - Annual Moisture Adjustment Factor, AMAF = 0.75;
    - Winter Moisture Adjustment Factor, WMAF = 0.78;
    - Decay Amplitude Factor, DAF = 1.0;
    - Topographical Adjustment Factor, TAF = 1.13.

Note that aerial reduction factors are already applied to the PMP rainfalls due to the catchment area being incorporated into the PMP rainfall estimation methodology.

A2.4 AREAL REDUCTION FACTORS

The areal reduction factor was obtained from the ARR data hub and has been applied based on the combined catchment size in the model for design events up to 0.1% AEP.

A2.5 TEMPORAL PATTERNS

A2.5.1 50% to 0.1% AEP design events

Temporal patterns were obtained from the AR&R 2016 data hub based on the centroid of the combined Charlevue Creek and Springton Creek catchment. The AR&R 2016 temporal pattern methodology involves the use of an 'ensemble' of 10 temporal patterns, which produces 10 design hydrographs (and peak discharges) for each duration for each AEP. For each location and AEP, the storm duration with the highest median peak design discharge of the ensemble is selected and the temporal pattern that produces the peak design discharge just above the ensemble median is adopted.

A2.5.2 Probable maximum flood design event

The temporal patterns for storm durations up to and including 12 hours were obtained from the GSDM methodology (BoM, 2003). Temporal patterns for durations longer than 12 hours were obtained for Coastal Zone storms from the GTSMR methodology (BoM, 2006).

A2.6 DESIGN RAINFALL LOSSES

For design events up to 0.1% AEP, an initial loss (IL) of 42 mm and continuing losses (CL) of 2.0 mm/hr were adopted for this assessment based on the AR&R 2016 data hub report. An IL of 0 mm and CL of 1 mm/hr were used for PMP design event.

The incorporation of pre-burst depths specified in AR&R 2016 data hub is achieved by applying median depth values (ratio multiplied by initial loss) at an initial timestep for each event duration. Table A.1 shows the adopted median pre-burst and depth ratio values used in calculating design rainfall continuing losses.

Table A.1 – Median pre-burst depths (mm) and ratios

Duration min (hours)	50% AEP	2% AEP	1% AEP
60 (1.0)	0.4 (0.012)	5.5 (0.070)	6.5 (0.074)
90 (1.5)	0.1 (0.003)	4.1 (0.046)	6.1 (0.061)
120 (2.0)	0.0 (0.001)	5.3 (0.054)	7.7 (0.069)
180 (3.0)	0.5 (0.011)	6.8 (0.062)	9.4 (0.076)
360 (6.0)	0.0 (0.000)	14.5 (0.108)	23.4 (0.153)
720 (12.0)	0.0 (0.000)	17.4 (0.104)	27.5 (0.143)
1080 (18.0)	0.0 (0.000)	17.6 (0.092)	27.8 (0.126)
1440 (24.0)	0.0 (0.000)	12.2 (0.058)	20.8 (0.085)
2160 (36.0)	0.0 (0.000)	10.6 (0.043)	18.5 (0.065)
2880 (48.0)	0.0 (0.000)	3.1 (0.011)	5.4 (0.017)
4320 (72.0)	0.0 (0.000)	0.0 (0.000)	0.0 (0.000)

A2.7 MODEL VALIDATION

The peak design discharges produced by the XP-RAFTS model were validated against the Rational Method and Regional Flood Frequency Estimation (RFFE) estimates.

A2.7.1 Rational method

The Rational Method was applied to a number of sub-catchments with areas less than 25 km^2.

Table A.2 compares the Rational Method results and XP-RAFTS peak discharges estimates at 4 sub-catchment outflow locations. The time of concentration was calculated using the Modified Friend's equation with no overland flow component.

The outflow locations used in the Rational Method calculation correspond to the XP-RAFTS nodes of SD02, SD15, SD21 and SD24. The Rational Method 1% AEP peak design discharges at these nodes are ranged between 13.8 m^3/s and 34.8 m^3/s. The estimated XP-RAFTS model discharges match the estimated Rational Method discharges well (within 10%) for sub-catchment SD15 and SD24, while the XP-RAFTS model gives a larger discharge compared to the RM estimates at sub-catchments SD02 and SD21.

Table A.2 – Comparison of Rational Method and XP-RAFTS model design discharges

Design event	Sub-catchment	Rational Method	XP-RAFTS	Difference
1% AEP	SD02	23.0	34.8	34%
	SD15	13.7	14.5	6%
	SD21	16.0	20.4	21%
	SD24	12.8	13.8	7 %

A2.7.2 RFFE estimates

The RFFE method was applied to the combined Charlevue Creek & Springton Creek catchment. Figure A.2 and Table A.3 show comparisons between RFFE estimates and XP-RAFTS model results. Design discharges obtained using XP-RAFTS match the RFFE estimates well (within +/-30%) for all design events.

The calibrated XP-RAFTS model was used to derive flood discharge hydrographs for use in the hydraulic model.

Table A.3 – Comparison of RFFE and XP-RAFTS model design discharges

AEP	Adopted XP-RAFTS design discharge (m^3/s)	RFFE discharge (m^3/s)			Difference
		Lower 5% confidence limit	Expected parameter quantile	Upper 95% confidence limit	
50%	180	57	149	391	17.1%
20%	-	137	345	877	
10%	604	199	544	1,480	10.0%
5%	-	262	798	2,420	
2%	1,061	345	1,240	4,410	-16.8%
1%	1,316	411	1,680	6,740	-27.6%

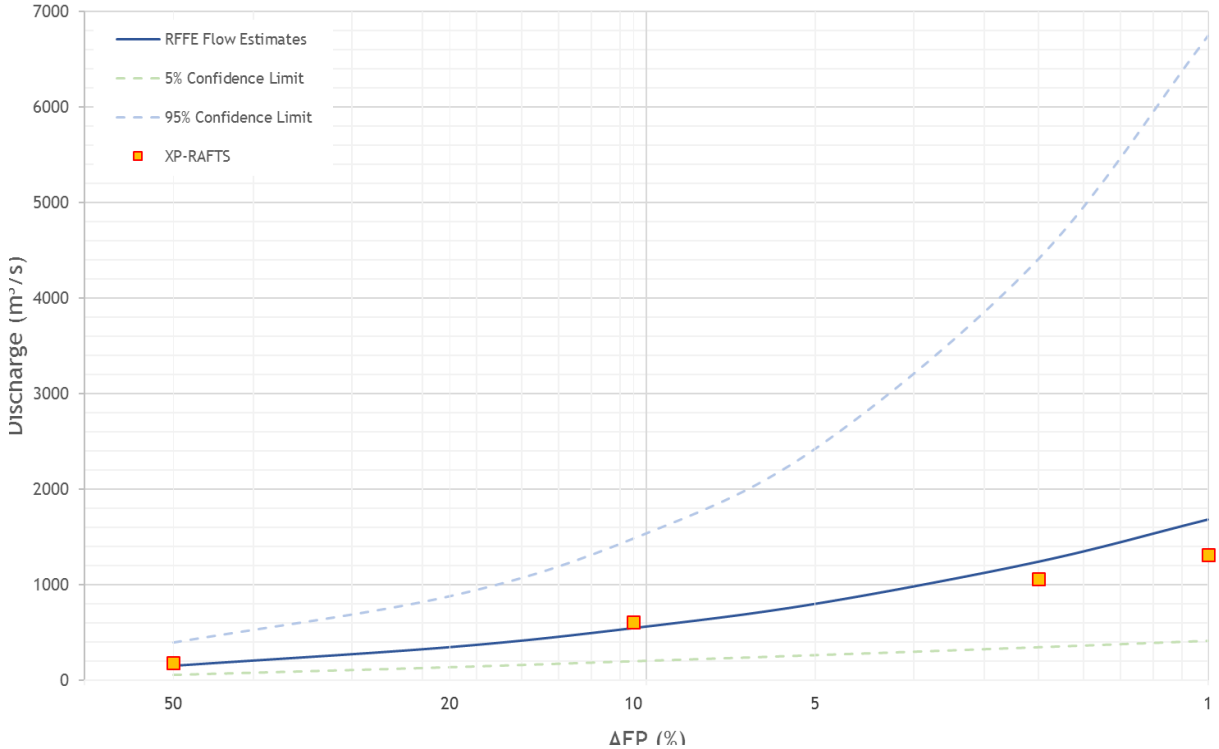

Figure A.2 - Comparison of RFFE and XP-RAFTS design discharges

A2.8 ADOPTED DESIGN DISCHARGES

Design discharges were estimated in accordance with AR&R 2016 guidelines for the 50% (1 in 2), 2% (1 in 50), 1% (1 in 100) and 0.1% (1 in 1,000) AEP events as well as the probable maximum flood (PMF) event.

Table A.4 shows XP-RAFTS predicted design peak discharges and relevant critical storm durations and temporal patterns for all modelled design events at the outlet (SD01) of the combined Charlevue Creek & Springton Creek catchment.

The design discharge hydrographs from the XP-RAFTS model were adopted as inflows to the TUFLOW hydraulic model.

Table A.4 - XP-RAFTS design discharges and critical durations at the outlet (SD01) of the combined Charlevue Creek & Springton Creek catchment

AEP	Combined Charlevue Creek & Springton Creek catchment		
	XP-RAFTS discharge (m^3/s)	Critical duration (hours)	Corresponding Temporal Pattern
50%	180	24	10
10%	604	24	10
2%	1,061	24	6
1%	1,316	24	2
0.1%	2,384	24	9
PMF	12,952	24	-

A3 Hydraulic modelling

A3.1 OVERVIEW

The TUFLOW hydrodynamic model (BMT WBM, 2016) was used to estimate flood extents and depths along the channel and floodplain of Charlevue Creek and Springton Creek and their tributaries for a range of design events. TUFLOW represents hydraulic conditions on a fixed grid by solving the full two-dimensional depth averaged momentum and continuity equations for free surface flow. The model automatically identifies breakout points and flow directions within the study area. All hydraulic modelling was undertaken using the TUFLOW Build 2018-03-AD HPC solver.

Figure A.3 shows the TUFLOW model boundary. The model covers an area of approximately 139.4 km^2 where the Project area is bounded by Charlevue Creek to the north and Springton Creek to the south.

The TUFLOW model was configured using a grid cell size of 5 metres. This provides a reasonable compromise between a coarse grid cell size sufficient for Charlevue Creek and Springton Creek, and a fine enough grid cell size required for the tributaries crossing the Project area.

A3.2 EXISTING CONDITIONS TUFLOW MODEL CONFIGURATION

A3.2.1 Topography

Topographic LiDAR survey data covering the majority of TUFLOW model area (purple region in Figure A.3) was provided by Magnetic South Pty Ltd.

Additional LiDAR data covering the area to the northeast near Dingo (green region in Figure A.3), was obtained from the Foundation Spatial Data Framework – Elevation and Depth portal (http://elevation.fsdf.org.au/) (referred to as ELVIS). The ELVIS LiDAR data is available on a 1 m grid and was acquired in 2012.

Hydrologically-enforced SRTM (Shuttle Radar Topography Mission) lidar data was used to cover an upstream portion of the Springton Creek floodplain (red region in Figure A.3). This data is available on a 30m grid, with a vertical accuracy of +/- 9.8 m. The SRTM was modified to better match the LiDAR at the boundary by lowering it by 1.8 m and applying a z-shape to smooth the transition between (geometry reinforcement in Figure A.4).

The combined data was converted into a digital elevation model (DEM) for use as the base TUFLOW model topography.

A3.2.2 Hydraulic roughness

Hydraulic roughness in the TUFLOW model is represented by Manning's 'n' roughness coefficients. Manning's 'n' values for the various land use types were selected based on typical published values. Land use types within the existing conditions model were identified using aerial photography.

Table A.5 shows the adopted Manning's 'n' values used in the model and Figure A.5 shows the locations of the Manning's 'n regions.

Table A.5 – Adopted hydraulic roughness Manning's 'n' values

Area	Manning's 'n'
Dense riparian vegetation	0.060
Creek / river channel	0.050
Pasture	0.035

A3.2.3 Inflow and outflow boundaries

Figure A.4 shows the locations of inflow and outflow boundaries in the TUFLOW model. The model includes a total of 16 inflow boundaries. The model inflow boundaries were applied within the 2D model domain using surface-area "SA" polygons. Using this approach, flows are initially applied to the lowest point within each SA polygon. Design discharge hydrographs for these inflow boundaries were obtained from the XP-RAFTS hydrologic model.

A3.2.4 Tailwater conditions

The downstream boundary was set to minimise its influence on predicted flood behaviour. Flood slopes between 0.1% and 0.15% were adopted for the Springton Creek outlet in northeast of the Project area. A 0.4% bed slope was applied for the model outlet at Stanley Creek north of the Project area.

A3.2.5 Hydraulic structures

Bridges and culverts within the Project area have been surveyed and modelled in the TUFLOW hydraulic model. Culverts are treated as 1D networks and bridges are modelled as 2D layered flow constrictions, with points snapped onto the lines to represent the road/rail elevation.

Under existing conditions, a total number of 4 culverts were modelled, two located on the east of Charlevue Creek and two located on the west of Charlevue Creek. Two bridges were modelled (Figure A.4). Both bridges are located on the Capricorn Highway, one across Springton Creek and one across Charlevue Creek. An 800 mm thick slab and 500 mm height guard rails were adopted for both bridges.

Table A.6 and Table A.7 provide summary information on the existing culverts and bridges located under Capricorn Highway and Blackwater railway line embankments included in the model.

Table A.6 - Culvert details

Name	Road/ Rail Crossing	Dimension	IL U\S (mAHD)	IL D\S (mAHD)
SM02_a	Capricorn Hwy	3 x 0.75h*1.2w RCBC	114.06	113.53
SM02_b	Blackwater Rly	12 x 1.65m RCPs	113.90	113.63
SM04_a	Capricorn Hwy	9 x 0.75h*1.2w RCBC	113.66	113.31
SM04_b	Blackwater Rly	10 x 1.38m RCPs	113.77	113.68

[a] - RCP = reinforced concrete pipe, RCBC = concrete box culvert

Table A.7 - Bridge details

Name	Road/Rail Crossing	U/S Invert (mAHD)	D/S invert (mAHD)
BRD01	Capricorn Hwy/ Springton Creek	106.85	106.90
BRD03	Capricorn Hwy/ Charlevue Creek	114.90	114.90

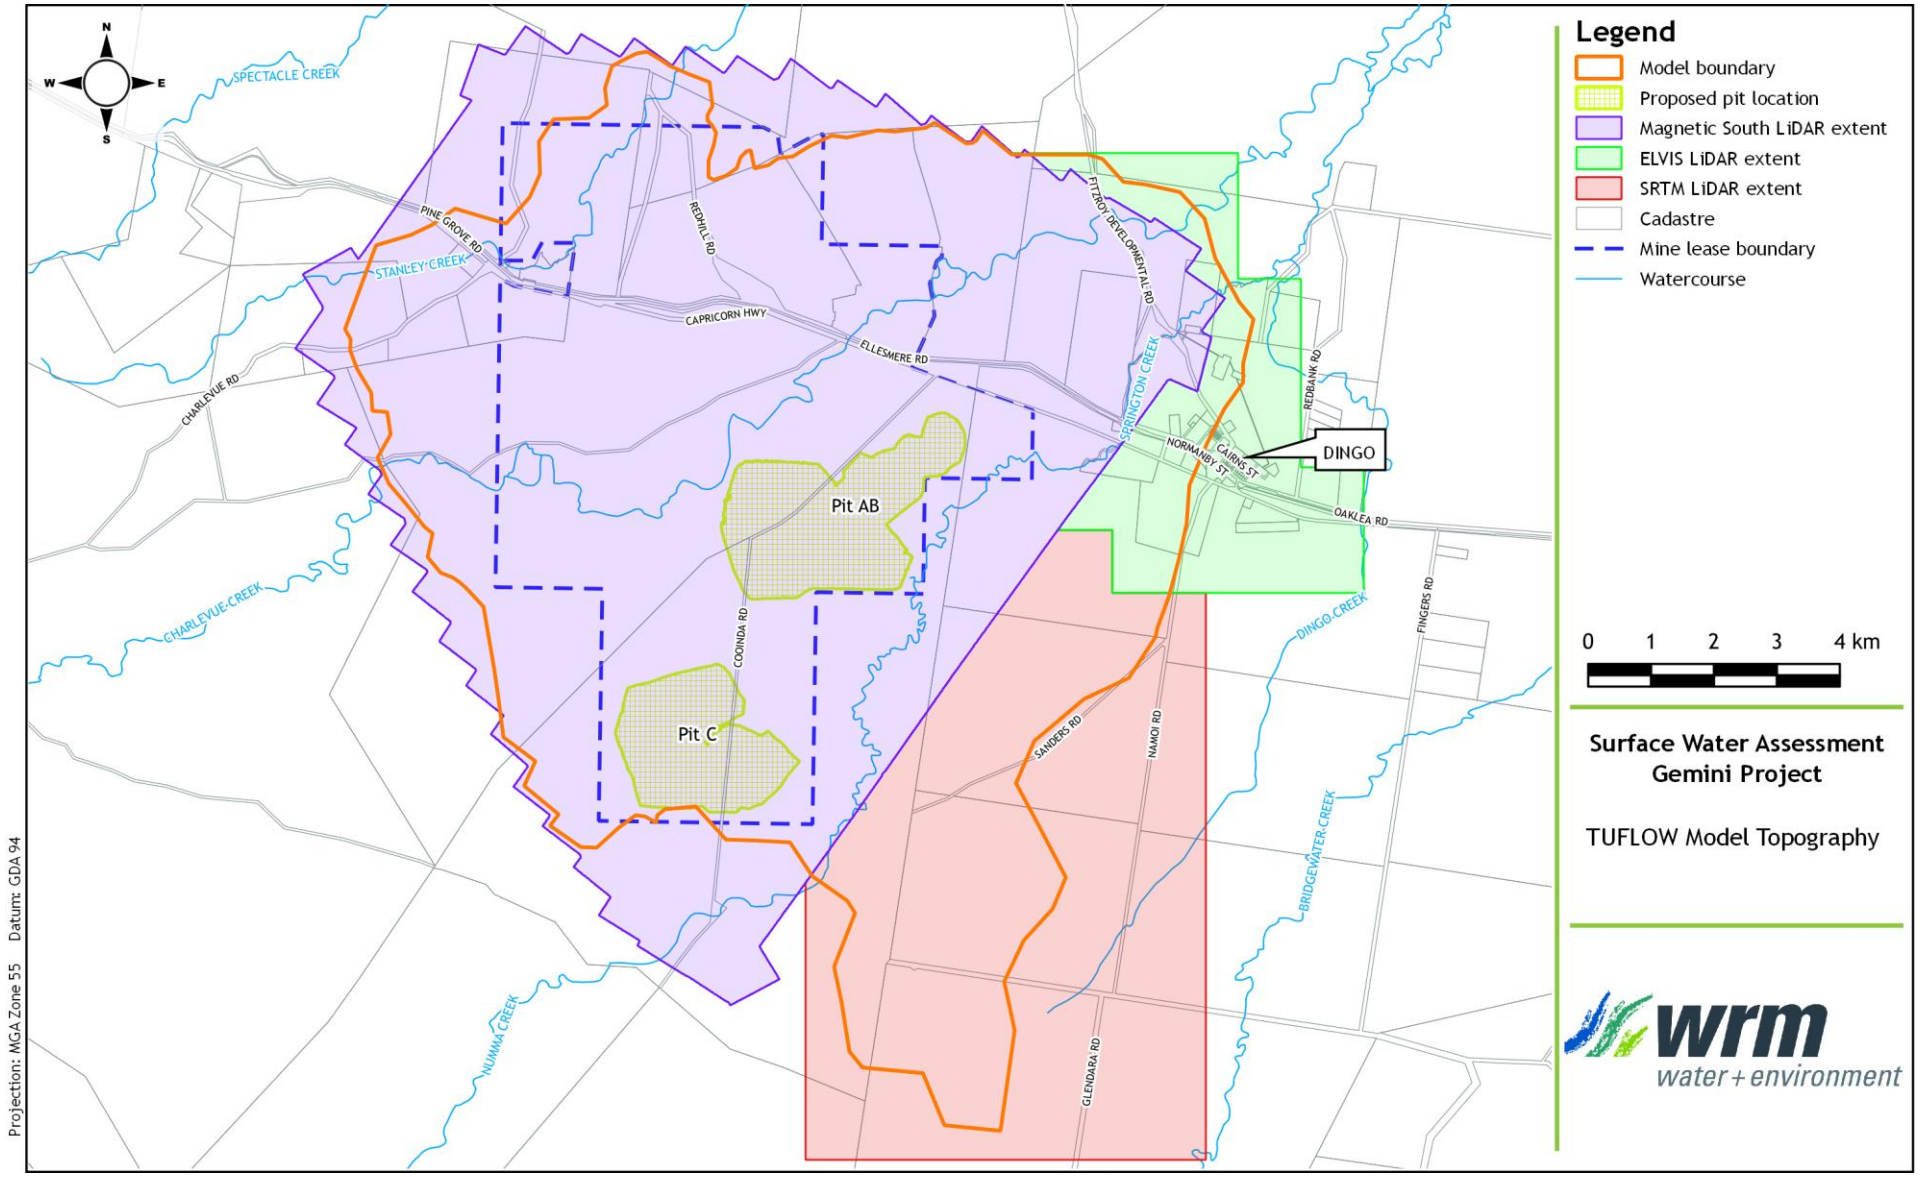

Figure A.3 – TUFLOW model topography

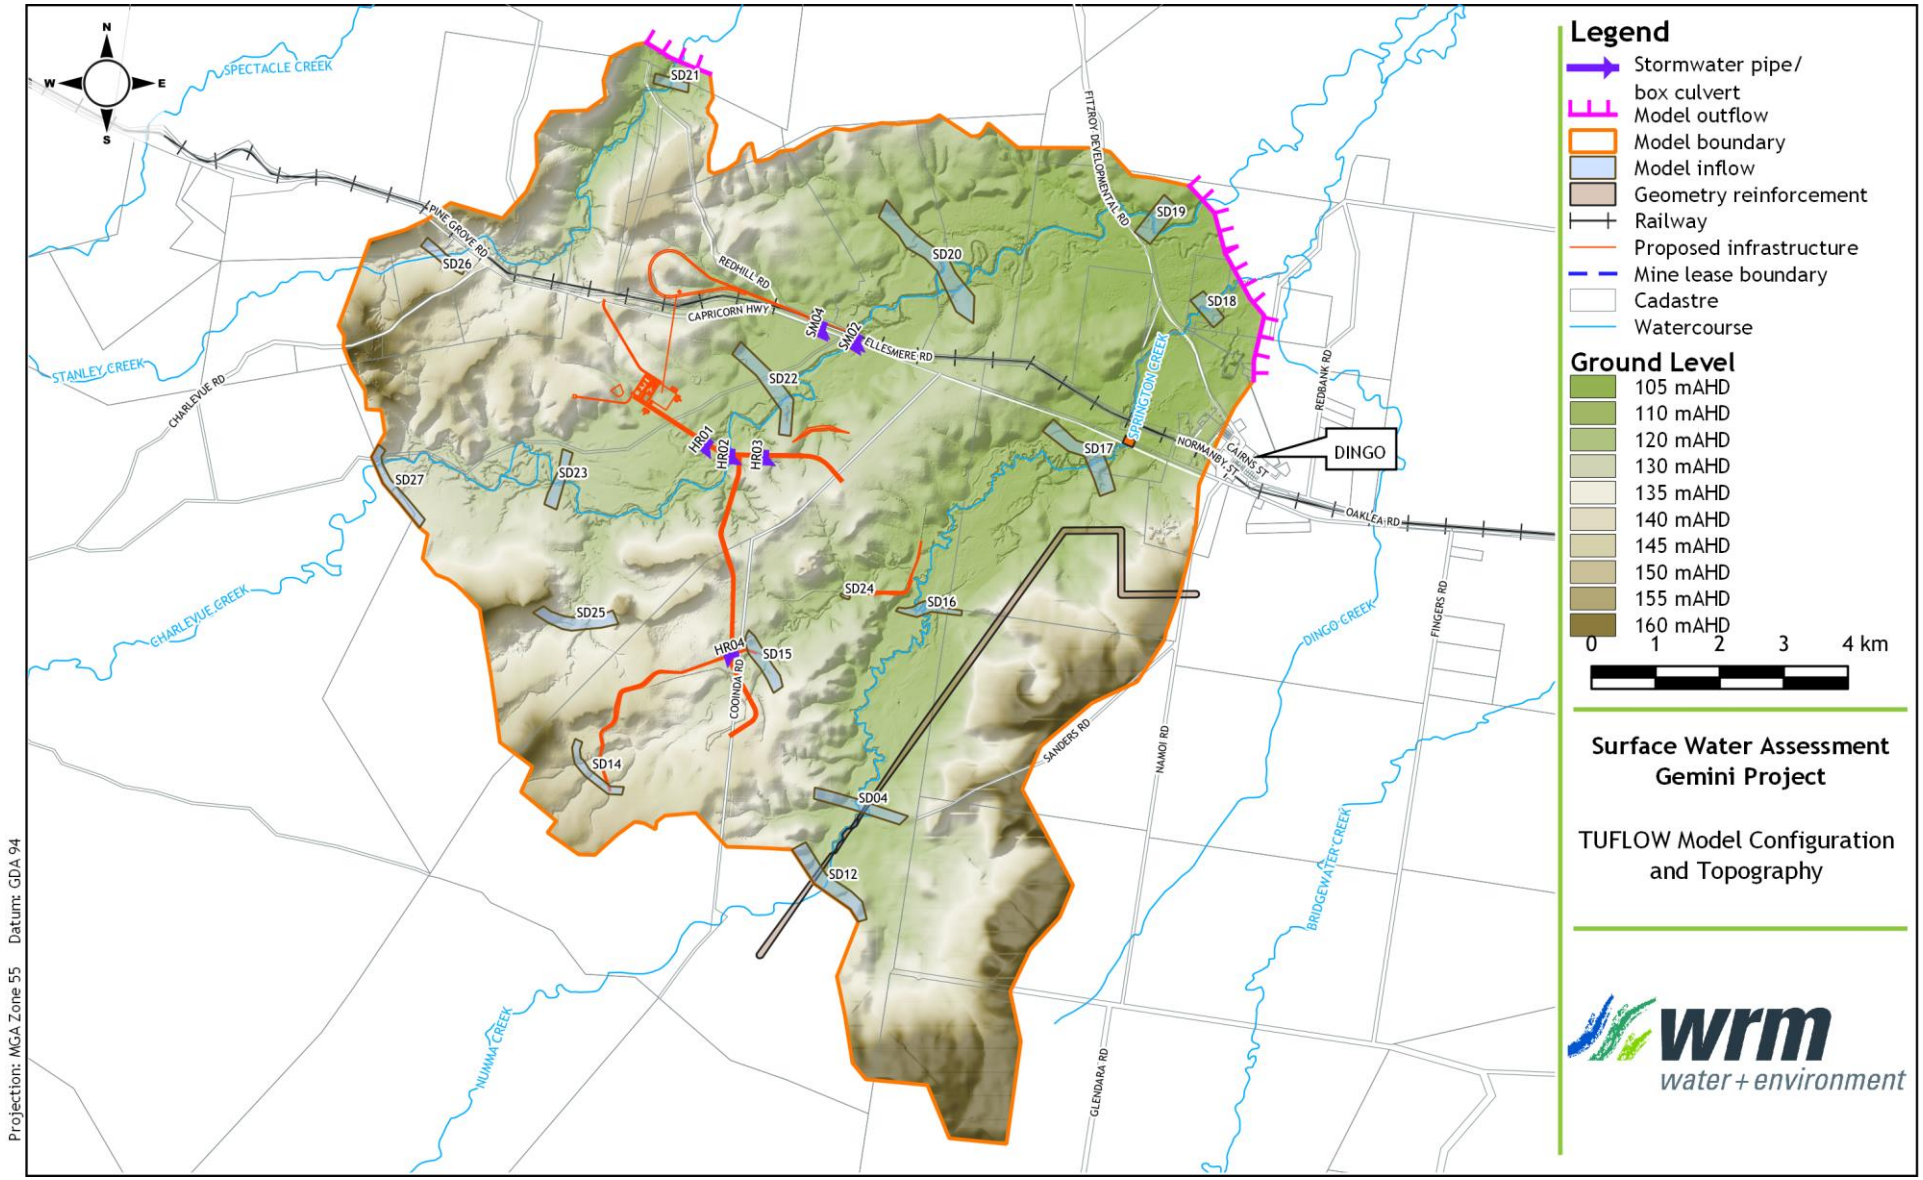

Figure A.4 – TUFLOW model configuration

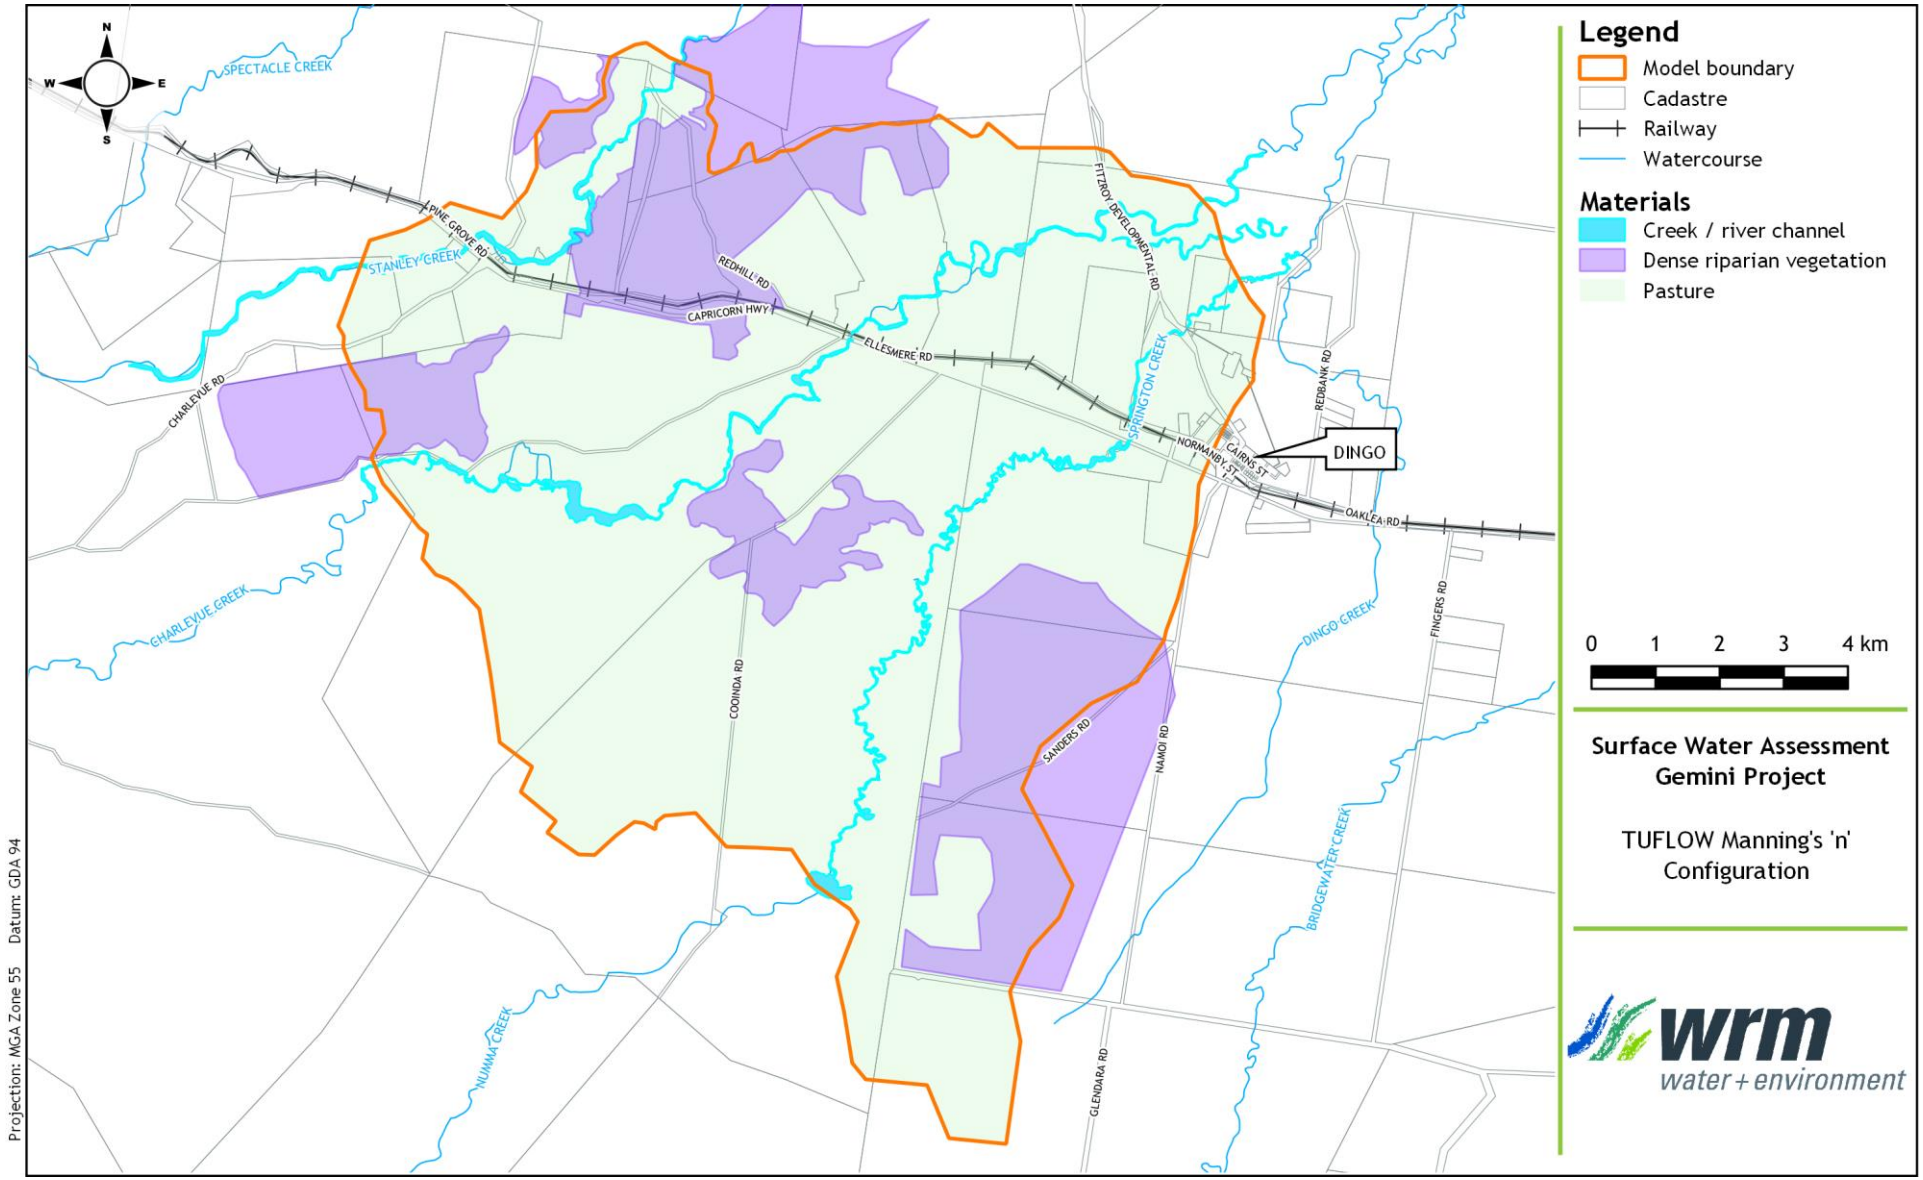

Figure A.5 – Manning's 'n' configuration

A3.3 DEVELOPED CONDITIONS TUFLOW MODEL

A3.3.1 Topography

A number of changes were made to the model DEM to reflect changes associated with:

- proposed overburden dumps and pit protection levees;
- haul roads connecting the two mining pits to the MIA and CHPP;
- diversion channels for the minor tributary of Springton Creek crossing the mine area.

The locations of these proposed structures are shown in Figure A.4.

A3.3.2 Hydraulic roughness

Land use types within the developed conditions model were identical to those defined for the existing conditions model.

A3.3.3 Inflow and outflow conditions

No changes to the existing conditions inflow and outflow locations were made.

A3.3.4 Hydraulic structures

Additional culverts under the proposed haul roads were added in the developed conditions. Details of the proposed Project culvert configurations are provided in Table A.8.

Table A.8 – Proposed new culverts in Project area

Name	Road/ Rail Crossing	Dimension	IL U\S (mAHD)	IL D\S (mAHD)
HR01	Haul Road (North)	3 x 0.9m RCPs	118.34	117.84
HR02	Haul Road (North)	3 x 2.1m RCPs	114.97	114.60
HR03	Haul Road (North)	2 x 0.9m RCPs	122.69	122.20
HR04	Haul Road (South)	3 x 0.9m RCPs	126.70	126.28

A3.3.5 Diversion channels

Earthworks models of the preliminary diversion channel designs were provided by TMM group and included in the model. The transitions between the diversion channels and the adjacent landforms were modified slightly to improve hydraulic performance.

A3.4 TUFLOW MODELLING RESULTS

Flood maps showing design peak flood depths and water level contours for the 1% AEP event under existing conditions and developed conditions are shown in Section A8.

Flood maps showing design peak flood velocities for the 1% AEP under existing and developed conditions are shown in Figure A.13 to Figure A.16 and Figure A.17 to Figure A.19 respectively.

Maps showing the water level difference between developed and existing conditions are shown in Figure A.20 to Figure A.21.

Flood mapping for a range of other design events (50% AEP,2% AEP, 0.1% AEP, and PMF) are provided in Section A8.

A4 Summary of findings

The purpose of this flood study was to:

- Define existing flood conditions across the Project area for a range of design events, in terms of peak water level, peak velocity, and water depth;
- Assess peak water levels and velocities along the levees proposed to protect the proposed works from flooding;
- Determine design flood conditions at the proposed haul road crossing, to assist in the preliminary design of cross-drainage infrastructure;
- Determine design flood conditions at the proposed railway crossing and to determine the potential for impacts on flood conditions;
- Assess the hydraulic conditions in the channels proposed to divert runoff in the unnamed Springton Creek tributary around both mining areas;
- Determine the residual impacts of the proposed Project during project operations.

An XP-RAFTS hydrologic model was developed to estimate design discharge hydrographs for the catchments of Charlevue Creek and Springton Creek which cross the Project area. In the absence of gauged streamflow data, the resulting peak discharges were validated against peak discharges estimated using the Rational Method and RFFE.

The model was used to estimate design discharges for the 50%, 10%, 2%, 1%, and 0.1% AEP events as well as the PMF design event in accordance with the AR&R 2016 approach using an ensemble of design temporal patterns.

- The 0.1% AEP design flood event was used in the design of flood levees;
- The 2% AEP and 1% AEP design events are of interest when assessing the impacts on road, rail and other off-site infrastructure;
- The PMF event was used in the risk analysis for the proposed final void location.

A TUFLOW hydraulic model was also developed to determine existing and developed conditions flood behaviour in Charlevue Creek, Springton Creek, and its unnamed tributary crossing the mine area. The adopted grid cell size was five metres, and the inflow boundaries were represented using design discharge hydrographs estimated using the XP-RAFTS runoff-routing model. The model incorporated the proposed works, including the haul roads, levees and diversion channels.

The outcomes of the study are as follows:

- The Project will temporarily increase Charlevue Creek flood levels in the immediate vicinity of the proposed haul road crossing. These impacts are contained within the mine lease area.
- There will be no impact on flood levels in Charlevue Creek or Springton Creek at the existing Capricorn Highway, Blackwater Rail corridor, or downstream of the Project area.
- While the unnamed tributary of Springton Creek is not a watercourse as defined under the Water Act, the diversion channel will be designed taking into consideration the principles set out in the Guideline: “Works that interfere with water in a watercourse – watercourse diversions” (DNRM, September 2014). This document sets out key design principles and requirements for the functional designs of permanent diversions. It includes guidance on watercourse diversion design and operation including maintenance, monitoring and revegetation. Preliminary designs are shown in Figure 7.3 to Figure 7.8 which also show the post development flood conditions with diversions and levees in place.

- The works at AB Pit will locally increase flood levels in Springton Creek by up to 0.22 m in the 1% AEP flood. These impacts would extend off the lease area onto land owned by Magnetic South Pty Ltd, and reduce with distance downstream of the boundary.
- There will be localised off-lease impacts on flood levels in the unnamed tributary of Springton Creek immediately upstream of AB Pit and C Pit.

Gemini Project – Groundwater Dependent Ecosystem Assessment

Prepared by 3d Environmental

for

Magnetic South Pty Ltd

V2_ 25 November 2020

Project No. 2020_253
Project Manager: David Stanton
Client: Magnetic South Pty Ltd
Purpose: Groundwater dependent ecosystem assessment for the Gemini Project, Magnetic South Pty Ltd.

Draft	Date Issued	Issued By.	Purpose
Revision 1	13 November 2020	David Stanton	First Draft GDE Assessment Report
Revision 2	25 November 2020	David Stanton	Second Draft following comments by G Brampston / Heath Carney.

NOTICE TO USERS OF THIS REPORT

Purpose of the report: 3D Environmental has produced this report in its capacity as consultant for and on the request of Magnetic South Pty Ltd (the "Client"). The information and any recommendations in this report are particular to the Specified Purpose and are based on facts, matters and circumstances particular to the subject matter of the report and the specified purpose (GDE Assessment) at the time of production. This report is not to be used, nor is it suitable, for any purpose other than the Specified Purpose. 3D Environmental disclaims all liability for any loss and/or damage whatsoever arising either directly or indirectly as a result of any application, use or reliance upon the report for any purpose other than the Specified Purpose.

Whilst 3D Environmental believes all the information in it is deemed reliable at the time of publication, it does not warrant its accuracy or completeness. To the full extent allowed by law, 3D Environmental excludes liability in contract, tort or otherwise, for any loss or damage sustained by any person or body corporate arising from or in connection with the supply or use of the whole or any part of the information in this report through any cause whatsoever.

Executive Summary

Magnetic South Pty Ltd (the 'Proponent') proposes to develop the Gemini Project, 110 km east of Emerald and 125 km west of Rockhampton, within the Bowen Basin, Central Queensland. The project centres on Mining Lease application 700056 and will mine metallurgical coal using open cut mining methods, with the operational footprint including both mining pits and associated infrastructure. An assessment of the presence of GDEs within the Project area is presented in this document as a component of the approval process.

To complete the GDE assessment, multiple lines of evidence including measurement of leaf water potential, soil moisture potential and analysis of stable isotopes from various sources were applied to assesses the dependence of vegetation in the Gemini Project area on groundwater. Based on a targeted survey effort, two areas of likely groundwater dependence, and hence GDEs, were recognised in the Project area being:

1. Charlevue Creek Area 1, being an area identified as a terrestrial GDE on Charlevue Creek, to the west and upstream of the mine infrastructure area.
2. Springton Tributary Area 1, being a terrestrial GDE associated with an ephemeral drainage system, currently located within the footprint of the mine infrastructure area.

The study confirmed that the Charlevue Creek GDE area is hosted in an area of recent river alluvium which forms a flood terrace that is dissected by the channel of Charlevue Creek and traversed by a series of flood overflow channels. The GDE area is supported by an unconfined, fresh and seasonal alluvial aquifer that is perched above the regional groundwater table associated with Tertiary, Permian and older alluvial sediments. The supporting perched aquifer is conceptualised to be seasonally recharged during surface flows including flood events and associated rainfall. Based on salinity data and stable isotope comparisons between twig xylem and groundwater samples, it is inferred that the perched aquifer is hydraulically disconnected from the regional Tertiary and alluvial aquifers which hold groundwater with salinity values that range from mildly to highly toxic to trees. Based on stable isotope data, there is no indication that trees at this site, nor any tree sampled during the GDE assessment is utilising groundwater associated with the regional Tertiary, alluvial or Permian coal seam aquifers to any significant degree.

The Springton Tributary Area 1 GDE system is supported by a seasonally variable perched aquifer system that is hosted in a thick, coarse sand horizon developed below the flood plain of the minor tributary. The strong iron staining associated with the sandy aquifer material provides evidence for considerable seasonal fluctuation in groundwater levels, which are inferred to recharge and drain rapidly in response to rainfall and surface flows. Similar to the Charlevue Creek GDE system, the Springton Tributary system is perched above the regional Tertiary groundwater table and trees at the site, based on evidence from stable isotope analysis, show no evidence for utilisation of the deeper groundwater system.

The Springton Tributary GDE system covers an area of 5.54 hectares and is located entirely within the mine infrastructure area, which necessities clearing and unavoidable direct impact. The environmental values and impacts associated with direct clearing of vegetation on are discussed in the Terrestrial Flora and Fauna Report (AARC 2019).

The Charlevue Creek GDE system is supported by an alluvial aquifer that is conceptualised to be perched above, and hydraulically disconnected from the deeper regional aquifers associated with the Tertiary sediments, older alluvial systems, and the Permian coal seams. Groundwater drawdown associated with mining void development is modelled to impact the regional groundwater table below the Charlevue Creek GDE system. Due to limited connectivity between the perched alluvium and deeper groundwater systems, it is anticipated that these impacts will not be propagated into the perched aquifer system. Furthermore, the perched aquifer that supports the Charlevue Creek GDE system is recharged by surface water flows, flooding and seasonal rainfall events which will not be altered by mining development.

Mitigations to prevent impact to the Charlevue Creek system include general operational measures associated with project approval conditions which include development of the Mine WMS and ESCP. With these routine mitigations, in conjunction with ongoing groundwater sampling of the existing groundwater monitoring network to be completed as part of the ongoing groundwater monitoring program, it is considered that the risk to the Charlevue Creek GDE system posed by mine development is negligible.

Glossary

Alluvial aquifer	An aquifer comprising unconsolidated sediments deposited by flowing water usually occurring beneath or adjacent to the channel of a river.
Aquifer	A geological formation or structure that stores or transmits water to wells or springs. Aquifers typically supply economic volumes of groundwater
Aquatic GDE	Vegetation supported by surface expression of groundwater (e.g. spring fed watercourses and associated fringing vegetation).
Base flow	Streamflow derived from groundwater seepage into a stream.
Capillary fringe	The unsaturated zone above the water table containing water in direct contact with the water table though at pressures that are less than atmospheric. Water is usually held by soil pores against gravity by capillary tension.
Confined aquifer	A layer of soil or rock below the land surface that is saturated with water with impermeable material above and below providing confining layers with the water in the aquifer under pressure.
Perched groundwater system	A groundwater system or aquifer that sit above the regional aquifer due to a capture of infiltrating moisture on a discontinuous aquitard.
Phreatic zone	The zone of sub-surface saturation separated from the unsaturated zone in unconfined aquifers by the water table.
Phreatophyte	Plants whose roots extend downward to the water table to obtain groundwater or water within the capillary fringe
Obligate phreatophyte	A plant that is completed dependent on access to groundwater for survival
Edaphic	Relating to properties of soil or substrate including its physical and chemical properties and controls those factors impose on living organisms.
Evapotranspiration	The movement of water from the landscape to the atmosphere including the sum of evaporation from the lands surface and transpiration from vegetation through stomata
Facultative phreatophyte	A plant that occasionally or seasonally utilises groundwater to maintain high transpiration rates, usually when other water sources aren't available.
Fractured rock aquifer	An aquifer in which water flows through and is stored in fractures in the rock caused by folding and faulting.
Fluvial	Relating to processes produced by or found in rivers
Groundwater	Those areas in the sub-surface where all soil or rock interstitial porosity is saturated with water. Includes the saturated zone and the capillary fringe.
Water table	The upper surface of the saturated zone in the ground, where all the pore space is filled with water.
Groundwater dependent ecosystems (GDE)	Natural ecosystems which require access to groundwater on a permanent or intermittent basis to meet all or some of their water requirements so as to maintain their communities of plants and animals, ecological processes and ecosystem services (Richardson et al. 2011)

Infiltration	Passage of water into the soil by forces of gravity and capillarity, dependent on the properties of the soil and moisture content.
Leaf water potential (LWP)	The total potential for water in a leaf, consisting of the balance between osmotic potential (exerted from solutes), turgor pressure (hydrostatic pressure) and matric potential (the pressure exerted by the walls of capillaries and colloids in the cell wall).
Leaf area index (LAI)	The ratio of total one-sided area of leaves on a plant divided by the area of the canopy when projected vertically on to the ground.
Local Meteoric Water Line (LMWL)	Describes the relationship between hydrogen and oxygen isotope (Oxygen-18 and Deuterium) ratios in local natural meteoric waters. LMWL is usually developed from precipitation data collected from either a single location or a set of locations within a "localised" area of interest (USGS, 2018).
Percolation	The downward movement of water through the soil due to gravity and hydraulic forces.
Permeability	A materials ability to allow a substance to pass through it, such as the ability of soil or rocks to conduct water under the influence of gravity and hydraulic forces.
Permanent wilting point	The water content of the soil at which a plant can no longer extract water and leaves will wilt and die. Usually -1.5 Mpa (-217 psi). Generally applied to crops although Australian flora typically have much larger stress thresholds.
Piston flow	The movement of a water front through the soil uniformly downwards to the aquifer, with the same velocity, negligible dispersion, pushing older water deeper into the soil profile.
Preferential flow	Movement of surface water rapidly from surface to aquifer along preferential flow paths, bypassing older moisture in the upper soil profile.
Unconfined aquifer	An aquifer whose upper surface is at atmospheric pressure, producing a water table, which can rise and fall in response to recharge by rainfall
Soil water potential	A measure of the difference between the free energy state of soil water and that of pure water. Essentially a measure of the energy required to extract moisture from soil.
Stable isotope	An isotope that does not undergo radioactive decay.
Standard Wilting Point	The minimum LWP or corresponding soil moisture potential that can be tolerated before a plant wilts in response to negative water supply. This is accepted at -15 bars or -1.5 MPa (or -217.55 PSI)
Specific Yield	The ratio of the volume of water that a saturated rock or soil will yield by gravity to the total volume of the rock or soil.
Surface water	Movement of water above the earths' surface as runoff or in streams
Transpiration	The process of water loss from leaves, through stomata, to the atmosphere.
Terrestrial GDE	Terrestrial vegetation supported by sub-surface expression of groundwater (i.e. tree has roots in the capillary fringe of groundwater table).
Vadose zone	The unsaturated zone, above the water table in unconfined aquifers

Water Potential	The free energy potential of water as applied to soils, leaves plants and the atmosphere.
Wetting front	The boundary of soil wet by water from rainfall and dry soil as the water moves downward in the unsaturated zone.

1.0 Introduction

Magnetic South Pty Ltd (Magnetic South) (the 'Proponent') proposes to develop the Gemini Project located approximately 110 km east of Emerald and 125 km west of Rockhampton, within the Bowen Basin, Central Queensland, herein referred to as 'the Project' (**Figure 1**). The project centres on Mining Lease Application (MLA 7000556) and will mine metallurgical coal using open cut mining methods, with the operational footprint including both mining pits and associated infrastructure.

Coal mining developments have potential to alter natural groundwater regimes or groundwater quality and may therefore impact on ecosystems that are reliant on a groundwater resource. These ecosystems are captured under the general term of groundwater dependent ecosystems (GDEs). This report provides an assessment of the presence of GDEs within the Project area and includes an assessment of potential project related impacts to GDEs.

1.1 Project Background

The main activities associated with the Project include:

- Exploration activities continuing to support mine planning.
- Development of a Mine Infrastructure Area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, explosives magazine and sewage, effluent and liquid waste storage.
- Construction and operation of a facilities specific to coal handling including Run-of-Mine (ROM) coal, product stockpiles and rejects bin/overflow.
- Construction and operation of a surface conveyor including rail loading facilities connecting to coal terminals at Gladstone for export.
- Construction of access roads from the Capricorn Highway to the MIA. Development of internal roads and mine haul roads will be ongoing including a causeway over Charlevue Creek.
- Installation of a raw water supply pipelines, 66 kV transmission line and substation.
- Development of mine areas (open cut pits) and out-of-pit waste rock emplacements as well as drilling and blasting of competent waste material.
- Mine operations using conventional surface mining equipment (excavators, front end loaders, rear dump trucks, dozers) and progressive placement of waste rock in emplacements adjacent to and near the open cut voids.
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works) with material sourced from quarries where required.
- Development of water storage dams and sediment dams, and the installation of pumps, pipelines, and other water management equipment and structures including temporary levees, diversions, and drains.

Mining will extract up to 1.9 Million tonnes per annum (Mtpa) ROM Coal, with an average 1.8 Mtpa for a construction/production period of approximately 20 years. The project footprint is shown in **Figure 1**.

1.2 Project Objectives

Objectives of GDE assessment are to:

- Identify if vegetation within and surrounding the Project area accesses and utilises groundwater for transpiration, either permanently or intermittently, consistent with classification of a GDE.
- Determine the source and nature of aquifers utilised by GDEs, if any.
- Identify the degree of dependence of vegetation communities on groundwater for survival and sustenance through periods of drought.
- Provide an assessment of potential mining impacts on identified GDEs extending throughout the life of the mine.

1.3 Relevant Legislation

Environmental Protection Act 1994: Under regulatory provisions of the Environmental Protection Act 1994 (EP Act), a site-specific Environmental Authority (EA) is required under Section 125 of the EP Act. A component of the EA will be requirement is to address impacts to GDEs, and this report has been prepared in response to an information request requiring further assessment of the potential for impact to GDEs.

1.4 GDE Definition Used for Assessment

The definition of a GDE applied to this assessment is consistent with the definition provided in the guidance document *Modelling water-related ecological responses to coal seam gas extraction and coal mining* prepared by Commonwealth of Australia (2015) on the advice from the Independent Expert Scientific Committee on Coal Seam Gas and Large Coal Mining Development (IESC) and IESC 2018a. This definition is described below:

> *Groundwater dependent ecosystems (GDEs): Natural ecosystems which require access to groundwater on a permanent or intermittent basis to meet all or some of their water requirements so as to maintain their communities of plants and animals, ecological processes and ecosystem services (Richardson et al. 2011). The broad types of GDE are (*from *Eamus et al. 2006a and 2006b):*
>
> - Ecosystems dependent on surface expression of groundwater (springs).
> - Ecosystems dependent on subsurface presence of groundwater (terrestrial GDEs).
> - Subterranean ecosystems (caves).

Ecosystems dependent on surface expression of groundwater are extended to spring fed streams and rivers, otherwise defined as aquatic GDE's.

1.5 Groundwater Definition Used in this Assessment

Eamus (2006a) defines groundwater (when related to GDEs) as;

> *'all water in the saturated sub-surface; water that flows or seeps downwards and saturates soil or rock, supplying springs and wells, water stored underground in rock crevices and in the pores of material'.*

For this assessment of GDEs, the term groundwater refers to those areas in the sub-surface where all soil or rock interstitial porosity is saturated with water including the associated capillary fringe. It is assumed that in the overlying unsaturated zone, water may be present in varying amounts over time although saturation is rarely reached during infiltration or percolation of rainfall, stream water or other surface sources of groundwater recharge moving under gravity. The definition of groundwater excludes wetting fronts, being the transitional zone between wet and dry soil that surrounds a water body; and ephemeral zones of saturation that result from rapid infiltration pf surface water, whereby the down-gradient migration of infiltrating water is merely slowed rather than halted.

1.6 Climatic Considerations

The annual rainfall at Duaringa Post Office (25km to the east) for January 2019 to June 2020, being the nearest reliable recording station to the Project, is presented in **Figure 2**. The data indicates below average rainfall for nearly all months through 2019 with a total rainfall of 321.3mm for the year, being half the long-term annual average of 704.3mm (BOM 2020a). February 2020, four months preceding the survey, was extremely wet with 346.7mm falling for the month compared to the long-term monthly average of 115.3mm. Following this intense period of precipitation, rainfall for the four months preceding the survey (March to June 2020) was dry with below average rainfall recorded across all months. There was no rainfall recorded at Duaringa for two weeks preceding the survey which was completed across 6 days from 27th June 2020 to 2nd July 2020.

Plant growth in the region is strongly limited by moisture rather than temperature (Hutchinson et al. 1992) which is reflected in the evapotranspiration rates at the Duaringa Post Office for the 2019 – 2020 period, with data for all months indicating evapotranspiration as being considerably higher than rainfall except in February 2020. Annual evapotranspiration rates tend to peak in January and are typically at their lowest in June / July (**Figure 3**) (BOM 2020a).

The region has experienced several significant drought events, many of which have resulted in tree dieback. The early to mid-1990's drought, the worst on record for central and north Queensland, and the millennium drought from 2000 through to 2007 both resulted in substantial dieback of native woodland habitats, typically affecting ironbark woodlands and most severely on basaltic substrates (Fensham and Holman 1999; Fensham et al 2009). **Figure 4** demonstrates the major climatic cycles in terms of Cumulative Rainfall Departure (CRD) (Weber and Stewart 2004), representing a cumulative departure of monthly rainfall from the long-term mean monthly rainfall (1990 to 2020) from point data at Dingo (SILO 2020). Strongly decreasing rainfall trends between 1990 to 1996; and 2000 to 2007 representing major drought periods are strongly evident. Following a period of relatively stable / average rainfall conditions occurring between 2013 to 2017, the current trend is for decreasing rainfall with below average conditions experienced post 2017 indicating a longer-term regime of ecological water deficit preceded the assessment. The analysis of cumulative rainfall departure is relevant to this assessment as shallow water tables generally follow similar trends, with rising water tables during upward precipitation trends.

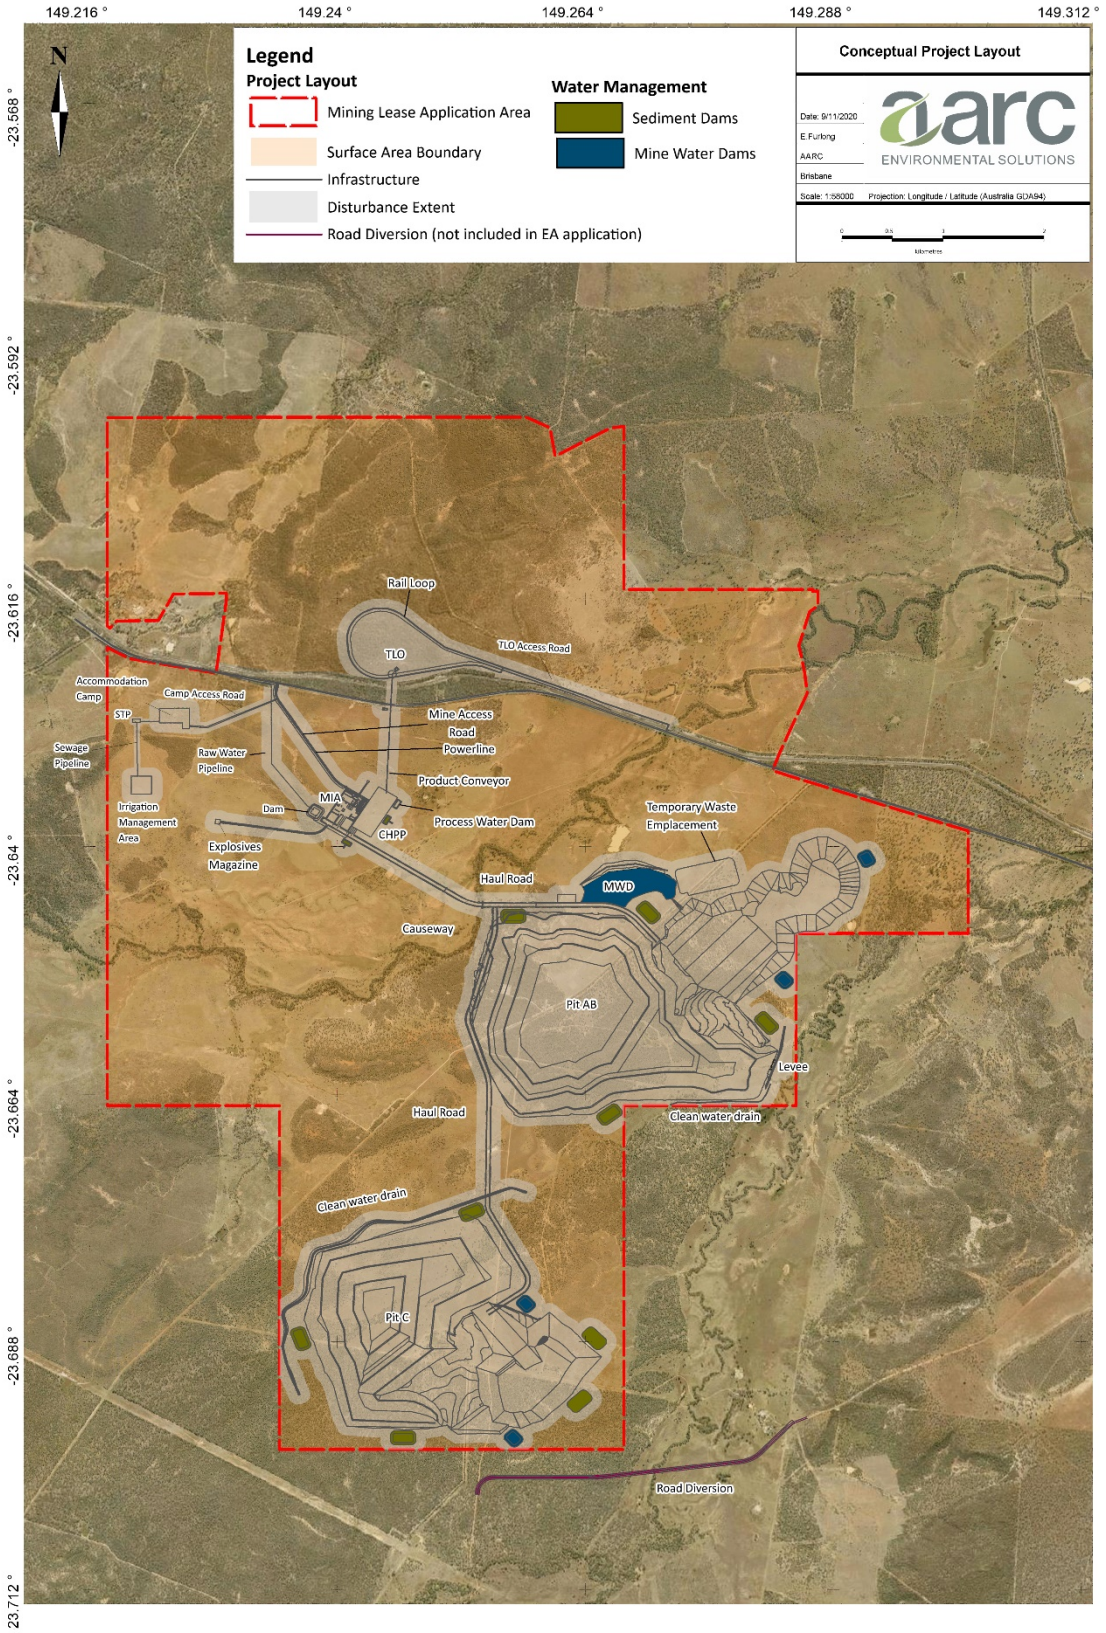

Figure 1. Project location and facilities.

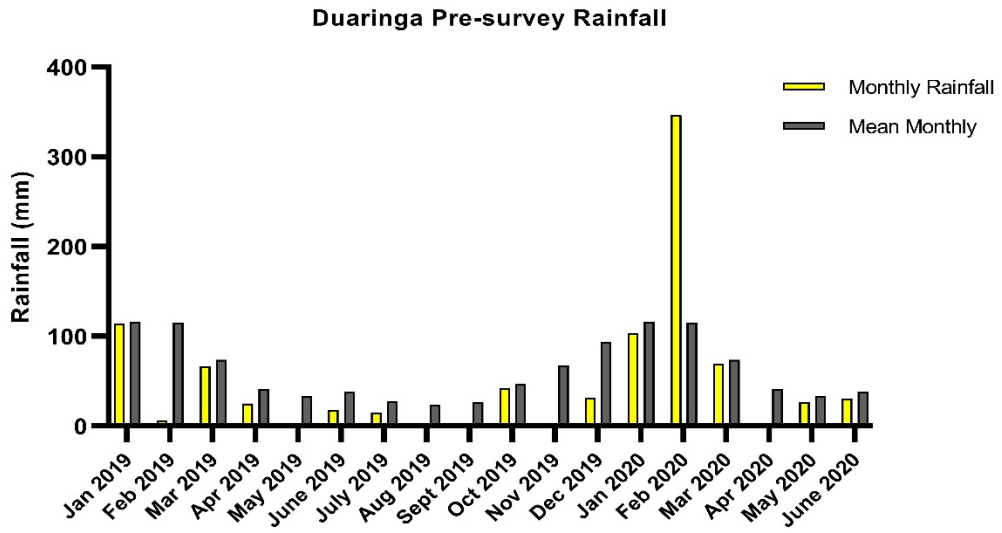

Figure 2. Rainfall for the period from January 2019 to June 2020 from the Duaringa Post Office recording station.

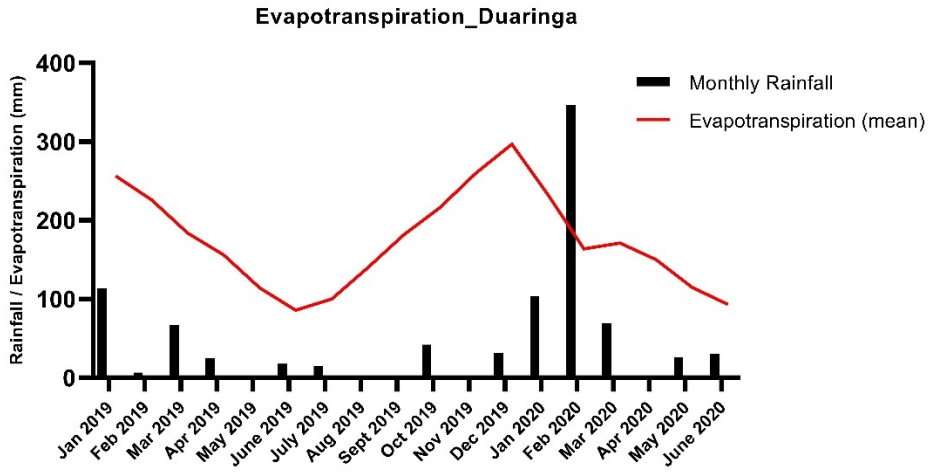

Figure 3. Evapotranspiration compared to rainfall for January 2019 to March 2020 from the Moranbah Airport.

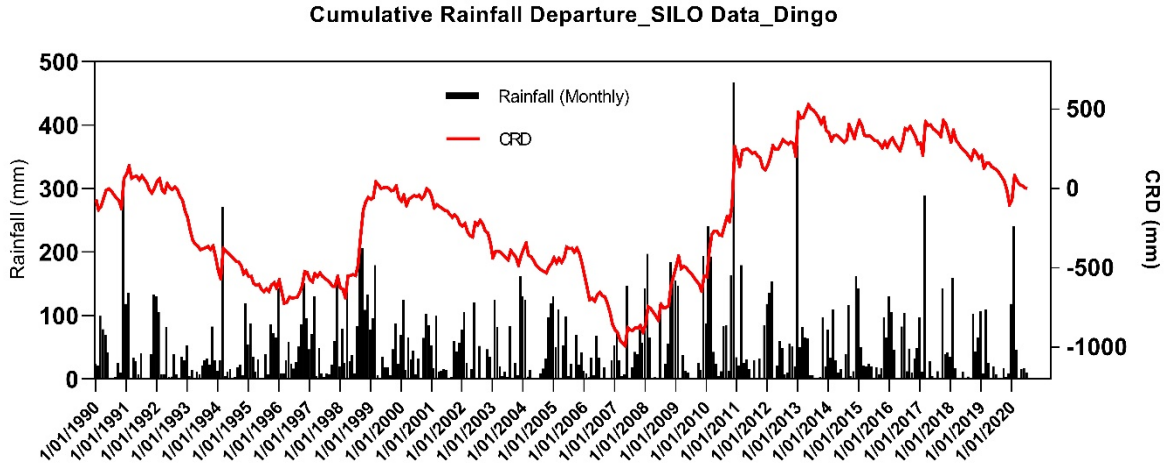

Figure 4. Cumulative Rainfall Departure calculated for Dingo from SILO (2020) indicating a drying climatic cycle leading up to the survey in June 2020.

2.0 Ecohydrological Setting

As GDEs define a continuum between groundwater, soils and surface ecology, this section provides a description of both biotic factors and abiotic controls, enabling linkages to be drawn between groundwater and terrestrial ecology within impact assessment sections.

2.1 Ecological Characteristics of GDE Species and Communities

2.1.1 Regional Ecosystems

Regional ecosystem (RE) mapping completed by AARC (2019), provided in **Figure 5**, for the Project defines broad number of regional ecosystems, typically dominated by eucalypt woodland and open forest habitats. This includes:

- RE 11.3.25, dominated by forest red gum (*Eucalyptus tereticornis)* and river red gum (*Eucalyptus camaldulensis)* with scattered Moreton Bay ash (*Corymbia tessellaris*), Clarkson's bloodwood (*Corymbia clarksoniana*) and river oak (*Casuarina cunninghamia*) is the dominant regional ecosystem associated with major watercourses and drainage lines in the Project area.
- RE 11.3.2, dominated by poplar box (*Eucalyptus populnea*) associated with loamy flood plain areas on older, higher alluvial terraces. RE11.3.2 is typically mapped as a terrestrial GDE in BOM GDE mapping databases (BOM 2020b).
- RE11.5.2, typically dominated by narrow leaf ironbark (*Eucalyptus crebra*) with scattered poplar box occurring on older residual sands and gravels above flood level.
- 11.7.2 dominated by lancewood (*Acacia shirleyi)* on residual jump ups.

The dominant species within these regional ecosystems and their potential capacity to utilise groundwater are discussed in **Section 2.1.3**.

2.1.2 Mapped Groundwater Dependent Ecosystems

The mapping of GDEs has been completed at a national level by the Bureau of Meteorology which has produced the GDE Atlas (BOM 2020b) which identifies the following GDEs types, consistent with the definition of a GDE applied in this assessment.

- **Aquatic** ecosystems that rely on the surface expression of groundwater–this includes surface water ecosystems which may have a groundwater component, such as rivers, wetlands, and springs. Marine and estuarine ecosystems can also be groundwater dependent, but these are not mapped in the Atlas.
- **Terrestrial** ecosystems that rely on the subsurface presence of groundwater–this includes all vegetation ecosystems.
- **Subterranean** ecosystems–this includes cave and aquifer ecosystems.

The BOM GDE layer has been compiled with national scale datasets and rules to describe the potential for groundwater interaction, and within the assessment area corresponds directly with GDE and potential aquifer mapping produced by DES (2018). Due to the limited ground verification, the dataset is considered unsuitable for site specific GDE assessment. The mapping of GDEs over the Project Area and surrounds, as produced by BOM (2020b) is provided in **Figure 6**. In general, this

assessment shows 'Low Potential' for 'Terrestrial' GDEs associated with riparian vegetation and watercourses. It is noted that an area mapped as a 'High Ecological Significance' wetland is also indicated on **Figure 6**, which in prior versions of the GDE Atlas was mapped as a 'Low Potential Aquatic GDE' (refer to Terrestrial Ecology Assessment prepared by AARC 2019). Updates to the GDE Atlas incorporated in August 2020 no longer consider this wetland area to represent a GDE, either terrestrial or aquatic.

2.1.3 Groundwater Dependent Species

Eucalypts: The GDE investigation area and surrounds are characterised by the presence of both river red gum (*Eucalyptus camaldulensis)* and forest red gum *(Eucalyptus tereticornis*) which typically form the upper canopy of the riparian ecosystem RE11.3.25. Moreton Bay ash *(Corymbia tessellaris)* and minor Clarkson's bloodwood (*Corymbia clarksoniana)* are found in some localities, more typically in elevated positions on the riverbank. Poplar box *(Eucalyptus populnea)* is more typically found on elevated upper terraces at greatest distance and elevation from the stream channel.

River red gum is a well-studied species known to have deep sinker roots, hypothesised to grow down towards zones of higher water supply (Bren et al., 1986) and the species mixes with forest red gum along the river frontage. For this assessment, the physiological attributes of river red gum and forest red gum are assumed to be similar as the species can inhabit and mix within a similar ecological niche. Forest red gum is however a more adaptable species, occupying dry hill slopes in some localities and it would be expected to be more tolerant of changes to hydrological regime than *Eucalyptus camaldulensis* which is a riparian specialist. Malik and Sharma (2004) found that *Eucalyptus tereticornis* also has a strong capacity to extract moisture from the shallow soil profile (0 – 150cm). Therefore, attributing forest red gum with the ecological characteristics of the more specialised river red gum is prudent from a risk management perspective, because it adopts the attributes of the species with the highest sensitivity.

River red gum is adapted to arid and semi-arid environments and will go through alternate phases of shedding and regaining its crown, depending on the availability of water and it is adapted to do so and over time and across the flood frequency classes, having capacity to self-regulate and adjust their transpiration rates to match the average flood return interval (Collof 2014) while the species maintain a strong capacity for genetic selection to increase capacity for the species to survive drought stress. Trees less able to survive drought tend to die off, hence the genes that are associated with drought tolerance traits become more common in the remaining population.

The species is considered opportunistic in its water use, sourcing water according to osmotic and matric water potential and source reliability (Thorburn et al., 1993; Mensforth et al., 1994; Holland et al., 2006; Doody et al., 2009) with the water requirements obtained from three main sources being groundwater, rainfall, and river flooding. Flooding enables the species to survive in semi-arid areas (ANBG 2004) where stands are intimately associated with the surface-flooding regime of watercourses and related groundwater flow. River red gum are considered a facultative phreatophyte, shifting between a combination of surface soil moisture and groundwater during periods of high rainfall, then shifting to exclusive use of groundwater during drier periods. They are likely to achieve this shift through inactivation of surface roots during drier periods with increased reliance on deeper tap roots when surface water is unavailable. River red gum will often use saline

groundwater in preference to fresh surface water, probably because it represents a more reliable supply (Colloff 2014). Doody et al. (2015) demonstrated that soil moisture alone can sustain the health of *Eucalyptus camaldulensis* through periods of drought up to six years before significant decline in tree health is noted.

The maximum potential rooting depth of river red gum is subject to considerable conjecture in current literature, although it is widely accepted that the species has capacity to access deep groundwater sources (Eamus et al 2006a). Horner et al. (2009) found rooting depths at 12–15 mbgl based on observed mortality in plantation river red gum forests on the Murray River Floodplain. From excavations in 20 year-old plantation forests of *Eucalytpus tereticornis,* Kallarackal and Somen (1998) found that roots were traceable to depths of 9.3 mbgl and Jones et al (2020) found maximum rooting depths of 8.1 mbgl in river red gum in a broad study area in the Great Artesian Basin. In conclusion, maximum rooting depth of red gum is likely to be variable, dependent on-site geology and depth to saturation with the capillary fringe being the general depth at which root penetration will be arrested (Eamus et al 2006b).

All eucalyptus species are potential users of groundwater (Cook et al 2007) although few studies demonstrating this dependence exist. Fensham and Fairfax (2007) consider both poplar box and narrow-leaved ironbark to possess a shallow rooting system with limited investment in deep root architecture, rendering them susceptible to droughting. Poplar box is more typically associated with upper terraces that are elevated above the river channel requiring a deeper rooting system to access groundwater. Narrow leaf ironbark generally occupies more elevated portions of the landscape, away from drainage lines where depth to groundwater would be greatest. For the remaining species, O'Grady et al (2006b) concluded the following when studying groundwater usage of trees on a tropical floodplain savannah:

1. Clarkson's bloodwood utilised groundwater when the water table was at 10 mbgl indicating the potential for the species to develop a deep sinker root. Clarkson's bloodwood should be considered a facultative phreatophyte. It is likely that Clarkson's bloodwood occurring on the banks of ephemeral watercourses will utilise groundwater if it is within reach of rooting depth and not saline.
2. Moreton Bay ash demonstrated groundwater usage when the water table was at 4 mbgl, although it is not known whether the species has capacity to utilise deeper groundwater sources. Moreton Bay ash should be considered a facultative phreatophyte.

Both Moreton Bay ash and Clarkson's bloodwood are scattered throughout the frontages of Springton and Charlevue Creek's within RE11.3.25, generally occupying lower terraces where depth to groundwater decreases.

River oak: The water use strategy of river oak (*Casuarina cunninghamiana)* appears dependent on its position relative to a watercourse. O'Grady et al (2006b) determined river oak mainly utilised river water when adjacent to a stream channel, which is its most common topographic position. There has been no demonstration that river oak has capacity to utilise deeper groundwater sources. River Oak is not considered to be groundwater dependent in the Project area.

Lancewood: The acacia's, in particular lancewood, are considered shallow rooted species and based on their ecological preference for elevated portions of the landscape, are considered unlikely to utilise groundwater to any degree.

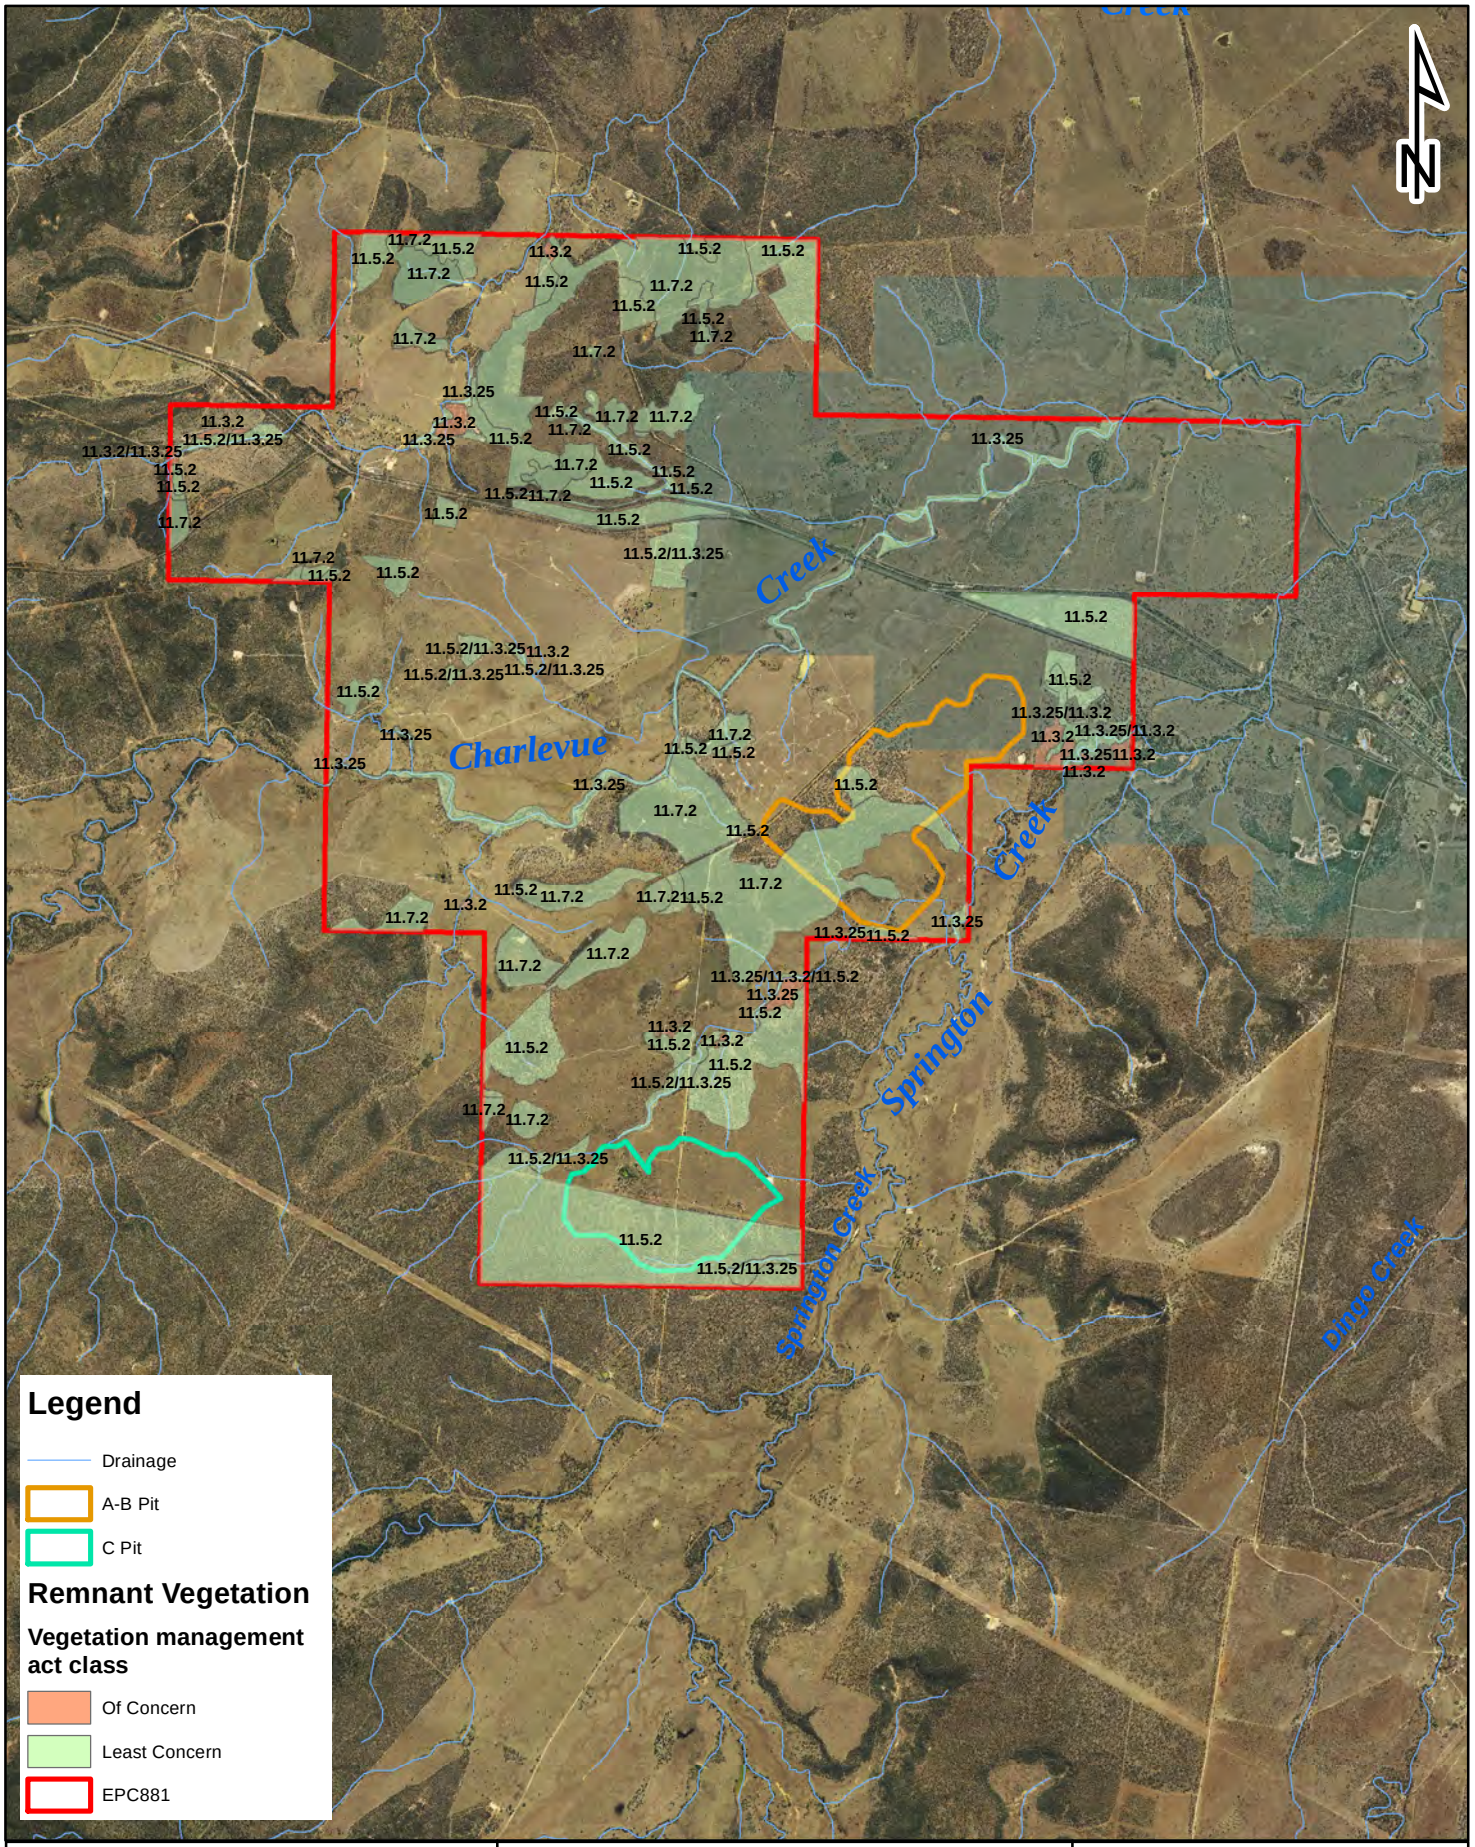
2.2 Hydrogeological Setting

The project mining area is in the north-west extent of the Bowen Basin, a broad sedimentary basin formed in the Permian / Triassic period with a variable cover of Tertiary period sediment and basic volcanic rocks (basalts). The surface geology is summarised from DNRM (2018) as below:

- Quaternary age alluvial deposits are associated with the major drainage features of Charlevue and Springton Creek's which occur to the west and east of the proposed mining area respectively.
- The Tertiary age Duaringa Formation dominates the surface geology providing exposures of weathered mudstone, sandstone, siltstone and conglomerate.
- Residual ferricrete occurs as scattered surficial deposits throughout the landscape.
- Permian period sedimentary rocks of the Rangal Coal Measures (Rr) which includes the economic seams to be mined, though are not exposed at the surface within the area of development (see **Figure 7**).

JBT Consulting (2020) describes the hydrogeological regimes associated with the various lithologies in the assessment area. Information from this assessment, coupled with more recent ground water quality data, is summarised below:

- Recharge of the alluvium is via direct rainfall with the water level ranging from 8.77 m to 11.19 mbgl for bores adjacent to the creek channels. The EC at bore DW7076W (Charlevue Creek alluvium) ranges from 14,439 µS/cm to 17,106 µS/cm. Field value from bore DW7292W1 (Springton Creek alluvium) range from 1669 - 5948 µS/cm. Hydraulic conductivity (K value) measured in the alluvium from a single monitoring bore is 0.097 m/day, with rates calculated by chloride mass balance to range from 0.4 to 0.8 mm/year indicative of extremely low rates of infiltration.
- The Tertiary sediments of the Duaringa formation are variably saturated with the elevation of the base of Tertiary being a control on the occurrence of water within the sediments. The water level with the Tertiary sediments ranges from dry (5 bores, ranging in depth from 14 to 23 m) to 15.38-44.74 mbgl (where water is present). Recharge of the Tertiary sediments is via direct rainfall calculated by chloride mass balance to range from 0.4 to 0.8 mm/year. The salinity of groundwater in the Tertiary sediments ranges from 1, 439 (DW7220W1) to 26, 831 µS/cm (DW7282W1) indicative of a low rate of recharge as well as a long residence time for groundwater.
- Groundwater in the Permian sediments occurs preferentially in the coal seams due to the open nature of the cleats, providing a conduit for infiltrating rainfall. Standing water level (SWL) in the coal seam ranges from 16.91 to 46.62 mbgl. Interburden is hydraulically tight with (K = 0.001 to 0.002 m/day) compared to the coal seams where hydraulic conductivity is typically much higher, ranging from 0.002 to 5.387 m/day. Salinity of groundwater in coal seams ranges from 984 µS/cm (DW7105W2 in the Pollux lower to upper seam) to 33,343 µS/cm.



While direct infiltration of rainfall will be the predominant source of groundwater recharge over much of the Project area, surface flows and seasonal flooding on drainage lines will provide a significant localised source of recharge for alluvial sediments, particularly along the major watercourses of Charlevue and Springton Creeks .

A summary of groundwater monitoring bores used to inform the assessment of GDEs, including target unit, standing water level (SWL), salinity (EC) is provided in **Table 1** summarised from the hydrogeology report produced by JBT (2020) and groundwater monitoring data collected in May to September 2020. The location of groundwater monitoring bores is shown in **Figure 8**.

Table 1. Details of groundwater monitoring bores used to inform assessment.

Hole	Groundwater Unit	SWL (mbgl)*	Field Salinity Range (µS/cm)**
DW7076W	Alluvium	8.77	14439 – 17106
DW7292W1	Alluvium	11.19	1669 - 5948
DW7220W1	Tertiary	15.38	1439 - 1757
DW7225W1	Tertiary	32.37	9425 – 10348
DW7282W1	Tertiary	26.25	22483 - 26831
DW7033W1	Tertiary	29.94	7001 - 7748

3.0 Methods

The following section provides an overview of methods used to assess groundwater dependence of vegetation within the Project Area and surrounds. It describes site selection, use of shallow hand auger holes, assessment of leaf water potential (LWP), soil moisture potential (SMP) and analysis of stable isotope composition in a manner that is consistent with Jones et al (2020) and supplemented with methodology from Richardson et al (2011), IESC (2018b) and Eamus (2009).

Field assessment was completed over a six-day period from the 27th June 2020 to 2nd July 2020. In prior reference to **Figure 3**, Weather conditions during the survey were mild to warm, with an estimated maximum daily temperature from 26°C to 30°C.

3.1 Site Selection

The survey focused on areas mapped as potential GDEs in BOM (2020b) with additional sites identified where vegetation characteristics were otherwise indicative of potential groundwater dependence. Assessment sites were generally confined to drainage lines including the larger systems of Springton and Charlevue Creek. In total, four broad areas were targeted for assessment (as per **Figure 9**) being:

1. Charlevue Creek Area1 providing representation of a reach of Charlevue Creek where riparian vegetation is well developed and preserved within a broad alluvial flood plain. Vegetation in this area is mapped as RE11.3.25 in AARC (2019) and the area is considered representative of the best developed and preserved riparian vegetation within the Project area. This area was targeted in Sites M7, M8 and M9. Charlevue Creek in this area is incised into a broad alluvial flood plain to a depth of approximately 6m with a sandy channel floor (see **Figure 9**).
2. Charlevue Creek Area 2 provides representation of a more disturbed reach of Charlevue Creek where riparian vegetation has been reduced to a thin strip within the confines of the river channel and immediate stream banks. This area is similar to Charlevue Creek Area 1 though vegetation is not as well preserved, and the area is not recognised as a potential GDE in the GDE Atlas (BOM 2020b). Charlevue Creek Area 2 was sampled in Sites M10 and M12.
3. Springton Creek Area 1 provides a representation of the riparian vegetation fringing Springton Creek which is in closest proximity to the proposed AB Pit. Vegetation on this reach is mapped as RE11.3.25 in AARC (2019) with flood plain vegetation, represented by RE11.3.2, extending for several hundred metres on either side of the flood channel in some localities. All fringing vegetation is mapped as a 'low potential' terrestrial GDE in the GDE Atlas (BOM 2020b). Springton Creek Area 1 was sampled at Sites M5, M6 and M14. Site M14 was specifically targeted within the road reserve as a representation of RE11.3.2 (*Eucalyptus populnea* dominant woodland), an ecosystem which could not be sampled elsewhere within the EPC Area due to land access restrictions.
4. Springton Creek Tributary Area 1, provided representation of a larger ephemeral tributary of Springton Creek which is closest to C Pit. Vegetation is mapped as a 'low potential' terrestrial GDE in the GDE Atlas (BOM 2020b). The area was assessed with Site M1 and M4.

Other more discrete targets were chosen to test for groundwater dependence in other areas including:

1. Site M2, targeting an area mapped as a 'low potential' GDE that was mapped as RE11.5.2 in vegetation mapping completed by AARC (2019).
2. Site M3, targeting a mapped 'low potential' GDE within a minor depression that drains into Springton Creek.
3. Site M11, targeting another area mapped as a 'low potential' GDE within a minor depression that drains into Charlevue Creek. Vegetation is mapped as RE11.5.2 in the terrestrial ecology report prepared by AARC (2019).
4. Site M13, targeting the riparian fringe of Charlevue Creek in an off-tenure location, within an area not recognised as a potential GDE (BOM 2020b).

The HES Wetland mapped to the east of the assessment area (see **Figure 6**) was also observed from the road edge during field inspection, though could not be accessed on foot due to entrance restriction imposed by the landowner. The location of all GDE assessment localities is shown in **Figure 10**.

3.2 Hand Auger Sampling

Where practical, a hand auger placed to a maximum depth of 2.35m was utilised to sample shallow soil and sub-soil and collect samples at varying depths in the soil profile. Hand auger placement was limited by substrate and the auger could not penetrate deeply in some localities due to hard substrates, or refusal occurred at relatively shallow depths in the soil profile due to the presence root material. In total, 19 auger holes were placed across the 14 GDE assessment sites. Within each auger hole, the following observations were made at regular depth intervals:

1. Soil structure, colour, and texture.
2. Presence of root matter.
3. Soil moisture / water and depth to saturation.

Soil sampling was undertaken at regular intervals (generally 0.2m with following samples taken every 0.5m) down the soil profile for analysis of stable isotopes of oxygen (δ18O) and deuterium (δ2H). Duplicate samples were retained for analysis of soil moisture potential (SMP). The location of hand auger samples is shown in figures relevant to each GDE assessment site (see **Section 4.0**).

3.3 Leaf Water Potential

Leaf Water Potential (LWP) is defined as the amount of work that must be done per unit quantity of water to transport that water from the moisture held in soil to leaf stomata. LWP consists of the balance between osmotic potential, turgor pressure and matric potential. It is defined as the amount of work that must be done per unit quantity of water to transport that water from the moisture held in soil to leaf stomata. It is a function of soil water availability, evaporative demand, and soil conductivity.

LWP was measured pre-dawn (prior to sunrise) as per standard protocol. Due to a lack of transpiration, LWP will equilibrate with the wettest portion of the soil that contains a significant amount of root material. Pre-dawn LWP will shift to a lower status as soil dries out on a seasonal basis (Eamus 2006a). Measurement pre-dawn LWP thus gives an indication of the water availability to trees at each assessment site and provides an indication as to whether trees are tapping saturated zones of the soil profile where water is freely accessible, or utilising moisture that is more tightly bound to soil particles.

Survey localities were visited pre-dawn (first light to pre-sunrise) and leaves were collected from the canopy with the aid of a 7.5m extension pole fitted with a lopping head. Leaves were collected from three to six mature canopy trees at each site with 66 trees sampled in total across all assessment areas. Collected samples were double bagged in black plastic to avoid moisture loss and sun exposure and LWP was measured on-site within half an hour of harvest. Suitable leaf material was trimmed with a fine blade and inserted into an appropriate grommet for sealing within a Model 3115 Plant Water Status Console (Soil Moisture Equipment Corp, 2007). The chamber was sealed and gradually pressurised with nitrogen until the first drop of leaf water emerged from the petiole. Two reading readings were taken at each GDE site to calculate an average with a third taken where significant differences between reading was noted. Readings were taken in pounds per square inch (PSI) which is converted to a negative value in millipascals (MPa) for direct comparison to SMP

measurements. The location of trees sampled for LWP relative to GDE assessment areas is shown in provided in **Section 4.0.**

3.4 Soil Moisture Potential

Duplicate samples collected during soil augering were subject to analysis of SMP (SMP) at regular intervals with an aim to collect samples at 0.2 mbgl, 0.5 mbgl and at 0.5 to 1.0m intervals to the end of hole. As samples were collected, they were immediately sealed in airtight plastic vials and placed on ice. For each interval sampled, one sample was dispatched to the Australian National University (ANU) Stable Isotope Laboratory (Farquhar Laboratory) for the analysis of the naturally occurring stable isotopes of hydrogen and oxygen within soil moisture (see **Section 3.6.1**). The second sample was retained for the measurement of laboratory tested SMP.

SMP, which includes the matric (dryness) and osmotic (saltiness) potential, is a measure of the energy required to extract moisture from soil. Water only has capacity to move down a hydraulic gradient from soil to root (Gardner 1960) and only areas in the soil profile that have a SMP that is less negative than measured pre-dawn LWP will be accessible as a source of moisture. It is widely agreed in ecohydrology and plant physiology fields, that large, mature trees are unable to extract moisture from regions in the soil profile where the total SMP is significantly below LWP measured in pre-dawn leaf material (Feikema et al. 2010, Lamontagne et al. 2005, Thorburn et al. 1994, Mensforth et al. 1994, Holland et al 2009 and Doody et al. 2015).

For crops, the maximum suction roots can apply to a soil/rock before a plant wilts due to negative water supply is approximately -15 bars or -1.5 MPa (or -217.55 psi). This wilting point is considered relatively consistent between all plant species (Mackenzie et al, 2004), although many Australian plants have adapted to conditions of low water availability and can persist strongly in soil conditions where soils moisture potential is below standard wilting point (Eamus 2006a). As a general measure however, where measured LWP is below standard wilting point, it indicates plant water deficit, and the tree is unlikely to be supported by a saturated water source unless highly saline.

The measurement of SMP was completed in the laboratory by a portable Dew Point Potentiometer (WP4C) (Meter Group Inc, 2017). The WP4C meter uses the chilled mirror dew point technique with the sample equilibrated within the headspace of a sealed chamber that contains a mirror and a means of detecting condensation on the mirror. Soil moisture potential samples were measured in megapascal pressure units (MPa). A single 7 ml soil sample was inserted into the WP4C meter using a plastic measuring tray with a stainless-steel base.

3.5 Stable Isotope Sampling and Analyses

Trees may utilise water from a range of sources including the phreatic zone (saturated zone), the vadose zone (unsaturated zone) and surface water. The stable isotopes of water, oxygen 18 (18O) and deuterium (2H) are useful tools to help define the predominant source of water used by terrestrial vegetation. The method relies on a comparison between the stable isotope ratios of water contained in plant xylem (from a twig or xylem core) with stable isotope ratios found in the various sources of water including a shallow groundwater table, potential sub-artesian aquifer water sources or shallow soil moisture. Methods used to assess stable isotopes are detailed below.

3.5.1 Soil moisture isotopes

Sampling was undertaken at regular intervals in auger holes to capture isotopic signatures from a range of potential plant moisture sources from the upper soil surface to the top of the phreatic zone in shallow water tables. The sampling intervals for soil moisture isotope analyses was dependent on auger yield and soil variation although in general, the initial soil sample taken within the top 20cm of the soil profile and subsequent samples taken at 0.5m intervals down the soil profile to the end of hole. Approximately 200mg of soil was collected for isotope analysis, sealed in airtight plastic sampling containers, double sleaved in click-seal plastic bags and placed on ice for storage prior to dispatch to ANU Stable Isotope Laboratory for analysis where they were snap frozen until analysis was complete.

3.5.2 Xylem water isotopes

Twigs were collected from the outer canopy branches of target trees used to sample LWP. The following sampling procedure was applied:

1. Outer branches of trees of the GDE target tree were harvested for twig material. Two duplicate samples were prepared from each branch for analysis.
2. The position of trees subject to assessment were marked with a GPS and structural measurements were recorded including height and diameter at breast height (dbh).
3. Outer branches from each tree were harvested with an extendable aluminium pole.
4. Stem material equivalent approximately 5cm in length was sourced using clean stainless-steel secateurs.
5. Bark was immediately removed, and stems were sealed in wide mouth sample containers with leakproof polypropylene closure (approx. 125ml volume) and immediately labelled with the tree number and placed in an iced storage vessel prior to dispatch to the ANU Stable Isotope Laboratory.
6. Upon receipt of samples at the ANU Stable Isotope Laboratory, samples were snap frozen (-18°C) until analysis.
7. For all twigs, samples were taken from xylem as close to the centre of twig as possible. For both xylem and soil samples, extracted water was analysed using a Picarro L2140i cavity ring-down spectrometer.

For xylem water analysis, multiple samples were taken from a single branch sample at all sampling localities. From each branch sampled, the twig samples retuning the lowest degree of isotopic enrichment was used as the reference. This is because there may be considerable partitioning of isotope ratios across a twig cross-section (moving from the xylem to phloem) and it is not always possible to sample the same region of a twig consistently when multiple samples are submitted for analysis. There is also potential for fractionation of stable isotope values, particularly 2H, during movement of water through the xylem from roots to leaves (Evaristo et al 2017, Petit and Froend 2018). As fractionation will likely result in isotopic enrichment rather than depletion, the least enriched sample from each tree is considered most likely to be representative of the soil moisture or groundwater source.

3.5.3 Groundwater monitoring bore sampling

To compare the isotopic signature of groundwater to that of vegetation, groundwater samples from developed monitoring wells were collected which were despatched to Australian National University (ANU) for analysis of stable isotopes of oxygen and deuterium. Monitoring wells where groundwater was sampled for stable isotope analysis have been indicated in **Table 1** (**Section 2.2**).

3.5.4 Data reconciliation and interpretation

Data interpretation followed a structured approach in which multiple lines of evidence were filtered to provide an assessment of groundwater dependence. The biophysical measurement of LWP formed the primary assessment, followed by the adjunct comparison with SMP, with stable isotope data used to provide supplementary evidence where ambiguity remained. Further context to the approach is provided below.

Step 1. LWP: An initial comparison was undertaken to identify individual trees with LWP measurements within the expected range for known terrestrial GDEs subject to various salinity regimes. This data is drawn from a range of published sources including Jones et al (2020), Holland et al (2006) and Mensforth et al (1994) and values are conservatively applied against laboratory calculated values for water at various salinity levels (Meter Group Inc, 2017):

- Expected LWP for trees in equilibrium with a fresh to brackish saturated source of moisture (EC<1500 µS/cm) = >-0.2MPa.
- Expected LWP for trees in equilibrium with a moderately saline soil moisture source (EC>1500 to 10 000 µS /cm) =<-0.2MPa to >-0.55MPa.
- Expected LWP for trees in equilibrium with a saline soil moisture source (EC>10 000 to 17 000 µS /cm) = <-0.55MPa to >-0.9MPa.

Trees that demonstrate LWP values that are more negative than expected ranges for the local groundwater salinity regime are assessed to not be groundwater dependent and not subject to additional scrutiny, other than for comparative purposes. A value of 17 000 µS /cm was chosen as a reference as this represents the upper levels of salinity measured in the alluvium at Springton monitoring bore DW7076W (**see Table 1**).

Step 2. SMP: For trees where LWP was within the expected range of values for GDE's under specific local salinity regimes, an assessment of SMP from the auger profile was undertaken to identify the likelihood that moisture for transpiration was being supplied from the upper soil profile, or whether deeper sources of moisture must be inferred. As described in **Section 3.4**, water only has capacity to move down a hydraulic gradient from soil to root meaning that only those portions of the soil profile that have a SMP that is less negative than measured pre-dawn LWP will be accessible as a source of moisture (Gardner 1960). This does not provide an absolute assessment of groundwater dependence though identifies potential sources of moisture to provide context to assessment of stable isotopes (Step 3).

Step 3. Stable Isotope Signatures: For trees that demonstrate potential groundwater dependence from LWP measurements, stable isotope signatures from the xylem samples were compared to signatures from the upper 2m of the soil profile, groundwater, and surface water from pools in creek lines to provide a fingerprint for the source of moisture being utilised.

Where three lines of evidence indicated utilisation of a groundwater source, the tree was generally accepted as being groundwater dependent. Where ambiguity remained in the assessment, additional features were considered including site specific geology, geomorphology, soil physical properties and depth to water table at the location were utilised to inform the final assessment of groundwater dependence for any tree or site.

3.6 Limitations and Other Information Relevant to the Assessment

This assessment provides a snapshot of eco-hydrological process at each of the four GDE assessment localities identified during pre-survey desktop assessment and field reconnaissance. Specific limitations include:

1. Climatic conditions preceding the assessment were dry, although preceding wet season rainfall events (in February 2020) would have saturated shallow portions of the soil profile with residual wetness being present in some soil horizons. Where ambiguity in biophysical measurements were apparent, stable isotope signatures were relied upon to differentiate groundwater from other soil moisture sources.
2. Access was limited in some localities due to landowner / site access restrictions. Sampling localities were modified prior to the assessment to allow sampling to be completed within the constraints of pre-dawn survey requirements. It is not anticipated that changes to original survey plans has negatively influenced or compromised the outcomes of the assessment.
3. Due to the intensive nature of the data collection, representative areas were chosen for GDE sampling which were used as a basis for extrapolation over broader areas considered to present similar ecohydrological function. The data collection process aimed to inform conceptualisation of the types of GDEs present on the site and their general distribution, so an informed risk assessment could be completed.
4. The ecological processes and hydrogeological conditions encountered within the Project area are complex and transient. Interpretations and conceptualisations presented here are based upon multiple lines of evidence and represent what the author considers is the most appropriate interpretation of the data. However continued refinement of the presented conceptual models may result from further data collection.

4.0 Results

Survey results are divided into individual sections which apply to the each of the assessment methods employed including, LWP, SMP and assessment of stable isotopes. For data interpretation and discussion, presented in **Section 5.0**, these data form multiple lines of evidence which are the basis for identification and characterisation of GDEs throughout the Project area.

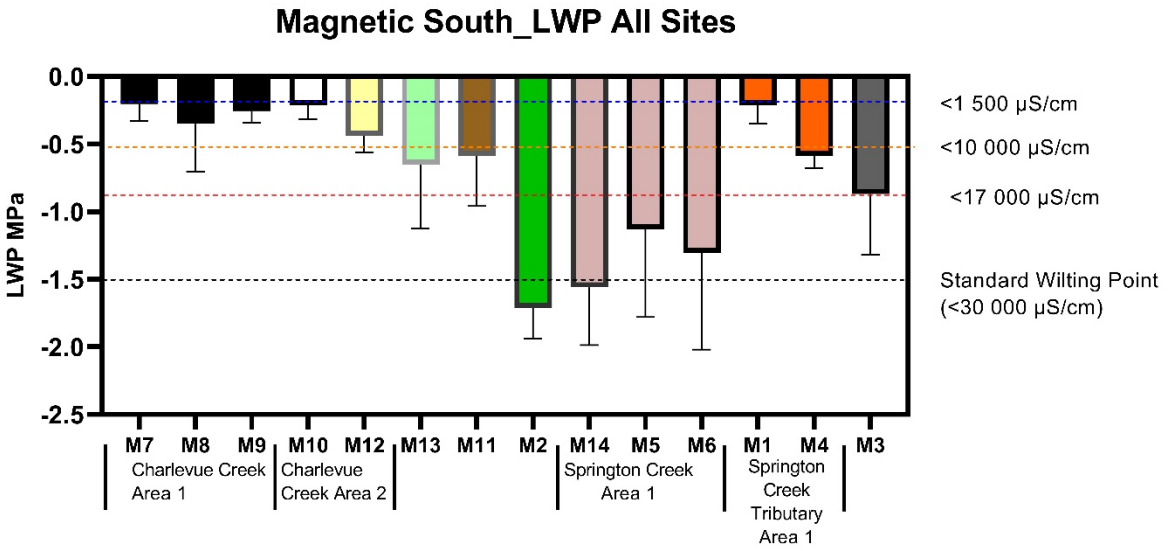
4.1 Leaf Water Potential Measurements

A summary of LWP sampling results for all trees, including locations of sampled trees relative to the watercourse is provided in **Appendix A.** Representation of average LWP results within the four broad assessment areas, including the 14 assessment sites is provided in **Figure 11** with spatial representation of average water availability per site provided in **Figure 12**. The results indicate:

1. The following sites demonstrate average LWP that is consistent with utilisation of a saturated low salinity (<1500 µS/cm) source of moisture, possibly groundwater, or near saturated portions of the soil profile:
    a. Charlevue Creek Area 1 (Sites M7, M8[1] and M9) and Site M10 at Charlevue Creek Area 2.
    b. Site M1 in Springton Tributary Area 1.
2. The following sites demonstrate average LWP values that suggest utilisation of a non-saturated source of readily available soil moisture in the vadose zone, or utilisation of a saline groundwater source with a salinity not greater than 10 000 µS/cm.
    a. Site M4 in Springton Tributary Area 1
    b. Site M12 in Charlevue Creek Area 2.
    c. Site M11 and Site M13.
3. The following sites demonstrate average LWP results indicative of moisture utilisation from a dry portion of the soil profile in the vadose zone.
    a. All sites associated with Springton Creek Assessment Area 1 (Site M5, Site M6 and Site M14).
    b. Site M2 and Site M3.

For point 3, the results of LWP analysis are more negative than would be imparted by use of saline groundwater in the alluvium, attributed with a maximum salinity of 17 000 µS/cm (based on monitoring bore DW7076W on Springton Creek). Based on these results, all sites associated with Springton Creek Assessment Area 1, Site M2 and Site M3 are unlikely to represent terrestrial GDEs with trees sourcing moisture from dry portions of the soil profile / vadose zone. Further analysis of assessment sites listed against Point 1 and Point 2 are provided in the following sections for SMP and stable isotopes. A more comprehensive analysis of LWP data for individual trees is provided in **Figure 13,** which indicates levels of water availability for different species sampled across all sites.

[1] Note average LWP results are inflated through inclusion of Tree 5, which is a Eucalyptus populnea on the margins of the flood plain.



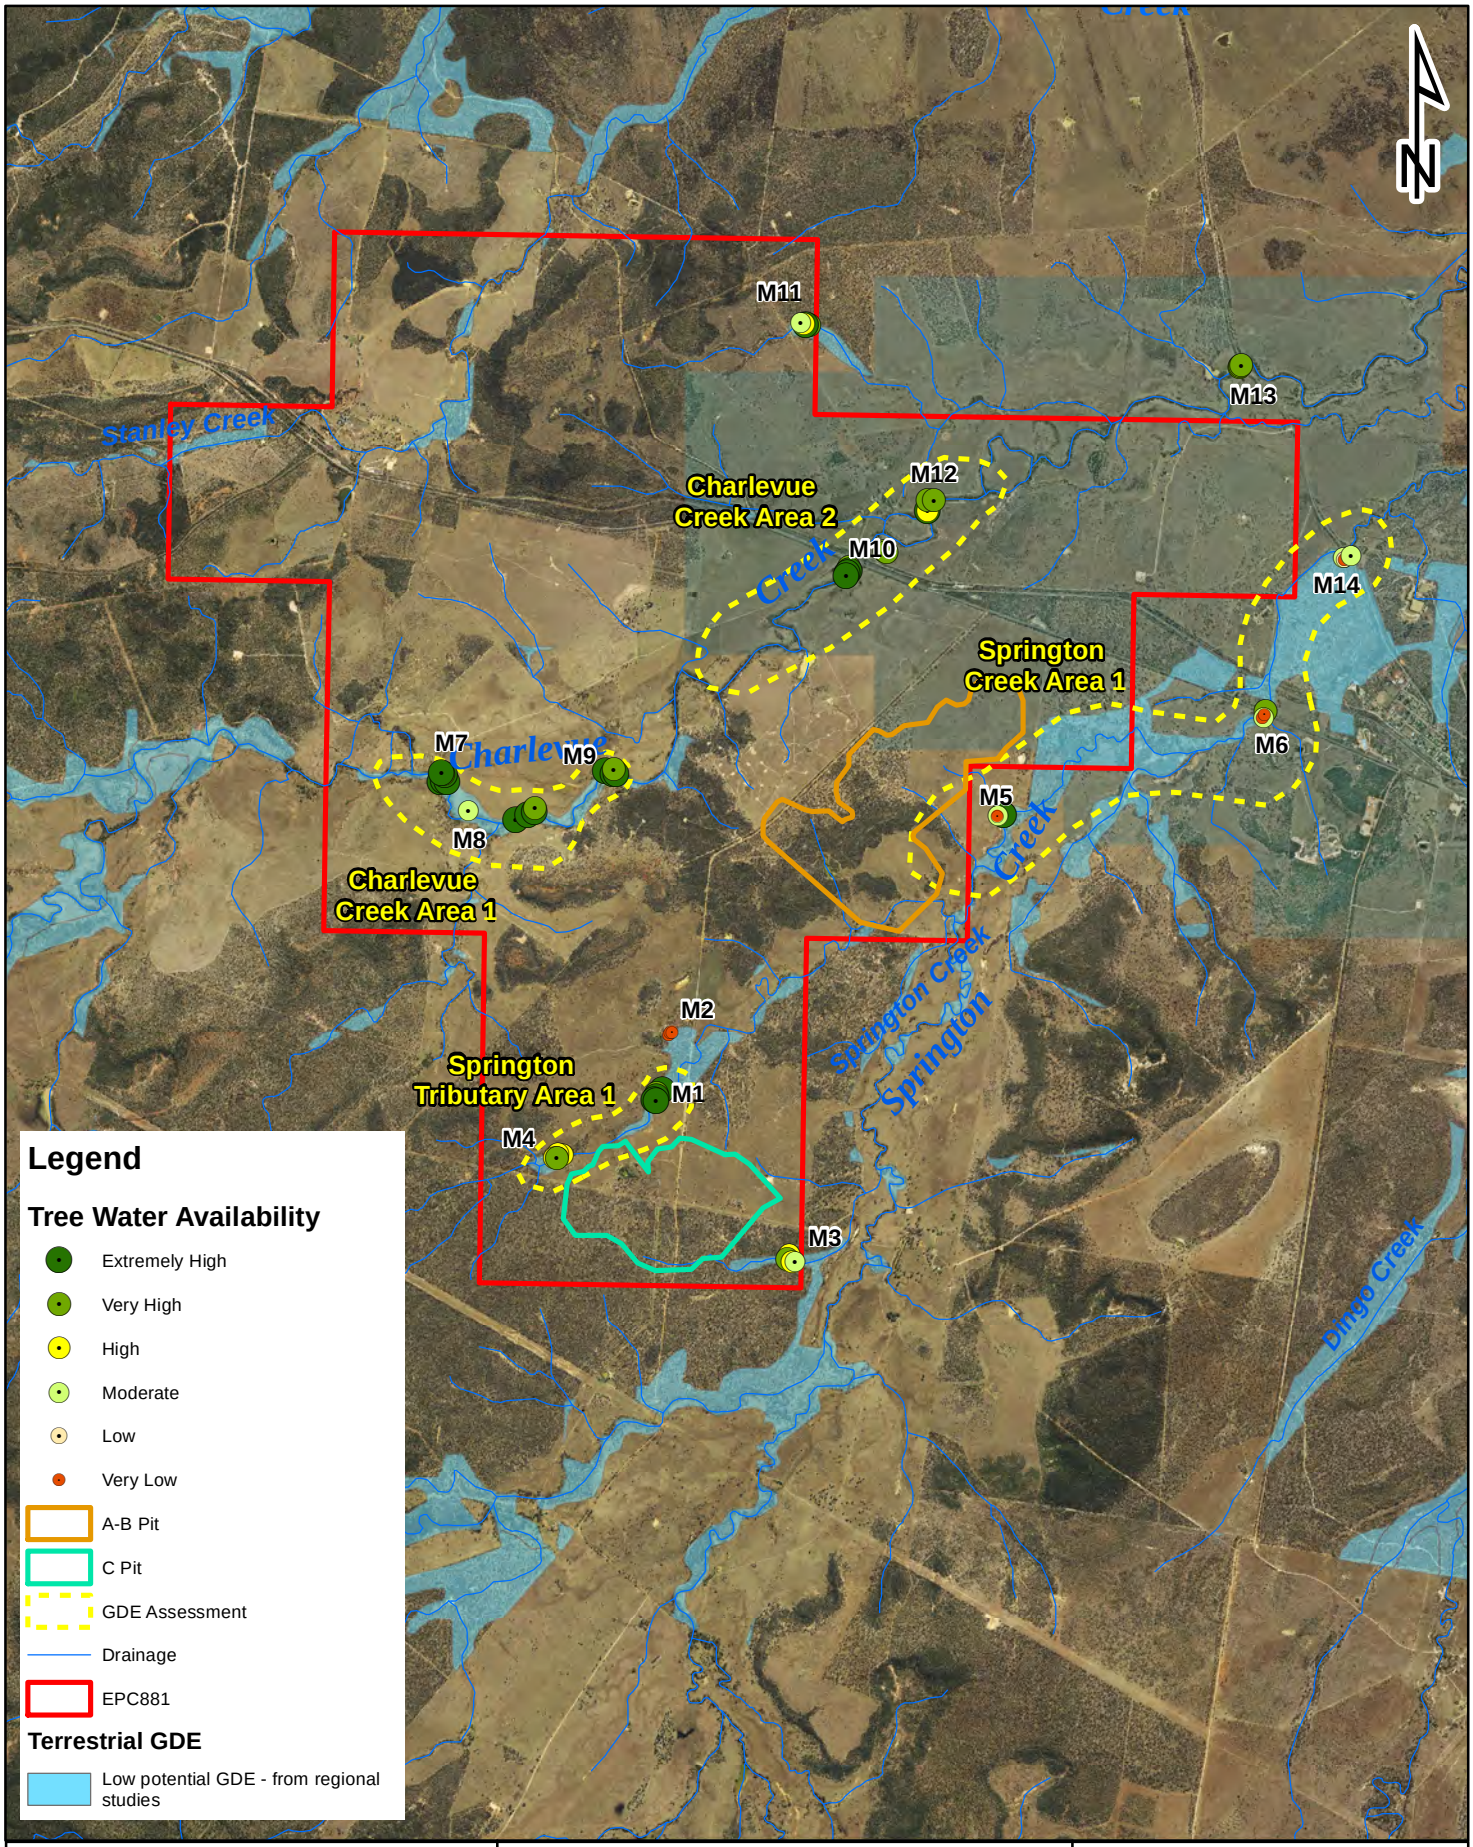


Figure 11. Average LWP readings for all GDE Assessment Areas. The blue line (>-0.2MPa) indicates typical LWPs for trees in equilibrium with a non-saline saturated source of soil moisture; the orange line (>-0.55MPa) indicating typical values for trees in equilibrium with a moderately saline soil moisture source (EC 10 000 µS/cm) and the red line indicative of trees in equilibrium with saline source of moisture at 17000 µS/cm. Standard Wilting Point (<-1.5MPa) is also indicated.

Figure 13 shows that LWPs for both *Eucalyptus tereticornis* and *Eucalyptus camaldulensis* vary considerably across the survey area with trees at Site M1, M7, M8 and M9 demonstrate extremely high water availability (>-0.2Mpa). In comparison, *Eucalyptus camaldulensis* at Site M5 and M6 (Springton Creek) demonstrate LWP indicative of extreme moisture deficit (<-2.0 MPa in some cases). This highlights the ability of both species to adapt to extremely dry conditions.

Both *Eucalytpus populnea* (Site M8, M2 and M14) and *Eucalyptus crebra* (Site M2) demonstrate high levels of water deficit at all sites (LWP values from -0.9MPa to -2.0MPa) consistent with the findings of Fensham and Fairfax (2007) that these species have limited investment in deep root architecture and are not adept at utilising deeper sources of soil moisture or groundwater. Similarly, the single coolabah (*Eucalyptus coolabah)* measured at Site M13 is suffering considerable water deficit, which would be expected considering the propensity of the species to occupy heavy clay soils which hold on to water very tightly when dry, and also provide an impediment to deeper root penetration. A spatial representation of water availability for individual trees measured at each assessment site is provided in **Figure 14** to **Figure 18**.

4.2 Hand Auger Profiling and Soil Moisture Potential

Summary profiles from hand auger holes for site where an auger was completed are provided in **Appendix B** which provide an indication of soil structure, texture and moisture content. As per **Section 3.5.4**, the purpose of the SMP testing is to identify, for those trees where LWP measurement indicate potential groundwater dependence, whether sufficient moisture is available in the upper unsaturated portion of the soil profile (i.e vadose zone) to explain LWP measurements that may be indicative of groundwater usage, either saline or otherwise. From **Section 4.1**, this includes the following:

1. All trees in Charlevue Creek Area 1 (except for Tree 5 at Site M8 being *Eucalyptus populnea)*.
2. Trees in Charlevue Creek Area 2 (including Site M10 and M12)
3. All trees in Springton Creek Tributary Area 1 (Site M1 and M4).
4. Tree 2, Tree 3 and Tree 4 at Charlevue Creek Site M13.
5. Tree 1, Tree 2 and Tree 3 at Site M11.

Where collected, data from other sites including Springton Creek Area 1, are also presented for comparative purposes. Penetration of the auger at Site M11 was arrested at a shallow depth (0.35 mbgl) due to intersection of basement rock, and at Site M6 where the alluvial soil profile was cemented. Auger profiles are not provided for these sites although soil samples were extracted from the stream bank for analysis of SMP and stable isotopes.

Charlevue Creek Area 1: Two auger holes were placed at both Site M7 and Site M9 to depths of 2.2mbgl with one auger hole placed on the terrace, and a second auger hole placed in the floor of the sandy creek channel. Details of auger holes (M7_AU1, M7_AU2 and M9_AU1 and M9_AU2) are provided in **Appendix B**. Additional auger holes were placed at Site M8 for the purpose of collecting samples for stable isotope analysis. Downhole SMP profiles for Site M7 and M9 are presented in **Figure 19a** and **Figure 19b** demonstrating that moisture availability generally increases with depth down the auger hole. For auger holes placed in the stream channel (M7_AU2 and M9_AU3), SMP was > -0.02MPa down most of the profile, corresponding with the LWP for most trees. This suggests that free water is available for tree uptake throughout most of the sandy soil profile. For augers placed on higher alluvial terraces, SMP increased significantly at depths below 1.5mgbl, and generally matched measured LWPs at depths of 2.2mbgl. This indicates moisture at, or deeper than this depth, is available for moisture uptake by trees.

Charlevue Creek Area 2: Single auger holes were placed at both Site M10 and Site M12 with M10_AU1 placed on the upper terrace (5m from top of bank) while M12_AU1 was placed in the channel floor, 5m below the terrace. For M10_AU1, SMP to depths of 2.2 mbgl was significantly more negative than LWP of trees sampled at the site (**Figure 20a**), indicating trees are sourcing moisture from regions of the soil profile that are deeper than 2 mbgl. For M12_AU1 (Site M12) SMP at depths below 1 mbgl matched measured LWP for trees at the site indicating that soil moisture within the profile below these depths is available for uptake by trees (**Figure 20b**). Auger M12_AU1 was completed at 1.2 mbgl due to a high density of tree root material which arrested deeper penetration of the auger.

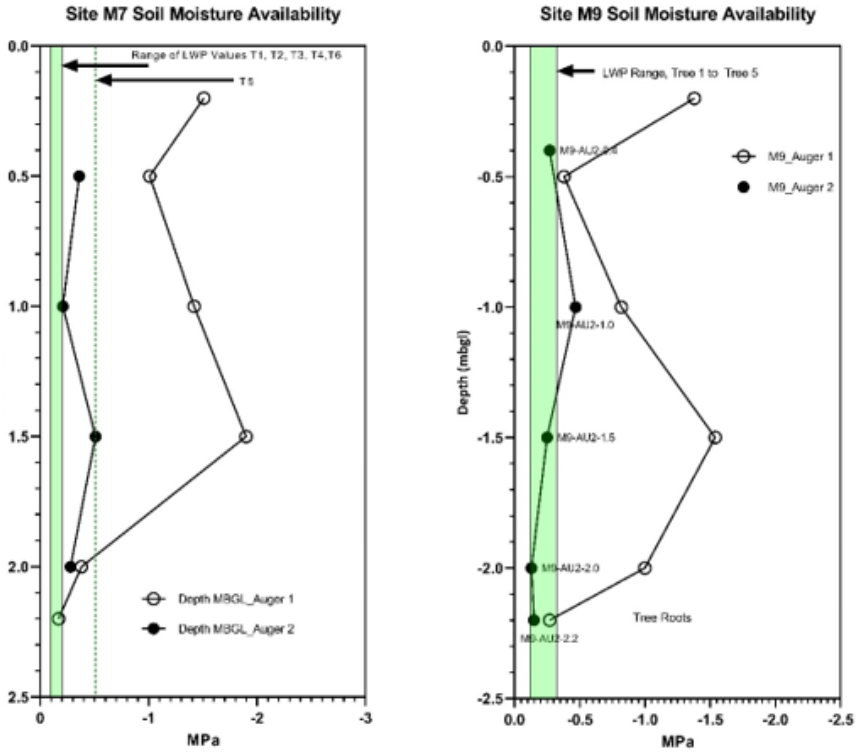

Figure 19. Downhole SMP for auger holes placed at Site M7 (19a) and Site M9 (19b on left) indicating increasing water availability at depths >2mbgl. The green shading indicates the range of LWPs measured in trees at these sites.

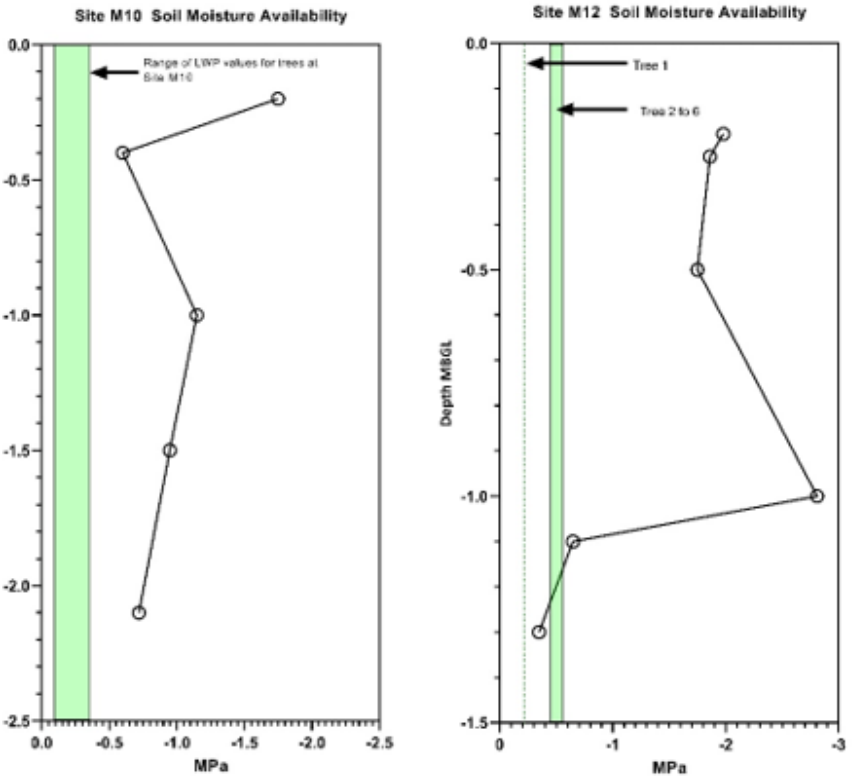

Figure 20. Downhole SMP for auger holes placed at Site M10 (20a) and Site M12 (20b on right) indicating increasing water availability at depths >2mbgl. The green shading indicates the range of LWPs measured in trees at these sites.

Springton Tributary Area 1: Single auger holes were placed at Site M1 and Site M4 at Springton Tributary Area 1. Site M1 was installed to a depth of 2.2m, with a coarse sand layer intersected between 1.5m and the end of hole (**Figure 21a**). The sand was strongly mottled with iron staining suggesting the sand formed a seasonal aquifer with strongly fluctuating water levels. While no free water was intersected in the auger, it is expected that saturation would occur rapidly after rainfall, and that free water may have been available deeper in the sandy profile. At 2.2 mbgl, a coarse gravel band was intersected which arrested deeper auger penetration and it is possible that free water may have been present at deeper levels in the soil profile. Downhole SMP does indicate high levels of moisture availability in the sand, matching LWP for trees measured at the site, and moisture would be available for uptake between 1.7 and 2.0 mbgl. For Site M4 (see **Figure 21b**), a fine silty sand was intersected between 1.0 and 1.3 mbgl with a hardpan at the base which arrested deeper auger penetration. The entire hole was dry with SMP that was considerably lower than LWP for trees recorded at the site, indicating that trees are most likely accessing soil moisture from deeper regions of the soil profile.

Springton Creek Area 1: There were severe difficulties installing auger holes into any of the three Springton Creek sites (M5, M6 and M14) due to the compacted nature of the soils, and basement rock outcrop in some localities. Auger penetration was arrested at Site M6 at 0.35 mbgl due to a cemented soil horizon and at M14, penetration was arrested at 1.2mbgl due to compacted soils. SMP measurements for Auger M14_AU1 ranged from -1.1 to -3.5 MPa, which corresponded to the low LWP measurements recorded in poplar box at the site (-1.1 to -2.0 MPa) suggesting that trees may be extracting moisture from the shallow soil profile in this locality.

A single auger hole was installed into the channel of Springton Creek at Site M5, to a depth of 1.9 mbgl. The hole was placed below Tree 3, which was the only tree at the site to demonstrate a high LWP (>-0.2 MPa) indicative of high moisture availability in the soil profile (see **Figure 13**). The results indicate SMP in the soil profile below the channel sufficiently explains the high LWP recorded in Tree 3, with moisture between 0.75 and 1.9 mbgl available for tree uptake (see **Figure 22**). Other trees (Tree 1, Tree 2, Tree 4, Tree 5 and Tree 6) all demonstrate significant water deficit indicating trees are accessing moisture from a much drier soil profile in those locations.

Site M13 (Charlevue Creek): Auger M13_AU1 was installed in the road reserve within the creek channel, encountering 2m of moist heavy clay. **Figure 23** demonstrates Tree 1 (*Eucalyptus coolabah),* which was located on the upper terrace 10 from the top of bank, was sourcing moisture from an extremely dry portion of the soil profile, and moist soil conditions were largely restricted to the channel where other trees were sampled. SMP in auger M13_AU1 is extremely high from surface down to 2.0 mbgl, accounting for the high LWP recorded in Tree 2 to Tree 4. The moist conditions recorded in the auger hole are likely to represent a wetting front below the stream channel, although no free water was intersected.

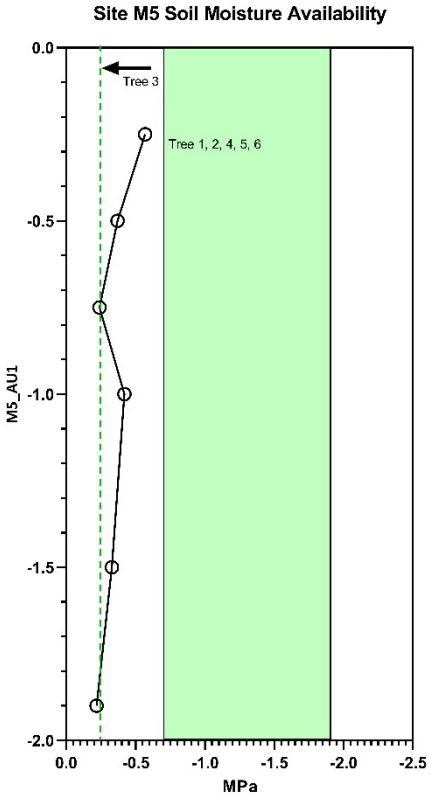

Figure 22. Soil moisture availability at site M5, Springton Creek Area 1.

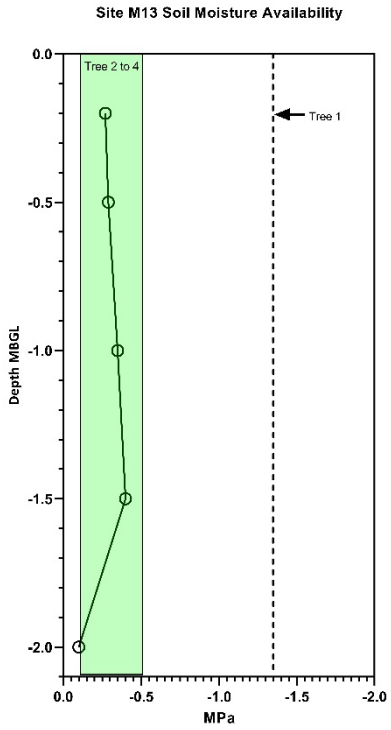

Figure 23. Soil moisture availability at Site M13, Charlevue Creek.

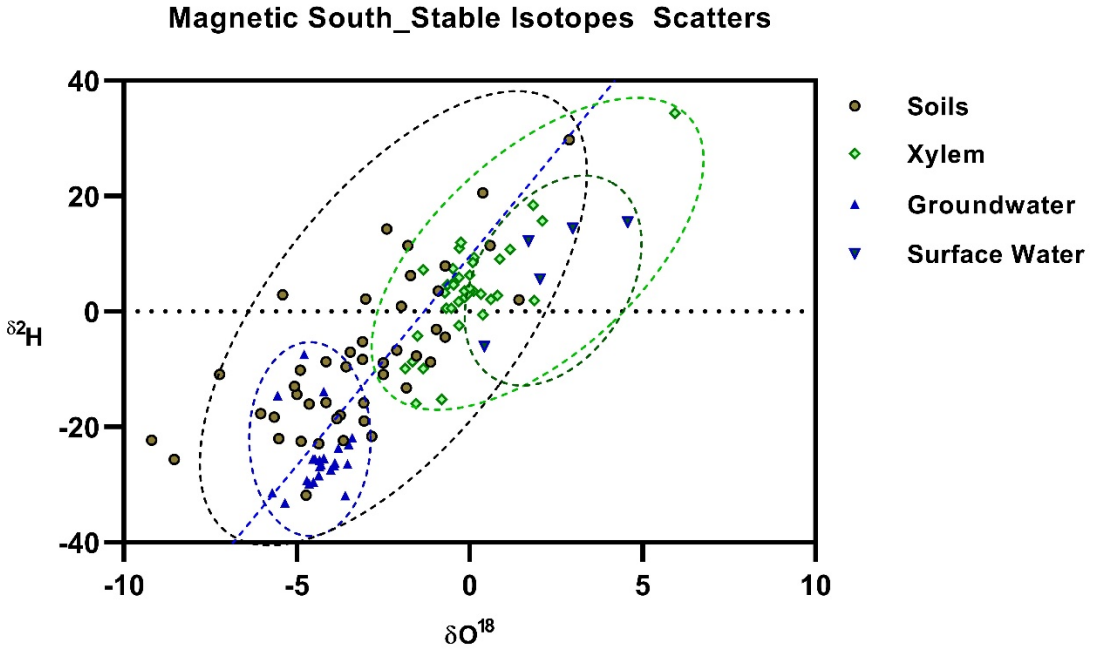

4.3 Stable Isotope Sampling and Analyses

Figure 24 shows stable isotope values (δ18O and δ2H) for all values including soil, surface water (from stream pools), groundwater and twig xylem water analysed during the assessment. The main groupings have been circled to better indicate the inter-relationship between the groups and highlight areas of dataset overlap. The scatter shows:

1. Broad isotopic overlap between soil and all other sample types, with soil presenting the greatest spread of isotopic values. Twig xylems samples were generally enriched above the soil and groundwater with some overlap between soil and groundwater.
2. Twig (xylem) samples and groundwater samples do not demonstrate any overlap with groundwater demonstrating much more depleted isotopic values, although twig samples overlap with isotopic values of surface waters.
3. There is no overlap between surface water samples and groundwater, the latter being subject to significant evaporative enrichment.

The broad scatter of isotopic values in the soil samples is expected, as this would be imparted by infiltration of surface water with varying degrees of isotopic enrichment including direct infiltration of unfractionated rainfall or infiltration of evaporatively enriched surface waters. The most significant feature is however the complete lack of overlap between twig samples (which are relatively isotopically enriched) and groundwater samples (isotopically depleted) indicating trees are not utilising groundwater in the regional Tertiary or alluvial aquifers to any degree, even when groundwater would be within reach of maximum rooting depth (e.g. SWL at 8.7 mbgl in alluvium at DW7076W and 11.19 mbgl at DW7292W1). This is not unexpected due to the salinity of groundwater that is typical of the regional aquifer systems. The results imply that any groundwater usage by trees on the Project site is from fresh perched aquifers that are recharged through infiltration of evaporatively enriched surface water and are disconnected from the regional aquifer. Note all stable isotope biplots include the Local Meteoric Water Line (LMWL) for Rockhampton from Crosbie et al (2012) which provides a reference to identify evaporative trends. Raw data for all isotopic samples is provided in **Appendix D**. Stable isotope results for individual sites are briefly discussed below:

Charlevue Creek Area 1 and Charlevue Creek Area 2: Biplots showing the isotopic composition of soils, twigs, groundwater, and surface water from Charlevue Creek Area 1 is shown in **Figure 25** and Charlevue Creek Area 2 in **Figure 26**. For both areas, the results highlight the strong differentiation between isotopic composition of twig samples and groundwater, indicating the regional groundwater table is not being utilised by trees to any degree. There is also no consistent pattern in the soil samples with isotopic enrichment being evident at various depths, where they match the isotopic compositions of twig samples (e.g. M7 Au1_2.0m; M7 AU1_1.15m at Charlevue Creek Area 1) indicating possible utilisation of moisture from those depths in the soil profile. Surface water samples were collected from an overflow channel at Site M8 for Area 1 and from a residual pool at M10 for Area 2, and both are isotopically enriched above all other samples, indicative of exposure to evaporative processes.

.

Figure 24. Stable isotope scatters for all data with LMWL for Rockhampton indicated in by the blue line after Crosbie et al (2012) shown as reference. The circles delineate the sample groupings of soils, xylem, groundwater and surface water.

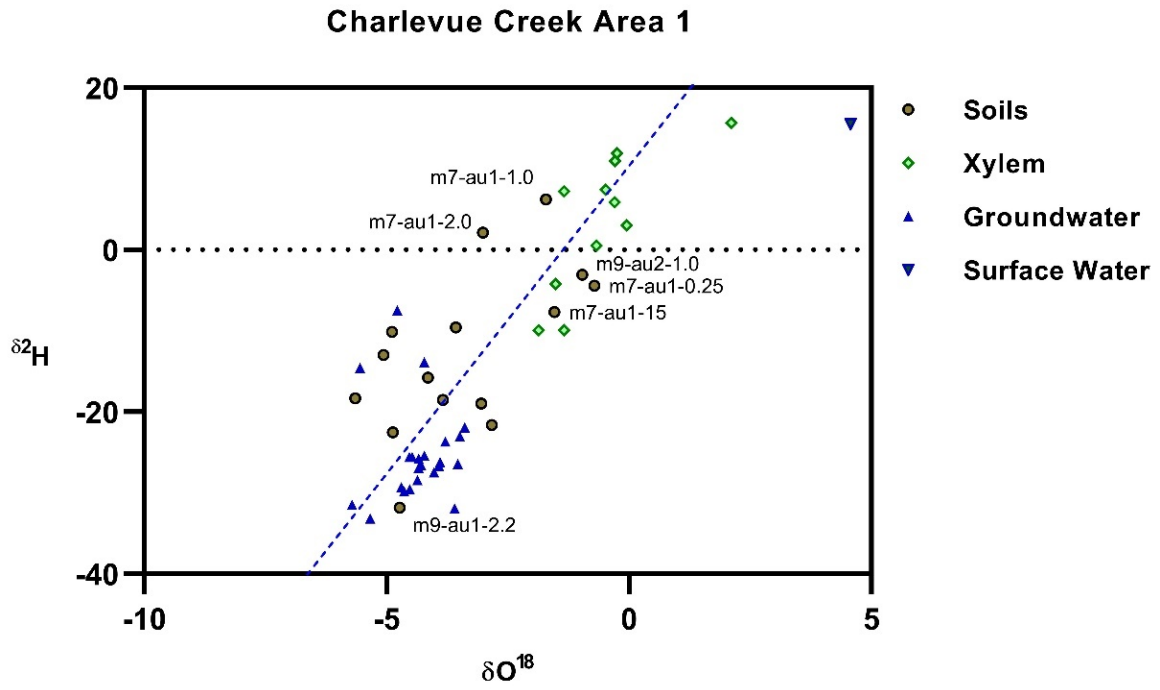

Figure 25. Stable isotope biplot for Charlevue Creek Area 1 with the LMWL shown in blue dashed line.

.

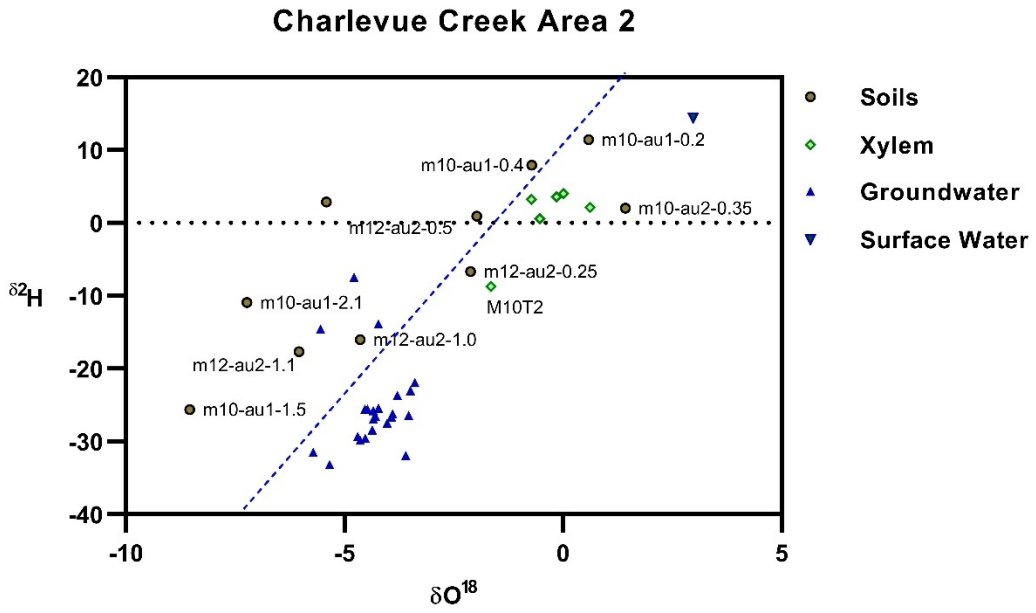

Figure 26. Stable isotope biplot for Charlevue Creek Area 2 with the LMWL shown in blue dashed line.

Springton Tributary Area 1: Biplots showing the isotopic composition of soils, twigs, and groundwater from Springton Tributary Area 1 (Site M1 and M4) is shown in **Figure 27.** Like Charlevue Creek Area 1 and Area 2, the results highlight the strong differentiation between isotopic composition of twig samples and groundwater, indicating the regional groundwater table is not being utilised by trees to any significant degree. There is overlap between twig samples and SMP from some soil samples (particularly M1_AU1_1.5) indicating moisture is being source from these regions by some trees. The enrichment of stable isotope values from twig samples indicates trees are utilising an evaporatively enriched source of moisture, most likely from zones that are deeper in the soil profile, where infiltrated surface water has been able to penetrate.

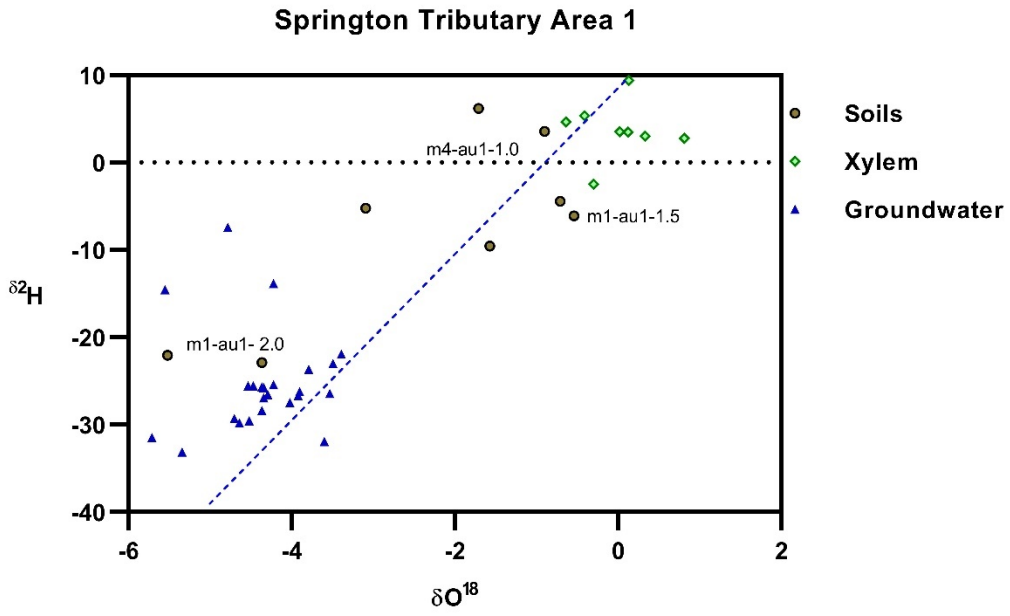

Figure 27. Stable isotope biplot for Springton Tributary Area 1 with the LMWL shown in blue dashed line.

Springton Creek Area 1: Biplots showing the isotopic composition of soils, twigs, groundwater and surface water from Springton Creek Area 1 (Site M5, M6 and M14) are shown in **Figure 28.** As per previous assessment areas, there is a strong differentiation between isotopic composition of twig samples and groundwater, indicating the regional groundwater table is not being utilised by trees to any degree. Soil samples are generally isotopically enriched over twig samples however, in auger sample M5_AU1, isotopic enrichment increases with depth in the soil profile (see **Figure 29**). This effect strongly suggests that Tree 3 at M5 (being the only tree with high LWP from Site M5) is utilising moisture at depth underneath the stream channel, where it is sourcing infiltrated surface flows that have been subject to evaporative enrichment.

Tree 1 at Site M6, a *Melaleuca leucadendra* on the margins of a semi-permanent waterhole, similarly demonstrates high LWP (see **Figure 13**). Isotopic analysis indicates this tree is utilising moisture directly from the surface water body as indicated by isotopic overlap with the surface water sample from this site (M6SW1 compared to M6_T1). The isotopic values of other trees generally overlap with the isotopic composition of soil moisture from deeper portions of the soil profile. From **Section 4.2 (Figure 22)**, this moisture is from a dry portion of the soil profile which is likely to be below the total depth of the auger profile at M5_AU1.

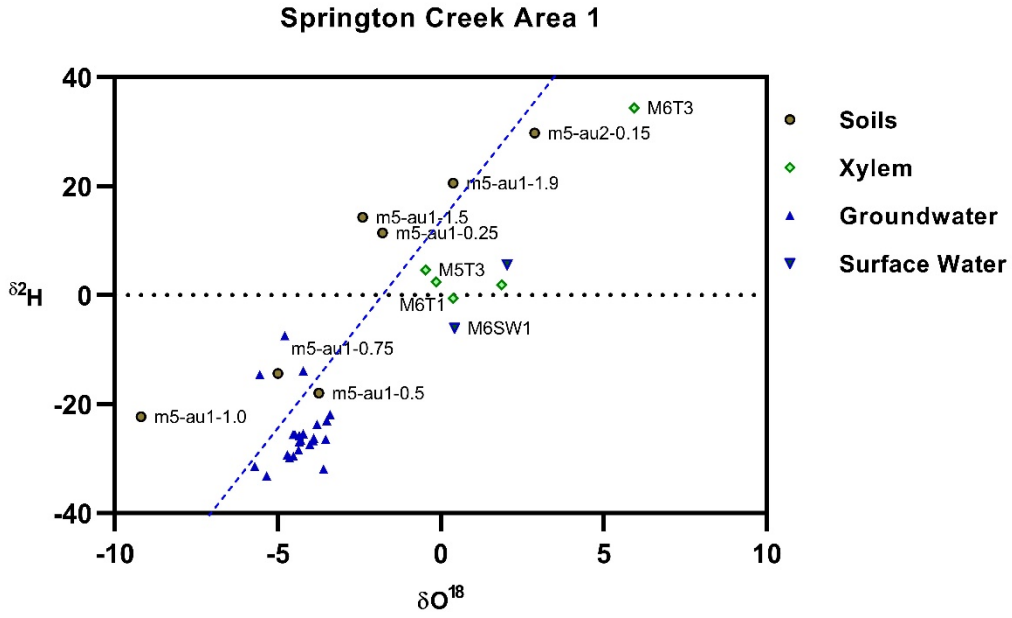

Figure 28. Stable isotope biplot for Springton Creek Area 1 with the LMWL shown in blue dashed line.

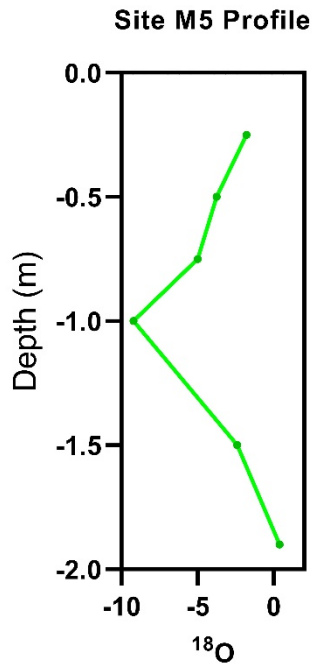

Figure 29. Isotopic profile downhole in Site M5 (M5_AU1) indicating increasing isotopic enrichment below 1 mbgl.

Site M13 (Charlevue Creek): A biplot showing the isotopic composition of soils, twigs, surface water and groundwater from Site M13 at Charlevue Creek is shown in **Figure 30.** The differentiation between isotopic composition of groundwater and twig samples is highly apparent. Twig samples overlap with the isotopic composition of the surface water sample collected at the site (M13SW1). This strongly suggests that trees at Site M13 are utilising water from the wetting front below the creek channel, in moist clays, which is consistent with the high LWP recorded from most trees at the locality (see Figure 13).

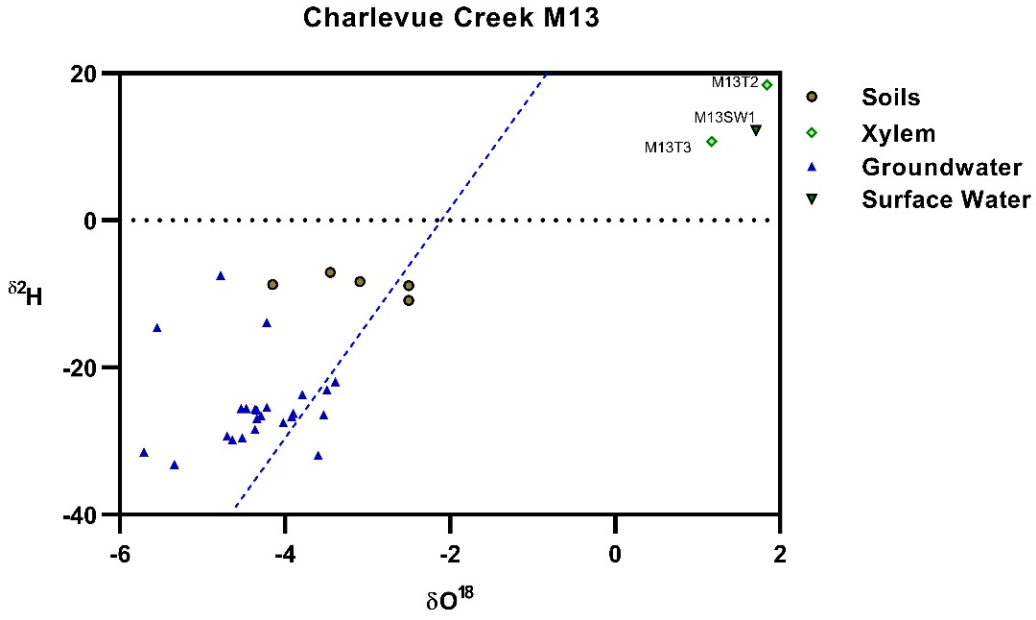

Figure 30. Stable isotope biplot for Charlevue Creek Site M13, demonstrating strong differentiation between groundwater and twig xylem.

Other Sites (M2, M3, M11): The remaining sites all demonstrate strong differentiation between groundwater samples and twig xylem, indicating that groundwater is not being utilised by trees at these localities to any significant degree (see **Figure 31**).

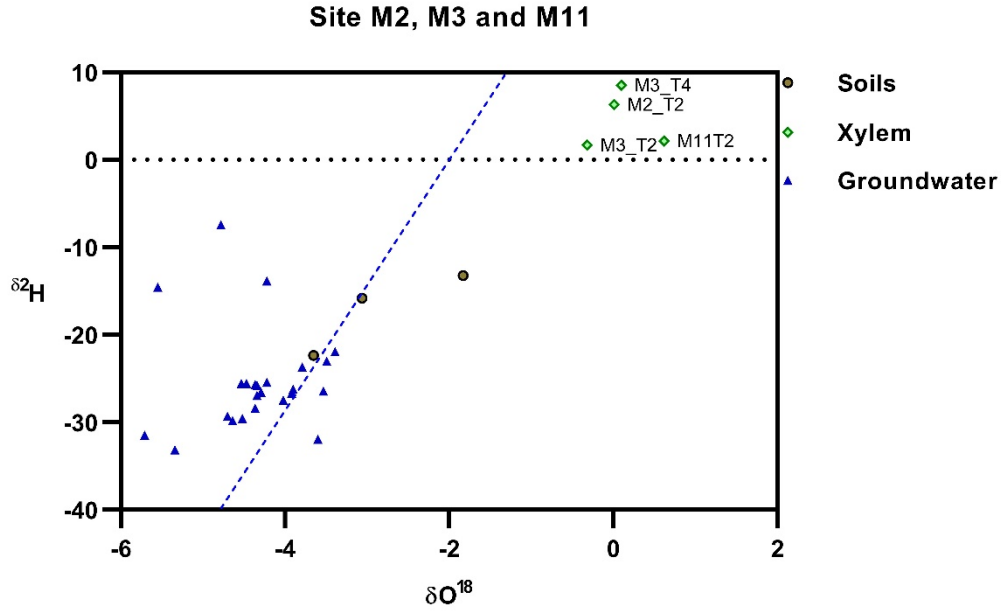

Figure 31. Stable isotope biplot for Charlevue Creek Site M2, Site M3 and Site M13, demonstrating strong differentiation between groundwater and twig xylem.

5.0 Discussion and Conceptual Site Models (CSMs)

5.1 Suitability of Groundwater Resources to Support GDEs

Groundwater may be hosted in nearly all geologies in some form and an assessment of its utility to support GDEs is required. The Permian Sediments (Rewan Group and Rangal Coal Measures) are low permeability units that are generally considered aquitards. Groundwater occurs in fracture zones and the degree of permeability is constrained by the degree of fracturing and the low primary porosity of the sediments. Coal seams are the primary aquifers in the Permian sediments and the upper units subcrop into the Tertiary sediments where there may be some leakage and exchange of groundwater between the two geological units. The shallowest recorded groundwater levels in the coal seams are from Pollox Upper Seam (17.04 mbgl) which is close to the inferred threshold depth beyond which tree roots / groundwater interaction is unlikely to occur (DNRM 2013). Similarly, the shallowest groundwater in the Tertiary sediments was recorded in DW7220W1 at 15.35 mbgl which is also at the inferred threshold for tree root penetration, while the groundwater in the alluvium may be considerably shallower (8.77 mbgl in DW7076) suggesting that it may be physically accessible to tree roots.

While physical accessibility provides one controlling factor, salinity also plays a significant role in determining the suitability of groundwater to support ecological processes, including its capacity to support terrestrial GDEs. A lower osmotic potential will be associated / measurable in the leaves of trees exposed to saline soils or groundwater, which will be reflected in a lower total LWP. Eamus et al (2006b) identifies river red gum as being a relatively salt-tolerant species, growing well in groundwater salinities of almost 1,500 µS/cm. In addition, Mensforth et al. (1994) identified that river red gum will continue to utilise groundwater with salinity as high as 40,000 µS/cm in the absence of a fresh source of soil moisture, although higher levels of tree stress will be apparent. Measured groundwater salinity in the alluvial and Tertiary sediments ranges from 1 439 µS/cm to 26 831 µS/cm, which would be in the mildly to highly toxic range for river red gum. Trees may prefer not to utilise brackish to saline groundwater if more suitable fresh water sources, including infiltrating rainfall and surface water, are available. Based on relatively unambiguous data from comparison of stable isotope signatures between twigs and groundwater, there is no indication that groundwater in even the shallowest regional aquifers within the physical reach of tree roots is being utilised by trees to any significant degree. Where LWP measurements indicate the likelihood that trees are utilising a saturated groundwater source, the stable isotope signatures from twigs indicate this groundwater must be from a perched source of fresh water that is disconnected from the regional groundwater table. Two areas where utilisation of a source of perched groundwater is indicated are identified on Charlevue Creek (particularly Charlevue Creek Area 1) and Springton Tributary Area 1, which are discussed in the following sections, with the location of these areas, relative to infrastructure areas shown in **Figure 32**. There is no evidence for trees associated with the main channel of Springton Creek, including the floodplain areas occupied by RE11.3.2 (*Eucalyptus populnea* dominant) are utilising groundwater from the regional alluvial or Tertiary aquifers.

5.2 Ecohydrological Function of the HES Wetland

The HES wetland feature is an internally drained clay pan with no external connections to watercourses or other wetland areas. Despite an extremely wet February four months prior to the

field inspection, there was no indication of any surface water associated with this feature. This suggests that there is no baseflow into the system, which would be expected if the wetland was linked to a semi-confined aquifer that is recharged directly by rainfall. Ponded surface water in the system clearly evaporates quickly, in conjunction with associated infiltration into the clay subsoil.

The HES wetland was observed from the roadside to comprise a low woodland with a predominant canopy of *Melaleuca nervosa* and emergent forest red gum (*Eucalyptus tereticornis).* Neither of these species are obligate phreatophytes, having capacity to survive in situations where considerable water deficit may occur, such a clay pans and dry hillslopes. While there is a possibility that the HES wetland is supported by a shallow fresh perched water table that is recharged directly by rainfall, there is no suggestion that the feature is supported by a deeper confined aquifer system that is linked to the coal seams proposed for mining. The feature is therefore not considered a concern for this assessment because:

1. The wetland is nourished by surface water flows from within its own internal catchment which does not form part of the mining footprint.
2. There is no indication of baseflow into the system, or inputs from groundwater linked to aquifers in the coals seams.

This is supported by information contained in both national (BOM 2020) and state (DES 2018) GDE mapping databases which do not support this feature as being a GDE.

5.3 Conceptual Site Models / Cross Sections.

Conceptual Site Models (CSMs) illustrating the conceptualised interaction between groundwater and terrestrial ecology have been developed for two likely GDEs in this section. The location of these cross sections is shown on **Figure 32,** being a north south block section through Charlevue Creek Area 1, and an east west cross section through Springton Creek Area 1. The purpose of the CSMs is to illustrate the interaction between terrestrial vegetation and sources of soil moisture for transpiration as they interact and vary on a seasonal basis. CSMs presented in this section are not drawn to scale and are intended to represent soil / moisture and tree relations diagrammatically. It is also noted that these areas provide the most extensive interpreted GDE areas within the Project site and provide a firm basis for conceptualisation of impacts. It is not possible however to exclude other areas where there may be minor or highly seasonal groundwater usage that is similar to what is conceptualised in the models, most likely on Charlevue Creek.

5.3.1 Charlevue Creek Area 1.

Figure 33 defines a N/S section through Charlevue Creek at the approximate location of **Cross Section A**, extending for approximately 500m to the south of the channel and 100m to the north. **Figure 33a** illustrates a dry season scenario where a shallow fresh water aquifer occurs at the base of recent flood plain sediments. The flood plain defines a broad 'flood terrace' that is confined between gentle Tertiary rises and is inferred to be a more recent alluvial feature than areas associated with Charlevue Creek that are otherwise mapped as alluvium. The flood terrace is strongly incised by the main channel of Charlevue Creek to depths of up to six metres and traversed by shallow overflow channels which are activated during periods of overbank flow. Water is held at depth in the dry

sandy creek bed, where residual, isotopically enriched surface water from prior flows remains hydraulically connected to alluvial aquifer. This connection may be broken during extended drought periods with evapotranspiration depleting the alluvial aquifer and, in this sense,, the alluvial aquifer is considered a seasonal feature. The shallow alluvial aquifer is also disconnected from the deeper, brackish to saline Tertiary aquifer that lies at the interface between Tertiary and weathered Permian sediments. While there is some diffuse leakage indicated from the perched into the Tertiary aquifer, this leakage is relatively minor, evidenced from the generally high and temporally consistent salinity of the Tertiary aquifer.

In **Figure 33b**, a flood scenario is indicated where overbank flow activates overflow channels, greatly enhancing recharge of the perched aquifer. The alluvial water table bulges due to bank recharge adjacent to the stream channel, and the watercourse loses surface flow into the alluvial sediments in a typical 'losing stream' scenario. Lateral infiltration of surface flows into the stream channel continues until the level of the surface water drops below the level of the recharged alluvial water table, as shown in the post flooding scenario (**Figure 33c**). In the post flooding scenario, baseflow from the alluvial water table back into the stream channel may occur, acting to sustain surface flows for a short period following flooding.It is noted that during flooding, the perched alluvial aquifer remains hydraulically disconnected from the Tertiary aquifer with only minor leakage through the Tertiary sediments. The salinity of the Tertiary system suggests that recharge through the Tertiary sediments occurs via diffuse 'piston flow' where the movement of a water front occurs through the soil uniformly downwards to the aquifer, pushing older water deeper into the soil profile. Preferential flow, where water migrates through the substrate rapidly via preferential flow paths is not anticipated as this would rapidly and permanently dilute the salinity of the Tertiary aquifer. Preferential flow would also create pathways for tree root penetration into the Tertiary groundwater system, for which there is no evidence.

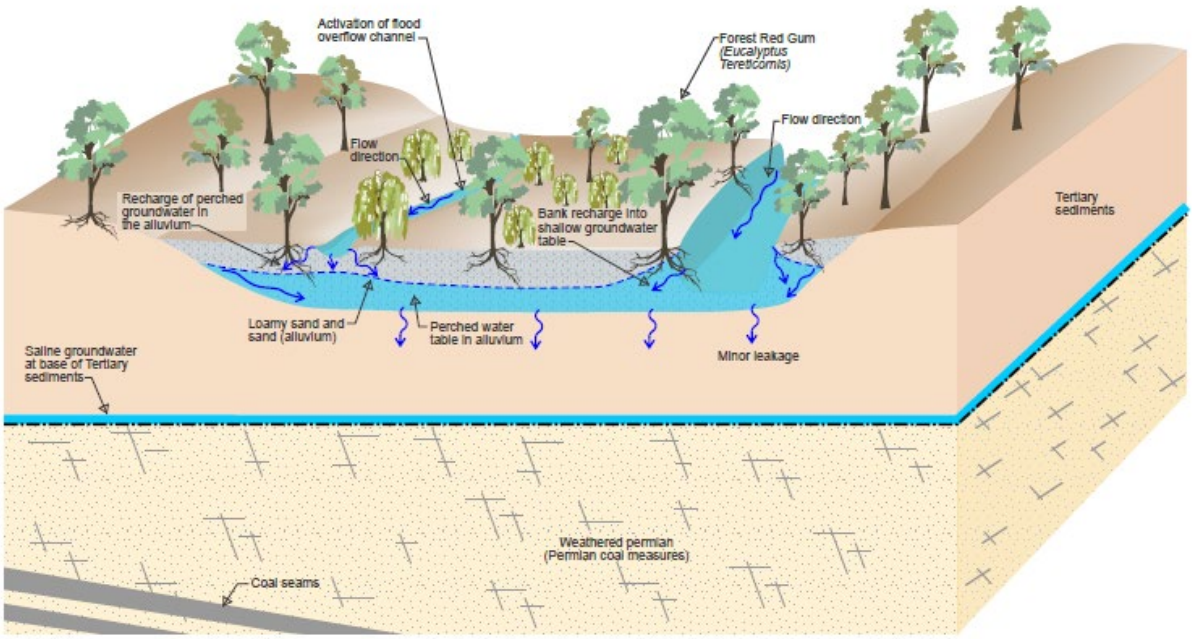

Figure 33c. Charlevue Creek Area 1- Post Flooding (Baseflow)

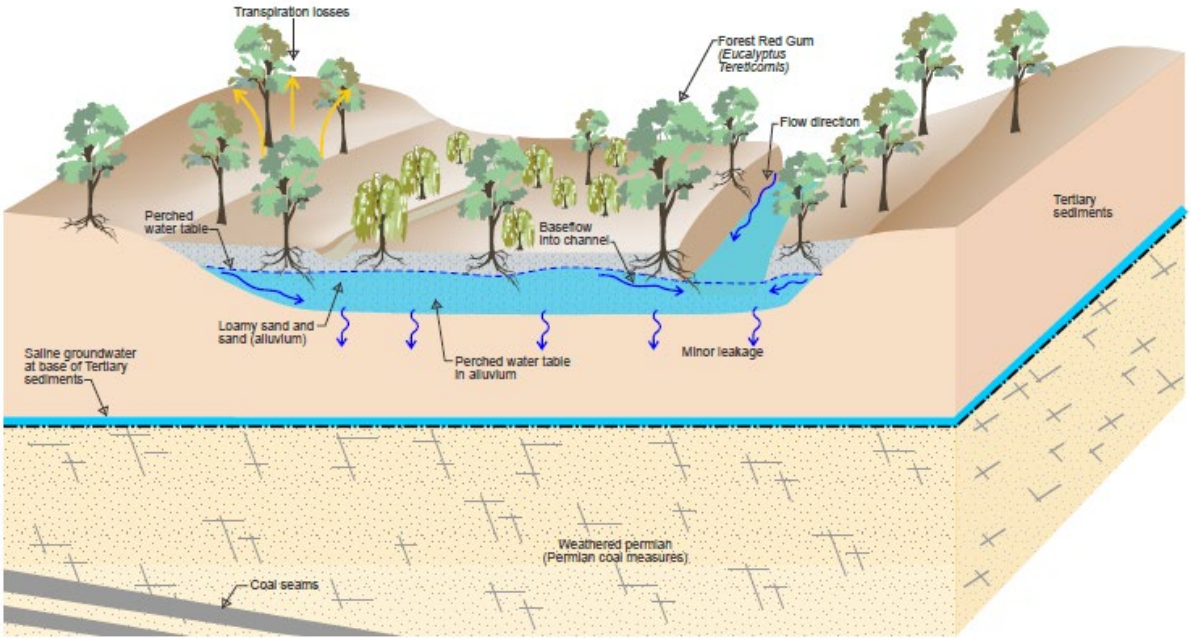

Figure 33. Conceptual model of the Charlevue Creek GDE system showing dry season scenario (33a), flooding scenario (losing system) (33b) and post flooding / baseflow scenario (33c).

5.3.2 Springton Tributary Area 1

The thick interval of coarse sand intersected in Auger holes (see profile for M1_AU1 in **Appendix B**) in this locality provides excellent aquifer material, and the presence of strong iron staining and mottling indicates that the sandy interval hosts a fluctuating perched seasonal aquifer that fills and drains rapidly in response to surface flows and seasonal rainfall. During the dry season, the perched aquifer is depleted rapidly through transpiration, with only minor leakage inferred into the underlying Tertiary sediments and groundwater table as shown in **Figure 34a.** Tree roots from the dominant red gum are inferred from stable isotope analysis to be utilising isotopically enriched moisture from the saturated portion of the sandy soil profile, with some shallow anchorage in the Tertiary sediments expected.

In the wet season (**Figure 34b**), the aquifer recharges rapidly through infiltration of surface water, which is enhanced by activation of numerous overflow channels, and drainage flows from the surface of the Tertiary system. The period that the aquifer material remains saturated will depend on follow up recharge and climatic factors, with greatest depletion occurring during periods of high evapotranspiration. Similar to the Charlevue Creek CSM, the salinity of the Tertiary system suggests that recharge through the Tertiary sediments occurs via diffuse 'piston flow' where the movement of a water front through the soil uniformly downwards to the aquifer occurs. While some leakage from the perched into the deeper Permian / Tertiary aquifer is expected, it is not considered to be a significant input into the deeper aquifer systems, as evidenced by their high, and relatively stable levels of groundwater salinity. Due to the low hydraulic conductivity of the Tertiary sediments, there is no capacity to sustain baseflow back into the drainage feature. Based on field evidence, the GDE system relies on its own local catchment and surface flows to replenish the perched groundwater system.

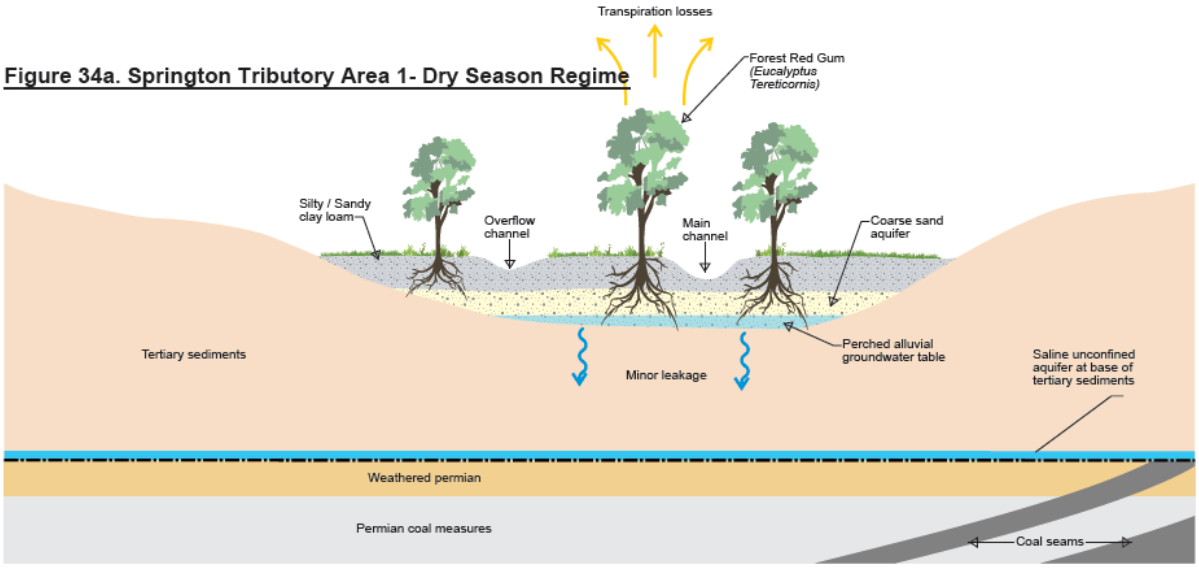

Figure 34a. Springton Tributory Area 1- Dry Season Regime

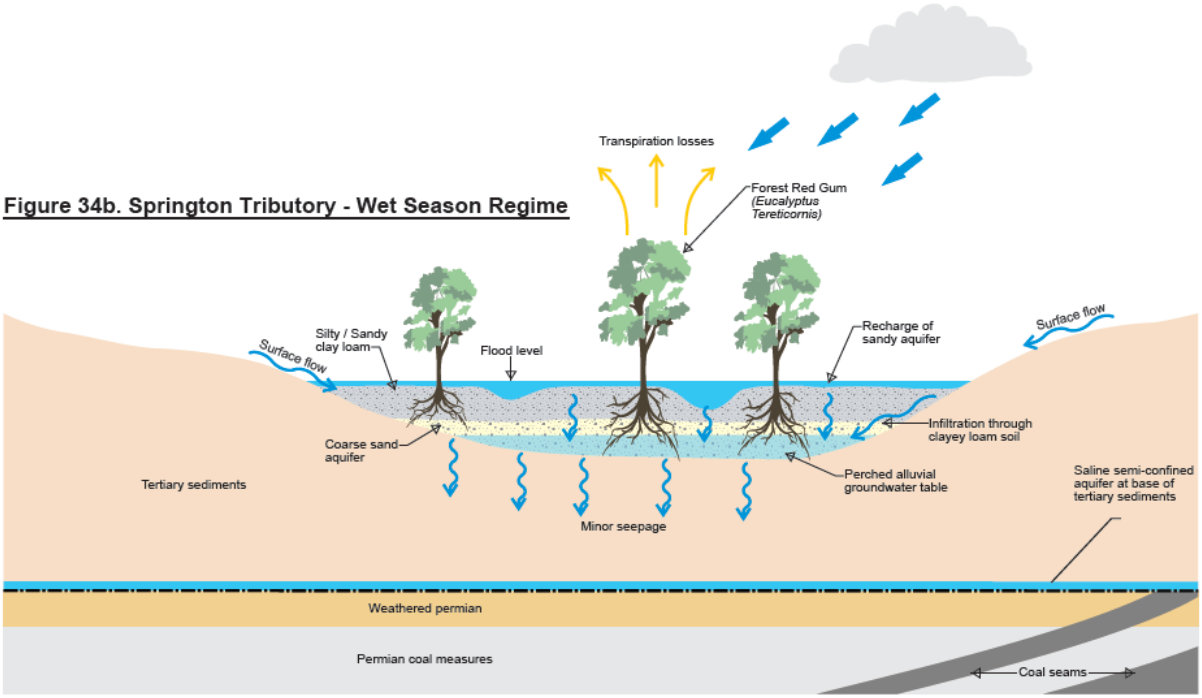

Figure 34. Cross section model of the Springton Tributary Area 1 perched aquifer system in the dry season (**Figure 34a**) and wet season (**Figure 34b**).

6.0 Assessment of Impacts to GDEs

Section 6.1 provides a summary of findings for the Charlevue Creek Area 1 and Springton Tributary Area 1 GDE areas, with potential impact mechanisms and their relevance to GDEs within the Gemini project area, discussed in **Section 6.4**. Potential measures for impact mitigation are provided in **Section 6.3** and a risk assessment has been undertaken in **Section 6.5** consistent with the approach identified in the IESC summary guide – assessing groundwater dependent ecosystems (IESC 2018c).

6.1 Summary of Findings Relevant to Impact Assessment

The assessment of impacts to GDEs is based on the findings of the extent and distribution of GDEs identified in this report, and the groundwater impact assessment report (JBT 2020). In summary:

Charlevue Creek Area 1 GDE System:

1. Charlevue Creek is an ephemeral watercourse system defined by an incised channel, up to six metres deep and up to 15 m wide. In this locality, the flood plain widens to form a broad flood terrace that is up to 200m wide, formed from well drained recent alluvial silts and sands.
2. The stream channel has a sandy floor that holds residual water from surface flows for an extended period into the dry season. Water held in the channel sands is conceptualised to have hydraulic linkage with a localised perched groundwater system, which becomes gradually depleted through transpiration into the dry season.
3. The depth of the perched aquifer would fluctuate seasonally with the likelihood that brief periods of baseflow are associated with retreating channel flows. For most of an annual seasonal cycle, the creek channel would be losing water into the alluvial sediments and perched groundwater table.
4. The hydraulic connectivity between the perched groundwater system and the deeper groundwater in the Tertiary sediments is insignificant although there may be minor leakage of groundwater from the perched groundwater system into the Tertiary sediments.
5. The observed good health of mature forest red gum in the Charlevue Creek system, coupled with the extremely high LWP measured during field assessment suggests that trees are not utilising saline groundwater from the Tertiary sediments to any degree, a statement which is strongly supported by analysis of stable isotope compositions from twigs and groundwater.

Springton Gully Area 1 GDE System

1. The Springton Tributary system is an ephemeral watercourse defined by a flat, weakly incised flood plain that has numerous overflow channels that are activated during flooding.
2. A seasonal aquifer is associated with a coarse sand interval intersected below the flood plain and main creek channel. The aquifer is conceptualised as being perched above the regional Tertiary aquifer and fluctuates seasonally dependant of surface flow inputs, with complete saturation potentially occurring during sustained flood events.
3. The hydraulic connectivity between the perched groundwater system and the deeper groundwater in the Tertiary sediments is predicted to be insignificant although there may be

minor leakage of water from the perched system into the Tertiary sediments. This is supported by the high, and relatively stable salinity levels reported from groundwater associated with the Tertiary system.

4. Red gum at this locality are conceptualised to be utilising the perched groundwater system to sustain transpiration into the dry season, though the perched aquifer will likely become depleted during extended periods without recharge.

6.2 Potential Impacts to GDEs

The GDE Toolbox (Richardson et al 2011), provides a starting point for investigating potential impacts on GDEs exposed to threat through the following impact mechanisms:

1. A total or partial loss or reduction in the volume or pressure of the aquifer being utilised by GDEs.
2. A change in the magnitude and timing of volume fluctuations in the aquifer being utilised by GDEs.
3. Changes to the interaction between surface flows and aquifers being utilised by a GDE.
4. Change in chemical composition of an aquifer detrimentally impacting the health of a GDE.

These potential changes can result in:

1. Loss of canopy vigour leading to senescence of groundwater dependent vegetation.
2. Changes to sub-canopy and groundcover because of increased light penetration through the canopy of senescing vegetation
3. Change in species composition with replacement of species not adapted to changing ecological parameters with species that have greater capacity to absorb change.

Direct clearing of a GDE system is also an additional impact which needs to be considered in the context of the Project.

6.2.1 Direct clearing

Vegetation clearing will result in direct impact to 5.54 ha of riparian vegetation (RE11.3.25) which is recognised as a GDE in the Springton Tributary Area 1 GDE system. This clearing action will result in direct removal of the area mapped as Springton Tributary Area 1 GDE system. The extent of clearing has been shown in **Figure 32** with further information on direct impacts is provided in the Terrestrial Ecology Assessment Report (AARC 2019). As this GDE system has been identified to be cleared, it is not considered further in the risk assessment which focuses on the GDEs associated with Charlevue Creek.

6.2.2 Partial or total loss or reduction in pressure of the aquifer being utilised by GDEs.

Charlevue Creek Area 1: The predicted water table drawdown (from JBT 2020) associated with development of mining voids is shown in **Figure 35.** Excluding the GDE area proposed for clearing, Charlevue Creek Area 1 is intersected by both the 2m and 5m drawdown contours which reflects drawdown in the water table associated with mining, affecting groundwater in the Tertiary and alluvial sediments. The alluvial landform associated with the Charlevue Creek GDE system supports a seasonal perched Aquifer. Based on salinity and stable isotope data collected from groundwater and

twigs, the perched aquifer is not considered to be hydraulically connected to the regional groundwater system associated within the Tertiary and older alluvial sediments. Furthermore, considering the perched groundwater system is not in hydraulic connection with regional groundwater table, this unit is not predicted to be subject to drawdown and no impact to groundwater dependent vegetation associated with Charlevue Creek will be incurred.

6.2.3 Change in the magnitude and timing of volume fluctuations in the aquifer being utilised by GDEs.

Volume fluctuations in the perched groundwater system associated with Charlevue Creek are regulated by surface flows rather than upward propagation of deeper regional groundwater tables. The interaction between surface flows and the perched groundwater system is elaborated further in **Section 6.2.4**.

6.2.4 Changes to the interaction between surface flows and aquifers being utilised by a GDE.

Streams in the Project area are ephemeral and based on the observed behaviour of other streams in the region, streamflow mostly occurs shortly after rainfall between September and April. The proposed mine operations and associated infrastructure footprint (MIA) are largely located outside of the Charlevue Creek and Springton Creek flood inundation areas (WRM 2019). The Charlevue Creek GDE system is located upstream from the proposed mining voids and there will be no loss of catchment area due to mining development that could potentially reduce upstream surface flows. Therefore, surface flow behaviour in the area upstream from the GDE area will be unaffected and similarly, there should be no change to either flood frequency, duration, or intensity that might impact recharge of the perched aquifer.

WRM (2019) report minor increases in flood level immediately upstream from the proposed haul road crossing with increases of 0.01 to 0.05m propagating upstream into the Charlevue GDE Area. These changes to flood intensity are considered insignificant in terms of recharge to the perched alluvial groundwater system.

The assessment of changes in flows, and changes in flood levels and velocities (WRM, 2019) demonstrates that the development of the mining operation will not result in a significant impact on the hydrology of Charlevue Creek to a degree that it would affect the recharge of the perched alluvial groundwater system that supports the GDE.

6.2.5 Change in chemical composition of an aquifer detrimentally impacting the health of a GDE

The perched groundwater system supporting GDEs on Charlevue Creek is underlain by an unconfined brackish to saline groundwater system in the Tertiary sediments and Permian coal seams. The potential for saline water from these groundwater units to contaminate the fresh perched groundwater system is negligible as upward propagation of saline water under hydrostatic pressure will not occur.

Other potential sources of water quality contamination would be from:

1. discharge of saline mine affected water, or saline leachate into the environs of Charlevue Creek, upstream from or potentially into the Charlevue GDE system. This could potentially increase the salinity of the perched groundwater system and impact GDE health.

2. Discharge of saline water from sediment dams upstream from, or into the Charlevue GDE system, potentially increasing the salinity of the perched groundwater system and impacting GDE health.

Water captured in sediment dams is expected to have low salinity and coarse sediments will settle out, such that any impacts to downstream water quality associated with discharge are expected to be minor (WRM 2019). The management of mine affected water is dealt with in **Section 6.4.1**, although WRM (2019) concludes that any unplanned overflows from the Mine Water Dam, would overflow to the mine pit with the only potential mine water release points being the Mining Infrastructure Area Dam spillways. These dams will be operated in such a way that the risk of release is small.

The groundwater impact assessment (JBT 2020) also concluded that there is no potential pathway for mine pit water from either the AB Pit, or the C Pit, via the base of the Tertiary sediments to migrate into sensitive ecological receptors and there is low risk that water from the mining void will contaminate surrounding groundwater systems.

6.3 Cumulative Impacts

JBT (2020) concluded that there are no existing mining operations within the zone of predicted groundwater drawdown from mining at the Project site, and therefore there are no cumulative impacts to assess.

6.4 Mitigation and Management Measures

It should be noted that the GDE assessment identified a GDE system that is subject to clearing impacts, which will need to be considered in the overall ecological offsets package. Apart from direct clearing impacts, **Section 6.2** identifies that in the absence of mitigation, the risk of impact to GDEs is considered low on account of the hydraulic disconnect between the aquifers supporting GDEs and the regional water table subject to potential impact during mining. While risk assessment is dealt with more comprehensively in **Section 6.5**, general operation measures that will minimise risk of impact to GDEs are provided in **Section 6.4.1.**

6.4.1 General operational measures

Under a project Environmental Authority, a water management system, whose primary objective is to minimise environmental harm, will need to be developed. Any Implemented site Water Management System (WMS) and associated Erosion and Sediment Control Plan (ESCP) will be directly applicable to management of potential impacts to GDEs.

WMS: Specific objectives under a WMS that are relevant to the management of impact to GDEs are:

- Mine affected water:
  - Ensure any controlled releases of mine affected water prevents environmental harm.
  - Minimise uncontrolled discharges in wet periods.
  - Understand, manage, and minimise the potential impact of the water management system on the regional groundwater system.
- Sediment water: Maintain the quality of water discharging from Erosion and Sediment Control (ESC) structures to as close to background levels as reasonably possible.
- Clean water: Separate from the mine affected and sediment water systems as much as practicable and allow it to pass uninterrupted through the catchment.
- Water from the mine Infrastructure area (MIA) (e.g. from fuel storage area): Ensure full separation from other water sources and manage under the specifications of AS1940 - Storage and Handling of Flammable and Combustible Liquids (WRM 2019).

ESCP: Sediment water containment (runoff from spoil and incomplete rehabilitated areas) is managed in accordance with a site ESCP. The ESCP adopts the three cornerstones of erosion and sediment control.

- Drainage control – prevention or reduction of soil erosion caused by concentrated flows and appropriate management and separation of the movement of diverted and surface water through the area of concern.
- Erosion control – prevention or minimisation of soil erosion (from dispersive, non-dispersive or competent material) caused by rain drop impact and exacerbated overland flow on disturbed surfaces.
- Sediment control – trapping or retention of sediment either moving along the land surface, contained within runoff (i.e. from up-slope erosion) or from windborne particles.

6.4.2 Groundwater monitoring

A comprehensive groundwater monitoring network will need to be maintained for the duration of the mining venture, extending into post closure periods. The purpose of the groundwater monitoring network will be to:

1. Assess the effects of extraction of authorised groundwater including the monitoring of:
   - impacts on any watercourses dependent on groundwater flow
   - impacts of other groundwater users
   - groundwater level in all identified geological units across and adjacent to mining infrastructure and voids.

- groundwater inflows and discharges from mine workings

2. To further refine and validate the groundwater flow model used to assess impacts to groundwater; and
3. To consider requirements of any regional groundwater monitoring and assessment program developed to address potential cumulative impacts.

6.5 Risk Assessment

Drawing on information on GDE presence and function from previous sections, a risk assessment has been prepared which presents the likelihood of an impact occurring and the consequence associated with that impact. The significance of the risks is described below:

- ***High significance:*** Complete destruction of a GDE in terms of complete loss of keystone species and conversion to an alternate degraded ecological state. Impacts are irreversible and the only feasible option for mitigation is an environmental offset under relevant environmental policy.
- ***Moderate significance:*** Degradation of a GDE to an extent that 25% or more keystone species are affected by the action. Impacts will be reversible only with mitigation.
- ***Low significance:*** Impacts are short in duration and reversible without mitigation required.
- ***Insignificant:*** Impacts are undetectable when assessed against a relevant ecological baseline.

The ranking applied to the assessment of likelihood including descriptor is provided in **Table 2**, descriptions of magnitude are applied in **Table 3** and the derived risk matrix is provided in **Table 4**. A list of applicable mitigations is provided in **Table 5**. The constructed risk assessment with a residual risk score is provided in **Table 6**.

Table 2. Descriptors and ranking for the likelihood of impact occurring.

Rank	Likelihood	Description
1	Highly unlikely	There is no precedent for this event in the industry and similar events have not previously occurred.
2	Unlikely	Impacts have been associated with previous industry actions although similar impact pathways are not identified for the Gemini project.
3	Possible	Impact pathways are not clearly understood and impacts have been previously associated with a similar industry action
4	Likely	Impacts have previously been associated with the industry and a clear impact pathway exists.
5	Highly likely	A common event that is consistently associated with a similar industry action/ of an action that is proposed to occur.

Table 3. Descriptors of Impact Magnitude applied in the risk assessment.

Magnitude	Description
Negligible	No impact identifiable above baseline ecological conditions
Low	Plant stress linked to mining activity that results in the reduction in volume and duration of groundwater supporting a GDE system that does not result in more than 5% dieback of mature canopy trees (defined as a canopy tree with DBH >60cm). Impact localised and reversible with mitigation.
Moderate	Plant stress linked to mining activity that results in the reduction in volume and duration of groundwater supporting a GDE system that does not result in more than 25% dieback of mature canopy trees (defined as a canopy tree with DBH >60cm). Impact is reversible with mitigation.
High	Significant harm (loss of 25 to 50% of mature canopy trees). Impact is reversible although a significant lag in return to pre-disturbance condition occurs (lag>20yrs). Vegetation is converted from remnant to non-remnant status and significant impacts to habitat for protected fauna species occurs. Biodiversity offsets may be required.
Severe	Irreversible impact to > 50% mature trees that cannot be mitigated. Vegetation is converted from remnant to non-remnant status and significant impacts to habitat for protected fauna species occurs. Biodiversity offsets will be required.

Table 4. Matrix applied in the risk assessment.

		Likelihood				
		Highly Unlikely (1)	**Unlikely (2)**	**Possible (3)**	**Likely (4)**	**Highly Likely (5)**
Consequence	**Severe**	Insignificant	Low	High	High	High
	High	Insignificant	Low	Moderate	High	High
	Moderate	Insignificant	Low	Moderate	Moderate	Moderate
	Low	Insignificant	Low	Low	Low	Low
	Negligible	Insignificant	Insignificant	Insignificant	Insignificant	Insignificant

Impact Pathway	Pre-mitigated Risk			**Comments**	Mitigation Measures	Residual Risk Ranking		
	Likelihood	Consequence	Risk			Likelihood	Consequence	Risk
Springton Tributary Area 1 GDE System								
1. Direct clearing of a GDE system.	5	Severe	High	The GDE is proposed to be cleared. Refer to Terrestrial ecology assessment report (AARC 2019) for clearing impacts.	5	5	Low	Low
2. A total or partial loss or reduction in the volume or pressure of the aquifer being utilised by GDEs.	NA	NA	NA		NA	NA	NA	NA
3. A change in the magnitude and timing of volume fluctuations in the aquifer being utilised by GDEs.	NA	NA	NA		NA	NA	NA	NA
4. Changes to the interaction between surface flows and aquifers being utilised by a GDE.	NA	NA	NA		NA	NA	NA	NA
5. Change in chemical composition of an aquifer detrimentally impacting the health of a GDE[1].	NA	NA	NA		NA	NA	NA	NA
Charlevue Creek GDE System								
1. Direct clearing of a GDE	1	Negligible	Insignificant	Mine and infrastructure footprint is located entirely outside the GDE area.	1	1	Negligible	Insignificant
2. A total or partial loss or reduction in the volume or pressure of the aquifer being utilised by GDEs.	2	Negligible	Insignificant	Perched groundwater system supporting GDE and underlying groundwater system in Tertiary sediments are not considered to have a significant hydraulic linkage.	4	1	Negligible	Insignificant
3. A change in the magnitude and timing of volume fluctuations in the aquifer being utilised by GDEs[1].	2	Negligible	Insignificant	Volume fluctuations in the perched groundwater system are regulated by surface flows, which will have very minor change due to lack of interruption	4	1	Negligible	Insignificant

Impact Pathway	Pre-mitigated Risk			**Comments**	Mitigation Measures	Residual Risk Ranking		
	Likelihood	Consequence	Risk			Likelihood	Consequence	Risk
				to upstream hydrology or catchment excision.				
4. Changes to the interaction between surface flows and aquifers being utilised by a GDE.	2	Low	Low	Flooding volume and frequency will not be significantly impacted by the Gemini development.	2, 3, 4	1	Low	Insignificant
5. Change in chemical composition of an aquifer detrimentally impacting the health of a GDE[1].	2	Low	Low	No controlled releases of mine water planned for either Charlevue Creek or Springton Creek. Uncontrolled releases of mine water are not predicted throughout the life of the mine.	2, 3, 4	1	Low	Insignificant

1. Assumes freshwater aquifers / groundwater with EC<1500 µS/cm. Withdrawal of saline aquifers / groundwater may have a positive impact on vegetation / habitat condition of a GDE

7.0 Conclusions

Multiple lines of evidence including measurement of LWP, SMP, stable isotopes and physical observation have been applied to assesses the dependence of vegetation in the Gemini Project area on groundwater. Based on the results of a single field survey event, two areas of likely groundwater dependence are recognised being:

1. Charlevue Creek Area 1, being an area identified as a terrestrial GDE on Charlevue Creek, to the west and upstream of the MIA.
2. Springton Tributary Area 1, being a terrestrial GDE associated with an ephemeral drainage system located within the footprint of the MIA.

The Charlevue Creek GDE area is hosted in an area of recent river alluvium, forming a flood terrace which is dissected by the channel of Charlevue Creek and traversed by a series of flood overflow channels. The GDE area is supported by an unconfined, fresh alluvial aquifer that is perched above the regional groundwater table associated with Tertiary, Permian and older alluvial sediments, and is seasonally recharged during surface flows including flood events and associated rainfall. Based on salinity data and stable isotope comparisons between twig xylem and groundwater samples, it is inferred that the perched aquifer is hydraulically disconnected from the regional Tertiary and alluvial aquifers which host groundwater with salinity values that range from mildly to highly toxic to trees. Based on stable isotope data, there is no indication that trees at this site, nor any tree sampled during the GDE assessment is using groundwater associated with the regional Tertiary, alluvial or Permian coal seam aquifers to any significant degree.

The Springton Tributary Area 1 GDE system is supported by a seasonally variable perched aquifer system that is hosted in a thick, coarse sand horizon developed below the flood plain of the minor tributary. The strong iron staining associated with the sandy aquifer material provides evidence for considerable seasonal fluctuation in groundwater levels, which are inferred to recharge and drain rapidly in response to rainfall and surface flows. Similar to the Charlevue Creek GDE system, the Springton Tributary system is perched above the regional Tertiary groundwater table and trees at the site, based on evidence from stable isotope analysis, show no evidence for utilisation of the deeper groundwater system.

The Springton Tributary GDE system, covering an area of 5.54 hectares is located within the MIA and is proposed for direct clearing impacts. Environmental offsets will be required as the only viable mitigation and these have been captured within offsets proposed for impacts to other significant terrestrial ecology values (as per AARC 2019).

The Charlevue Creek GDE system is supported by an alluvial aquifer that is perched above, and hydraulically disconnected from the deeper regional aquifers associated with the Tertiary, older alluvium, and Permian coal seams. Groundwater drawdown associated with mining void development is modelled to impact the regional groundwater table below the Charlevue Creek system. However, it is not anticipated that these impacts will not be propagated into the perched aquifer due to limited hydraulic connectivity between the perched and deeper aquifer systems that

will be impacted by groundwater drawdown. The Charlevue Creek GDE system is recharged by surface water flows, flooding and seasonal rainfall which will not be altered by mining development.

Mitigations to prevent impact to the Charlevue Creek system include general operational measures associated with project approval conditions which may include development of the Mine WMS and ESCP. Based on these mitigations, it is considered that the risk to the GDE system posed by mine development is negligible.

Appendix B – Auger Hole Logs

Site No	Auger No	Y	X	Summary	Position	Special features / Tree roots	Depth metres
M3	AU1	-23.69573	149.26631	0-0.25m - fine sand, yellow grey, moist; 0.25 - 0.5m - fine silty sand, moist and yellow with abundant tree roots; 0.5 - 0.75m fine silty sand, moist yellow. EOH at 0.75m on indurated sandstone.	In base of drainage depression	0.5 with abundant fine tree roots	0.75
M2	AU1	-23.67421	149.2538	0-0.75m - dry hard setting silty clay loam, grey brown. EOH @ 0.75m due to density of substrate.	Loamy plain with no distinctive features	0	0.75
M1	AU1	-23.67978	149.25313	0-0.25 - Grey yellow silty loam, dry to moist with tree roots; 0.35m abundant ironstone mottles; 0.25 - 0.5m -Loamy sand, yellow with iron staining and orange / brown mottles; 0.5 - 1.2m - yellow to orange loamy sand becoming coarse loamy sand, moist with strong iron mottling and staining; 1.2 - 1.5m - coarse sand merging on gravel with strong iron mottling, strong yellow to orange iron staining (moist to wet); 1.5 - 1.7 - yellow orange clayey sand with abundant mottling; 1.75- sand with iron cement, strong yellow to orange staining. EOH 1.8m	In base of channel overflow, 2m from base of Tree 3.	Dense tree roots at 0.25m depth	1.8
M1	AU2	-23.68063	149.2525	0-0.5 - Grey yellow silty loam, dry to moist with tree roots; 0.5 - 1m - fine loamy sand with minor clay nodule. Moist, yellow brown; 1 - 1.25m - Fine, moist yellow brown clayey sand with abundant ironstone staining and mottles; 1.25 - 1.5m - ironstained clayey fine sand to medium sand, yellow, moist to very moist; 1.5 - 2.0m - moist orange clayey sand with abundant iron mottling and staining; 2.0 - 2.2m- Moist orange clayey sand with some coarse sand layers, ,minor gravel fragments. EOH 2.2m	In base of channel overflow, 2m from base of Tree 5.	Dense tree roots at 0.25 to 0.5m depth	2.2
M4	AU1	-23.68622	149.2423	0-0.25 - Silty loam, dry, brown-grey with weak iron mottling and nodules; 0.25 - 1m, orange brown silty loam, slightly moist with week iron mottling and staining; 1-1.35m, fine silty sand, grey brown with abundant iron staining and mottling, slightly moist to moist; 1.4m EOH in cemented sand, hardpan layer with ironstone gravel.	Broad poorly defined drainage depression / flood plain, located near weakly incised drainage depression		1.4
M5	AU1	-23.65310404	149.287946	0-0.5m, silty coarse sand and gravel, moist red brown; 0.5m - 0.75m, grey brown fine clayey sand, moist with abundant fibrous tree roots; 0.75m - 1.0m, clayey sand, moist, red brown with ironstone mottling; 1.0 - 1.5m - clayey sand, moist, grey brown with abundand mottling and iron staining; 1.5 - 1.9 - yellow brown silty sand and gravel, moist with cemented hardpan / sandstone at 1.9m EOH.	Placed in stream channel at base of channel floor.	Abundant fibrous tree roots at 0.5m	1.9
M5	AU2	-23.65296	149.28802	Base of channel in grey brown silty / sandy loam. Minor seepage into creek channel	Base of bank adjacent to channel floor.		0.2
M6	AU1	-23.642758	149.314953				0.2
M7	AU1	-23.65010901	149.230038	0-0.35m - fine loamy sand, moist to wet, red brown; 0.35 - 1.0m - fine loamy sand, red brown, moist to wet; 1.0 - 2.2m - uniform moist to wet, red brown sandy loam. Fine tree roots dispersed throughout soil profile.	River flood plain 5m from top of bank.	Dense tree roots at 0.5m; Fine tree root recorded at 1.0 to end of hole dispersed throughout soil profile.	2.2
M7	AU2	-23.649934	149.229753	0 - 0.3, coarse brown sand, dry; 0.3 - 0.5 - moist clayey sand, red brown; 0.5 - 1.0 - Coarse river sand with some clay bands and charcoal, red brown to brown, wet to moist. EOH in wet sand at 2.0m.	Base of sandy channel		2
M8	AU1	-23.65427197	149.237651	0 - 1.0, coarse brown sand, with some clay nodules and charcoal, wet to moist. EOH in wet sand at 2.0m; 1.0 - 1.2m, coarse clayey sand with charcoal, moist to wet. EOH at gravel bed with tree roots immediately above gravel.	Base of sandy channel	1.2m at interface of sand and gravel. Tree roots to 0.25cm, scattered.	1.2

Site No	Auger No	Y	X	Summary	Position	Special features / Tree roots	Depth metres
M9	AU1	-23.64940401	149.246728	0 - 0.25, fine, dry sandy loam, red brown; 0.25 - 0.5m, sandy loam, red brown, abundance of fine tree roots; 0.5 - 1.0m, red brown moist sandy loam, abundant fine tree roots. 1.0 - 1.5m, red brown moist sandy loam, no tree roots; 1.5 - 2.2m, uniform red brown sandy loam, dry with no tree roots.	Top of bank, 4m from edge of channel incision	Fine tree roots to 1.0m.	2.2
M9	AU2	-23.64929304	149.246615	0 - 0.4m, moist, medium to coarse sand, grey brown; 0.4 - 1.0m, medium coarse, grey brown sand to clay sand with charcoal fragments. Moist to wet; 1.0 - 1.5m, medium to coarse fluvial sand, clayey nodules and charcoal, wet to saturated; 1.5 - 2.2, medium to coarse clay sand, clay nodules and charcoal that is wet to very wet. Matted red-gum tree roots at 2.2m at base of sand.	Base of sandy channel	Fine tree roots (red gum) to 25mm recorded at EOH.	2.2
M10	AU1	-23.629771	149.271611	0-0.5m, Red brown silty loam, dry with fine tree roots; 0.5 to 1.5m, red brown silty clay loam, uniform texture becoming moister toward base of hole; 1.5 - 2.1m, friable silty / sandy loam, red brown becoming moist. Abundant tree roots at base of hole.	Upper terrace 5m from top of bank.	Fine tree roots (red gum) to 25mm recorded at EOH.	2.1
M11	AU1	-23.60657701	149.266711	Fine to medim dry sand from surfance to end of hole.	Margins of sandy channel		0.25
M11	AU2	-23.60659302	149.266782	Sand in creek bank, in tree root zone, above base of sandstone basement.	In creek bank		0.5
M12	AU2	-23.62301339	149.280268	0- 0.5, clayey sand, dry, grey brown with abundant fine tree roots; 0.5 - 0.75, clayey sand, grey brown, dry to moist; 0.75 - 1.2, heavy clay, dry, orange brown with charcoal. EOH at 1.2m due to tree roots	Base of incised channel into clay basement	Refusal at end of hole due to dense tree roots.	1.2
M13	AU1	-23.60993698	149.311725	0 - 1.5m, silty clay loam to silty clay, grey brown, with charcoal fragments, moist. Fine tree roots dispersed thoughout clay; 1.5 -2m, loamy clay, grey brown with minor iron mottling, dense and moist. EOH at 2.0m due to extreme clay plasticity.	In stream channel, at base of floor, auger hole penetrated to depths > 1.5m below depth of the surface water.	Dispersed throughout soil profile, to 25mm diameter.	2
M14	AU1	-23.62814499	149.322902	0- 1.2, Silty clay loam, grey brown, dry. Uniform from top of hole to base.	Flood plain surface, 25m from drainage channel.		1.2

Appendix F. Rehabilitation Risk Assessment

Ref.	Risk Description				Control Effectiveness	Risk Evaluation					Risk Rating				Count				Final Risk Rating	Management Effectiveness
Risk Type (T=Threat) Category Subcategory Item	Risk Scenario/Threat Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Controls		Likelihood - Frequency	Likelihood - Probability	Health	Safety	Environment	Compliance	Health	Safety	Environment	Compliance	IV	III	II	I		
T A	**In Pit and Out pit waste**																				
T A 01	**Safe**																				
T A 01 01	Surface roughness (rockiness, depressions) in excess of that expected for the PMLU	Erosion gullies etc due to subsoil/ topsoil characteristics/availability, inadequate surface preparation, poor early germination, localised settlement, rock used for erosion control	Safety hazard for personnel, stock and wildlife	Surface preparation measures (initial), monitoring, maintenance controls (pre-closure), risk assess controls when designed and placed and modify as required, post-closure monitoring.	C2	P			L				II			0	0	1	0	II	
T A 01 02	Slope steepness in excess of that expected for the PMLU	Inappropriate landform design, landform design restrictions	Safety hazard for personnel, stock and wildlife	Landform design criteria appropriate to PMLU, operational slope controls	C1		U		L				I			0	0	0	1	I	
T A 02	**Stable - geotechnical risk**																				
T A 02 01	Significant slope failure	Excessive slope steepness, physical material properties, poor drainage, adverse rainfall event	Localised land impacts and downstream water quality impacts	Geotechnical analysis undertaken where appropriate, slope moderation, adequate drainage design constructed, rapid revegetation	C2		U		M	M			II	II		0	0	2	0	II	
T A 03	**Stable - erosional risk**																				
T A 03 01	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Dispersive topsoils and subsoils, adverse weather events	Localised land impacts and downstream water quality impacts	Soil sampling and analysis prior to rehabilitation. Landform design moderating slope, adequate/effective subsoil and topsoil amelioration, prompt revegetation establishment, revegetation monitoring and management as required, sediment controls during establishment.	C2	U				M				II		0	0	1	0	II	
T A 03 02	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Inadequate rehabilitation drainage capacity and/or design	Localised land impacts and downstream water quality impacts	Drainage network design with acceptable design standards for drainage structures, avoidance of flow concentration, subcatchment delineation, sufficient water storage structures, engineered flow channels, effective revegetation techniques, rehabilitation monitoring and management as required	C2	U				M				II		0	0	1	0	II	
T A 03 03	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Adverse climatic events and/or climatic sequences beyond design capacity	Localised land impacts and downstream water quality impacts	Existing rehabilitation of waste emplacements, downstream sedimentation controls, prompt revegetation, monitoring of drainage performance, maintenance and remediation as required.	C2	U				M				II		0	0	1	0	II	
T A 03 04	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Rehabilitation failure/ vegetation disease/loss, climatic events, other	Localised land impacts and downstream water quality impacts	Landform design moderating slope, adequate effective subsoil and topsoil amelioration, prompt revegetation establishment, revegetation monitoring, management and remediation as required.	C2	U				M				II		0	0	1	0	II	
T A 04	**Non-polluting - geochemical risk**																				
T A 04 01	Acid and saline drainage generation	Adverse waste rock geochemistry	Revegetation performance impacts, water quality in pit lake and downstream receiving environment, and dependent ecosystem impacts, groundwater impacts (incl.GDEs)	Out of pit waste emplacement to be constructed to design specifications as prepared by an AQP. Negative NAPP waste rock materials, low propensity for saline drainage. Coal rejects to be encapsulated deep within waste emplacements. Routine confirmatory geochemical testing. Regular monitoring and assessment of runoff and pit lake water quality.	C2		P			L				II		0	0	1	0	II	
T A 05	**Non-polluting - other environmental harm**																				
T A 05 01	Not applicable															0	0	0	0		
T A 06	**Sustainable - PMLU**																				

Ref.	Risk Description				Risk Evaluation						Risk Rating				Count					
Risk Type (T=Threat) Category Subcategory Item	Risk Scenario/Threat Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Controls	Control Effectiveness	Likelihood - Frequency	Likelihood - Probability	Health	Safety	Environment	Compliance	Health	Safety	Environment	Compliance	IV	III	II	I	Final Risk Rating	Management Effectiveness
T A 06 01	Insufficient pasture density/diversity and recruitment	Weather, poor soil characteristics, poor management practices impacting germination, vegetation establishment and PMLU density metrics, and shortage of topsoil resources	Insufficient pasture productivity	Improving rehabilitation methodologies, rehabilitation area monitoring and assessment, undertake repairs and maintenance works as required	C1	U				L				I		0	0	0	1	I	
T A 06 02	Insufficient topsoil resources onsite available to undertake rehabilitation activities	Poor management practices, shortage of topsoil resources	Poor vegetation establishment, insufficient habitat suitable for native fauna, insufficient pasture productivity	Adequate topsoil stockpiling and management strategies, annual review of topsoil inventory	C2	U				M				II		0	0	1	0	II	
T A 06 03	Pests and weeds	Poor local, regional or site property management practices.	Increased risk of not achieving designated PMLU	Pest and weed management practices, monitoring programs to allow early detection and management, intensify monitoring and management measures as appropriate.	C1	U				L				I		0	0	0	1	I	
T B	**Temporary waste emplacement**																				
T B 01	**Safe**																				
T B 01 01	Surface roughness (rockiness and depressions) in excess of that expected for the PMLU	Erosion gullies etc due to some dispersive subsoils/ topsoils, inadequate surface preparation, localised settlement	Safety hazard for personnel, stock and wildlife	Surface preparation measures (initial), maintenance controls (pre-closure), rehabilitation monitoring and assessment, undertake repairs and maintence as required	C2	P		L					II			0	0	1	0	II	
T B 01 02	Slope steepness in excess of that expected for the PMLU	Landform not constructed to design	Safety hazard for personnel, stock and wildlife	Dump and slope survey controls, reshaping to design	C1	U		L					I			0	0	0	1	I	
T B 02	**Stable - geotechnical risk**																				
T B 02 01	Significant slope failure	Landform not constructed to design, excessive slope steepness, physical material properties, inadequate drainage controls, adverse rainfall event	Localised land impacts and downstream water quality impacts	Slope moderation, maximum slopes subject to engineered design by geotechnical analysis, provision of adequate drainage infrastructure, rapid revegetation, rehabilitation monitoring and assessment, undertake repairs and maintenance as required	C2	U		M	M				II	II		0	0	2	0	II	
T B 03	**Stable - erosional risk**																				
T B 03 01	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Dispersive topsoils and subsoils, adverse weather events	Localised land impacts and downstream water quality impacts	Landform design moderating slope, adequate/effective subsoil and topsoil amelioration, prompt revegetation establishment,sediment controls during vegetation establishment, revegetation monitoring, revegetation maintenace and repairs as required, modify revegetation methods and techniques and other contributing factors to improve the likelihood of revegetation success on rehabilitated slopes where required	C1	U				L				I		0	0	0	1	I	
T B 03 02	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Inadequate rehabilitation drainage capacity and/or design	Localised land impacts and downstream water quality impacts	Drainage network design with acceptable design standards for drainage structures, avoidance of flow concentration, subcatchment delineation, sufficient water storage structures, engineered flow channels, effective revegetation techniques, rehabilitation monitoring, regular (typically annual) review of water management design parameters, monitoring of drainage network performance, prompt remediation and causal feedback loop to water management system review	C1	U				L				I		0	0	0	1	I	

Ref.				Risk Description				Control Effectiveness	Risk Evaluation				Risk Rating				Count				Final Risk Rating	Management Effectiveness
Risk Type (T=Threat)	Category	Subcategory	Item	Risk Scenario/Threat Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Controls		Likelihood - Frequency	Likelihood - Probability	Health	Safety	Environment	Compliance	Health	Safety	Environment	Compliance	IV	III	II	I		
T	B	03	03	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas	Adverse climatic events and/or climatic sequences beyond design capacity	Localised land impacts and downstream water quality impacts	Existing rehabilitation of waste rock emplacements, downstream sedimentation controls, prompt revegetation, regular (typically annual) review of water management design parameters, monitoring of drainage network performance, undertake repairs and maintenance as required, prompt remediation and causal feedback loop to water management system review	C2		P			L				II		0	0	1	0	II	
T	B	03	04	Initial/ongoing gully, pipe and/or sheet erosion of rehabilitated areas (medium-long term risk)	Rehabilitation failure/ vegetation disease/loss, climatic events (drought), other	Localised land impacts and downstream water quality impacts	Landform design moderating slope, adequate/effective subsoil and topsoil amelioration, prompt revegetation establishment, modify revegetation methods and techniques and other contributing factors to improve the likelihood of revegetation success on rehabilitation slopes, rehabilitation area monitoring and assessment, undertake repairs and maintenance as required.	C2		P			L				II		0	0	1	0	II	
T	**B**	**04**		**Non-polluting - geochemical risk**																				
T	B	04	01	Acid and saline drainage generation	Adverse waste rock geochemistry	Revegetation performance impacts, downstream receiving environment water quality and dependent ecosystem impacts	Negative NAPP waste rock materials, low propensity for saline drainage generation. All waste material to be removed and followed by confirmatory geochemical testing of exposed subsoil. Monitoring and assessment of runoff water quality.	C1		U			L				I		0	0	0	1	I	
T	**B**	**05**		**Non-polluting - other environmental harm**																				
T	B	05	01	Not applicable															0	0	0	0		
T	**B**	**06**		**Sustainable - PMLU**																				
T	B	06	01	Insufficient pasture density/diversity and recruitment	Weather, poor soil characteristics, poor management practices impacting and PMLU density metrics, and shortage of topsoil resources	Insufficient pasture productivity	Improving rehabilitation methodologies, rehabilitation area monitoring and assessment, undertake repairs and maintenance works as required	C2		P			L				II		0	0	1	0	II	
T	B	06	02	Insufficient topsoil resources onsite available to undertake rehabilitation activities	Poor management practices, shortage of topsoil resources	Poor vegetation establishment, insufficient habitat suitable for native fauna, insufficient pasture productivity	Adequate topsoil stockpiling and management strategies, annual review of topsoil inventory	C2		U			M				II		0	0	1	0	II	
T	B	06	03	Pests and weeds	Poor local, regional or site property management practices	Increased risk of not achieving designated PMLU	Pest and weed management practices, monitoring programs to allow early detection and management, intensify monitoring and management measures as appropriate	C1		U			L				I		0	0	0	1	I	
T	**C**			**Residual void lakes**																				
T	**C**	**01**		**Safe**																				
T	C	01	01	Void overtopping	Extreme rainfall events beyond design capacity, insufficient water level monitoring	Increased hazard to humans and animals	Long term groundwater modelling and final void water balance confirms the final void will remain as a sink with no risk of overtopping. Void walls and base constructed to design criteria.	C1		R		L				I			0	0	0	1	I	
T	C	01	02	Cattle, humans or wildlife access to the residual void	Insufficient warnings, barriers preventing access to hazardous areas, fencing/bunding breaks, unauthorised access	Falls, slips, trips impacting humans, livestock and wildlife. Livestock accessing void water for drinking	Signage, physical barriers, slope moderation, conduct a risk assessment of controls when designed and placed. Modify as required. Post closure monitoring.	C2		U		M				II			0	0	1	0	II	
T	**C**	**02**		**Stable - geotechnical risk**																				

Ref.	Risk Description				Risk Evaluation						Risk Rating				Count					
Risk Type (T=Threat) Category Subcategory Item	Risk Scenario/Threat Title	Causes (Triggers / Indicators)	Impacts (Consequences)	Controls	Control Effectiveness	Likelihood - Frequency	Likelihood - Probability	Health	Safety	Environment	Compliance	Health	Safety	Environment	Compliance	IV	III	II	I	Final Risk Rating	Management Effectiveness
T C 02 01	Final void walls subject to significant slope failure	Excessive slopes, inadequate design, not constructed to design, inadequate drainage controls, adverse weather event	Localised impacts to land (highwall) and residual void water quality	Slope moderation, final landform design, maximum slopes subject to engineered design, assessment of construction materials by a suitably qualified person, provision of adequate drainage infrastructure, geotechnical assessment undertaken at closure. Certification by a suitably qualified expert that the final landform is stable and constructed according to design criteria.	C3		P		M	M			III	III		0	2	0	0	III	M3
T C 03	**Stable - erosional risk**																				
T C 03 01	Initial/ongoing gully, pipe and/or sheet erosion of the void walls	Faults and fractures in the underlying geology, adverse weather events	Localised land impacts, water quality impacts (water contained within the pit)	Landform design in accordance with geotechnical assessment of the site, monitoring and management as required.	C3	P			L	M			II	III		0	1	1	0	III	M3
T C 03 02	Initial/ongoing gully, pipe and/or sheet erosion of the void walls	Inadequate design, erodible topsoil and subsoils	Localised land impacts, water quality impacts (water contained within the pit)	Landform including highwalls and site drainage network to be constructed as designed. Monitoring of drainage networkvperformance, prompt remediation. Certification by a suitably qualified person that the final landform is stable and constructed according to design criteria	C3		P		L	M			II	III		0	1	1	0	III	M3
T C 03 03	Initial/ongoing gully, pipe and/or sheet erosion of the void walls	Adverse climatic events and/or climatic sequences beyond design capacity	Localised land impacts, water quality impacts (water contained within the pit)	Final void designed to prevent excessive runoff from entering the final void during rainfall events. Prompt remediation, post-weather event monitoring of final void water quality, high walls and low wall	C3		P			M				III		0	1	0	0	III	M3
T C 04	**Non-polluting - geochemical risk**																				
T C 04 01	Release of void water to the receiving environment	Void long term water level lies above natural groundwater level, overtopping, floodwater ingress.	Adverse impacts to downstream surface water quality, groundwater quality and dependent ecosystems (including GDEs).	Long term groundwater modelling and final void water balance confirms the final void will remain as a sink with no risk of overtopping. Final voids are located outside PMF levels. Monitoring of pit water quality to be undertaken and assessed against model predictions. Geotechnical/geochemical assessment, groundwater monitoring program	C1		R			L				I		0	0	0	1	I	
T C 04 02	Exposure of reactive material conatined within void (i.e. tailings, PAF)	Pit completely dries out exposing reactive material to air (oxidising conditions)	Worsening void quality - increased consequences if water is released from void	Geochemical assessments have shown low acid producing potential of waste. Constant characterzation is expected for constant monitoring of potential acid forming material	C1		U			L				I		0	0	0	1	I	
T C 05	**Non-polluting - other environmental harm**																				
T C 05 01	Not applicable															0	0	0	0		
T C 06	**Sustainable - PMLU**																				
T C 06 01	Not applicable																				
T D	**Residual void highwalls**																				
T D 01	**Safe**																				
T D 01 01	Surface roughness (rockiness and depressions) in excess of that expected for the PMLU	Erosion gullies etc due to some dispersive subsoils/ topsoils, inadequate surface preparation, localised settlement	Safety hazard for personnel, stock and wildlife (terrestrial and aquatic)	Surface preparation measures (initial), maintenance controls (pre-closure), rehabilitation monitoring and assessment, undertake repairs and maintence as required, adequate safety bunding and fencing installed around highwall perimeter.	C3		P		M	M			III	III		0	2	0	0	III	M3
T D 01 02	Slope steepness in excess of that expected for the PMLU	Landform not constructed to design	Safety hazard for personnel, stock and wildlife	Slope survey controls, reshaping to design, adequate safety bunding and fencing installed around highwall perimeter.	C3		P		M	M			III	III		0	2	0	0	III	M3
T D 02	**Stable - geotechnical risk**																				

Ref.	Risk Description				Control Effectiveness	Risk Evaluation					Risk Rating				Count				Final Risk Rating	Management Effectiveness

Rehabilitation transect pro-forma

Project:				
Date:		Season:	Wet Dry	
Recorder:				
Transect name:				
Start point:	Easting:		Northing:	
End point:	Easting:		Northing:	
Datum:			Zone:	
Photo No:	Start (0 m):	Mid (50 to 0 m)	Mid (50 to 100 m)	End (100 m):

Site Location:	
Landscape Context*:	
Notes:	

* rocky hill, slope, valley bottom, floodplain, clay plains, etc.

Erosion pattern^	Slope (º)	Slope aspect# (e.g. Slope direction in degrees)

^ refers to the combination of local relief and slope class (refer to Speight (2009) classification system attached).

At the mid-point record the direction in degrees, of the downward slope of the transect. For flat areas record a dash.

P-EA-100114292: Magnetic South Pty Ltd – Landholder statement regarding intent to retain site infrastructure

Magnetic South Pty Ltd (Magnetic South) has considered the potential economic benefits of retaining infrastructure proposed to be constructed as part of the Gemini Coal Mine. Infrastructure such as access roads, dams and workshops are consistent with the current land use and approved grazing post-mining land use (PMLU).

Magnetic South is the landholder and the environmental authority holder of the properties underlying ML 700056 upon which environmentally relevant activities are proposed to be undertaken, and therefore wishes to advise the Department of Environment, Tourism, Science and Innovation (DETSI) its intention to retain the following infrastructure for use in future agricultural undertakings:

Infrastructure	Description
Access roads and tracks	Roads to be used for equipment access, mustering, firebreaks and general transportation around the properties.
Water storages	Raw water and sediment dams are to be used for stock watering purposes and erosion and sediment control structures where required.
Workshop	For machinery and storage associated with pastoral activities.
Powerline	Used to provide grid electricity to the retained workshop to facilitate pastoral activities.

Water storages and infrastructure to be retained have been identified as RA8 and RA10, respectively, in the proposed PRCP. These locations are further identified in the spatial information submission accompanying this application.

MAGNETIC SOUTH

Magnetic South Pty Ltd understands its obligations and general environmental duty under the Environmental Protection Act 1994 to not carry out any activity that causes or is likely to cause environmental harm unless all reasonable and practicable measures to prevent or minimise the harm are taken. To that end, the infrastructure listed above will be rehabilitated and/or maintained sufficiently so that the structures do not pose harm to future agricultural undertakings or the receiving environment.

Yours sincerely,

Mr James Xu
Magnetic South – Resource Development – Divisional Manager
(BSc(Geology) MBA MAusIMM)

1 Introduction

Magnetic South Pty Ltd has commissioned AARC Environmental Solutions Pty Ltd (AARC) to develop an Erosion Stability Assessment (ESA) for the Gemini Coal Mine (the Project).

This assessment has been prepared to satisfy the information requirements of the Guideline – Progressive Rehabilitation and Closure Plans (DESI 2024) – specifically, the completion of erosion modelling to predict the long-term stability of final landforms at the Project.

Erosional stability for the Project has been assessed using the Water Erosion Prediction Project (WEPP) model. The WEPP model was used to predict long-term stability outcomes for final landforms (both existing and proposed) on site.

The WEPP model is a process-based, distributed parameter, continuous simulation erosion prediction model. It considers various factors, including slope design, climate information, vegetation management structures and soil parameters (National Soil Erosion Research Laboratory 1995).

WEPP modelling was used to assess the erosional stability of various representative rehabilitated slopes, as identified in the final landform.

1.1 Project description

The Project is situated within the Bowen Basin, approximately 110 km east of Emerald and 125 km southwest of Rockhampton, in central Queensland. The Project is comprised of a single Mining Lease (ML 700056), which covers a total area of 6121 ha.

The Gemini open cut metallurgical coal mine will produce PCI coal and coking coal for export to the international steel-making industry. The Project targets a mining output of 1.9 Mtpa ROM and is scheduled to operate 24 hours a day, 7 days a week, during its operating life.

The open cut mining areas will be developed using a conventional truck and shovel mining method with excavators and haul trucks. The coal product will be transported via the Blackwater railway to the Port of Gladstone for export to international markets. The overall Project term is anticipated to be 37 years from the grant of the ML, including initial construction, mine operation, and rehabilitation activities. On Project commencement, mine construction activities are expected to take approximately six months to establish the necessary infrastructure for overburden removal, followed by an additional 18 months to initiate coal production.

1.2 Scope

The following scope of work has been completed for the erosion stability assessment:

- review of the proposed final landform design;
- review of rehabilitation monitoring data associated with existing rehabilitation areas;
- erosion modelling (WEPP analysis) for slopes in the final landform;
- recommendations of suitable landform design criteria and vegetation cover criteria for inclusion in the Progressive Rehabilitation and Closure Plan (PRCP); and
- recommendations for other management actions and measurable objectives to ensure the long-term stability of rehabilitated slopes.

This assessment incorporates modelling and analysis of theoretical surface erosion risk for structures. The assessment does not address the geotechnical stability of the constructed landforms or the associated risk of mass failure.

1.3 Current landform design

Post-mining land use descriptions for land disturbed by mining activities are described in the proposed PRCP. Landform design criteria for all rehabilitation areas for the final landforms are as follows:

- For waste rock emplacement (WRE) landforms and final void low walls:
  - a maximum slope angle of 6°;
  - a maximum uninterrupted batter slope length of 230 m; and
  - separated by flat berms of 10 to 15 m width, designed not to concentrate runoff.
- For final void high walls:
  - a maximum slope angle of 18° where located within the unconsolidated sediments and saturated tertiary; and
  - an overall angle of 55° by constructing 50 m high batters at 65°, incorporating 15 m wide intermediate benches.

For the final void high wall, only the 18° slopes and benches will support growth media and seeding, with the batters remaining as throw-blasted rock. Given that the benches will be flat and, therefore, subject to minimal erosion, this assessment only considers the WRE and low wall slopes and the 18° high wall slopes.

2 Methodology

2.1 Soil profile

WEPP soil profiles were generated from the twelve soil management units (SMUs) were included for modelling derived from the Gemini Soil and Land Suitability Assessment (AARC 2019) (see Figure 1), namely:

- Anderson
- Barry
- Charlevue
- Cooinda
- Ellesmere
- Geoffrey
- James
- Kosh
- Namoi
- Nigel
- Normanby
- Wallace

The following data types were included in the WEPP soil profile based on the surface soil properties of each SMU, which is representative of the expected topsoil depths to be applied to the post-mining landforms:

- sand (%);
- clay (%);
- organic (%);
- CEC (meq/100g);
- rock (%);
- soil texture; and
- albedo.

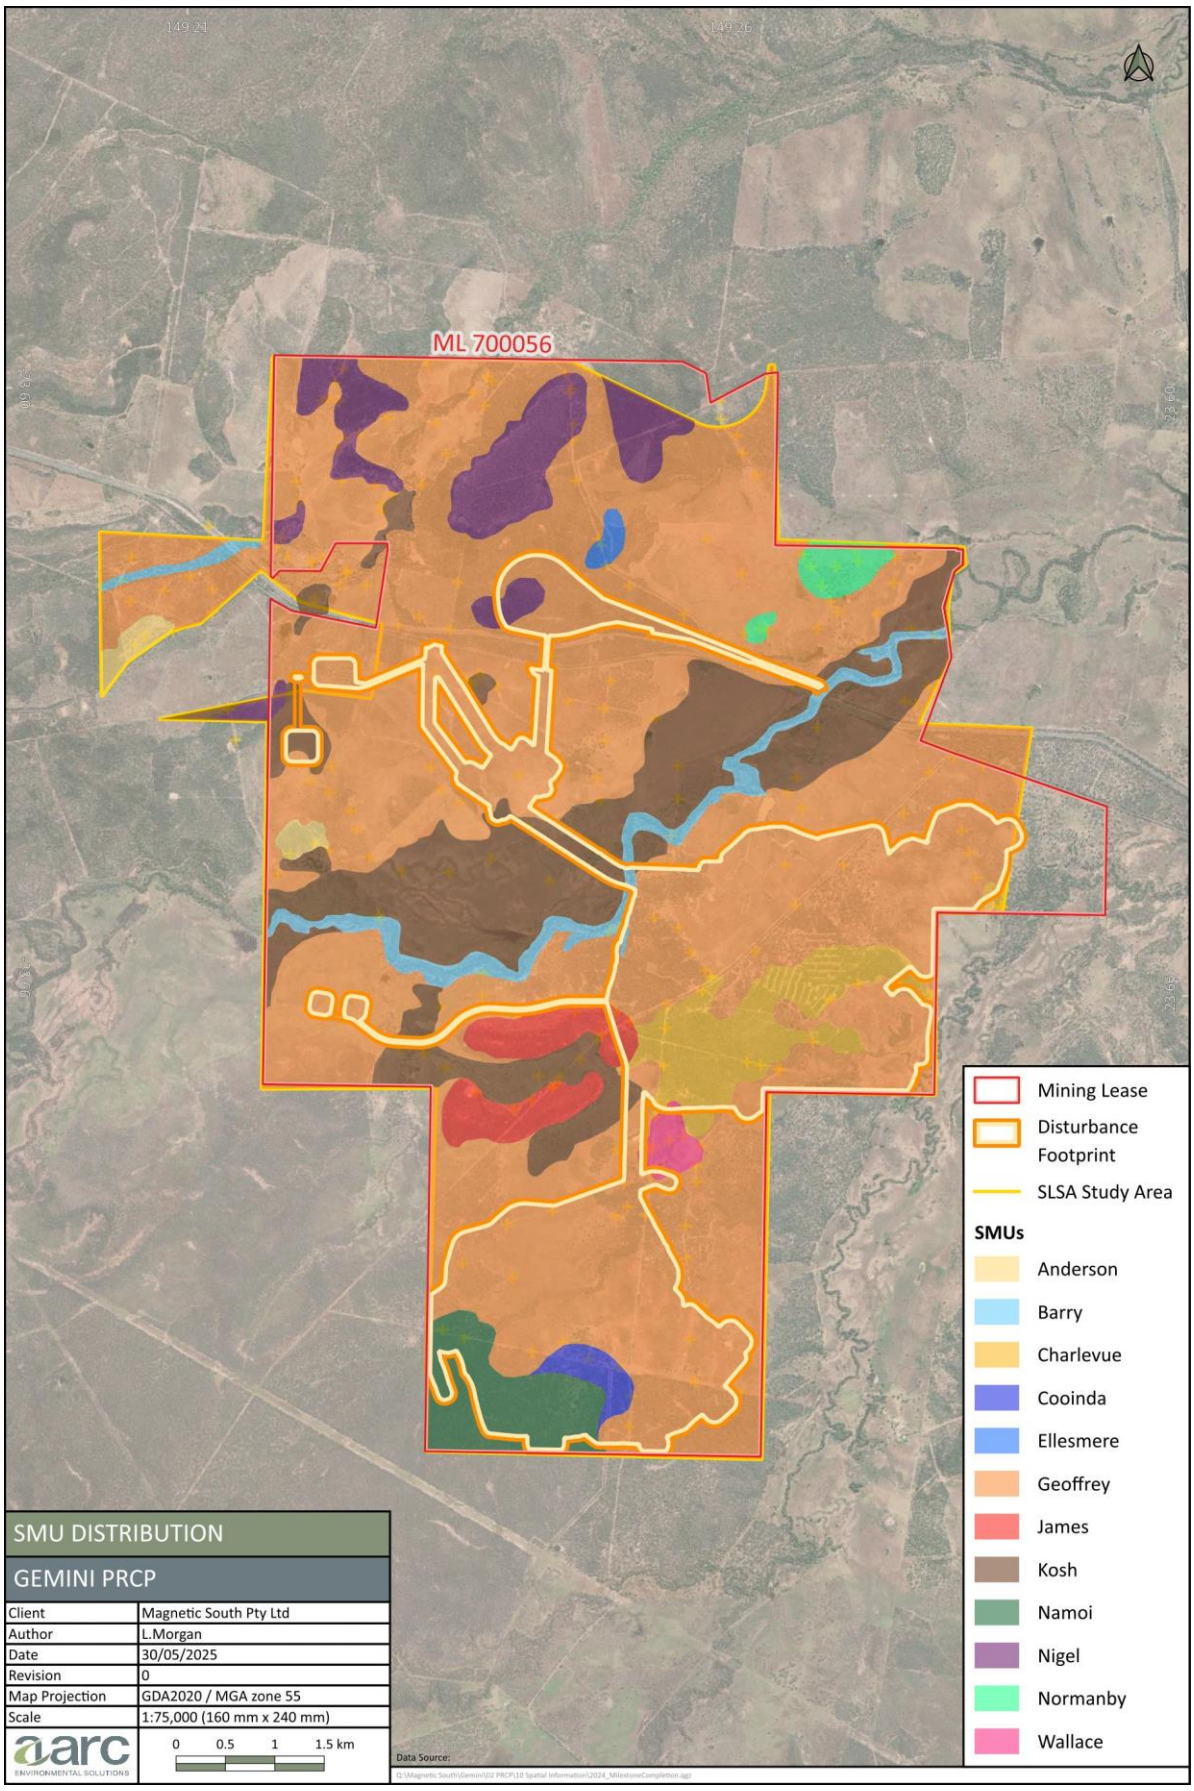

Figure 1: SMU Distribution at Gemini

The initial saturation was left at a default value of 75%, and interrill erodibility, rill erodibility, critical shear and effective hydraulic conductivity were estimated from the model for each soil profile. The following functions are used to estimate interrill erodibility (K_i), rill erodibility (K_r), critical shear (τ_c) and effective hydraulic conductivity (K_b) (National Soil Erosion Research Laboratory 1995; Alberts *et al.* 1995).

For soils that contain 30% or more sand:

$$K_i = 2728000 + 192100 \times VFS$$

$$K_r = 0.00197 + 0.00030 \times VFS + 0.03863 \times e^{-1.84 \times ORGMAT}$$

$$\tau_c = 2.67 + 0.065 \times CLAY - 0.058 \times VFS$$

For soils that contain less than 30% sand:

$$K_i = 6054000 - 55130 \times CLAY$$

$$K_r = 0.0069 + 0.134 \times e^{-0.20 \times CLAY}$$

$$\tau_c = 3.5$$

Where, VFS is percent very fine sand, $ORGMAT$ is the organic material contained in the surface soil, and $CLAY$ is percent clay.

In estimating effective hydraulic conductivity (K_b) for soils that contain 40% or more clay, the following function is used:

$$K_b = -0.265 + 0.0086 \times SAND^{1.8} + 11.46 \times CEC^{-0.75}$$

For soils that contain less than 40% clay:

$$K_b = 0.0066 \times e^{\frac{244}{CLAY}}$$

Where $SAND$ is percent sand, CEC is cation exchange capacity (mg/100g), and $CLAY$ is percent clay.

Interrill erodibility, rill erodibility, critical shear and effective hydraulic conductivity values for all topsoil samples considered can be found in Appendix A. Considering the accuracy of the internally calculated baseline parameters, published literature based on the latest version of WEPP suggests that satisfactory predictions of runoff and soil loss can be made without additional laboratory testing (Wang et al. 2022). As such, it is reasonable to conclude that the baseline erodibility parameters are sufficient for predicting runoff and soil loss.

2.2 Climate

For each day of the simulation, WEPP requires ten daily weather variables, namely precipitation depth and duration, peak storm intensity and time to peak, minimum and maximum temperatures, dew point temperature, solar radiation, wind speed and direction. For inclusion into the WEPP model for runoff and erosion prediction, these observation parameters were generated using CLIGEN.

CLIGEN is a stochastic weather generator that produces daily estimates of precipitation, temperature, dewpoint, wind, and solar radiation for a single geographic point, using monthly parameters (means, standard deviations, skewness, *etc*.) derived from historic measurements (Nicks *et al.* 1995). CLIGEN requires

a .PAR file, which was constructed using the methods outlined in Yu (2005). All parameters required a total of 12 entries, with each entry often corresponding to average values in each month. Additionally, as the U.S. Department of Agriculture created WEPP, all parameters used in creating the climate file are converted to U.S. customary units.

In developing the parameter file, daily weather data was sourced from SILO using the grid-point data method from 25 July 1998 to 24 July 2011. The data was taken from point 148.40, -22.45 and contained the following parameters:

- daily rainfall (mm);
- maximum temperature (°C);
- minimum temperature (°C);
- radiation (MJ/m^2); and
- relative humidity at maximum temperature (%).

The above information was used for the following CLIGEN parameters:

- mean rainfall amount on wet days (in - 12 values, one for each month);
- standard deviation of rainfall amount on wet days (12 values, one for each month);
- skewness of daily rainfall amount on wet days (12 values, one for each month);
- probability of a wet day following a wet day (12 values, one for each month);
- probability of a wet day following a dry day (12 values, one for each month);
- the mean daily minimum temperature (°F - 12 values, one for each month);
- standard deviation of the minimum temperature (12 values, one for each month);
- the mean daily maximum temperature (°F - 12 values one for each month);
- standard deviation of the maximum temperature (12 values, one for each month);
- the mean solar radiation (langleys - 12 values, one for each month); and
- standard deviation of daily solar radiation (12 values, one for each month).

As there were no onsite rainfall intensity measurements for the Project, 6-minute pluviograph data was sourced from the Bureau of Meteorology. The Iffley weather station (034100) pluviograph data was used for its proximity to the site and most recent records, spanning 25 July 1998 to 24 July 2011. This information was used for the following CLIGEN parameters:

- mean maximum 30-min rainfall depth (in - 12 values, one for each month); and
- empirical distribution of the relative time to peak (12 values).

The initial parameters relating to daily rainfall, temperature and solar radiation were sourced directly from the SILO data.

The probability of a wet day following a wet day ($\Pr(W|W)$) and the probability of a wet day following a dry day ($\Pr(W|D)$) was calculated as follows (Yu 2005; Wang *et al.* 2018):

$$\Pr(W|W) = \frac{Nww}{Ndw + Nww}$$

$$\Pr(W|D) = \frac{Nwd}{Ndw + Ndd}$$

Where:

- a critical precipitation amount (cr) of 0.2 mm was set, such that a wet day is one where $r \geq cr$ where r is the amount of precipitation observed on that day;
- Ndd was the total number of dry days in a month following a dry day;
- Ndw was the total number of dry days in a month following a wet day;
- Nwd was the total number of wet days in a month following a dry day; and
- Nww be the total number of wet days in a month following a wet day.

To estimate the mean maximum 30-min rainfall depth, the number of 30-minute (Δt) wet intervals (M) within a day such that any rainfall events within a day form a single storm event was calculated. The storm duration in minutes (D) was then calculated using the formula derived by Yu (2005) and Wang *et al.* (2018):

$$D = M\Delta t$$

The mean maximum 30-min rainfall depth ($\mathrm{MX.5P}$) was then calculated using the formula (Yu 2005; Wang *et al.* 2018):

$$\mathrm{MX.5P} = \frac{1}{k}\sum \max I_{30}$$

Where, be I_{30} is the maximum 30-minute interval within the storm duration and $\max I_{30}$ is the 30-minute interval of each month be for each year for k (months).

In determining the empirical distribution of relative time to peak, the peak intensity (i) of a storm event must first be calculated. The time to peak intensity of a storm (t_p) can be given by (Yu 2005; Wang *et al.* 2018):

$$t_p = \frac{i - 0.5}{M}$$

The empirical distribution of time to peak ($TimePk$) is calculated using the following formula (Yu 2005; Wang *et al.* 2018):

$$TimePk(i) = \frac{Ntp(i)}{Ntp(12)} \text{ for } i = 1, 2, \dots, 12$$

Where, taking the values calculated for t_p, let $Ntp(i)$ be the number of wet days with $tp \leq \frac{i}{12}$ for $i = 1, 2, \dots, 12$, as per a 12-break probability distribution.

Finally, dew point (T_{dp}) was estimated using the formula proposed by Lawrence (2005):

$$T_{dp} \approx T_{\circ F} - \frac{9}{25}(100 - RH)$$

Where, $T_{\circ F}$ is maximum temperature in degrees Fahrenheit, and RH is relative humidity at the maximum temperature.

The parameters calculated above were then entered into a PAR file and processed in WEPP using the Climate Builder tool. CLIGEN v5.3 was then used to build the final climate file.

2.3 Slope profile

Slope profiles were constructed based on the maximum design specifications outlined in Section 1.3 for the WRE and low wall slopes and the 18° high wall slopes. Two slope profiles were used for the erosion modelling, one representing the WRE and low wall slopes (WRE slope) and the other representing the high wall slopes (high wall slope).

The WRE slope was modelled to a length of 230 m at a slope angle of 6° (approximately 10.51%), consistent with the maximum uninterrupted batter length. Batters were not included in the erosion modelling on the

basis that these structures will act as a deposition zone for sediment leaving the slope and dissipate surface runoff. As such, the erosive processes will be isolated for each batter and should be modelled as such.

The high wall slope was modelled to a length of 155 m at a slope angle of 18° (approximately 32.49%), consistent with the slope design assessed as part of the geotechnical modelling for the final void high walls.

2.4 Vegetation management

Simulated vegetation cover was produced based on the proposed rehabilitation milestones and PMLUs. In WEPP total vegetation cover includes both live and dead vegetation with fixed rooted plant species, described as 'canopy cover' in the WEPP model, and litter/organic materials, described as 'residue cover', which includes 'rill cover' and 'interrill cover' in the WEPP model (National Soil Erosion Research Laboratory 1995). As such, vegetation cover includes both canopy cover and groundcover for the purposes of determining the minimum cover required to ensure slope stability.

In creating the land use management parameters for WEPP modelling, cover classes were established at 5% intervals ranging from 0% to 100%. Vegetation cover was fixed at these percentages throughout the WEPP simulations, such that consistent cover was maintained across the 100-year simulation period without growth or decay.

3 Results

As part of construction activities on site, topsoil stripping to a depth of 30 cm will be undertaken and stockpiled for rehabilitation of the site. These topsoil stockpiles will be dumped in cleared areas adjacent to mining activities to reduce haul time during rehabilitation works and to improve the likelihood that rehabilitation is consistent with the pre-mining land use and condition. As such, WRE slopes and final void high walls will generally be rehabilitated with the pre-mining topsoil located beneath the proposed disturbance, consistent with the rehabilitation practices outlined above. Impacted SMUs over the proposed disturbance area and their locations relevant to the WREs and final void high walls can be found in Table 1.

Table 1: SMUs impacted by the Gemini Coal Mine

SMU	Area Impacted (ha)	Percentage (%)	Impacted by WRE	Impacted by High Wall
Barry	7.8	0.40	Yes	No
Charlevue	217.8	11.07	Yes	Yes
Cooinda	34.9	1.77	Yes	Yes
Geoffrey	1477.0	75.06	Yes	Yes
James	16.5	0.84	Yes	No
Kosh	59.5	3.02	No	No
Namoi	132.5	6.73	Yes	Yes
Nigel	16.5	0.84	No	No
Wallace	5.3	0.27	Yes	No

In total, 504 100-year WEPP iterations were run, covering the range of slopes, SMUs and land use management profiles identified above. To determine the maximum potential erosivity of the slope, the average annual soil loss, expressed in tonnes per hectare per year (t/ha/yr), for each iteration was calculated and assessed against a target and maximum erosion rate. A target (or 'tolerable') erosion rate of 5 t/ha was adopted for assessing land suitability and erosivity risk (Landloch 2013; Howard and Loch 2019). Additionally, a maximum tolerable erosion rate of 10 t/ha was adopted, as the rate was considered acceptable for mining rehabilitation purposes (Lu 2001). The results of this analysis can be found in Figure 2 and Figure 3 for the WRE and high wall slopes, respectively.

Additionally, based on the topsoil rehabilitation considerations provided in Table 1, analysis of soil loss for only the SMUs underlying the WRE and high wall slopes can be found in Figure 4 and Figure 5, respectively.

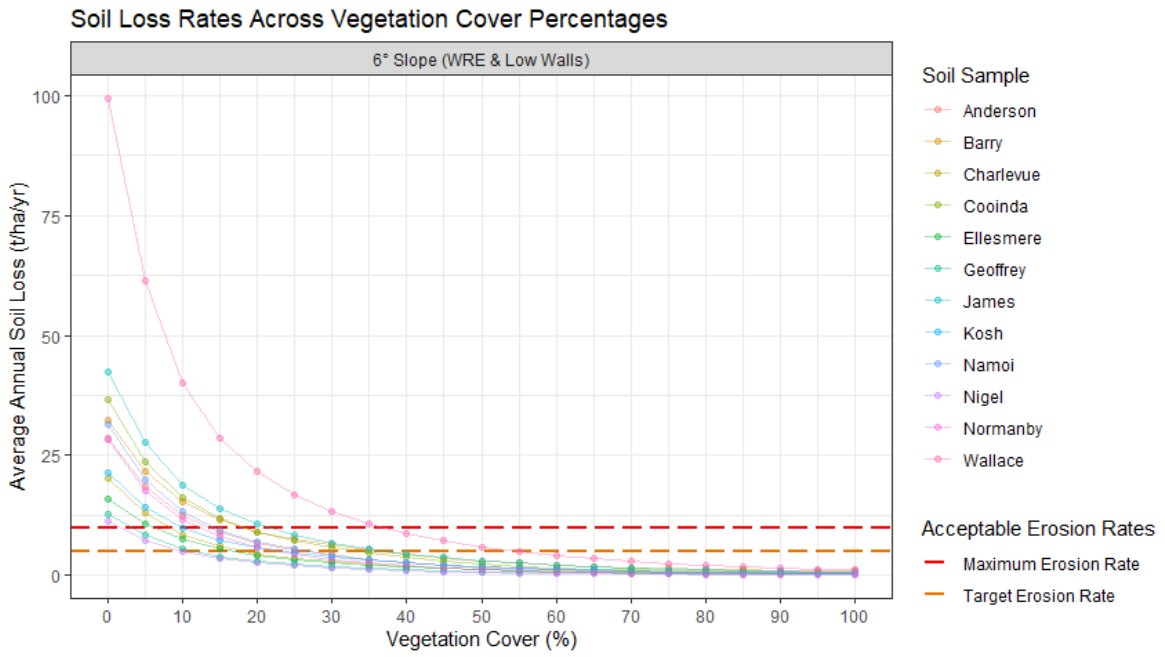

Figure 2: WRE slope average annual soil loss rates (t/ha/yr)

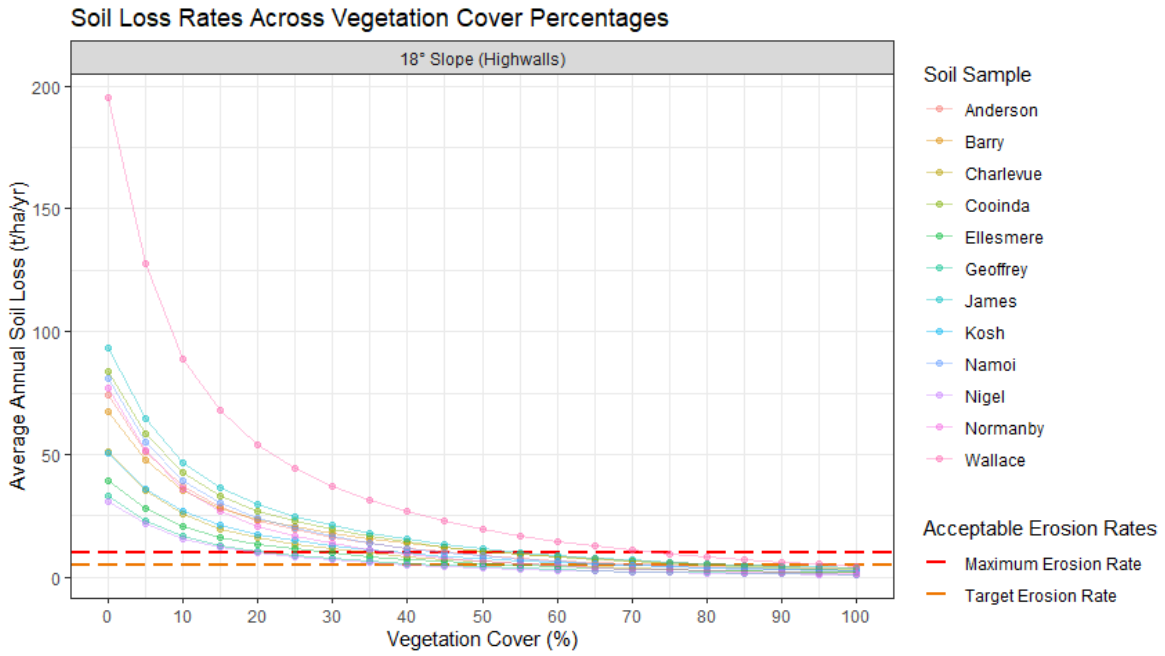

Figure 3: High wall slope average annual soil loss rates (t/ha/yr)

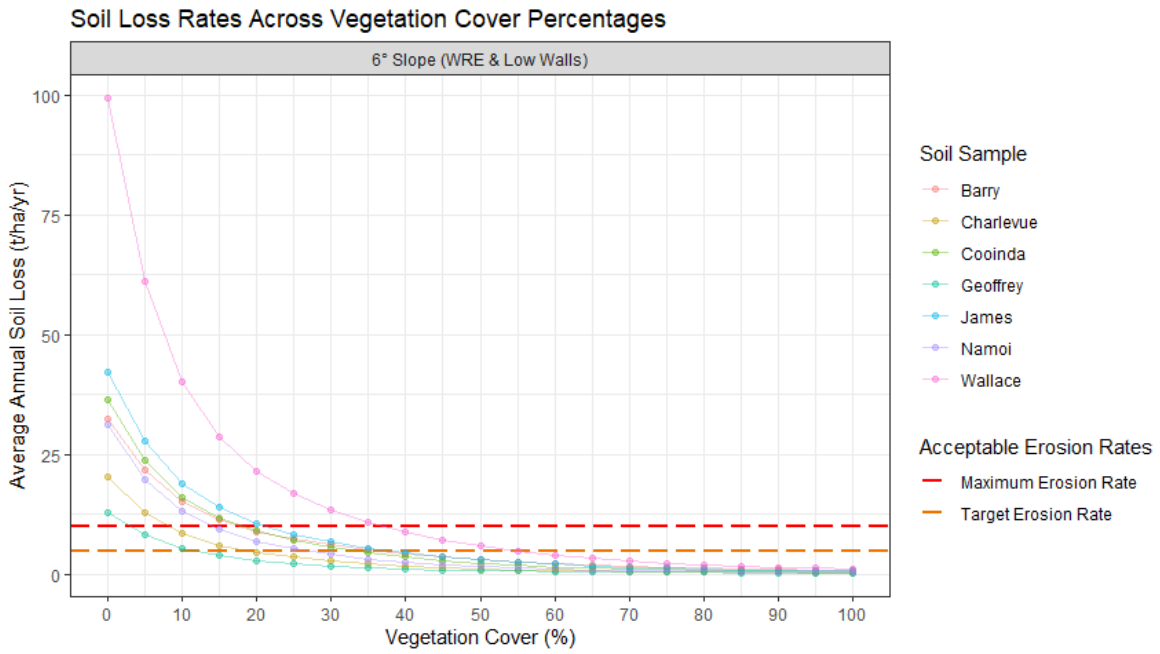

Figure 4: WRE slope average annual soil loss rates (t/ha/yr) including impacted SMUs

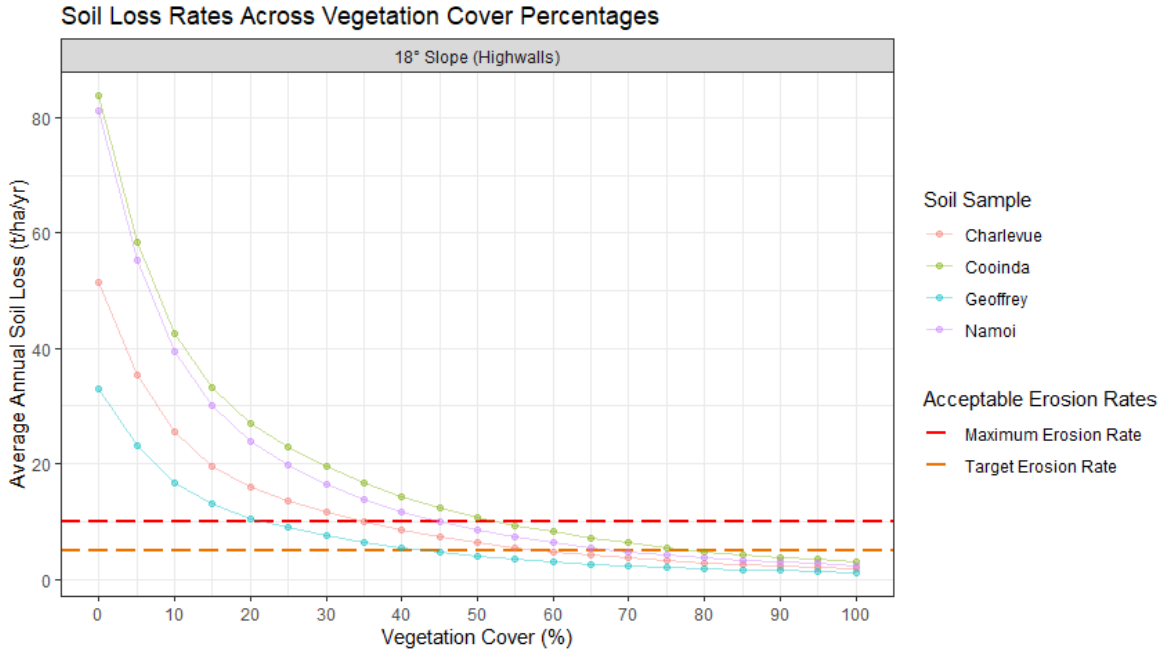

Figure 5: High wall slope average annual soil loss rates (t/ha/yr) including impacted SMUs

To support the above results, summary statistics for each slope and SMU combination were calculated and provided in Table 2, with impacted SMUs for each slope type highlighted in green. The base-case soil loss, being a slope with 0% cover, is provided in addition to the mean soil loss over the 21 cover options simulated for each combination. Furthermore, the minimum vegetation cover required to remain within the maximum and target erosion rates are also provided.

Table 2: Summary statistics for each slope based on SMU

Slope	SMU	Base-case Soil Loss (t/ha/yr)	Mean Soil Loss (t/ha/yr)	Minimum Vegetation Cover (Target Erosion Rate) (%)	Minimum Vegetation Cover (Maximum Erosion Rate) (%)
WRE Slope	Anderson	28.45	4.88	30	15
	Barry	32.31	6.42	40	20
	Charlevue	20.31	3.39	20	10

	Normanby	77.26	14.66	60	40
	Wallace	195.34	38.64	100	75

4 Discussion and recommendations

For a slope to be stable, it is assumed that rilling must be minimal and that no active rill or gully erosion is occurring. As described in Section 3, the target and maximum tolerable erosion rates have been adopted to assess erosion potential and landform stability. These values were applied against the annual total soil loss to assess erosion stability across the entire slope.

The key drivers of erosivity on the site are slope design, topsoil and vegetation cover. Overall, there is a significant difference in the erosion rates when comparing total annual soil loss observed between the WRE and high wall slopes, as well as the vegetation cover within each slope. Such a result is to be expected, given the importance of vegetation cover in reducing erosion rates and stabilising slopes and the effect of slope on water runoff and velocity (Landloch 2013). Considering both slope designs proposed by the Project, adequate ground cover and topsoil management is necessary to maintain slope stability and minimise the effects of erosion along rehabilitated slopes.

4.1 WRE slope

For the conceptual WRE slope design, the average base-case soil loss was 31.69 t/ha/yr, with an average mean soil loss of 5.45 t/ha/yr. The maximum vegetation cover required to achieve the target erosion rate for all SMUs was 55% (Wallace), with a maximum vegetation cover of 40% (Wallace) required to achieve the maximum tolerable erosion rate. Assessing only the impacted SMUs, the maximum vegetation cover required to achieve the target erosion rate was 40% (James).

Based on the above results, the WRE slope can achieve a stable slope with 55% vegetation cover where topsoiled with any SMU located within the mining lease. Assuming that the slopes are topsoiled based on the pre-mining SMUs underlying the WREs, the vegetation cover required to achieve a stable slope is 40%.

To ensure that the WRE slopes achieve stability, grazing should be limited on the WRE slopes until vegetation cover is equal to or greater than 40% cover to ensure the long-term stability of the landform (Landloch 2013), assuming that the WRE slopes will be rehabilitated using topsoil from the pre-mining SMUs impacted by the landform. Where topsoil limitations result in the rehabilitation of WREs using other SMUs within the mining lease, a vegetation cover of 55% is required to ensure slope stability across all SMUs. Of note, as a grazing post-mining land use has been nominated for the WRE slopes, a higher vegetation cover should be targeted for rehabilitation to ensure sufficient pasture is available for grazing without compromising slope integrity.

4.2 High wall slope

For the conceptual high wall slope design, the average base-case soil loss was 73.13 t/ha/yr, with an average mean soil loss of 18.85 t/ha/yr. The maximum vegetation cover required to achieve the target erosion rate for all SMUs was 100% (Wallace), with a maximum vegetation cover of 75% (Wallace) required to achieve the maximum tolerable erosion rate. Assessing only the impacted SMUs, the maximum vegetation cover required to achieve the target erosion rate was 80% (Cooinda).

While this assessment has considered the erodibility of the high wall slopes on the basis of topsoil application, the Gemini PRCP proposed that the growth media for the high wall consist of hydromulch applied to throwblasted materials and not a standard topsoil application applied to the WREs. Due to the limitations of the WEPP modelling software, the erosivity of the high wall slopes based on these vegetation management parameters cannot be effectively assessed. However, hydromulching has been shown to reduce erosivity by upwards of 94% compared to base-case soil erosion (0% vegetation cover). In this case, the WEPP modelling likely overestimates the erodibility of the high wall slopes, given the effectiveness of hydromulch in reducing soil erosion in the establishment phase. Despite this, the erodibility values of the SMUs located on site were used to assess the vegetation cover required to ensure the high wall slopes remained stable. As such, the high wall slopes can achieve a stable slope with 80% vegetation cover based on the soil profiles of the pre-mining SMUs underlying the high walls. This vegetation cover may be an overestimation, given the considerations provided above.

1 Introduction

AARC Environmental Solutions (AARC) was commissioned by Magnetic South Pty Ltd (Magnetic South) to prepare an Erosion and Sediment Control Plan (ESCP) for the Gemini Project (the Project). The ESCP is developed in accordance with the conditions in the Environmental Authority (EA) Permit (P-EA-100114292) granted to the site, including the requirement for exploration activities to be conducted in accordance with the standard conditions in the '*Eligibility criteria and standard conditions for exploration and mineral development projects*'.

1.1 Purpose

The purpose of this erosion and sediment control plan is to outline the general strategies to be implemented at the Project to prevent and/or minimise erosion and the release of contaminated stormwater runoff or mine-related sediment into receiving waters.

1.2 Scope

The Project consists of a single Mining Lease (ML) 700056 located approximately 3 km from Dingo township within the Bowen Basin in Queensland. The ESCP specifies erosion and sediment control measures appropriate for the exploration activities and early works construction. The process for developing the ESCP includes:

- The identification of areas of potential erosion risk arising from stormwater runoff for all Project stages
- An assessment of the erosion risks related to the Project, and
- Nomination of appropriate erosion and sediment control measures applicable to the identified areas of erosion risk and having the objective of reducing the potential for the Project to impact the receiving environment.

1.3 Environmental authority requirements

This ESCP aims to minimise the impacts on receiving waters from exploration and early works construction activities and addresses the relevant requirements of conditions F15 and F16 of the Gemini Coal Mine EA, as listed in Table 1.

Table 1: EA Condition requirements

EA Condition Number	Addressed in	Condition
F15	ESCP	An Erosion and Sediment Control Plan must be developed by an appropriately qualified person within one (1) month of the grant of ML700056 or prior to commencement of mining activities whichever is sooner, and implemented for all stages of the mining activities on the site to minimise erosion and the release of sediment to receiving waters and contamination of stormwater.
F16	ESCP	Stormwater, other than mine affected water, is permitted to be released to waters from: a) Erosion and sediment control structures that are installed and operated in accordance with the Erosion and Sediment Control Plan required by Condition F15; and b) Water management infrastructure that is installed and operated, in accordance with a Water Management Plan that complies with Conditions F3 to F5 (inclusive) for the purpose of ensuring water does not become mine affected water.

2 Project description

The Gemini Project is a greenfield, open-cut metallurgical coal mine producing pulverised coal injection (PCI) coal and coking coal for export to the international steel making industry.

The Project is located within the Bowen Basin, a well-established coal mining area with existing transport infrastructure. The Project will bring benefits to the local community, region, Queensland and the Commonwealth through direct employment opportunities, royalties and taxes. The Project will also utilise the services of regional suppliers of rail, power, water, communications, contractors, service providers and local businesses, which will have a positive economic impact beyond direct employment. The Project term is anticipated to be 25 years from the grant of the mining lease (ML), with this term including initial construction, mine operation and rehabilitation activities.

It is anticipated that it will take approximately six months to establish the necessary infrastructure to commence overburden removal and 18 months to commence coal production.

The main activities associated with the Project include:

- Exploration activities continuing in order to support mine planning.
- Development of a mine infrastructure area (MIA) including mine offices, bathhouse, crib rooms, warehouse/stores, workshop, fuel storage, refuelling facilities, wash bay, laydown area, sewage, effluent and liquid waste storage and a helipad.
- Construction and operation of a coal handling and preparation plant (CHPP) and coal handling facilities adjacent to the MIA, including run-of-mine (ROM) coal and product coal stockpiles and rejects bin/overflow (coarse and fine rejects).
- Construction and operation of a surface conveyor from the product stockpiles to a train load out (TLO) facility and rail loop connecting to the Blackwater Railway to transport product coal to coal terminals at Gladstone for export.
- Construction of an accommodation facility within the bounds of the ML.
- Construction of access roads from the Capricorn Highway to the MIA and the TLO facility.
- Installation of a raw water supply pipeline to connect to the Blackwater Pipeline network.
- Construction of a 66 kV transmission line and switching/substation to connect to the existing regional network.
- Other associated minor infrastructure, plant, equipment and activities.
- Development of mine areas (open-cut pits) and out-of-pit waste rock emplacements.
- Drilling and blasting of competent waste material.
- Mine operations using conventional surface mining equipment (excavators, front-end loaders, rear dump trucks, dozers).
- Mining up to 1.9 Mtpa ROM coal (average of 1.8 Mtpa) for a construction/production period of approximately 20 years.
- Progressive placement of waste rock in.
- Emplacements, adjacent to and near the open-cut voids.
- Mine voids behind the advancing open-cut mining operations.
- Progressive rehabilitation of waste rock emplacement areas and mined voids.
- Progressive establishment of soil stockpiles, laydown area and borrow pits (for road base and civil works; material will be sourced from local quarries where required).
- Disposal of CHPP rejects (coarse and fine rejects) in out-of-pit spoil dumps, and in-pit behind the mining void.
- Progressive development of internal roads and haul roads including a causeway over Charlevue Creek to enable coal haulage and pit access.
- Development of water storage dams and sediment dams, the installation of pumps, pipelines and other water management equipment and structures, including temporary levees, diversions and drains.

Existing local and regional infrastructure, facilities and services would be used to support Project activities. These include the SunWater water distribution network, the Aurizon rail network, Ergon's electricity network, the Capricorn Highway and Gladstone export coal terminals.

This ESCP addresses erosion and sediment control during the exploration and early works construction activities in Gemini.

2.1 Location and setting

The Project is situated within the Bowen Basin, approximately 110 km east of Emerald and 125 km southwest of Rockhampton, in central Queensland (Figure 1). Blackwater, a larger town serving mines in the region, is located approximately 34 km to the west (Figure 1). The small rural townships of Bluff and Dingo are located approximately 15 km west and 3 km east of the Project, respectively (Figure 1).

The Project is located within the Central Highlands Regional Council (CHRC) local government area (LGA), which covers approximately 60,000 km^2 and supports a population of more than 30,000 residents living in Arcadia Valley, Bauhinia, Blackwater, Bluff, Capella, Comet, Dingo, Duaringa, Emerald, Rolleston, Sapphire Gemfields, Springsure and Tieri. Nearby mining operations include Yarrabee Coal Mine (approximately 34 km to the northwest), Jellinbah Mine (approximately 32 km to the northwest), Curragh Coal Mine (approximately 33 km to the northwest), and the Blackwater Mine (approximately 36 km to the southwest) (Figure 2). Taunton National Park is situated to the north of the Project's mining lease (ML) area, whilst Walton State Forest is approximately 6 km to the west, and Blackdown Tablelands National Park is located approximately 9 km to the southwest of the ML (Figure 2). The Capricorn Highway, which is a state-controlled road, links Rockhampton with western Queensland (Figure 1). Capricorn Highway traverses the ML and links the townships of Bluff and Dingo (Figure 2). The Aurizon Blackwater Rail System (Blackwater Railway) tracks along the northern side of the Capricorn Highway (Figure 1 and Figure 2). A stock route (ID: 413CENT) tracks alongside the Capricorn Highway and is currently open but classified as minor and unused. Publicly gazetted roads, including Sanders, Namoi, Charlevue, Cooinda, Red Hill, Normanby and Ellesmere, provide local access (Figure 2).

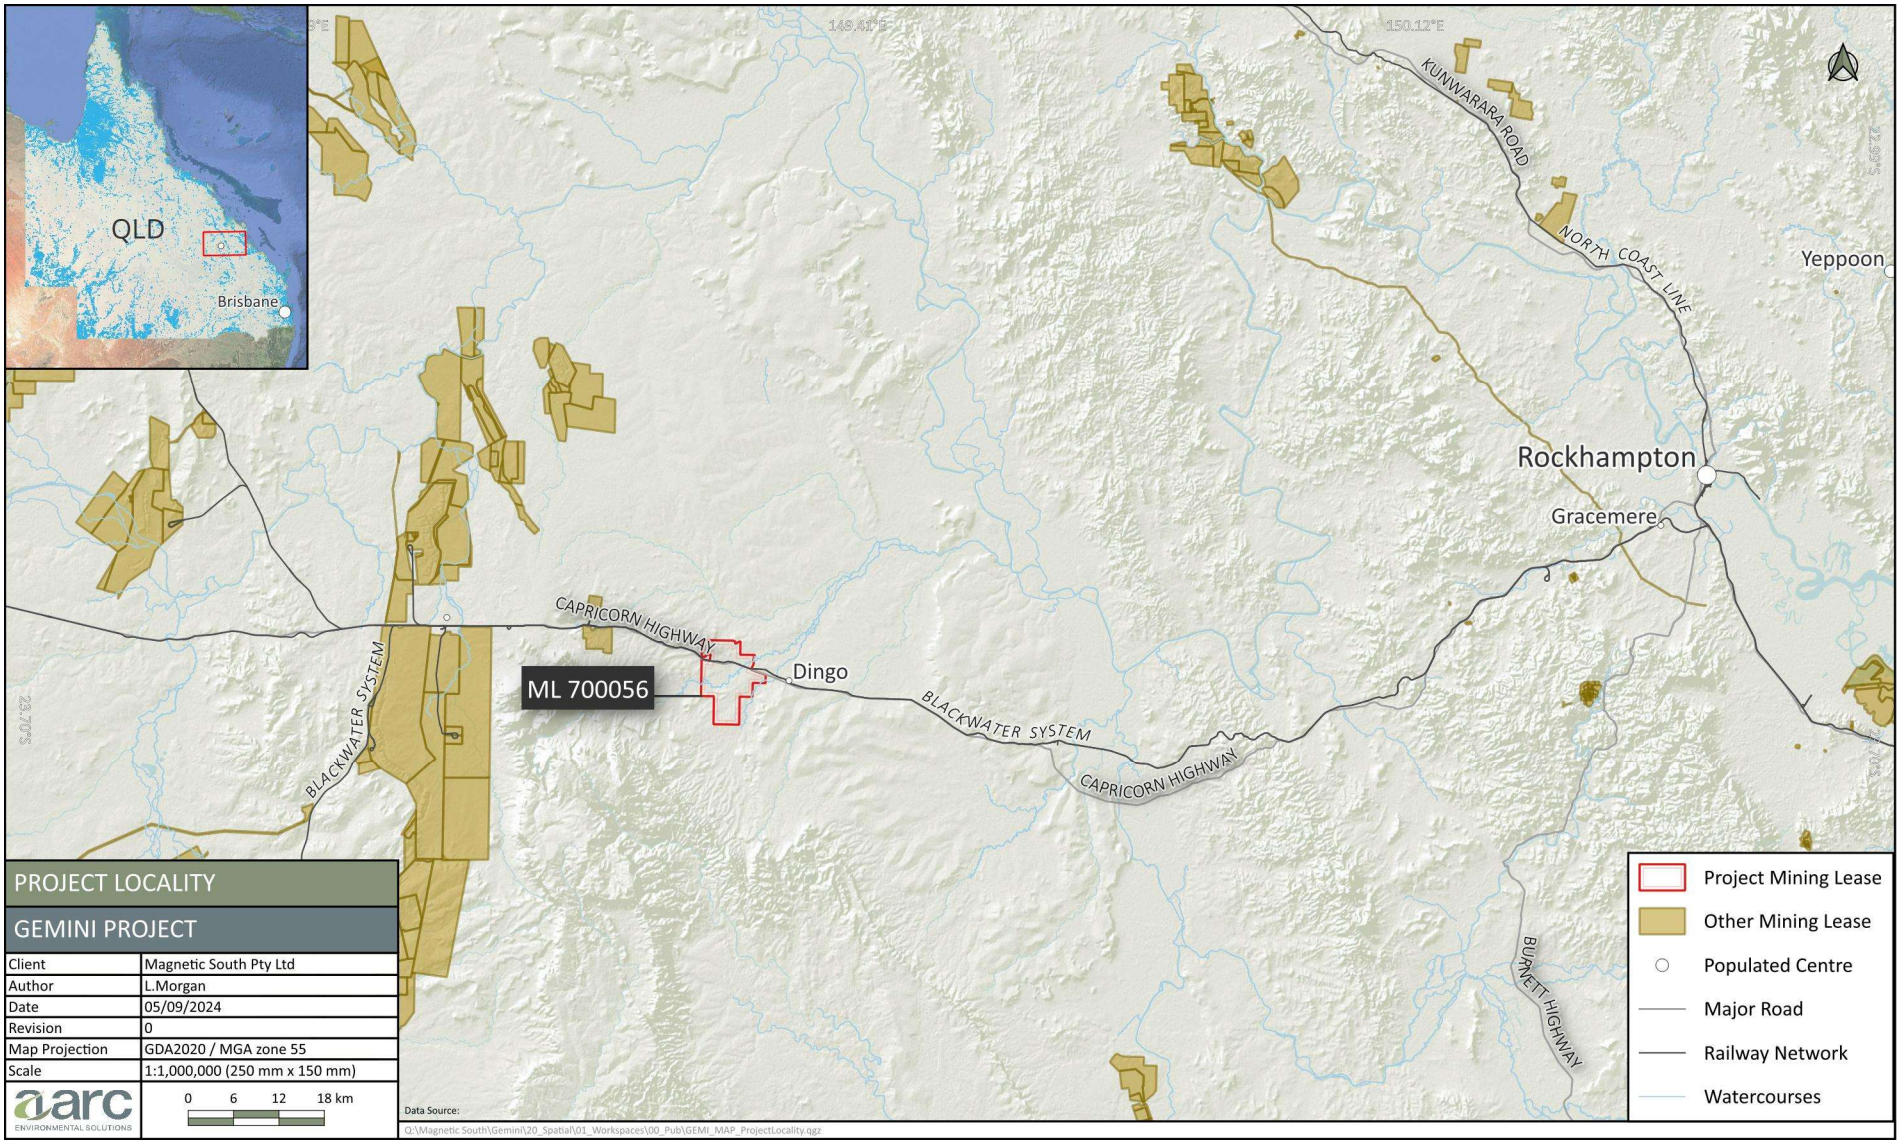

Figure 1: Locality plan

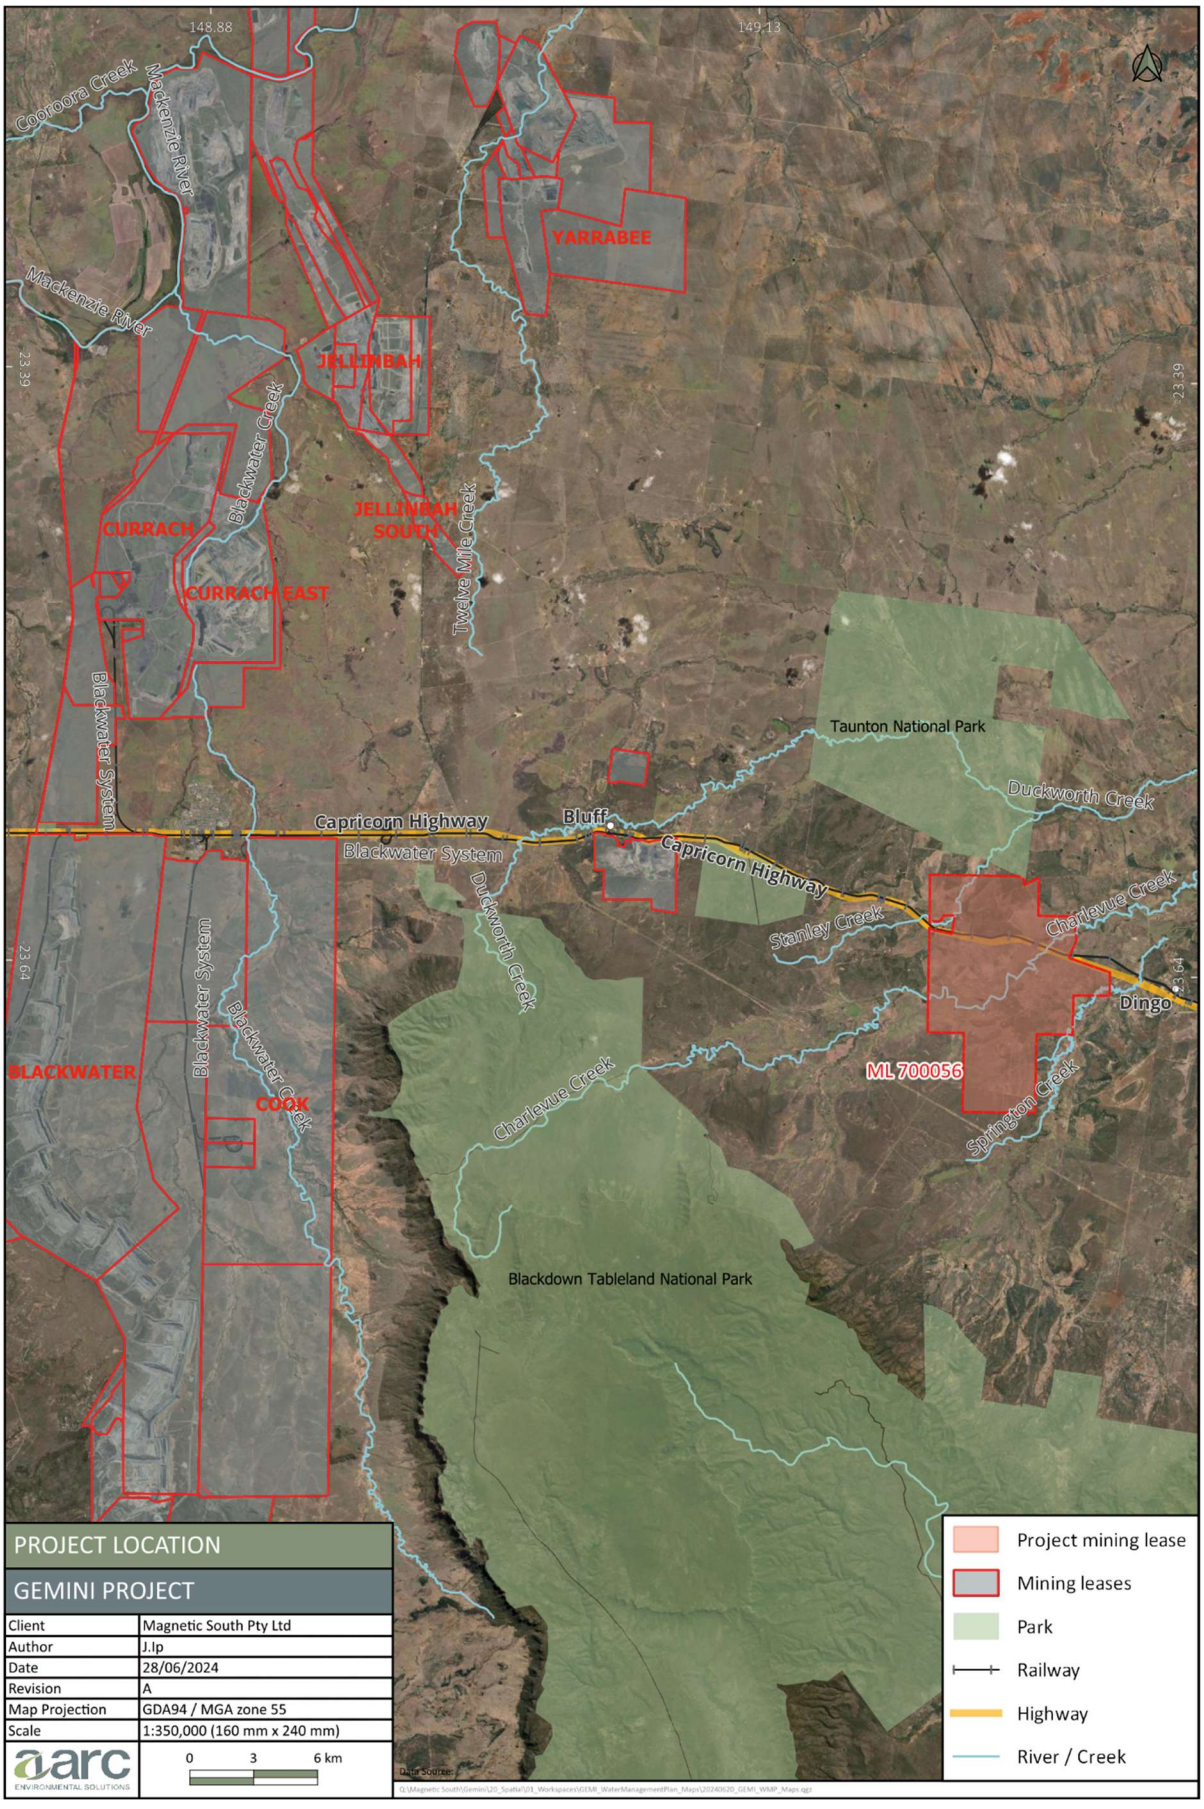

Figure 2: Project location

2.2 Landscape

The Project lies within the Fitzroy River Basin, which encompasses an area of 142,545 square kilometres (km^2) and contains the Comet, Connors, Dawson, Don, Nogoa and Mackenzie Rivers, which make up its six sub-catchment areas (BoM 2018; DES 2018).

The Project lies within the Mackenzie River sub-catchment, which covers a total area of 12,985 km^2, and is situated in the centre of the Fitzroy River catchment. The major water body associated with the Project site is Charlevue Creek, which dissects the mining lease in a north-easterly direction. This creek begins within the boundaries of Blackdown Tablelands National Park, flowing north-east before joining with Springton Creek and the Fitzroy River and eventually reaching the Pacific Ocean approximately 46 km north of Gladstone.

Two significantly smaller creeks, Stanley and Springton, cross the Project boundaries in the north-west and south-east respectively. These two creeks eventually converge with the Mackenzie River. Associated tributaries, dams and drainage features also appear across the site. Figure 2 displays the extent of the watercourses associated with the study area.

The topography of the land varies from flat to undulating hills, with elevation within the Project area ranging between 120 - 150 m above sea level. The landscape is influenced by the presence of Charlevue Creek and its associated flood plains, which have relatively lower elevations than the surrounding landscape of undulating hills. The topography of the Project is representative of the surrounding region.

The majority of the Project is comprised of agricultural land used primarily for low-intensity cattle grazing, with the Capricorn Highway and five gazetted roads (Charlevue, Cooinda, Red Hill, Normanby and Ellesmere) crossing the Project.

2.2.1 Site infrastructure

Site infrastructure required for the undertaking of exploration activities and early constructions may include:

- access roads and tracks;
- drilling pads;
- laydown and maintenance pads;
- demountable offices;
- carpark areas;
- sumps;
- geophysical survey lines; and
- bunds and/or diversion drains.

2.3 Local climate

The Project area has a climate classification of 'subtropical' (moderately dry winter) using the Bureau of Meteorology's (BoM) modified Köppen climate classification system. The local region experiences a subtropical climate characterised by high variability seasonal rainfall subject to cyclic wet summer and dry winter seasons, with variable temperature and evaporation. Predominantly, wind blows from the southeast and east in the region.

Local meteorological conditions have been compiled using data from the Scientific Information for Land Owners (SILO) Data Drill. The Data Drill accesses grids of climate data available from surrounding BoM point observations and then creates interpolated climate values for the requested location. The SILO climate data was obtained for coordinates that correspond to the approximate centre of the Project ML. The daily rainfall, maximum and minimum temperature data between January 1889 and May 2024 has been utilised to produce a climatograph for the Project (Figure 3).

The mean annual rainfall for the Project region is approximately 674.13 mm with an average annual (pan) evaporation of 2,026.82 mm, which exceeds rainfall for every month of the year (Table 2). Rainfall is highly seasonal, with November to March generally accepted as the 'wet season' and rainfall during this time accounting for approximately 67.10% of the region's total yearly rainfall. The 'dry season' usually occurs from April through to October, with monthly rainfall totals below 45 mm consistently throughout this period. The rainfall data for this region is consistent with the Köppen classification of 'subtropical' (moderately dry winter).

The hottest months typically occur between October and March, while the coolest months occur between May and September. The highest mean maximum temperature typically occurs in January (33.76°C) and the lowest mean minimum temperature in July (7.81°C).

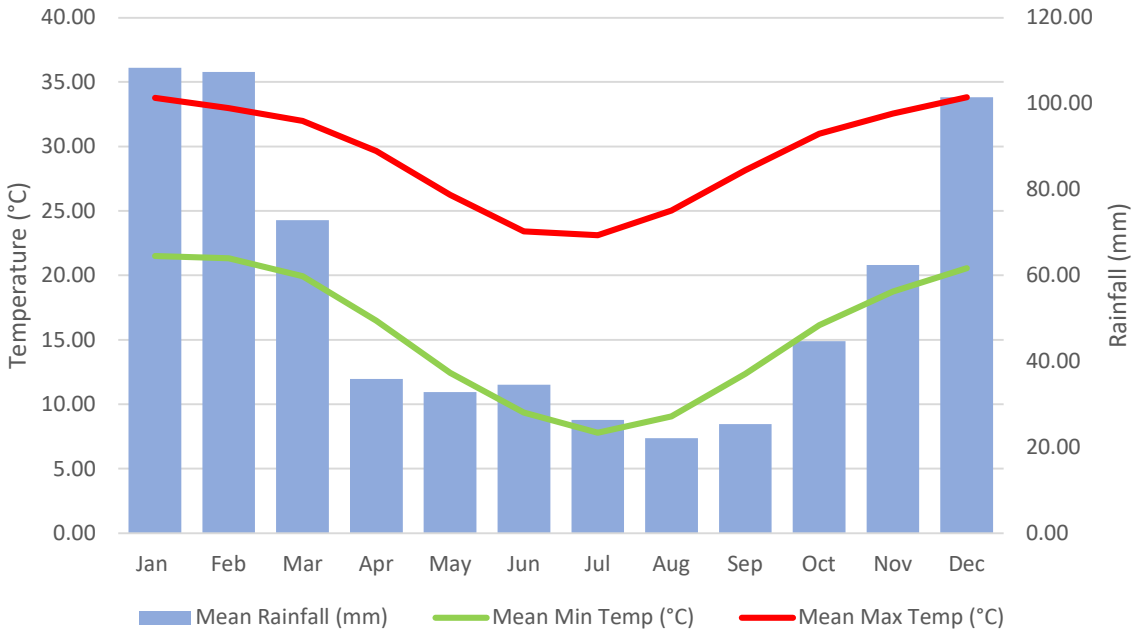

Figure 3: Climatograph of the Project site (January 1889 – May 2024)

Table 2: Average monthly rainfall and evaporation

	Average rainfall (mm)	Average evaporation (mm)
Jan	108.28	225.72
Feb	107.36	183.38
Mar	72.88	187.94
Apr	35.89	149.09
May	32.82	116.20
Jun	34.53	93.24
Jul	26.38	101.73
Aug	22.13	131.00
Sep	25.35	170.52
Oct	44.67	210.25
Nov	62.42	222.13
Dec	101.42	235.61
Total	674.13	2026.82

2.4 Soil and land suitability assessment

The Project site is characterised by fluvial plains surrounding significant waterways. It is mostly composed of stable flood plains traversed by a branching pattern of drainage floors. The majority of deposits are weathered alluvium, with slopes of coarser or finer textured alluvium (depending on flow patterns). Channels can be up to 30 m wide and 3 m deep, with fringing riparian vegetation. Main drainage floors can then extend 800 m outwards, with deep texture contrasting sandy loams over mottled clays and open spaces of *Eucalyptus tereticornis* (Blue gum) and *Eucalyptus crebra* (Narrow-leaved ironbark) with sparse shrubs. Large plains surround drainage features (up to 3 km wide), which can contain either deep texture contrast soils with *Eucalyptus populnea* (Poplar box) woodlands or deep layered soils on alluvium with woodlands of Blue gum and Narrow-leaved ironbark. Slopes within this land unit are usually the result of strongly gilgaied shrink-swell clays, forming depressions of finer soil textures with *Acacia harpophylla* (Brigalow) scrub.

Soil management units (SMUs) are described in Table 3. The majority of the site (66%) has a soil profile that consists of texture contrast soils with soft conditions. Where soils have been exposed due to extensive clearing and insufficient groundcover, extensive washouts and large erosion gullies were observed. In the process of mine development and operation, the clearing of vegetation, topsoil stripping and stockpiling, construction of infrastructure and exposure of slopes all increase the erodibility of soils present. When considering the development of erosion control structures, the dispersive tendencies of these soils require consideration. Figure 4 shows the SMU locations throughout the Project.

Table 3: Soil management units and erodibility

SMU	Description	Surface Area (ha)	Percentage of Study Area (%)	Erodibility
Anderson	Red Kurosol	37.78	0.61	Unlikely
Barry	Brown Dermosol	156.5	2.54	Unlikely
Charlevue	Red or Brown Dermosol	232.9	3.79	Likely
Cooinda	Brown Dermosol	34.94	0.57	Likely if disturbed
Ellesmere	Red Dermosol	14.59	0.24	Likely if disturbed
Geoffrey	Brown Sodosol	4061	66	Likely if disturbed
James	Red Dermosol	145.2	2.36	Unlikely
Kosh	Brown Dermosol	924	15	Highly likely
Namoi	Red Dermosol	177.6	2.89	Likely if disturbed
Nigel	Brown Kandosol	284.6	4.63	Unlikely
Normanby	Red Kandosol	48.5	0.79	Unlikely
Wallace	Black Vertosol	32.04	0.52	Likely if disturbed

2.5 Regional geology

The geology of the Dingo area is dominated by its position within the Bowen Basin. The Bowen Basin is one of Queensland's largest depositional zones, forming through a period of rifting and subsidence lasting from the Early Permian to Mid-Triassic. The area surrounding the Project is dominated by clastic sedimentary rocks of marine and lacustrine origin, including sandstones, conglomerates, mudstones, siltstones and coal (AARC 2019).

The surface geology within the Project area is identified below and represented in Figure 5:

- Qa-QLD (Qa) – Quaternary clay, silt, sand and gravel; flood-plain alluvium;
- Td-QLD (Td) – Tertiary duricrusted palaeosols at the top of deep weathering profiles, including ferricrete and silcrete; duricrusted old land surfaces;
- Duaringa Formation (Tu) – Eocene-Oligocene mudstone, sandstone, conglomerate, siltstone, oil shale, lignite and basalt; and
- Gyranda Subgroup (Pwy) – Late Permian sedimentary unit comprised of siltstone and shale with minor tuff and volcanilithic sandstone and rare coal (lower part - Banana Formation); calcareous sandstone, mudstone and siltstone (upper part - Wiseman Formation).

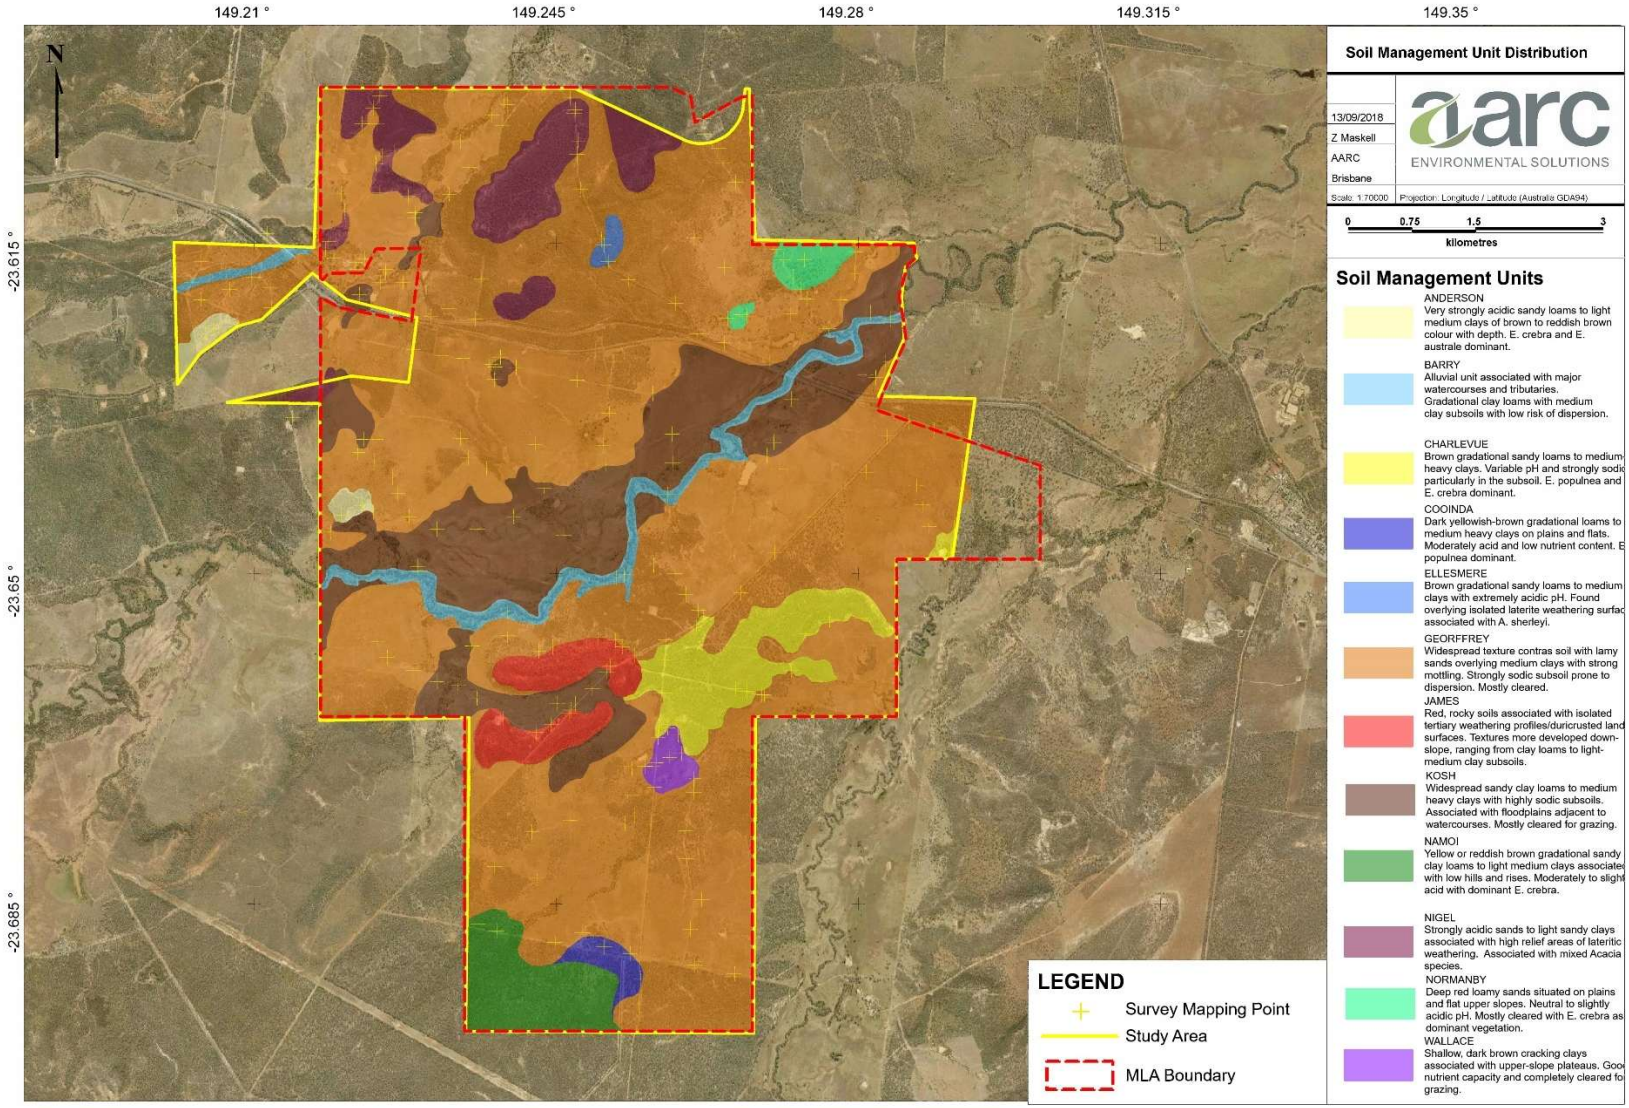

Figure 4: SMU Map of Project Site

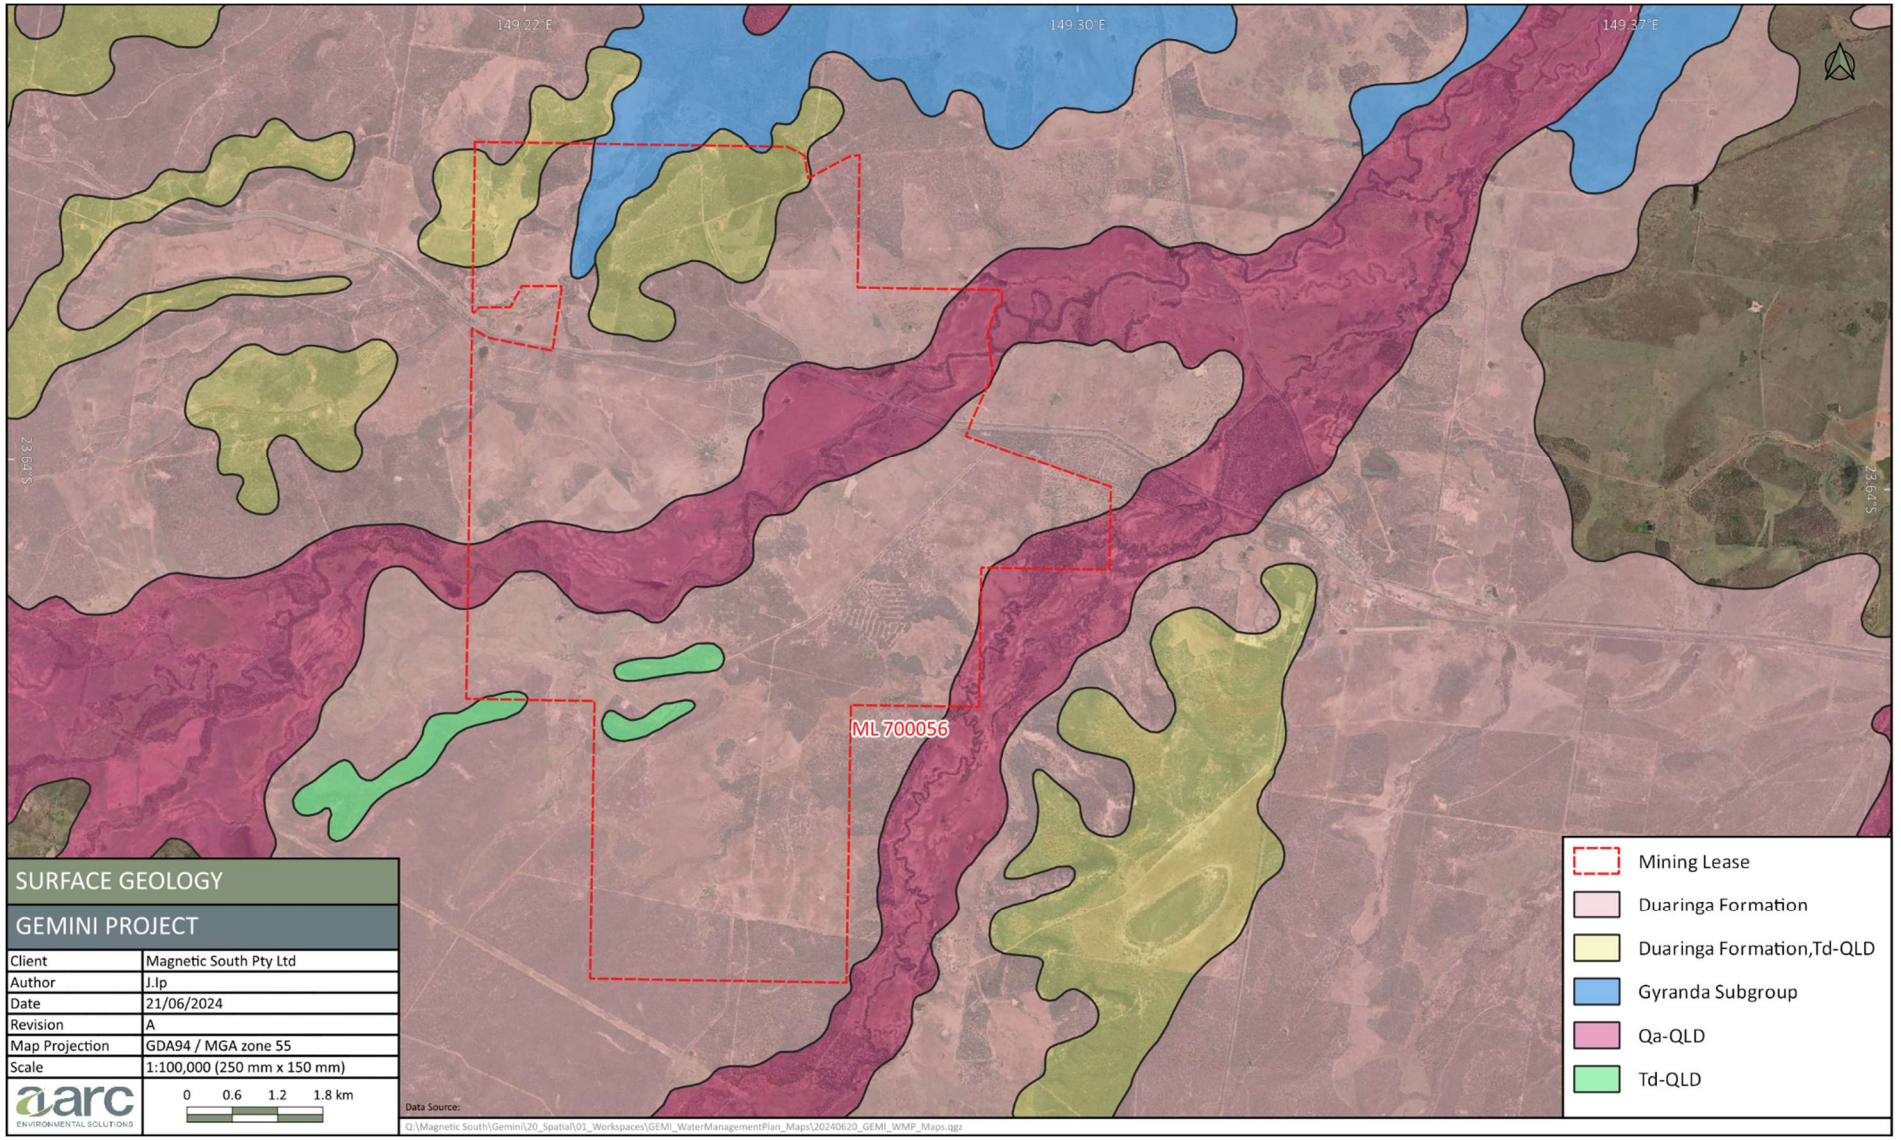

Figure 5: Surface geology

2.6 Exploration activities

A land disturbance management system will be implemented for all land disturbance works within ML 700056.

Exploration drilling will be done prior to the commencing of mining activities. All exploration sites are small in scale, consisting of a cleared flat square pad of 625 m^2 with the drill hole positioned in the centre. Where required, sumps will be dug within the pad footprint to a depth of at least one metre to temporarily store any water or waste material resulting from drilling activities. Stripped topsoil will be stockpiled and stored on the cleared pad while exploration activities are ongoing. Each exploration site is selected so that environmentally sensitive areas or waters will not be disturbed.

All exploration drill holes and sumps are temporary and will be capped and backfilled after the exploration activity is completed (within six months of drilling), in addition to topsoil spreading and re-seeding where required.

2.7 Early works construction activities

Early works construction activities will be undertaken in relation to mine infrastructure development, including access roads, laydowns, maintenance pads, installation of offices and carparks, and other associated infrastructure. Construction activities will generally consist of vegetation clearing, topsoil stripping and soil compaction to prepare areas for infrastructure development. Some areas may also require gravel application, bitumen sealing or material build-up to achieve final height designs. Excavation activities will be required for the construction of sediment and clean water dams, as well as bunding where required.

2.8 Water quality

From samples taken during 2018 and 2019, water quality on site generally appears to be poor, with no surface flow due to the ephemeral nature of the creeks present on site. Exceedances in WQOs included turbidity and hydrocarbons, which were potentially due to the agricultural practices present and the nearby Capricorn Highway.

2.9 Water management principles

The 'Water Management Plan' (WMP) for the Project is based on the following key principles:

- Divert clean catchment water around mining works to the extent practicable;
- Use/recycle lesser quality water in preference to higher quality water;
- Use potentially contaminated water in preference to imported raw water or uncontaminated water; and
- Manage water storages and transfers within the site in order to:
    - Maximise onsite storage to meet reasonably anticipated periods of wet and dry weather; and
    - Minimise disruption to mining operations.

2.10 Water management plan for exploration activities

2.10.1 Water management

For water management during exploration activities, water has been classified into two types, shown in Table 4, with the basis of likely water quality characteristics.

The proposed strategy for the management of surface water at the Project is based on the separation of water from different sources based on anticipated water quality. A conceptual WMP was developed for the Project (AARC 2024). Based on the expected runoff and groundwater inflow quality, the WMP separates water into two segregated management systems:

1. Mine affected water (MAW) system: will manage runoff and seepage from mine affected water contained in the sumps associated with drill holes.

2. Sediment water system: runoff from cleared early works construction, exploration drill pads and associated topsoil and overburden stockpiles will be managed under this ESCP, which is to be implemented throughout the Project.

A site water balance model has been developed by WRM to determine the most appropriate design of the WMP. The site water balance forms the basis of impact assessment and infrastructure design for the site.

Table 4: Site water types

Water Type	**Definition**
Mine affected water	Per the definition included in P-EA-100114292, mine affected water: a) means the following types of water: i. pit water, tailings dam water, processing plant water; ii. water contaminated by a mining activity which would have been an environmentally relevant activity under Schedule 2 of the Environmental Protection Regulation 2008 if it had not formed part of the mining activity; iii. rainfall runoff which has been in contact with any areas disturbed by mining activities which have not yet been rehabilitated, excluding rainfall runoff discharging through release points associated with erosion and sediment control structures that have been installed in accordance with the standards and requirements of an Erosion and Sediment Control Plan to manage such runoff, provided that this water has not been mixed with pit water, tailings dam water, processing plant water or workshop water; iv. groundwater which has been in contact with any areas disturbed by mining activities which have not yet been rehabilitated; v. groundwater from the mine's dewatering activities; vi. a mix of mine affected water (under any of paragraphs i-v) and other water. b) does not include surface water runoff which, to the extent that it has been in contact with areas disturbed by mining activities that have not yet been completely rehabilitated, has only been in contact with: i. land that has been rehabilitated to a stable landform and either capped or revegetated in accordance with the acceptance criteria set out in the environmental authority but only still awaiting maintenance and monitoring of the rehabilitation over a specified period of time to demonstrate rehabilitation success, or ii. land that has partially been rehabilitated and monitoring demonstrates the relevant part of the landform with which the water has been in contact does not cause environmental harm to waters or groundwater, for example: a. areas that are been capped and have monitoring data demonstrating hazardous material adequately contained within the site; b. evidence provided through monitoring that the relevant surface water would have met the water quality parameters for mine affected water release limits in this environmental authority, if those parameters had been applicable to the surface water runoff, or iii. both.
Sediment water	Surface water runoff from areas that are disturbed by mining operations (including out-of-pit waste rock emplacements). This runoff does not come into contact with coal or other carbonaceous material and may contain high sediment loads but does not contain elevated levels of other water quality parameters (e.g. electrical conductivity, pH, metals, metalloids, non-metals). This runoff must be managed to ensure adequate sediment removal prior to release to receiving waters. Note that prior to release through sediment control structures, this water is considered mine affected water.

3 Source and risk assessment of erosion and sedimentation

3.1 Sources of erosion and sediment

During exploration and early works construction, the potential source of erosion and sediment includes:

- cleared construction and exploration pads, including topsoil and subsoil stockpiles required for rehabilitation works;
- drilling waste material stored within the exploration pad footprint;
- the clearing of land for access roads and tracks, pads, demountable offices, especially those that cross path with watercourse, drainage features and other water bodies; and
- the movement of equipment within and around drilling locations and for construction activities.

3.1.1 Clearing of land for exploration pads

During the clearing of land for pads, there will be significant disturbances within individual drill sites as the soil is exposed. Therefore, during these works, erosion and sediment control measures need to be put in place to prevent potential erosion and sediment runoff across the work areas. It is expected that the risk of erosion and sediment transportation will be low at exploration drill pads. Given the nature of exploration activities and the practicality of moving and operating exploration equipment, drill pads and the surrounding areas are generally flat, grazing landscapes where flow velocities are reduced compared to sloped areas. As such, the erosive potential of overland flows in exploration areas is expected to be much lower than compared to operational mining disturbance, such as waste rock dumps and other such landforms.

Bunding will be rehabilitated after the bare earth has been stabilized.

3.1.2 Topsoil within exploration pads

Any topsoil removed during the construction of exploration pads will be stored within the pad footprint to minimise disturbance to the surrounding environment. While there is a low potential for splash erosion, sheet and rill erosion and sediment runoff are unlikely due to the pad being flat.

Despite the low risk, work sites with the potential for erosion occurrence will be contained by bunding. Rehabilitation of pads and sumps will facilitate a reduction in erosion and sediment loads in surface water.

3.1.3 Clearing of land for access roads and tracks

Some exploration sites may require clearing vegetation for safe access. However, such clearing activity may cause significant risks for erosion and sedimentation, particularly if roads and tracks intersect with watercourses, drainage features and other water bodies. Therefore, during these works, erosion and sediment control measures need to be put in place to prevent potential erosion and sediment runoff across the work areas. Given the nature of exploration activities, as discussed in Section 3.1.1, the erosive potential of overland flows in exploration areas is expected to be much lower, while access roads and tracks that cross paths with watercourses are expected to moderate.

3.1.4 Traffic

Heavy vehicles and heavy machinery are expected to use the access roads and tracks with exposed soil frequently, which will disturb soil stability and may create ruts, increasing the risk of erosion. Therefore,

during the period when access roads and tracks are frequently in use, and if erosion risk is identified as high, erosion and sediment control structures will be in place as required.

Most exploration access roads and tracks are not expected to be retained. If the roads/tracks are required for future project operation access, it will be maintained, monitored and managed. If the roads/tracks were not required for project operational access but were requested by the landholder, they will be the landholder's responsibility to manage the risk of erosion.

3.1.5 Early works construction activities

Construction activities include two stages: land clearing and facility construction. Significant disturbances within the cleared land are expected due to larger areas of exposed soil compared to exploration pads. Any topsoil removed will be stockpiled on site. As a result, erosion and sediment control measures need to be implemented during these works, where required, to prevent potential erosion and sediment runoff across the construction areas. As exposed soil will be stabilised and covered by construction materials as soon as possible, the potential sediment runoff in construction areas is expected to be much lower than that of operational mining disturbances.

4 Erosion risk assessment and management

This section of the report assesses the potential for soil loss on the exploration and early works construction sites. This will assist in identifying appropriate control measures to reduce the potential for erosion and sediment loss across the site.

4.1 Objectives and targets

The main objectives of this ESCP are to reduce the potential for erosion and sediment discharge to maintain downstream environmental values and water quality objectives.

The objectives of this ESCP are defined in Table 5.

Table 5: ESCP objectives

Objectives	Targets	Indicators
Minimise erosion on site and in immediate surroundings	No reports of erosion incidents	Incident reports relating to instances of erosion
Minimise movement of sediment off-site	Retention of MAW and SAW on site	Incident reports of any uncontrolled releases from site
Ensure erosion and sediment controls are operating and maintained effectively	Regular checks of sediment control structures with accumulated sediment removed	Indicators for maximum allowable sediment storage and records of maintenance checks

4.2 Control approach

The controls for erosion and sediment during exploration and early construction activities are developed with regard to the following documents:

- the relevant environmental authority;
- the relevant sections of *Eligibility criteria and standard conditions for exploration and mineral development projects v2.0*; and
- soil erosion and sediment control in *Engineering Guidelines for Queensland Construction Sites*.

4.3 Potential erosion and contaminant sources and controls

During exploration and early works construction activities, land clearing will be limited to ensure that disturbance areas are minimised.

When required, sediment control infrastructure will be in place to prevent erosion and runoff. The requirements of sediment and erosion control measures across the site, which will require construction and maintenance, will include:

- bunding surrounding access track, bare topsoil areas and overburden, when needed or required by the conditions, in built to direct surface water flow to sediment dams;
- diversion bunding to redirect clear water flow away from overburden or bare earth;
- construction of sediment dams; and
- Temporary sediment fences during construction in drainage lines for long term sediment control structures.

4.3.1 Control measures for cleared land for exploration pads

Drill pads with increased risk of erosion, such as those located in sloped areas or close to riverine, will require additional erosion prevention and mitigation measures to ensure cleared areas remain stable. Such measures will be implemented on an ad hoc basis and may include water diversion drains, sediment capture bunding or other such banks.

4.3.1.1 Low risk

For cleared exploration pads where the risk of erosion and sedimentation is assessed as low, compacted materials will be used to form embankments on the edge of pads to avoid leaking of water pooled on the pad or clean water entering the pad from overland flow.

4.3.1.2 Moderate risk

In situations where exploration pads are located on steeper slopes, compacted embankments will be built higher and enhanced to withstand the overland flow to prevent water entering into or leaking from the exploration pad.

In situations where exploration pads are located in close proximity to waters (including natural and artificial waters) and there is a high likelihood of sediment entering surrounding waters, perimeter bunds will be implemented around exploration pads. Bunding will be maintained to ensure integrity and non-impedance of natural drainage features.

4.3.2 Topsoil from exploration pads

Due to the geochemical characteristics of the materials, the environmental risk associated with topsoil and subsoil stockpiles is low. However, to prevent the mix of topsoil and subsoil, both materials will be stored as two piles at a safe distance within the exploration pad, which is isolated from the surrounding environment by the compacted embankments.

4.3.3 Control measures for access roads and tracks

Generally, most access roads and tracks are expected to be temporary and therefore, only have minimal erosion risk. However, if the landholder requests to retain the roads/tracks, it will be the landholder's responsibility to maintain the roads/tracks and manage erosion risks.

4.3.4 Control measures for access roads and tracks close to / crossing watercourses

During the planning stage, the routing of access roads and tracks will be designed to minimise their proximity to watercourses. Roads and tracks should be aligned to avoid watercourses whenever practical. However, when it is unavoidable for a road or track to cross a watercourse, temporary crossing (e.g. drainage culverts) may be used to minimise soil disturbance.

4.3.5 Traffic

To mitigate the erosion risk of vehicles travelling on access roads and tracks, the following measures will be implemented, if appropriate:

- Vehicles to be restricted to access tracks and designated roads;
- Cleaning and/or maintenance of vehicles or plant equipment to be undertaken within a work area that is able to capture and treat runoff; and
- Speed limits to be observed by all site personnel and visitors to reduce the likelihood of creating deep ruts or other such damage to access tracks.

4.3.6 Construction activities

Silt fences will be installed to capture sediment runoff after land clearing, prior to the commencement of early works construction activities where appropriate. Topsoil removed will be stockpiled to a maximum height of 2 m on site and will be separated from overburden stockpiles to prevent the mix of topsoil and overburden.

It is the responsibility of the sub-contractor to implement relevant erosion and sediment management controls during the construction period to prevent or minimise the risk of erosion and sediment runoff.

4.4 Rehabilitation and closure

The rehabilitation of exploration pads aims to create a stable landform resistant to erosion. As detailed in the WMP, the drill hole and sump for each exploration pad will be capped and backfilled, respectively, after the exploration activity is completed.

The cleared pad will be rehabilitated within six months of the completion of works in the area. The pad will be revegetated to lower the risk of surface water erosion during rain and flow events. Seeding topsoil stockpiles will help manage short-term potential topsoil loss in low-activity areas.

During rehabilitation works, vegetation cover, diversity and soil loss will be monitored to ensure minimal bare earth is exposed. Planning will ensure that topsoil stockpiles will be repurposed for rehabilitation or seeded to ensure retention of topsoil for future use.

Revegetation efforts will be adequate to protect soil from potential erosion following the low-impact disturbance from exploration activities in the long term. Prior to the establishment of vegetation on rehabilitated areas, activities to ensure maximum potential for revegetation of areas are to be undertaken. These measures include:

- erosion and sediment control structures will not be removed until disturbed areas have been stabilised;
- temporary seeding of stockpiles will be utilised as appropriate for rehabilitation areas including topsoil stockpiles;
- exposed surface will be ripped and left with sufficient surface roughness to minimise the potential for erosion;
- bunds will be implemented across contours in order to capture and slow runoff; and
- disturbed areas will be contoured to ensure all runoff is directed through erosion and sediment controls and onsite water management systems.

5 Administration

5.1 Land disturbance permitting system

A land disturbance management system will be implemented for all land disturbance works within ML 700056.

The land disturbance management system will collect details of the disturbance site and ensure that activities comply with the relevant EA conditions and internal management plans. EA conditions will be reviewed prior to the commencement of activities to ensure that key considerations have been appropriately addressed and implemented.

Upon completion of exploration activities, a final compliance check and documentation of disturbances will be conducted and recorded within the system.

5.2 Monitoring and maintenance

Regular monitoring of construction, operation and rehabilitation areas will be undertaken. Contractors conducting construction and rehabilitation works of erosion and sediment controls will be responsible for maintaining surface water diversion structures and erosion control measures.

Routine inspections of all Project areas will be undertaken until rehabilitation completion criteria have been satisfied. Inspections will be completed prior to expected rainfall events to ensure the performance of control measures. Coincidental observations are encouraged to be reported by personnel to management.

Periodic inspections of site drainage systems will be undertaken, especially prior to the wet season and when any major change is implemented or planned. Amendments to the existing erosion and sediment controls and WMP will be undertaken as required.

5.2.1 Corrective Actions

Where required the following actions are to be taken:

- in the event of an environmental incident, appropriate response measures will be implemented to ensure environmental harm from the event is minimised (i.e. restoration of erosion, repairing sediment and erosion control structures);
- any non-conformances will be corrected as soon as possible and strategies identified, evaluated and implemented to reduce the likelihood of the incident re-occurring;
- any non-conformances and corrective actions will be closed out as soon as practicable;
- where erosion and sediment control devices are found not to be in accordance with this plan or relevant guidelines, work in the affected area will cease and corrective actions taken prior to recommencing works;
- an incident report will be filled out if any non-conformances with this plan for construction or rehabilitation are found;
- revision of construction, operation and rehabilitation activities as required; and
- erosion and sediment control devices will be cleared, repaired or replaced whenever inspections show signs of non-compliance or ineffective capability or capacity.

5.3 Reporting

5.3.1 Internal

Incident reports will be used to inform and drive corrective actions. These reports are to be completed as soon as possible after becoming aware of an incident.

5.3.2 Regulatory authority

The Magnetic South Site Manager, or their delegate, will notify the DESI within 24 hours of becoming aware of an incident that has the potential to cause, or threaten to cause, material or serious environmental harm.

5.4 Records

Inspection checklists and audits performed for erosion and sediment control will be stored within the Magnetic South Management System.

5.5 Review

This document will be reviewed before commencement of construction on site.

5.6 Training

Relevant personnel will be trained in erosion and sediment control procedures including this document and other relevant legislation.

5.7 Responsibilities

Roles and responsibilities are outlined in Table 6.

Table 6: Roles and responsibilities

Role	Responsibility
Site Manager or Delegate	• Ensure resources are available to implement the contents of this plan. • Facilitate ESCP reviews. • Report incidents to DESI.
Site Environmental Officer	• Implement contents of this plan. • Train Staff in environmental awareness, issues and requirements of ESCP. • Facilitate monitoring of requirements in ESCP. • Report non-conformances to technical services. • Manage and ensure actions are closed out. • Advise on EA conditions. • Investigate environmental incidents and provide assistance with DESI where necessary.
Employees	• Be familiar with contents of ESCP. • Undertake erosion and sediment control works. • Report visual degradation or apparent non-conformances with this ESCP within shifts as observed.
Contractors	• Undertake corrective actions as soon as practicable. • Report and non-conformance/environmental incidents within same shift as noticed. • Be familiar with contents of ESCP. • Prepare design and plan for construction.

1 INTRODUCTION

1.1 PROJECT OVERVIEW

The Gemini Project is a proposed open cut coal mine in the Fitzroy Basin. The proposed mine development site is located approximately 7.6 km west of the town of Dingo and 19.4 km southeast of Bluff.

The mine development schedule includes two open cut pits (Figure 1.1), and two residual voids will remain post-mining, which are anticipated to accumulate water over time to an equilibrium water level.

The post mining land use (PMLU) for the Project is proposed to be primarily grazing, and where the final landform is not suitable for a grazing, areas of native ecosystem habitat suitable for native flora and fauna will be introduced.

As shown in Figure 1.1, A single out-of-pit waste rock emplacement is associated with each pit. Minor drainage works and a levee are required to the southeast of Pit AB to ensure high flows from an unnamed second order tributary of Springton Creek do not access the pit during operations. In addition, a drain is required to divert clean runoff from the upper reaches of the unnamed second order tributary of Springton Creek around the out-of-pit waste rock emplacement associated with Pit C.

1.2 SCOPE OF THIS STUDY

This report presents the methodology and results of hydrologic and hydraulic modelling undertaken to assess the flood behaviour in the reaches of Charlevue Creek, Springton Creek and its tributaries in the vicinity of the proposed final landform.

The modelling results define the existing flood conditions, as well as conditions after the establishment of the final landform to support the Progressive Rehabilitation and Closure Plan (PRCP). The specific outcomes of the study are to:

- Define and map existing flood conditions across the Project area for a range of design flood events, in terms of peak water levels and peak velocities;
- Assess the long-term flood conditions in events up to the probable maximum flood and the residual impacts of the Project following mine closure.

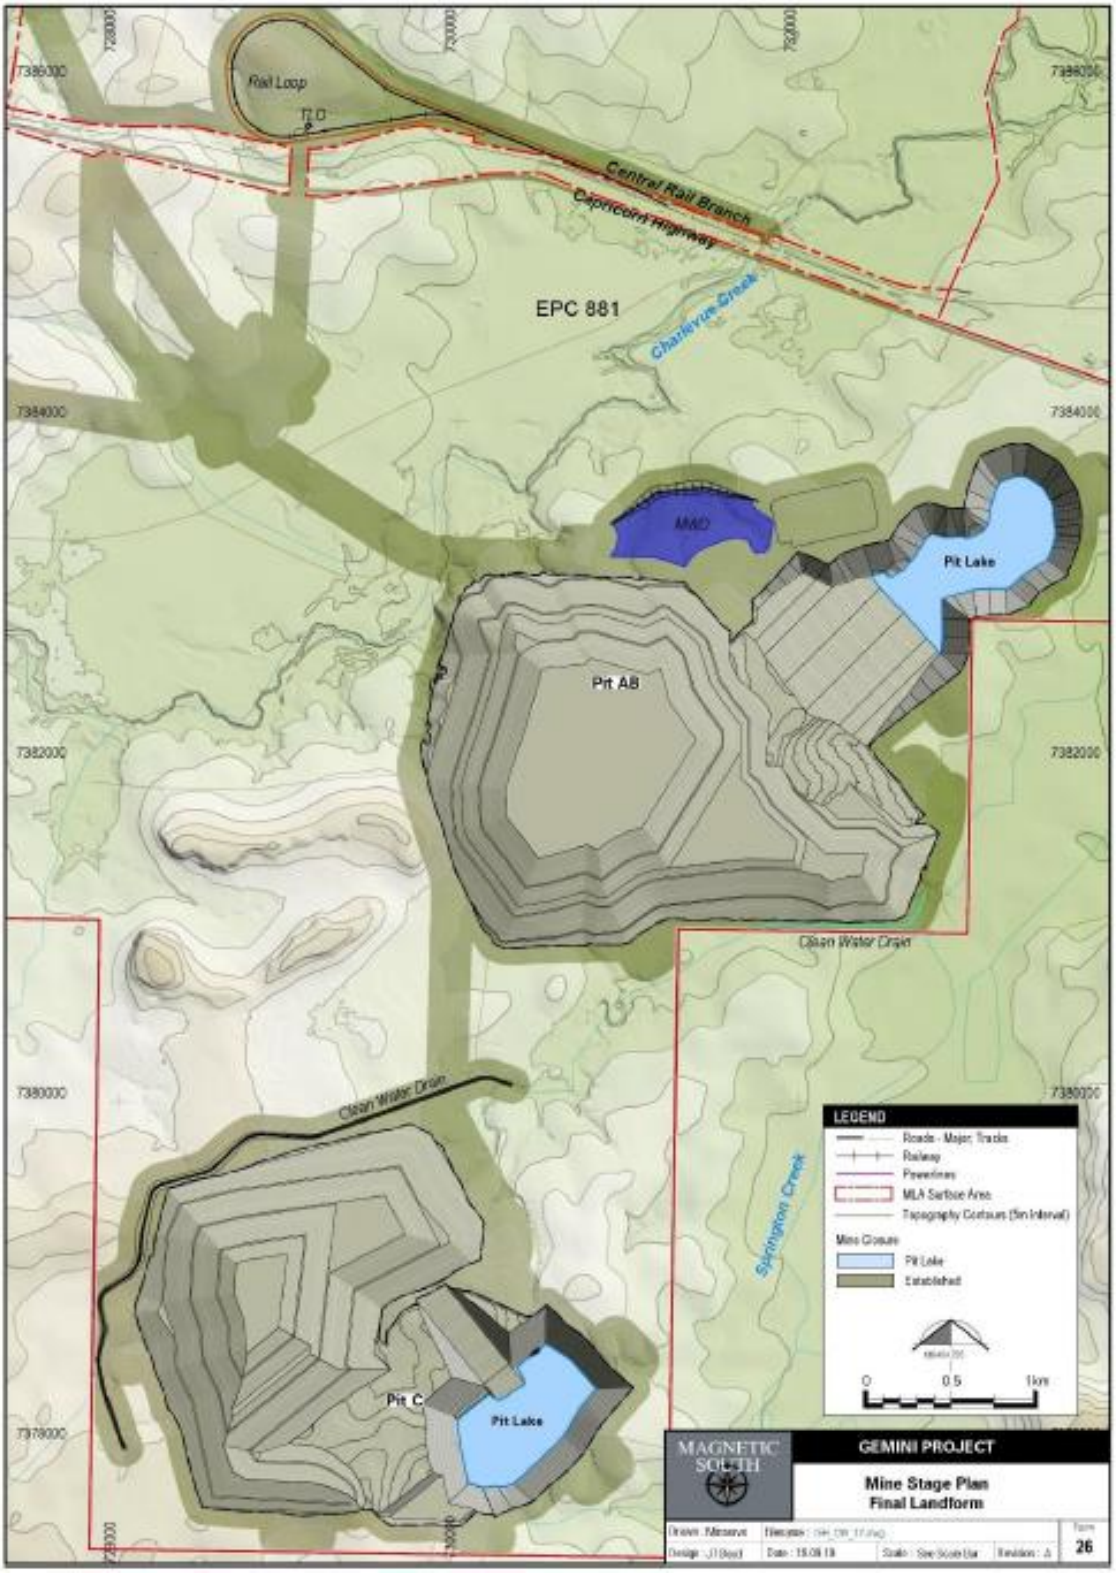

Figure 1.1 Proposed post mining landform

2 ESTIMATION OF DESIGN DISCHARGES

2.1 CATCHMENTS AND DRAINAGE

As shown in Figure 2.1, the mine area is in the catchment of Springton and Charlevue Creeks. These streams flow generally northeast, with Charlevue Creek joining Springton Creek approximately 3.6 km downstream of the Project, before joining the Mackenzie River approximately 47 km further downstream.

Charlevue Creek has a catchment area of approximately 343 km^2 to its confluence with Springton Creek, and Springton Creek has a catchment area of 325 km^2 to the confluence with Charlevue Creek.

The proposed final landform encroaches into the margins of the floodplains of both Charlevue and Springton Creeks.

2.2 METHODOLOGY

The XP-RAFTS runoff-routing model (XP Software, Version 2018.1.2) was used to estimate design discharges for the Charlevue Creek and Springton Creek catchments. In the absence of suitable stream gauge data, the peak discharges estimated by the XP-RAFTS model were validated against the Rational Method and Regional Flood Frequency Estimation (RFFE) estimates.

The validated XP-RAFTS model was used to estimate design discharges based on design rainfall and temporal pattern data developed using AR&R 2019 methodology (Ball et al, 2019). Design discharge hydrographs were estimated for the 50%, 10%, 2%, 1% and 0.1% annual exceedance probability (AEP) design discharges as well as the probable maximum flood (PMF) design discharge.

2.3 XP-RAFTS MODEL CONFIGURATION

2.3.1 Spatial configuration

Figure 2.2 shows the XP-RAFTS model configuration adopted in the vicinity of the Project area. The hydrologic model includes both Charlevue Creek catchment and Springton Creek catchment to 4 km downstream of the confluence of Charlevue Creek and Springton Creek. The combined catchment has a total area of 688 km^2, consisting of 43 sub-catchments.

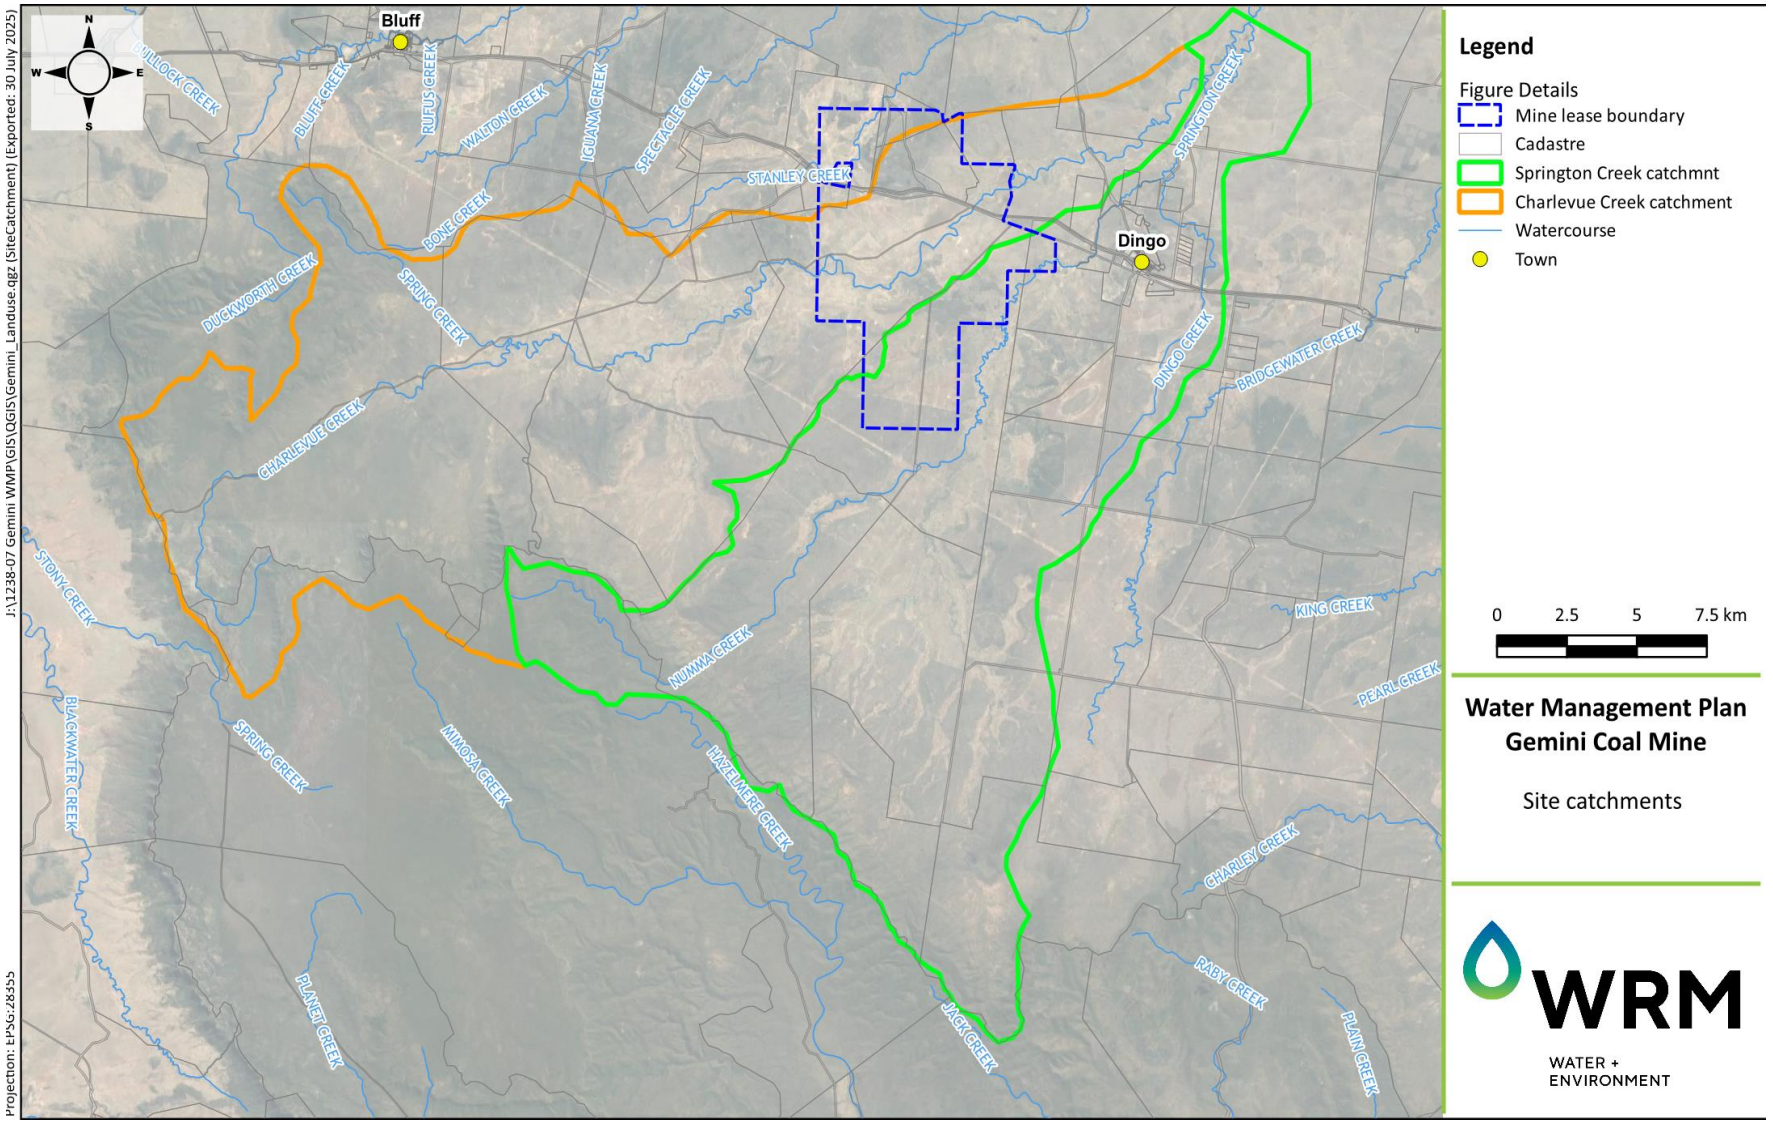

Figure 2.1 Site catchments

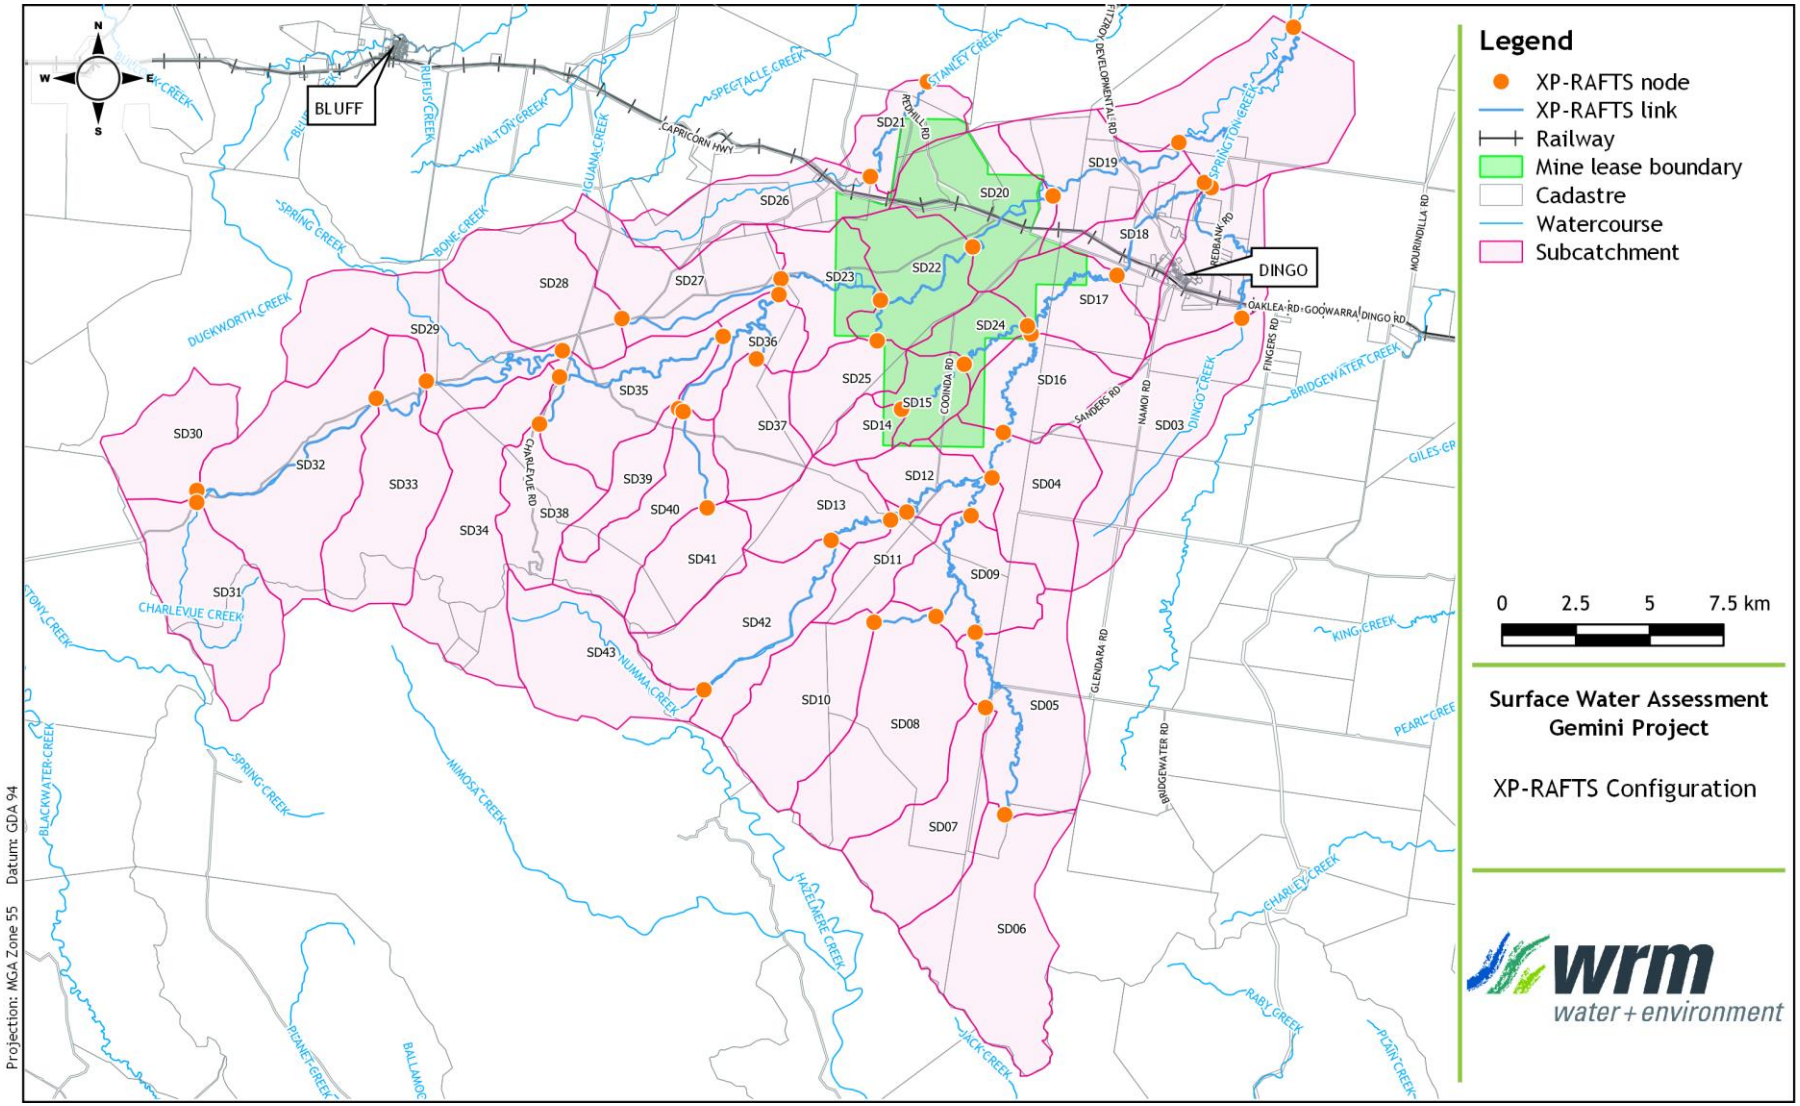

Figure 2.2 XP- RAFTS model configuration

2.3.2 Sub-catchment parameters

The XP-RAFTS model uses a single sub-catchment approach to determine runoff hydrographs, based on the overall sub-catchment parameters (fraction impervious, roughness and slope). Sub-catchment fraction impervious and roughness (Manning's 'n') parameters were weighted based on the various land use types in each sub-catchment based on available topographic data and aerial photographs.

Table 2.1 presents the adopted sub-catchment parameters including catchment area, percentage impervious, catchment slope and PERN 'n' catchment roughness coefficients.

Model parameters for each sub-catchment were determined as follows:

- A percentage impervious of zero was adopted for all sub-catchments;
- Catchment slopes were determined based on the available topographic data;
- A sub-catchment storage coefficient multiplication factor 'Bx' of 1.0 was adopted for all events;
- Sub-catchment PERN 'n' values were determined based on the density of vegetation in each sub-catchment. The adopted sub-catchment PERN 'n' value was 0.05 for sub-catchments with largely bushland areas; and
- Initial (IL) and continuing (CL) losses for the validation events were determined based on the recommended AR&R 2019 data hub parameter. The selection of initial and continuing losses for design events is described in Section 2.7.

Table 2.1 Adopted XP-RAFTS sub-catchment parameters

SD42	0.20	0	7.33	0.05

2.3.3 Routing parameters

Channel routing in the XP-RAFTS model was configured based on specifying a 'K' and 'X' value for each routing link. An 'X' value of 0.25 was adopted for all routing links. The 'K' values represent estimated flow travel times (in hours) and were calculated based on the flow path lengths and an assumed conservative flow velocity of 1 m/s.

2.4 DESIGN RAINFALL DEPTHS

2.4.1 50% to 0.1% AEP design events

Design rainfall depths and intensities were derived using intensity-frequency duration (IFD) data obtained from the Bureau of Meteorology's (BoM's) 2016 Rainfall IFD Data System. Design rainfall IFDs were obtained based on the centroid point location at the combined Charlevue Creek and Springton Creek catchment.

Design rainfalls for the 50% to 0.1% AEP design events were adjusted to account for the impacts of climate change for the SP2-4.5 scenario for the year 2040. The projected global temperature increase for this scenario relative to the 1961-1990 baseline is 1.4 degrees C.

For the PMP, the rainfall was adjusted for the "worst case" scenario of SSP5-8.5 for the year 2100. The projected global temperature increase for this scenario relative to the 1961-1990 baseline is 4.5 degrees C. The factors applied to the rainfalls for the different durations are shown in Table 2.2.

Table 2.2 Design rainfall factors for ARRv4.2 climate change adjustment

Duration	SP2-4.5	SP5-8.5
< 1 hour	1.22	1.86
1.5 hours	1.20	1.77
2 hours	1.19	1.71
3 hours	1.17	1.64
4.5 hours	1.16	1.58
6 hours	1.15	1.54
9 hours	1.14	1.50
12 hours	1.13	1.47
18 hours	1.12	1.43
> 24 hours	1.12	1.41

2.4.2 Probable maximum flood design event

PMP rainfall depths for durations up to 6 hours were estimated using the methodology given in The Estimation of Probable Maximum Precipitation in Australia: Generalised Short Duration Method (GSDM) (BoM, 2003).

PMF rainfall depths for durations longer than 6 hours were estimated using the standard methodology given in *The Estimation of Probable Maximum Precipitation: Generalised Tropical Storm Method Revised* (GTSMR) (BoM, 2006).

The followings parameters were adopted:

- For GSDM:
  - The terrain was assumed to be 100% rough, S = 0;
  - Elevation Adjustment Factor, EAF = 1.0;
  - Moisture Adjustment Factor, MAF = 0.85.
- For GTSMR:
  - Located in the coastal zone;
  - Annual Moisture Adjustment Factor, AMAF = 0.74;
  - Winter Moisture Adjustment Factor, WMAF = 0.78;
  - Decay Amplitude Factor, DAF = 1.0;
  - Topographical Adjustment Factor, TAF = 1.0.

Note that aerial reduction factors are already applied to the PMP rainfalls due to the catchment area being incorporated into the PMP rainfall estimation methodology.

2.5 AREAL REDUCTION FACTORS

The areal reduction factor was obtained from the ARR data hub and has been applied based on the catchment size to the Gemini Project (approximately 265 km^2 at the location of the mine voids) for design events up to 0.1% AEP. Areal reduction factors are included in the PMF rainfall calculation methodology.

2.6 TEMPORAL PATTERNS

2.6.1 50% to 0.1% AEP design events

Temporal patterns were obtained from the AR&R 2019 data hub based on the centroid of the combined Charlevue Creek and Springton Creek catchment. The AR&R 2019 temporal pattern methodology involves the use of an 'ensemble' of 10 temporal patterns, which produces 10 design hydrographs (and peak discharges) for each duration for each AEP. For each location and AEP, the storm duration with the highest mean peak design discharge of the ensemble is selected and the temporal pattern that produces the peak design discharge just above the ensemble mean is adopted.

2.6.2 Probable maximum flood design event

The average variable method (AVM) temporal pattern for storm durations up to and including six hours were obtained from the GSDM methodology (BoM, 2003). The AVM temporal pattern for durations of 24 hours and longer were obtained for Coastal Zone storms from the GTSMR methodology (BoM, 2006). For durations between six hours and 24 hours both the GSDM and GTSMR temporal patterns were applied.

2.7 DESIGN RAINFALL LOSSES

For design events up to 0.1% AEP, an initial loss (IL) of 42 mm and continuing loss (CL) of 2.0 mm/hr were adopted for this assessment based on the AR&R 2019 data hub report. These losses were adjusted in accordance with ARR's guidance on climate change to 43.3 mm (IL) and a continuing loss of 2.1 mm/hr.

An IL of 0 mm and CL of 1 mm/hr were used for PMF design event.

The incorporation of pre-burst depths specified in AR&R 2019 data hub is achieved by applying median depth values (ratio multiplied by initial loss) at an initial timestep for each event duration.

Table 2.3 shows the adopted median pre-burst and depth ratio values used in calculating design rainfall continuing losses.

Table 2.3 Median pre-burst depths (mm) and ratios

Duration min (hours)	50% AEP	2% AEP	1% AEP
60 (1.0)	0.4 (0.012)	5.5 (0.070)	6.5 (0.074)
90 (1.5)	0.1 (0.003)	4.1 (0.046)	6.1 (0.061)
120 (2.0)	0.0 (0.001)	5.3 (0.054)	7.7 (0.069)
180 (3.0)	0.5 (0.011)	6.8 (0.062)	9.4 (0.076)
360 (6.0)	0.0 (0.000)	14.5 (0.108)	23.4 (0.153)
720 (12.0)	0.0 (0.000)	17.4 (0.104)	27.5 (0.143)
1080 (18.0)	0.0 (0.000)	17.6 (0.092)	27.8 (0.126)
1440 (24.0)	0.0 (0.000)	12.2 (0.058)	20.8 (0.085)
2160 (36.0)	0.0 (0.000)	10.6 (0.043)	18.5 (0.065)
2880 (48.0)	0.0 (0.000)	3.1 (0.011)	5.4 (0.017)
4320 (72.0)	0.0 (0.000)	0.0 (0.000)	0.0 (0.000)

2.8 MODEL VALIDATION

The peak design discharges produced by the XP-RAFTS model were validated against the Rational Method and Regional Flood Frequency Estimation (RFFE) estimates.

2.8.1 Rational method

The Rational Method was applied to a number of sub-catchments with areas less than 25 km^2.

Table 2.4 compares the Rational Method results and XP-RAFTS peak discharges estimates at 4 sub-catchment outflow locations. The time of concentration was calculated using the Modified Friend's equation with no overland flow component.

The outflow locations used in the Rational Method calculation correspond to the XP-RAFTS nodes of SD02, SD15, SD21 and SD24. The Rational Method 1% AEP peak design discharges at these nodes ranged between 15.1 m^3/s and 26.7 m^3/s. The estimated XP-RAFTS model gives larger discharges compared to the RM estimates at all sub-catchments.

Table 2.4 Comparison of Rational Method and XP-RAFTS model design discharges

Design event	Sub-catchment	Rational Method	XP-RAFTS	Difference
1% AEP	SD02	26.7	54	102%
	SD15	16.2	24	48%
	SD21	18.7	32	71%
	SD24	15.1	22	46%

2.8.3 RFFE estimates

The RFFE method was applied to flows at the combined Charlevue Creek/Springton Creek catchment (SD01) as well as to Springton Creek upstream of the Capricorn Highway (SD17).

Table 2.5 and Figure 2.3 compare the RFFE estimates and XP-RAFTS model results at SD01, while Table 2.6 and Figure 2.4 and compare results at SD17.

A comparison of the results at these two locations shows the wide variability in the RFFE. At SD01 the modelled XP-RAFTS flows are generally significantly higher and at SD17 the modelled XP-RAFTS flows are generally significantly lower. The model parameters obtain a compromise between the higher and lower results.

The validated XP-RAFTS model was used to derive flood discharge hydrographs for use in the hydraulic model.

Table 2.5 Comparison of RFFE and XP-RAFTS model design discharges at SD01

AEP	Adopted XP-RAFTS design discharge (m^3/s)	RFFE discharge (m^3/s)			Difference
		Lower 5% confidence limit	Expected parameter quantile	Upper 95% confidence limit	
50%	214	39	64	110	-70.1%
20%	521	152	250	426	-52.0%
10%	802	286	480	934	-40.1%
5%	1,059	445	798	1,957	-24.6%
2%	1,570	662	1,382	4,905	-12.0%
1%	1,942	817	1,970	9,474	1.4%

2%	646	533	908	2,254	40.6%
1%	802	686	1,278	3,938	59.4%

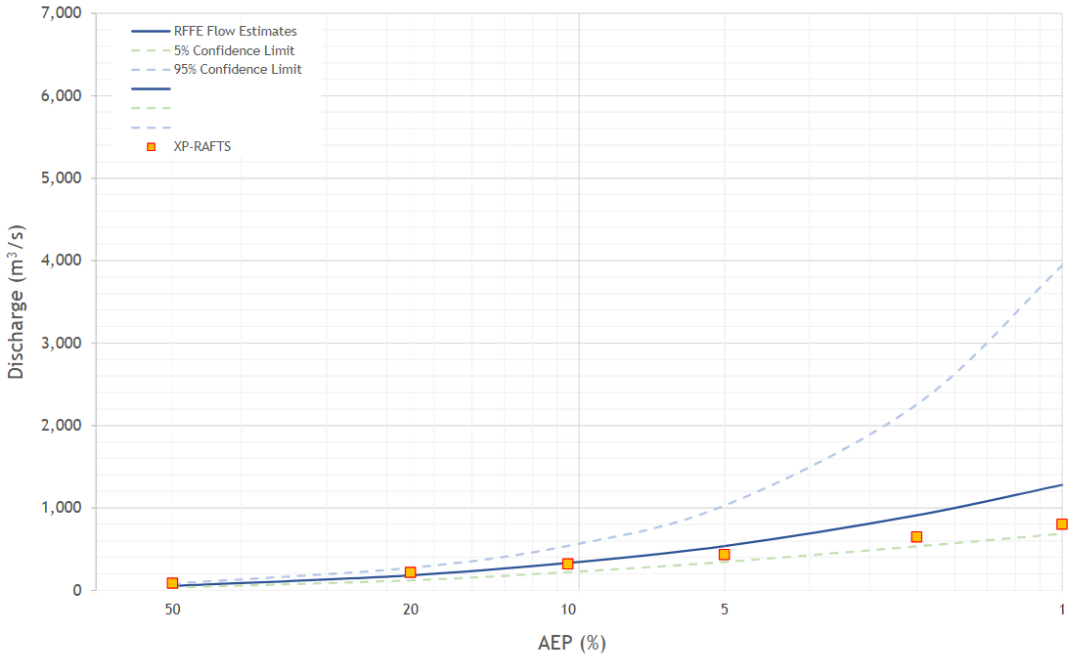

Figure 2.4 Comparison of RFFE and XP-RAFTS design discharges at SD17

2.9 ADOPTED DESIGN DISCHARGES

Design discharges were estimated for the 50% (1 in 2), 2% (1 in 50), 1% (1 in 100) and 0.1% (1 in 1,000) AEP events as well as the probable maximum flood (PMF) event.

Table 2.7 shows XP-RAFTS predicted design peak discharges and relevant critical storm durations and temporal patterns for all modelled design events at the outlet (SD01) of the combined Charlevue Creek and Springton Creek catchment for events up to the 0.1% (1 in 1,000 AEP). All flows include climate change adjustment for the 2040 time-horizon under SSP2-4.5.

For the PMF, the peak design flow for the 2100 time-horizon under SSP5-8.5 is 13,470 m^3/s (critical duration 12hrs GTSMR temporal pattern).

The design discharge hydrographs from the XP-RAFTS model were adopted as inflows to the TUFLOW hydraulic model.

Table 2.7 XP-RAFTS design discharges and critical durations at the outlet (SD01) of the combined Charlevue Creek and Springton Creek catchment

AEP	Combined Charlevue Creek & Springton Creek catchment		
	XP-RAFTS discharge (m^3/s)	Critical duration (hours)	Corresponding Temporal Pattern
50%	214	18	9
10%	802	18	4
2%	1,570	18	5
1%	1,942	18	5
0.1%	3,390	12	9

3 HYDRAULIC MODELLING

3.1 OVERVIEW

The TUFLOW hydrodynamic model (BMT WBM, 2025) was used to estimate flood extents and depths along the channel and floodplain of Charlevue Creek and Springton Creek and their tributaries for a range of design events. TUFLOW represents hydraulic conditions on a fixed grid by solving the full two-dimensional depth averaged momentum and continuity equations for free surface flow. The model automatically identifies breakout points and flow directions within the study area. All hydraulic modelling was undertaken using the TUFLOW Build 2025.0.0 HPC solver.

Figure 3.1 shows the TUFLOW model boundary. The model covers an area of approximately 139.4 km^2 where the Project area is bounded by Charlevue Creek to the north and Springton Creek to the south.

The TUFLOW model was configured using a grid cell size of 5 metres. This provides a reasonable compromise between a coarse grid cell size sufficient for Charlevue Creek and Springton Creek, and a fine enough grid cell size required for the tributaries crossing the Project area.

3.2 EXISTING CONDITIONS TUFLOW MODEL CONFIGURATION

3.2.1 Topography

Topographic LiDAR survey data covering the majority of TUFLOW model area (purple region in Figure 3.1) was provided by Magnetic South Pty Ltd.

Additional LiDAR data covering the area to the northeast near Dingo (green region in Figure 3.1), was obtained on a 1 m grid. The data was acquired in 2012 The Department of Natural Resources and Mines, Manufacturing and Regional and Rural Development as part of the Queensland LiDAR Data - Inland Towns Stage 4_2012 Project. Airborne Laser Scanning (ALS) data was acquired from a fixed wing aircraft between 18 June 2012 and 7 September 2012. The quoted accuracy is:

- Vertical: +/- 0.15m Standard Error (68% confidence level or 1 sigma)
- Horizontal: +/- 0.45m Standard Error (68% confidence level or 1 sigma)

The above datasets were supplemented with Fugro ROAMES Power Network Survey DEM Data (Emerald campaign, Cycle 6). This data was provided as part of a project funded by the Great Barrier Reef Foundation, which re-analysed point cloud data captured for the purpose of surveying vegetation and structural risk to power infrastructure to extract and generate ground surface datasets om a 0.5m grid. The grids are quoted to have an accuracy of better than 0.15 m vertical and 0.50 m horizontal accuracy. The original LiDAR data was acquired over mobilisations between 13/03/2018 and 13/04/2018.

Small sections of the upper reaches of the Springton Creek flood plain were not covered by the above LiDAR data sources, and in these locations (yellow region), the Copernicus 30 m DEM was used to supplement the data. The Copernicus GLO-30 DEM is based on the radar satellite data acquired during the TanDEM-X Mission, which is funded by a Public Private Partnership between the German State, represented by the German Aerospace Centre and Airbus Defence and Space. In areas where the Copernicus DEM 30m covers well-defined sections of the floodplain (on grassed areas), the median difference Copernicus 30 m DEM elevation and the overlapping LiDAR is less than 0.4 m.

The combined data was converted into a digital elevation model (DEM) for use as the base TUFLOW model topography. Areas where the DEM is based on the coarse Copernicus grid data are located well upstream of the mine lease and proposed final landform and have no impact on modelled flood conditions in the vicinity of the mining area.

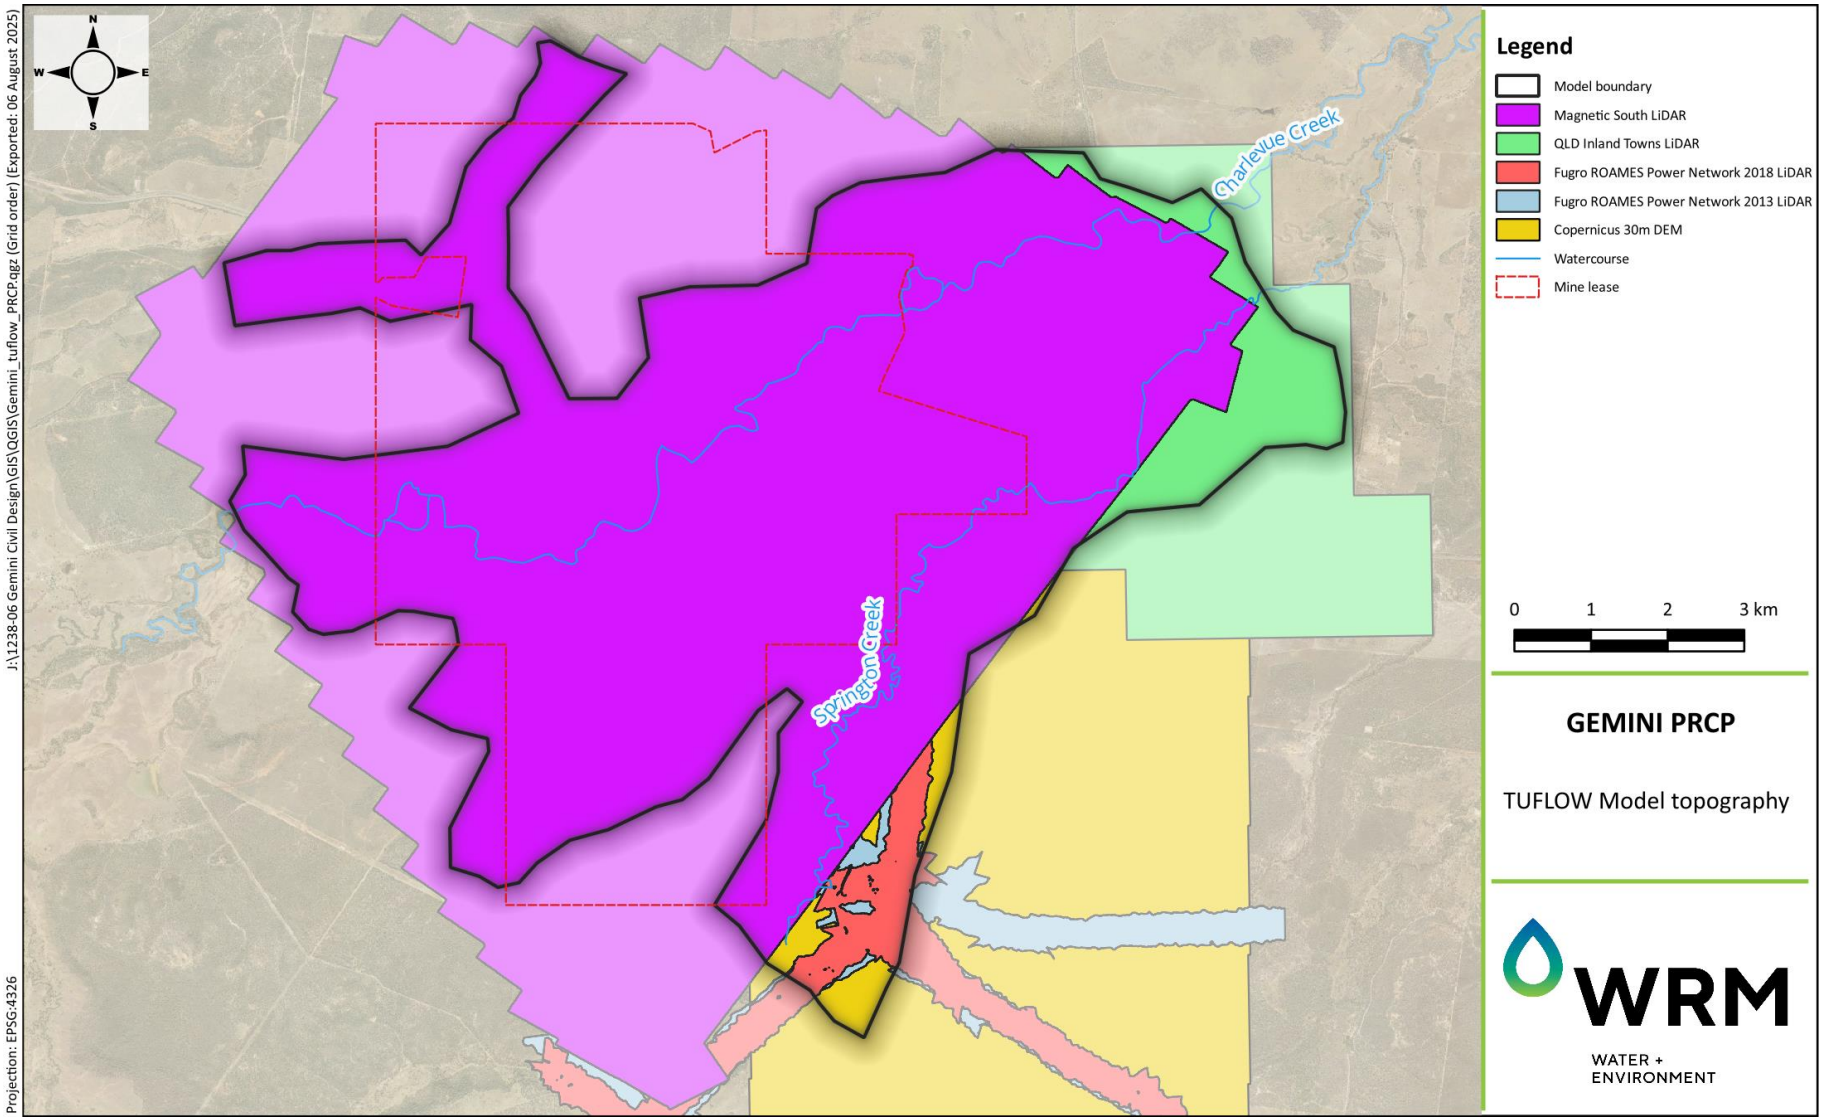

Figure 3.1 TUFLOW model topography

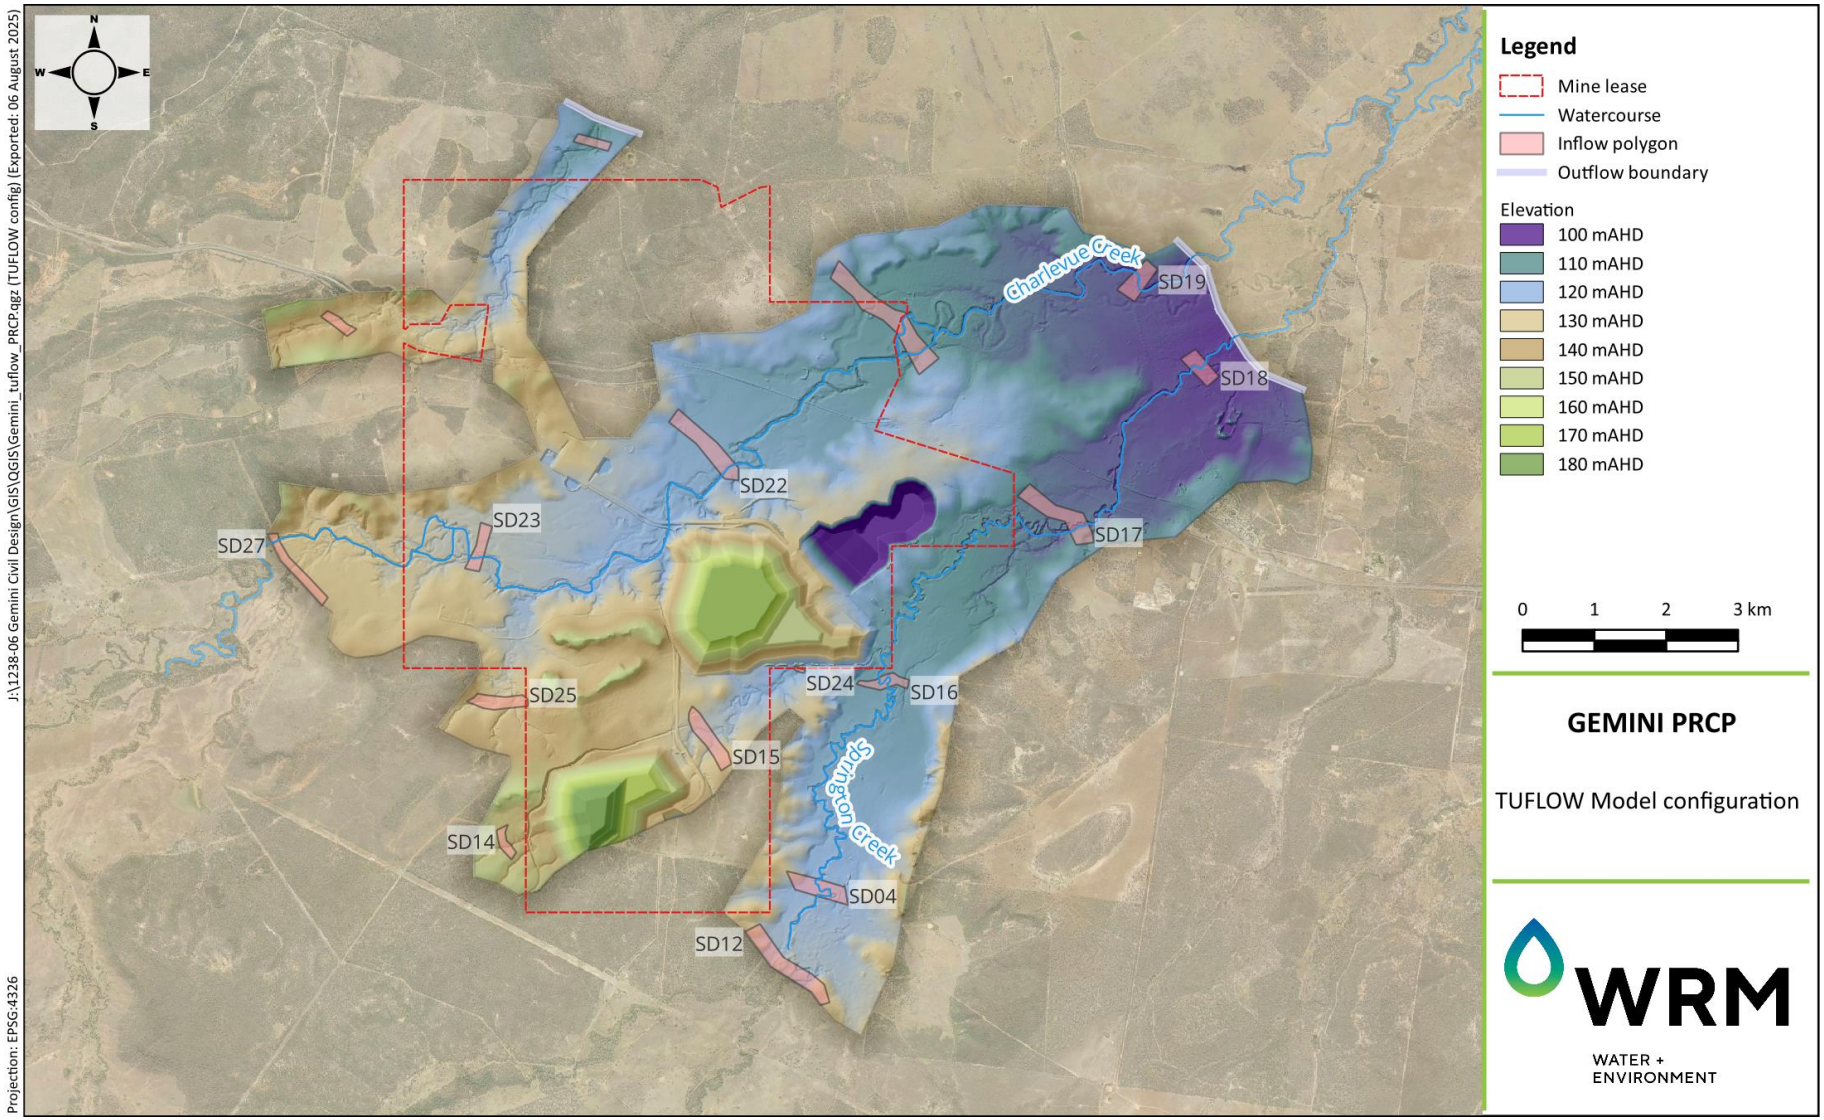

Figure 3.2 TUFLOW model configuration – post closure landform

3.2.2 Hydraulic roughness

Hydraulic roughness in the TUFLOW model is represented by Manning's 'n' roughness coefficients. Manning's 'n' values for the various land use types were selected based on typical published values. Land use types within the existing conditions model were identified using aerial photography.

Table 3.1 shows the adopted Manning's 'n' values used in the model and Figure 3.3 shows the locations of the Manning's 'n regions.

Table 3.1 Adopted hydraulic roughness Manning's 'n' values

Area	Manning's 'n'
Dense riparian vegetation	0.060
Creek / river channel	0.050
Pasture	0.035

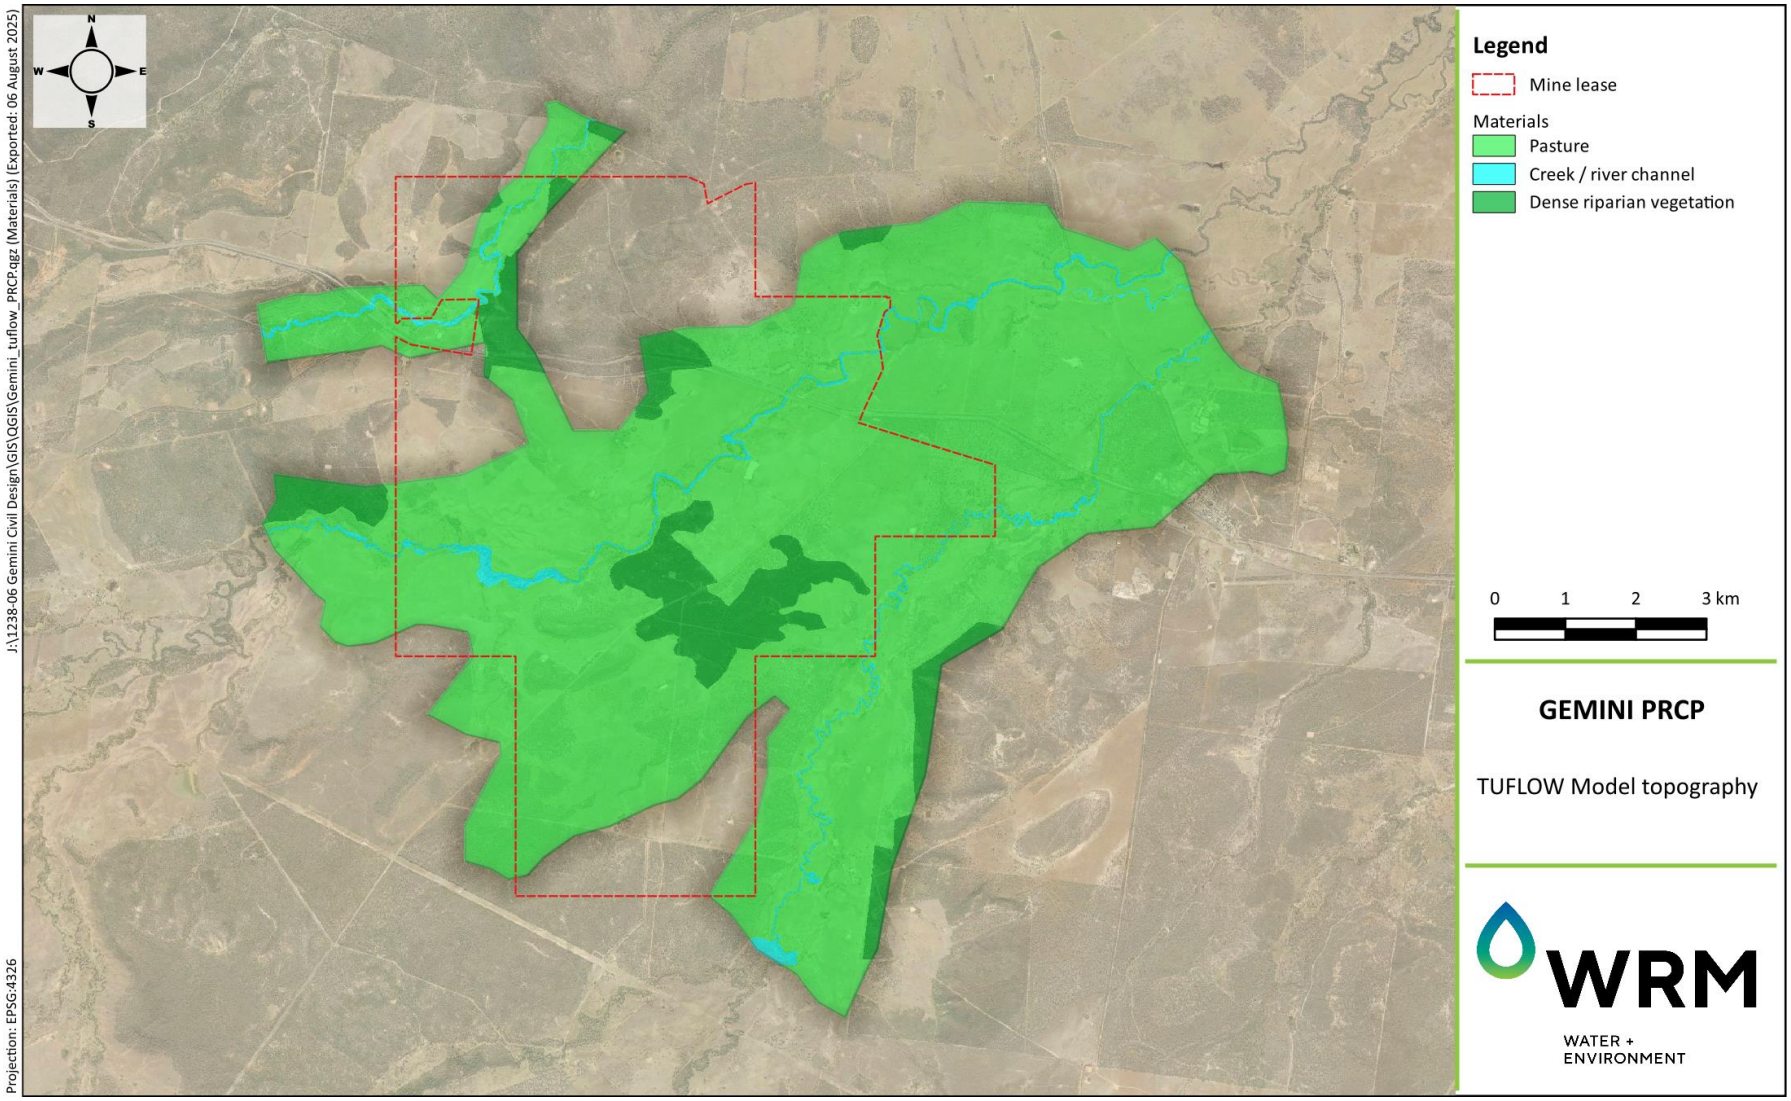

Figure 3.3 Manning's n configuration

3.2.3 Inflow and outflow boundaries

Figure 3.2 shows the locations of inflow and outflow boundaries in the TUFLOW model. The model includes a total of 16 inflow boundaries. The model inflow boundaries were applied within the 2D model domain using surface-area "SA" polygons. Using this approach, flows are initially applied to the lowest point within each SA polygon. Design discharge hydrographs for these inflow boundaries were obtained from the XP-RAFTS hydrologic model.

3.2.4 Tailwater conditions

The downstream boundary was set to minimise its influence on predicted flood behaviour. Flood slopes between 0.1% and 0.15% were adopted for the Springton Creek outlet in northeast of the Project area. A 0.4% bed slope was applied for the model outlet at Stanley Creek north of the Project area.

3.2.5 Hydraulic structures

Bridges and culverts within the Project area have been surveyed and modelled in the TUFLOW hydraulic model. Culverts are treated as 1D networks and bridges are modelled as 2D layered flow constrictions, with points snapped onto the lines to represent the road/rail elevation.

Under existing conditions, a total number of 4 culverts were modelled, two located on the east of Charlevue Creek and two located on the west of Charlevue Creek. Two bridges were modelled (Figure 3.1). Both bridges are located on the Capricorn Highway, one across Springton Creek and one across Charlevue Creek. An 800 mm thick slab and 500 mm height guard rails were adopted for both bridges.

Table 3.2 and Table 3.3 provide summary information on the existing culverts and bridges located under Capricorn Highway and Blackwater railway line embankments included in the model.

Table 3.2 Culvert details

Name	Road/ Rail Crossing	Dimension	IL U\S (mAHD)	IL D\S (mAHD)
SM02_a	Capricorn Hwy	3 x 0.75h*1.2w RCBC	114.06	113.53
SM02_b	Blackwater Rly	12 x 1.65m RCPs	113.90	113.63
SM04_a	Capricorn Hwy	9 x 0.75h*1.2w RCBC	113.66	113.31
SM04_b	Blackwater Rly	10 x 1.38m RCPs	113.77	113.68

a – RCP = reinforced concrete pipe, RCBC = concrete box culvert

Table 3.3 Bridge details

Name	Road/Rail Crossing	U/S Invert (mAHD)	D/S invert (mAHD)
BRD01	Capricorn Hwy/ Springton Creek	106.85	106.90
BRD03	Capricorn Hwy/ Charlevue Creek	114.90	114.90

3.3 DEVELOPED CONDITIONS TUFLOW MODEL

3.3.1 Topography

A number of changes were made to the model DEM to reflect changes associated with:

- proposed overburden dumps and pit protection levees;
- haul roads connecting the two mining pits to the MIA and CHPP;
- diversion channels for the minor tributary of Springton Creek crossing the mine area.

The locations of these proposed structures are shown in Figure 3.1.

3.3.2 Hydraulic roughness

Land use types within the developed conditions model were identical to those defined for the existing conditions model.

3.3.3 Inflow and outflow conditions

No changes to the existing conditions inflow and outflow locations were made.

3.3.4 Hydraulic structures

Additional culverts under the proposed haul roads were added in the developed conditions. Details of the proposed Project culvert configurations are provided in Table 3.4.

Table 3.4 Proposed new culverts in Project area

Name	Road/ Rail Crossing	Dimension	IL U\S (mAHD)	IL D\S (mAHD)
HR01	Haul Road (North)	3 x 0.9m RCPs	118.34	117.84
HR02	Haul Road (North)	3 x 2.1m RCPs	114.97	114.60
HR03	Haul Road (North)	2 x 0.9m RCPs	122.69	122.20
HR04	Haul Road (South)	3 x 0.9m RCPs	126.70	126.28

3.3.5 Diversion channels

Earthworks models of the preliminary diversion channel designs were added to the DEM. Neither of the diverted tributaries are defined as watercourses under the Water Act. Magnetic South has committed to ensuring they are designed and constructed generally in accordance with the design principals set out in the guideline; Works that interfere with water in a watercourse for a resource activity- watercourse diversions authorised under the Water Act 2000 [OSW/2019/4599] (DNRME 2019).

4 MODEL RESULTS

Maps showing design 0.1% AEP peak flood depths and velocities under existing conditions are shown in Figure 4.1 and Figure 4.2 respectively.

Maps showing design 0.1% AEP peak flood depths and velocities under post-closure conditions are shown in Figure 4.3 and Figure 4.4 respectively.

Figure 4.5 shows the extent and depth of flooding in the PMF (with climate change impacts under SSP5-8.5 for the year 2100) assuming the final landform includes bunding on the eastern edge of Pit AB to exclude floodwaters.

Flood mapping for a range of design events (50% AEP, 2% AEP, 0.1% AEP, and PMF) are provided in Appendix A for both existing and developed conditions.

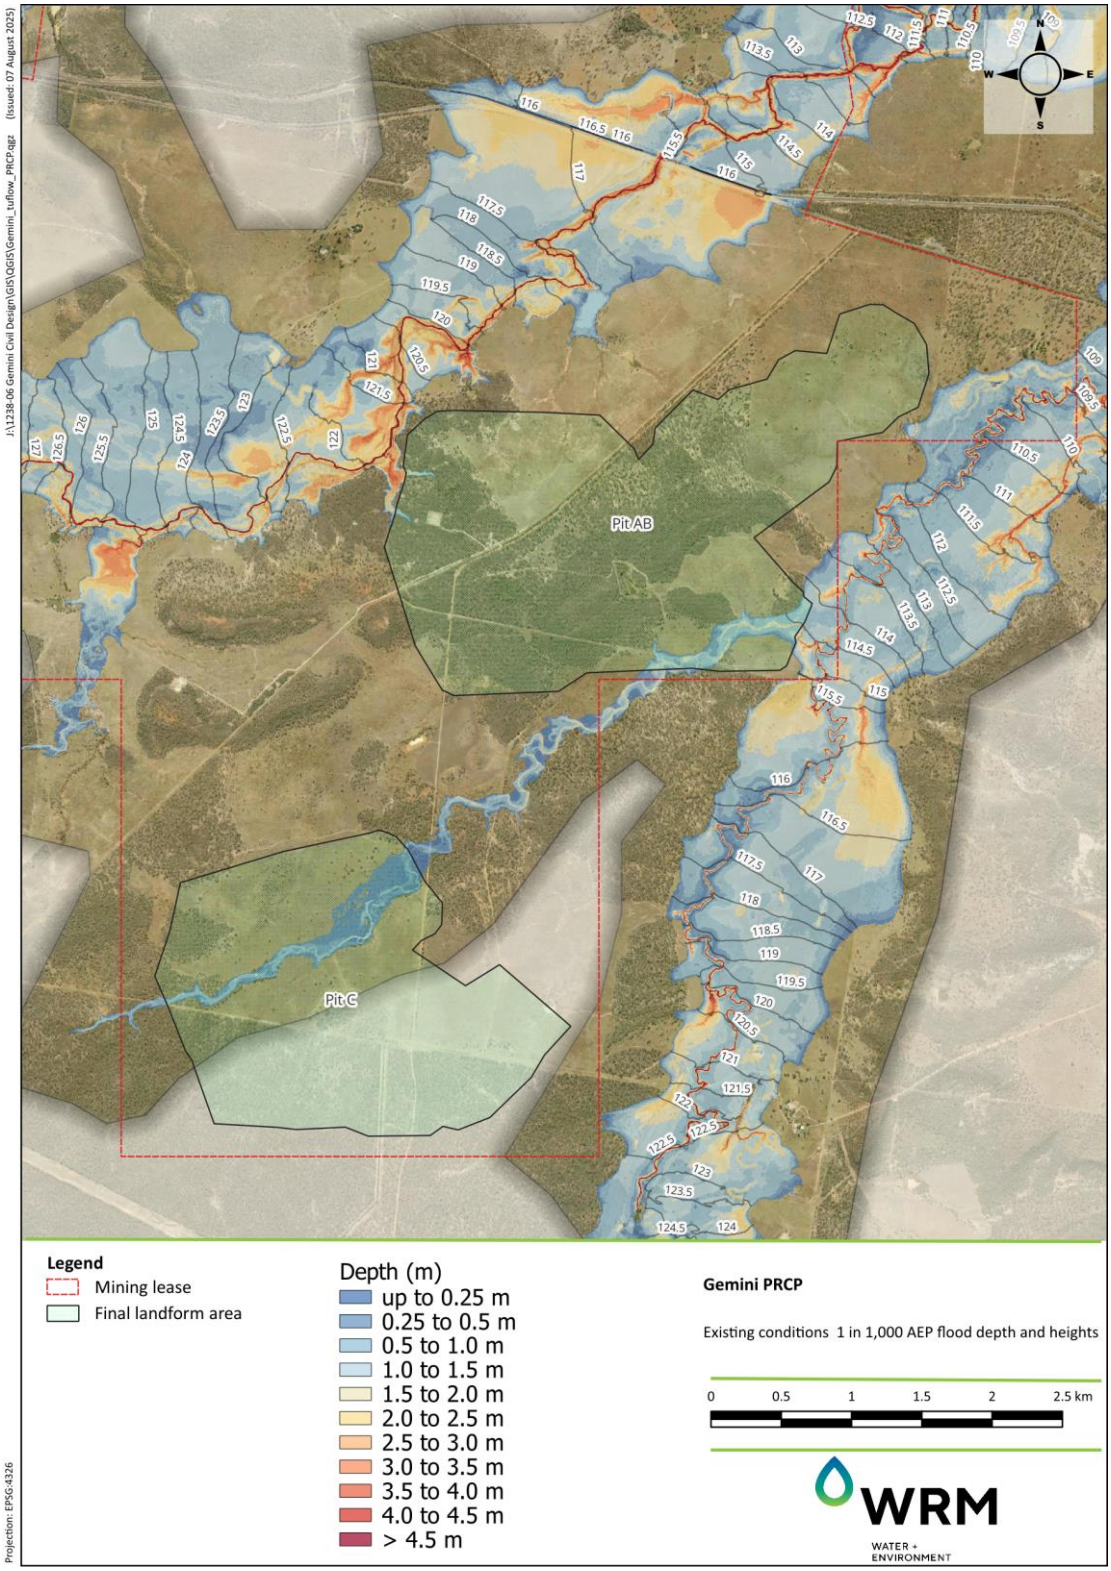

Figure 4.1 Existing conditions - peak flood depths and water levels - 0.1% AEP

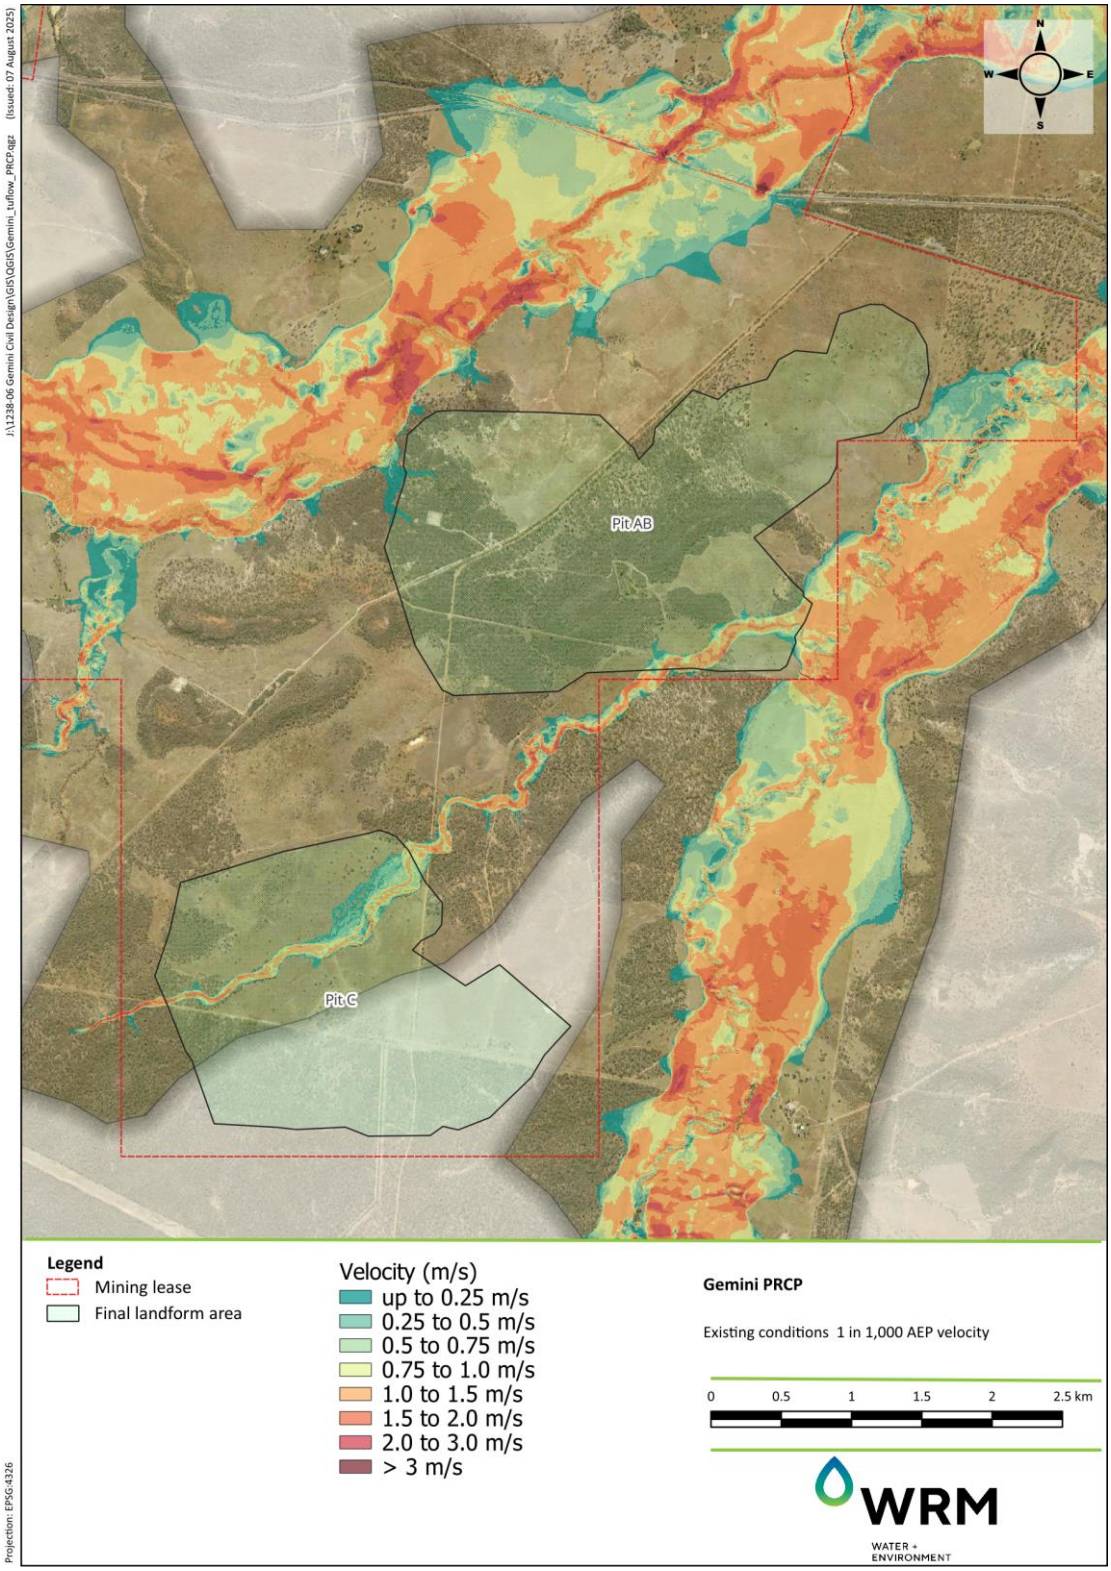

Figure 4.2 Existing conditions - peak flood velocities - 0.1% AEP

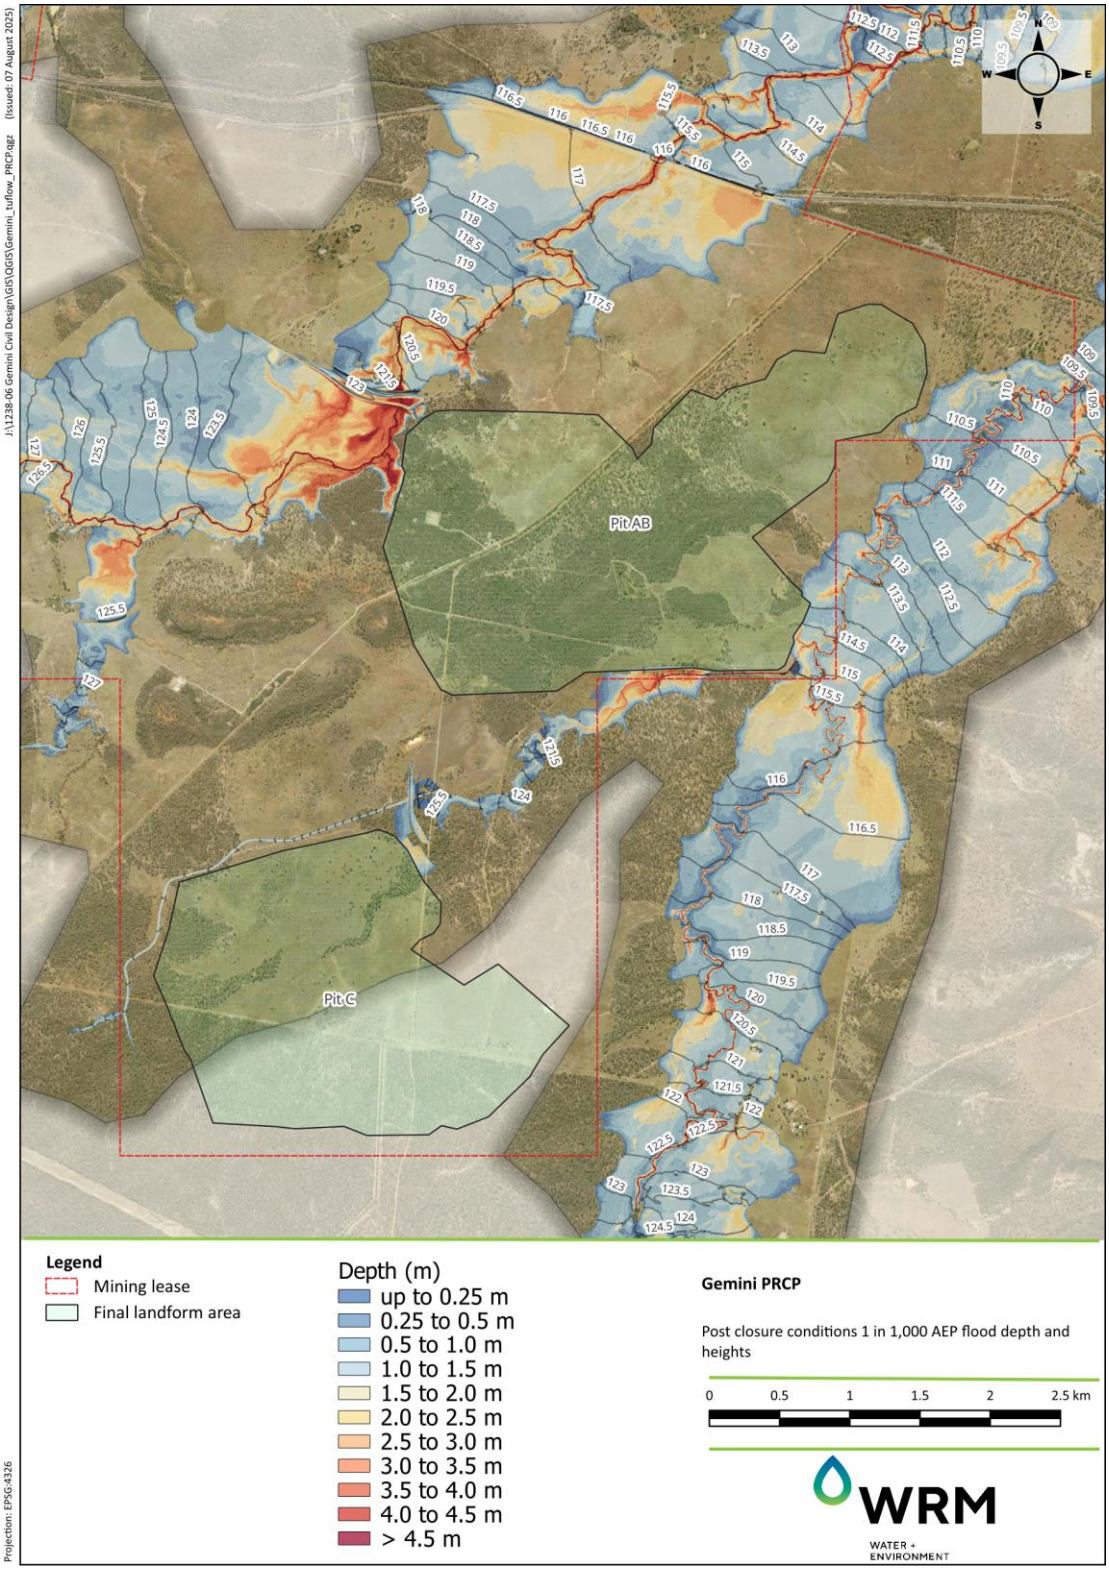

Figure 4.3 Post closure conditions - peak flood depths and water levels - 0.1% AEP

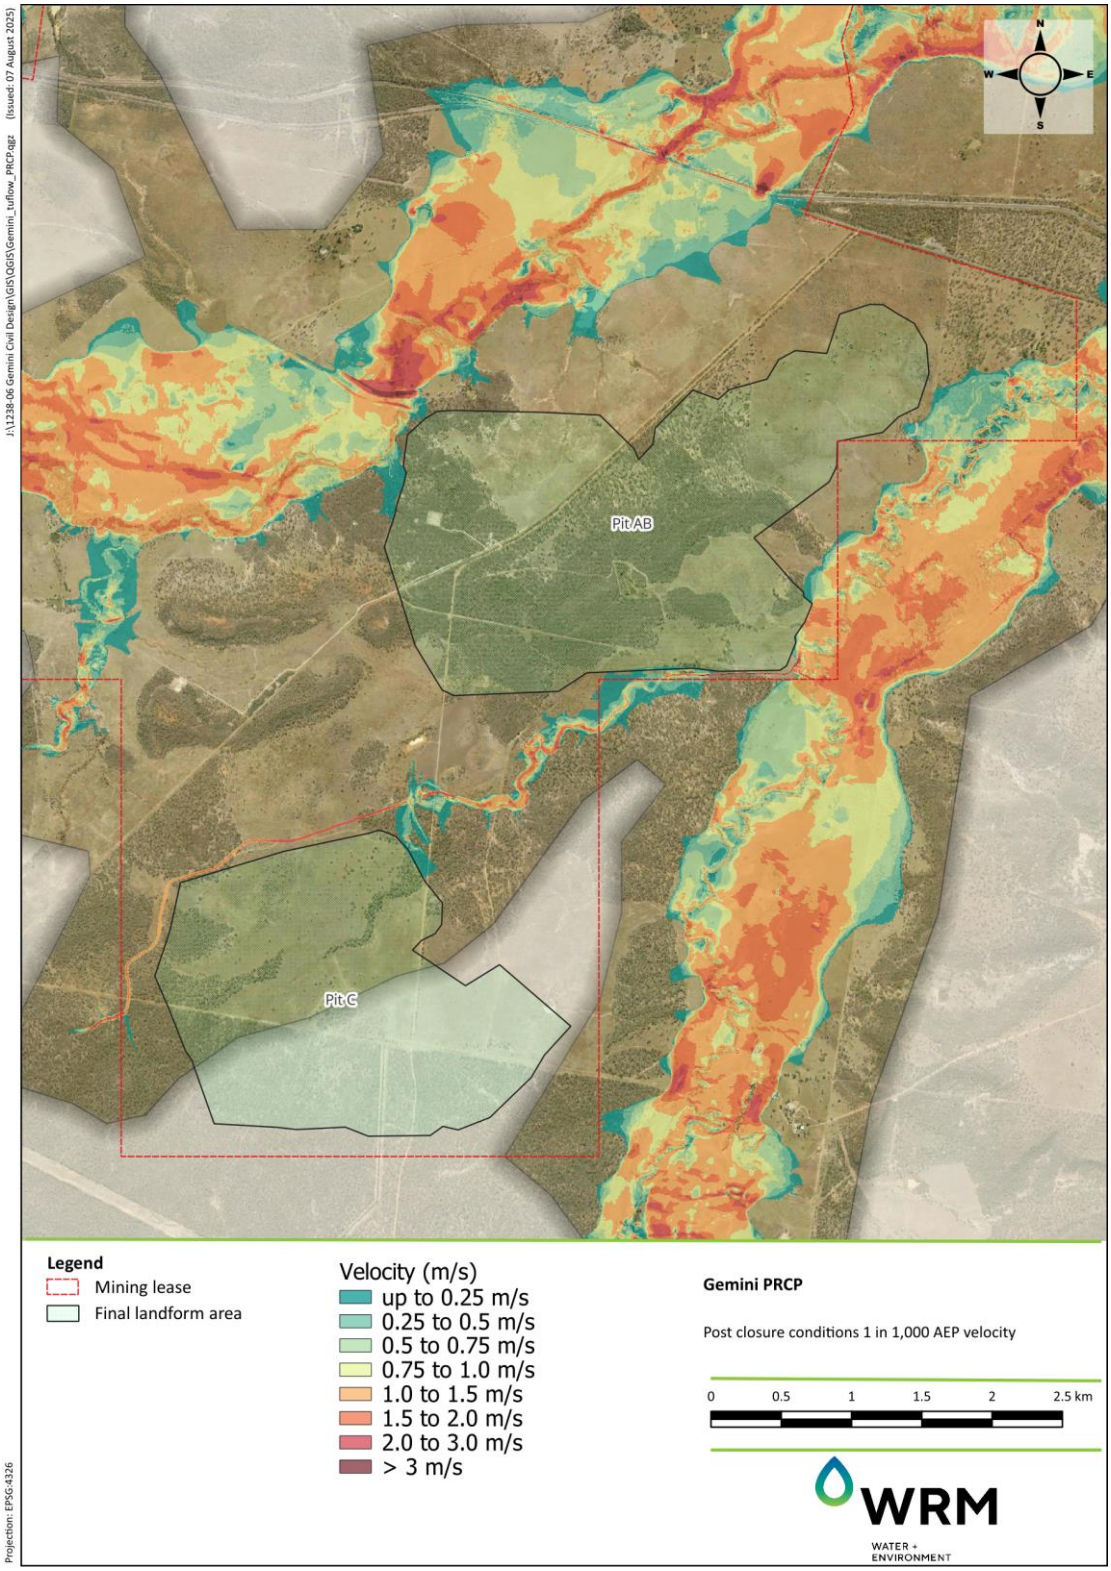

Figure 4.4 Post closure conditions - peak flood velocities - 0.1% AEP

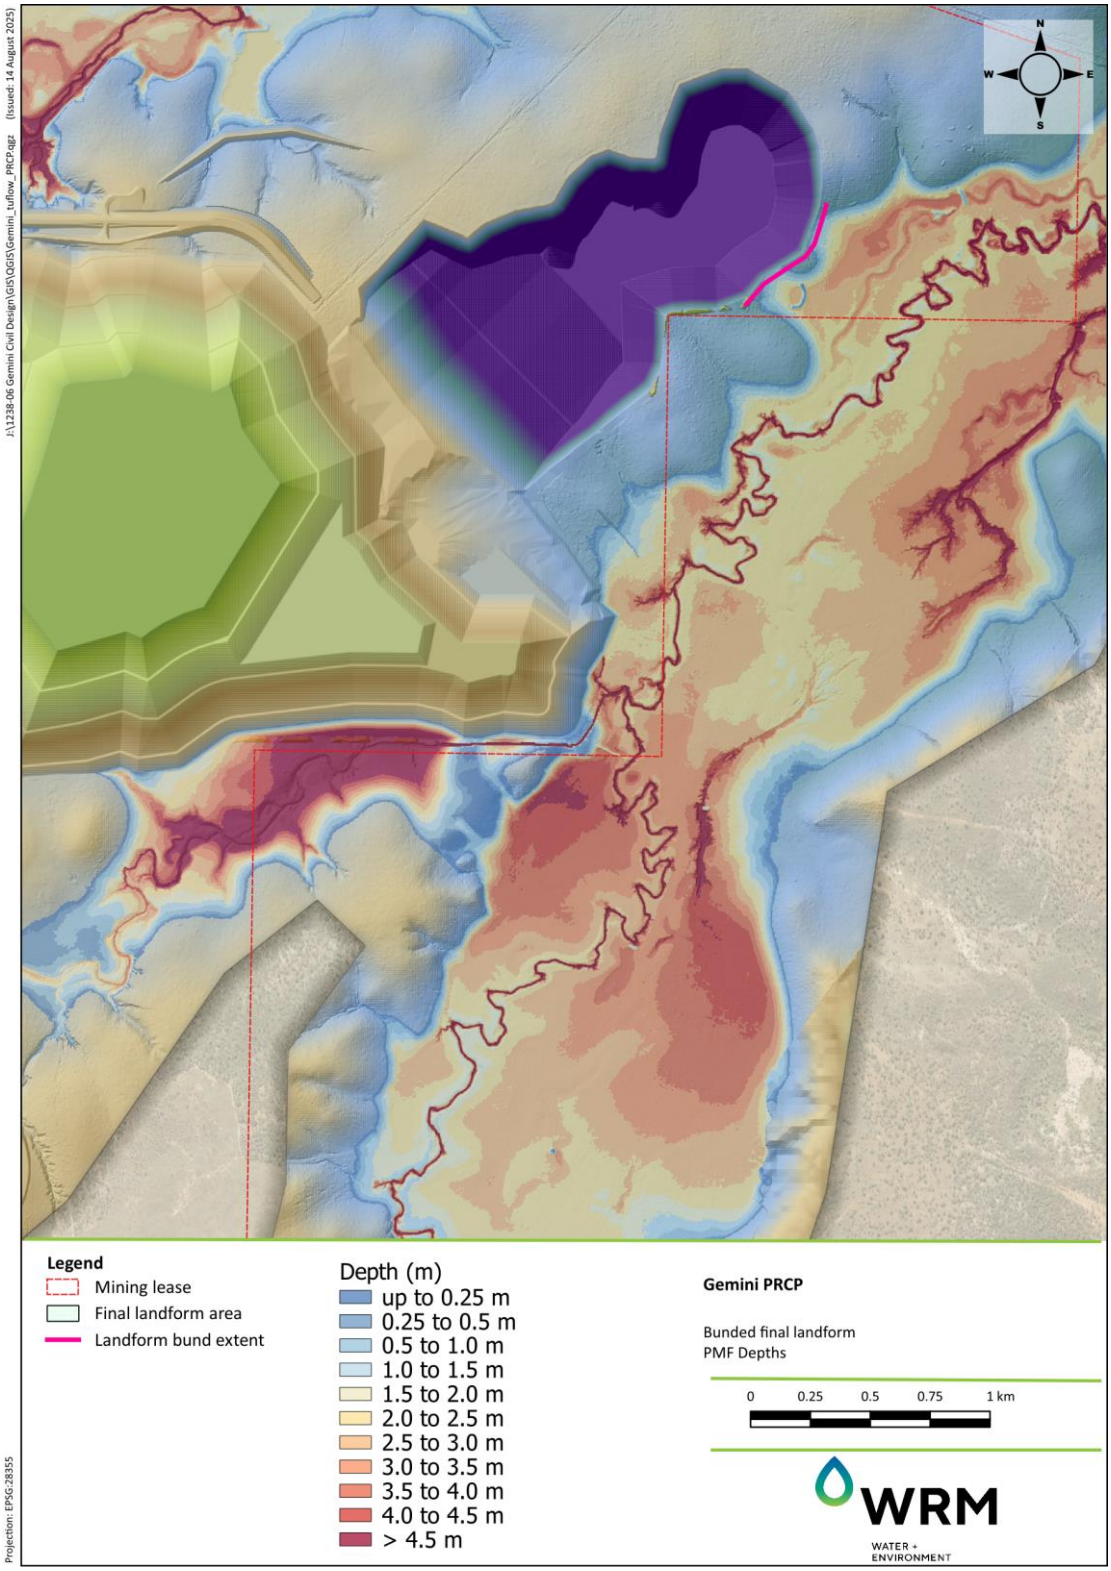

Figure 4.5 Post closure conditions - peak flood depths and water levels – PMF with bunded landform

5 SUMMARY OF FINDINGS

The purpose of this flood study was to:

- Define existing flood conditions in the vicinity of the final landform for a range of design events, in terms of peak water level, peak velocity, water depth, shear stress and stream power;
- Assess peak water levels adjacent to the proposed final voids as well as velocities, stream power and shear stress along the landform including the channels proposed to divert runoff in the unnamed Springton Creek tributary around both mining areas;

An XP-RAFTS hydrologic model was developed to estimate design discharge hydrographs for the catchments of Charlevue Creek and Springton Creek which cross the Project area. In the absence of gauged streamflow data, the resulting peak discharges were validated against peak discharges estimated using the Rational Method and RFFE.

The model was used to estimate design discharges for the 2%, 1%, and 0.1% AEP events as well as the PMF design event in accordance with the AR&R 2019 approach using an ensemble of design temporal patterns.

Design rainfalls were adjusted in accordance with the AR&Rv4.2 guidance for climate change impacts. For the PMP, rainfalls were adjusted for global temperature projected for the 2100 horizon under SSP5-8.5. For smaller rainfall events, the adjustment was to 2040 under SSP2-4.5, which is consistent with current practice for the design in accordance with the Guideline: "*Works that interfere with water in a watercourse – watercourse diversions*"

A TUFLOW hydraulic model was developed to determine existing and developed conditions flood behaviour in Charlevue Creek, Springton Creek, and its unnamed tributary crossing the mine area. The adopted grid cell size was five metres, and the inflow boundaries were represented using design discharge hydrographs estimated using the XP-RAFTS runoff-routing model. The model incorporated the proposed landforms, including the haul roads and diversion channels.

The outcomes of the study are as follows:

- The proposed final voids are outside the 0.1% AEP flood extents (even after design rainfalls are adjusted to account for climate change under Shared Socioeconomic Pathway (SSP) SSP5-8.5 for the 2100 time horizon).
- Under PMF flood conditions, with design rainfalls adjusted for climate change under Shared Socioeconomic Pathway (SSP) SSP5-8.5, the PMF flood level would flow into the Pit AB final void at a depth of approximately 0.2 m. However, these inflows could be avoided by bunding the eastern edge of the void (up to height of approximately 1 m plus freeboard) for a length of approximately 600 m (refer Figure 4.5).
- There will be localised off-lease impacts on flood levels in the unnamed tributary of Springton Creek immediately upstream of Pit AB and Pit C.
- The model results show the preliminary designs of the proposed diversions of the unnamed tributary of Springton Creek around the proposed landform would result in flow conditions that are not consistent with the Guideline: "*Works that interfere with water in a watercourse – watercourse diversions*" (DNRM, September 2014). However, neither of the diverted tributaries are defined as watercourses under the Water Act.
